Divert Water Conservation Area 3A and 3B flows to Central Lake Belt Storage Area. The purpose of this component is to capture excess water above target stages in Water Conservation Area 3A and 3B and divert it through modified structures at S-9 and S-31 to the Central Lake Belt Storage Area via the L-33 borrow canal. Approximately 2.0 acres of open pastureland in Miami-Dade County was valued for this component. The total estimated real estate cost of this component is $277,000, which includes the estimated lands and damages costs, Federal and non-Federal administrative/acquisition costs, and a contingency. No improvements or relocation assistance costs were included.

Component BBB6 (Alternatives C & D)

South Miami-Dade County Reuse (South District Reclaimed Water Treatment Plant). The purpose of this component is to augment water supply to the South Biscayne Bay and Coastal Wetlands Enhancement Project; to restore overland flow in the coastal area; to recharge groundwater; to enhance groundwater discharge to Biscayne Bay; and to provide saltwater intrusion benefits to the southern part of Miami-Dade County through the use of superiorly treated reclaimed water from the South District Wastewater Treatment Plant. Approximately 200 acres of land in Miami-Dade County would be required for this component. The total estimated real estate cost of this component is $3,324,000, which includes the estimated lands and damages costs, Federal and non-Federal administrative/acquisition costs, and a contingency. No improvements or relocation assistance costs were included.

Component CCC6 (Alternatives C & D)

Big Cypress/ L-28 Interceptor Modifications: The purpose of this component is to alleviate over-drainage in northeast Big Cypress, Kissimmee, Billy and Mullet Slough area, ensure applicable water quality treatment and restore sheetflow to wetland areas in northeast Big Cypress Addition. Approximately 1,900 acres of sugar cane land in Hendry, Collier and Broward Counties were valued for this component. The total estimated real estate cost of this component is $6,675,000, which includes the estimated lands and damages costs, Federal and non-Federal administrative/acquisition costs, and a contingency. No improvements or relocation assistance costs were included.

Component DDD5 (Alternatives A, B, C & D)

Caloosahatchee Backpumping with Stormwater Treatment Area. The purpose of this component is to increase the regional water resources by capturing excess C-43 Basin runoff and diverting it into Lake Okeechobee after treatment through a stormwater treatment area when storage is available in the Lake. Approximately 5,000 acres of pastureland in Hendry and Glades Counties were valued for this component. The total estimated real estate cost of this component is $13,179,000, which includes the estimated lands and damages costs, Federal and non-Federal administrative/acquisition costs, and a contingency. No improvements or relocation assistance costs were included.

Component FFF5 (Alternatives C & D)

Biscayne Bay Coastal Canals. The purpose of this component is to maintain higher stages in the C-102 and C-103 Canals for urban and environmental water supply. A proposed borrow canal will interconnect the downstream reaches of the C-102 and C-103 Canals. Approximately 350 acres of land located within Miami-Dade

County would be required for this component. The total estimated real estate cost of this component is $5,655,000, which includes the estimated lands and damages costs, Federal and non-Federal administrative/acquisition costs, and a contingency. No improvements or relocation assistance costs were included.

Component GGG6 (Alternative D)

C-51 and Southern L-8 Reservoir. The purpose of this component is to reduce the number, magnitude, and volume of discharges to the Lake Worth Lagoon; to provide water supply deliveries to the Northwest Fork of the Loxahatchee River, Lake Worth Drainage District and the West Palm Beach Water Catchment Area; and to provide flood peak attenuation to the C-51 and southern L-8 Basins. Approximately 1,800 acres in Palm Beach County would be acquired for this component. The total estimated real estate cost of this component is $27,351,000, which includes the estimated lands and damages costs, Federal and non-Federal administrative/acquisition costs, and a contingency. No improvements or relocation assistance costs were included.

Component HHH6 (Alternative D)

West Dade Reuse. The purpose of this component is to enhance groundwater recharge to the Bird Drive Recharge Area, and to provide water supplies to the South Dade Conveyance System and Northeast Shark River Slough. Approximately 100 acres of vacant land in Miami-Dade County was valued for this component. The total estimated real estate cost of this component is $3,540,000, which includes the estimated lands and damages costs, Federal and non-Federal administrative/acquisition costs, and a contingency. No improvements or relocation assistance costs were included.

F.8 RECOMMENDED PLAN-ALTERNATIVE D-13R

As Alternatives A through D were being formulated, more extensive real estate information was being obtained from the South Florida Water Management District, on lands that it had already acquired within components of the alternatives. Additionally, attempts were made to obtain information on the estates owned by South Florida Water Management District in lands within existing canal rights-of-way as well as the width of the rights-of-way. The teams from Real Estate Division and Planning Division also met to discuss the different components and the variables that would determine the contingencies for the components in Alternative D13R. Real Estate Division was requested to provide for each component a range of values (cost estimates). The range would present an estimated low-end cost, an estimated high-end cost, and the estimated probable cost for each component in the Initial Draft Plan. Estimated low-end, estimated probable, and estimated high-end costs are based on a number of different scenarios, which are discussed further in each of the components. After review of information obtained from the South Florida Water Management District, costs for the Initial Draft Plan were modified accordingly. Additional acreage was added to some of the components, because it was determined that South Florida Water Management District did not own some of the lands that were thought to be owned by it during the review of Alternatives A through D. Contingencies on each of the components could be reduced, if mineral interests outstanding in third parties were not acquired. A method of accomplishing this would be to secure a release of the right of entry to the surface from the owner of the third party mineral interest (see discussion in Paragraph 22 below). After completion of the Initial Draft Plan, South Florida Water Management District and other component proponents provided additional real estate information, including revised acreages and revised recommended land costs that have been incorporated into the recommended Comprehensive Plan.

Component A6

Component A6 is a storage reservoir and stormwater treatment area located north of Lake Okeechobee with a total storage capacity of 200,000 acre-feet. The purpose of the storage reservoir is to increase the capacity of the hydrologic system to better meet the water management objectives associated with flood protection, water supply and environmental enhancement and to reduce nutrient loads flowing to the lower Kissimmee River and Lake Okeechobee. The additional water storage capacity allows for greater detention of water during wet periods for subsequent use during dry periods. It is also anticipated that this increased storage capacity will shorten the duration and frequency of both high water levels in the Lake that are stressful to the Lake littoral ecosystems, and large discharges from the Lake that are disruptive to the downstream estuary ecosystems. Water from Lake Okeechobee is to be pumped into this storage reservoir when the climate-based inflow forecast projects that the Lake water level will rise significantly above those levels that are desirable for the Lake littoral zone. During the dry season, flows will be allowed back to the Lake from the reservoir when the Lake level is projected to fall to within three-quarters of a foot of the supply-side management line in the same dry season, or below 11.75 feet NGVD in the upcoming wet season. During the wet season, flow will be allowed from the reservoir to the Lake, when climate-based inflow forecast projects less than 1.5 million acre-feet of inflow during the next 6 months, and the Lake water level is either currently below 11.75 feet NGVD or projected to be in supply-side management during the upcoming dry season. There will be an inflow pump station with a capacity of 4,800 cfs and an outflow structure with a capacity of 4,800 cfs.

This component could lie in any of three counties north of Lake Okeechobee (Glades, Highlands, or Okeechobee). The counties appear to be primarily agricultural in nature and the approach to locating this component would be to stay in an area that was as rural as possible. The range of values estimated for this component are between $400 to $2,500 per acre for pasture land and other general agricultural uses; however, sales are dated due to slow growth and stabilized communities. Citrus is a large crop in some of the counties being analyzed. Older citrus grove sales in various counties reflect an estimate of value between $8,000 to $12,000 per acre. More recent citrus grove sales reflect an estimate between $4,000 and $6,000 per acre, generally. It is not anticipated that this component will have any impacts to commercial or residential properties, therefore, no commercial or residential sales are considered at this time. There are several large ownerships in these counties and sales are dated and sparse. Since this component covers such a large area, 20,000 acres, and the exact location has not been determined, and there are unknown land parameters; only very broad generalities can be surmised. There are no values being included for improvements at the present time.

Due to an indefinite location within the three counties being considered for this component, an estimated value of $6,000 per acre is being used for the estimated probable cost. As such, 20,000 acres at $6,000 per acre yields an estimate of $120,000,000 for the estimated probable land cost of Component A6. The number of affected ownership tracts is unknown, but is projected to be approximately 360 tracts. Based on this, the Federal administrative/acquisition cost is estimated at $2,160,000, and the non-Federal administrative/acquisition is estimated at $4,320,000. The number of residential and/or business relocations is unknown. A contingency of 50 percent is added to this component to cover these unknowns. The total estimated probable real estate cost of this component is $189,720,000.

The estimated low-end real estate cost of this component is $46,614,000. This estimate is based on the assumption that the site would be located in Okeechobee County on 18,720 acres identified as a potential site. This site is valued at $26,816,000. The same acquisition/administrative estimates apply, but the contingency factor is lowered to 40 percent due to identification of a potential site.

The estimated high-end real estate cost of this component is at $249,720,000. This is assuming that the site could be in any of the three counties and would include more citrus groves than pasture/crop land. The estimated land costs for the 20,000 acres is $160,000,000. The same acquisition/administrative estimates apply as well as a 50 percent contingency.

Component B2

Component B2 is a storage reservoir in the St. Lucie/C-44 Basin to be located in Martin County. The purpose of the storage reservoir to capture local runoff from C-44 Basin. The reservoir will be designed for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. It will have an inflow pump station with a 1,000 cfs capacity and an outflow structure with an 800 cfs capacity.

The general area designated for this 10,000-acre storage reservoir is north of the St. Lucie Waterway, and in an easterly direction of Indiantown. The specific site has not been selected and mapped. The general area identified appears to be primarily in citrus groves. Aerials available of this area show a preponderance of groves, which are assumed to be citrus.

Based on grove sales and sales listings in the area a value of $6,000 per acre or a total probable land value estimate of $60,000,000 for 10,000 acres of groves in the general area of this component. There are no values being placed on crops or improvements in this estimate. The number of affected ownership tracts is unknown, but is projected to be approximately 25 tracts. Based on this, the Federal administrative/acquisition cost is estimated at $150,000 and the non-Federal administrative/acquisition cost is estimated at $300,000. The number of residential and/or business relocations is unknown. A contingency of 50 percent is added to this component to cover these unknowns. The total estimated probable real estate cost of this component is $90,675,000.

The estimated low-end real estate cost of this component is $78,585,000, which reflects a 30 percent contingency on the estimated land costs of $60,000,000, and the assumption that the Federal and non-Federal administrative/acquisition costs would remain as set forth above. The 30 percent contingency is based on the assumptions that the site would include low cost or no improvements, there would be little or no severance damages, and minimal relocation costs.

The estimated high-end real estate cost of this component is $93,375,000. This is assuming that all the lands are groves at $6,000 per acre for a total estimated land cost of $60,000,000 and all 25 tracts contain improvements valued at $50,000 for each parcel ($1,250,000 total) and the owners will have to be relocated at an estimated cost of $550,000. The Federal and non-Federal administrative/acquisition costs would remain the same as set forth above and the contingency would be 50 percent.

Component D5

Component D5 is a storage reservoir with Aquifer Storage and Recovery in the Caloosahatchee/C-43 Basin to be located within Hendry, Glades or Lee Counties. The purpose of the storage reservoir(s) with aquifer storage and recovery is to capture basin runoff and releases from Lake Okeechobee. These facilities will be designed for water supply benefits, some flood attenuation, and to provide environmental water supply deliveries to the Caloosahatchee Estuary. Excess runoff from the C-43 Basin and Lake Okeechobee flood control discharges will be captured by the proposed C-43 reservoir(s). Water from the reservoir(s) will be used to provide environmental deliveries to the Caloosahatchee Estuary, to meet demands in the Caloosahatchee Basin and to inject water into the aquifer storage and recovery wellfield for long-term (multi-season) storage. Water from the aquifer storage and recovery facilities will be used to meet environmental demand of the estuary and meet basin demands. Any estuarine demands not met by basin runoff, the reservoir, and the aquifer storage and recovery system, will be met by Lake Okeechobee, as long as Lake Stage is above 11.5 feet NGVD. Lake water is also used to meet the remaining basin demands subject to supply-side management. The C-43 reservoir is operated in conjunction with Component DDD5, the Caloosahatchee Backpumping Facility, which includes a stormwater treatment area for water quality treatment. If the levels of water in the reservoir exceed 6.5 feet and Lake Okeechobee is below the pulse release zone, then water is released and sent to the backpumping/treatment facility at 2,000 cfs. The component will also have a total of 44, 5-million gallons per day (MGD) aquifer storage and recovery wells with inflow limited to 220 MGD and outflow structures limited to 220 MGD. The reservoir inflow pump will have a capacity of 3,800 cfs with an outflow structure capacity of 3,000 cfs.

This is a 20,000 acre storage site may be located in Glades, Lee or Hendry Counties. However, this no site has been finalized. Sales available on general agricultural land in these counties were from $400 to $2,500 per acre. Groves are estimated at $6,300 per acre. There can be no specific values included for structures as none are identified. More specific land uses can not be identified with the data currently available.

Based on the indefinite location, it is assumed that half of the required acreage (10,000 acres) would likely be sugar cane/pasture land at a value estimated at $2,500 per acre, and the other half of the required land (10,000 acres) would be groves at a value estimate of $6,300 per acre. This assumes that no significant amount of residential, or commercial property will be involved. Therefore 10,000 acres at $2,500 yields $25,000,000 and 10,000 acres at $6,300 yields $63,000,000 for a total of $88,000,000 in probable land costs for this component.

The number of affected ownership tracts is unknown, but is projected to be approximately 23 tracts. Based on this, the Federal administrative/acquisition cost is estimated at $138,000 and the non-Federal administrative/acquisition cost is estimated at $276,000. The number of residential and/or business relocations is unknown. A contingency of 50 percent is added to this component to cover these unknowns. Both the estimated probable and estimated high-end real estate cost estimates are the same for this component, $132,621,000.

The estimated low-end real estate cost of this component is $63,018,000, which reflects a probability that all 20,000 acres would be sugar cane/pasture land at $2,500 per acre for a total land value of $50,000,00 and that Federal and non-Federal administrative/acquisition costs would be the same as set forth above. A 25 percent contingency was applied. This contingency is based on the assumptions that the site would consist mostly of unimproved pastureland and that there would be only 23 affected tracts.

Component G6

Component G6 is a storage reservoir in the Everglades Agricultural Area conceptually located in Palm Beach County between the Miami & North New River Canals. The component will include Bolles and Cross Canal conveyance capacity improvements. The purpose of the storage reservoir is: (a) to improve the timing of environmental deliveries to the Water Conservation Areas, including reducing damaging flood releases from the Everglades Agricultural Area to the Water Conservation Areas; (b) to reduce Lake Okeechobee regulatory releases to estuaries; (c) to meet supplemental agricultural irrigation demands; and (d) to increase flood protection within the Everglades Agricultural Area. Conveyance capacity of the Miami and North New River Canals between Lake Okeechobee and the storage reservoir(s) is increased to convey additional Lake Okeechobee flood control releases that would have otherwise been discharged to the Caloosahatchee and St. Lucie Estuaries. Conveyance capacity of the Bolles and Cross Canals between the Miami and Hillsboro Canals is increased to facilitate interbasin transfers for storage and flood protection. The component will be operated so that inflows are from Lake Okeechobee regulatory discharges and runoff from Miami and North New River and canal basins. The reservoir will be divided into three compartments.

Compartment 1: 20,000 acres, meets Everglades Agricultural Area irrigation demands only. The source of water is excess Everglades Agricultural Area runoff. Inlet capacities for excess runoff are 2,700 and 2,300 cfs, for the Miami Canal and the North New River Canal Basins, respectively. Outlet capacities for Everglades Agricultural Area demands are 3,000 and 4,400 cfs, for the Miami Canal and the North New River Canal Basins. Overflow to compartment 2A occurs when the depth of water approaches 6 feet maximum and Lake Okeechobee regulatory discharges are not occurring or impending. Excess Everglades Agricultural Area runoff is diverted to compartment 2A only if Water Conservation Area 3A is too deep.

Compartment 2A: 20,000 acres, meets environmental demands as a priority, but can supply a portion of Everglades Agricultural Area irrigation demands if environmental demands equal zero. The sources of water are overflow from compartment 1 and Lake Okeechobee regulatory releases including the weather forecasting to initiate storage usage. Compartment 2A will be operated as a dry storage reservoir and discharges made down to 18 inches below ground level. This compartment will have inflow pumps with capacity of 4,500 cfs and 3,000 cfs for diversion of Lake Okeechobee regulatory releases from the Miami Canal and the North New River Canal, respectively, and an outflow structure with a capacity of 3,600 cfs at 6 feet head to Stormwater Treatment Area 3/4. The component also increases the conveyance capacity in the Miami, North New River and Bolles and

Cross Canal by 200 percent, with outflow structures to the Miami Canal of 4,500 cfs and to the North New River Canal of 3,000 cfs.

Compartment 2B: 20,000 acres, meets environmental demands as a priority. The sources of water are overflow from compartment 1 and 2A and Lake Okeechobee regulatory releases only during the extreme wet events. Compartment 2B will be operated as a dry storage reservoir and discharges made down to 18 inches below ground level. The conveyance of the northern reaches of the Miami and North New River Canals in the Everglades Agricultural Area are tripled (200 percent increase) for Lake Okeechobee regulatory releases. Structures with a capacity of 4,500 cfs for diversion of regulatory releases through the Miami Canal and 3,000 cfs for diversion of regulatory releases through the North New River Canal are added to compartments 2A and 2B. When the reservoir depth falls below 1.5 feet, Lake Okeechobee is used for meeting supplemental irrigation and environmental demands. The flows will be delivered to the Water Conservation Areas through Stormwater Treatment Area 3/4.

The Department of Interior and South Florida Water Management District are acquiring property in the Everglades Agricultural Area, known as the Talisman property, utilizing funds from the Farm Bill (Public Law 104-127, Section 390)-Interior funding and South Florida Water Management District funds. The purchase of the Talisman property will provide approximately 45,000 acres of the 60,000 acres required for this component. The purchase price for the Talisman property ($152,500,000) is being funded by the Department of Interior and South Florida Water Management District. The Department of Interior is contributing $108,000,000 and the South Florida Water Management District will contribute $44,500,000 ($25,500,000 for the lands to be utilized as stormwater treatment areas to be acquired pursuant to the State's Everglades Forever Act and $19,000,000 for the purchase of the retention rights of Talisman). The $19,000,000 will be applied to the Restudy cost share of the South Florida Water Management District; however, the $25,500,000 will not be credited. The lands ultimately acquired will eventually be transferred to the South Florida Water Management District and can be utilized for this component. The South Florida Water Management District and Interior are working on a series of exchange agreements with private parties that may provide up to 45,114 acres for this component. Additionally, Interior has funded through a Farm Bill grant, funding for the purchase of an additional 1,233 acres by South Florida Water Management District in the amount of $3,090,800. The South Florida Water Management District is also purchasing 5,280 acres in the same area for approximately $20,000,000 that could be utilized for this component. This land is a sod farm. Approximately $111,100,000 of Interior funds will be applied as part of the Federal cost share for this component. As this component requires a 60,000-acre storage site, for planning purposes, it is estimated that the remaining acreage required for this component will be approximately 8,400 acres. The remaining 8,400 acres are valued partly as sugar cane and partly as sod farms. Sales for lands in sugar cane are valued from $2,800 to $3,400 per acre in this area. However, there are other agricultural uses (sod farms) in this area that have a range in value between $3,700 and $4,000 per acre. This is an area of largely open agricultural lands. For planning purposes, it is assumed that of the remaining 8,400 acres; 4,000 acres would be in sugar cane valued at $3,400 per acre for a total of $13,600,000, and the remaining 4,400 acres would be sod farms at $4,000 per acre for a total of $17,600,000, therefore this 8,400 acres is valued at $31,200,000. The total estimated probable and estimated high-end real estate lands and damages valuation for this area would be $70,200,000 ($31,200,000-8,400 acres + $19,000,000 Talisman retention + $20,000,000 –5,280 acre sod farm).

The number of affected ownership tracts is unknown, but is projected to be approximately 18 tracts. The Federal administrative/acquisition cost is estimate at $9,000 per tract and non-Federal administrative/acquisition cost is estimate at $18,000 per tract. Based on this, the Federal administrative/acquisition cost is estimated to be $162,000 and the non-Federal administrative/acquisition cost is estimated to be $324,000. The number of residential and/or business relocations, mineral activity, and severance damages are unknown. A contingency of 50 percent is added to 8,400 acres land cost of $31,200,000 ($15,600,000 contingency) and the administrative/acquisition costs to cover these unknowns. Both the estimated probable and estimated high-end real estate cost estimates are the same for this component, $86,536,000 for the remaining acres required.

The estimated low-end real estate cost of this component is $63,006,000. This assumes the low-end range of value ($2,800) per acre for the remaining 8,400 acres ($23,520,000) added to the Talisman retention ($19,000,000) and the cost for the 5,280 acre sod farm ($20,000,000) for the lands and damages estimate. All the other cost estimates remain the same as the probable/high-end cost estimate, including a 50 percent contingency on the $23,520,000 and the Federal and non-Federal administrative/acquisition costs.

Component K6

Component K6 is a modification of the L-8 project, which includes a proposed reservoir as described in component GGG6 and an Aquifer Storage and Recovery capacity of 50 million gallons per day. It is located in the Water Preserve Area in Palm Beach County and comprises 380 acres (not including the proposed storage reservoir as described in component GGG6). The purpose of this component is to reduce water supply restrictions in the Northern Palm Beach County Service Area by capturing more of the annual discharges from portions of the southern L-8, C-51 and C-17 Basins and route this water to the West Palm Beach Water Catchment Area. Intent is to increase water supply availability and provide pass through flow to enhance hydroperiods in Loxahatchee Slough and increase base flows to the Northwest Fork of the Loxahatchee River. The component would be operated to capture excess L-8, C-51 and C-17 Basin water to meet urban water supply demands in the Northern Palm Beach County Service Area and enhance hydroperiods in the Loxahatchee Slough. Water would be diverted through the M-Canal to the Water Catchment Area. Stormwater treatment areas will be provided to meet all water quality standards required if necessary. The component will have aquifer storage and recovery well with a capacity of 50 million gallons per day to provide water during regionally triggered droughts and as a means of reducing withdrawals from the West Palm Beach Water Catchment Area when the water levels are substantially below the target hydrograph. The majority or all of the 50 million gallons per day aquifer storage and recovery well clusters will be located in the vicinity of the City of West Palm Beach Water Treatment Plant (Clear Lake). However, due to modeling limitations, the aquifer storage and recovery wells will be located in the West Palm Beach Water Catchment Area. During periods when the West Palm Beach Water Catchment Area is above 18.0 feet NGVD, an additional (above the flow rate required to supply the water treatment plant) 50 million gallons per day (78 cfs) will be sent to Lake Mangonia for subsequent storage through the aquifer storage and recovery clusters (surficial well discharging into a Floridan well). The aquifer storage and recovery wells will provide water directly to Lake Mangonia when water levels in the West Palm Beach Water Catchment Area are within 0.2 feet of the level that triggers regional supply to the West Palm Beach Water Catchment Area. Another part of the component will be to increase the pumping capacity from the L-8 Tieback into the M-Canal to 300 cfs to increase the volume of water captured from the southern L-8 Canal and deliver it to the Water Catchment Area. This pump has dual purposes, 1) to capture L-8 Basin runoff when available and 2) to deliver regional deliveries when needed. This component also assumes that the Indian Trail Improvement District will adopt an operation plan which promotes water conservation by prioritizing discharge so that excess storm water is first offered to the West Palm Beach Water Catchment Area through installation of 2 pumps (300 cfs and 200 cfs) and secondarily discharged through off peak releases to the C-51 Canal via the M-1 Canal. For this alternative, pumping from Indian Trail Improvement District into the M-Canal for subsequent discharge into the West Palm Beach Water Catchment Area will be assumed to occur under the following conditions: (a) when the City of West Palm Beach Water Catchment Area has sufficient need for imported water as defined by being below 18.2 feet NGVD; (b) when water levels in the lower M-1 Basin exceed 14.0 feet NGVD during the wet season (June 1 through October 31) or 16.0 feet NGVD during the dry season (November 1 through May 31) the lower M-1 Basin may discharge up to 200 cfs for subsequent storage; and (c) when water levels in the upper M-1 Basin exceed 15.0 feet NGVD during the wet season or 16.0 feet NGVD during the dry season) the upper M-1 Basin may discharge up to 300 cfs for subsequent storage. Other features will be to (a) increase the conveyance of the M-Canal between the pump and the West Palm Beach Water Catchment Area to accommodate the increased inflow from the L-8 Canal and the Indian Trail Improvement District; and (b) to install a new structure in the south leg of C-18 just south of the west leg to facilitate better management of water levels and discharges from the Loxahatchee Slough. The new gravity structure would consist of a variable discharge up to 400 cfs and emergency overflow weirs; install a 50 cfs pump for water supply deliveries to utilities. A recharge canal may be improved to convey deliveries to utilities. Additionally a Stormwater Treatment Area(s) may be needed upstream of the Water Catchment Area to attain acceptable water quality standards and to accommodate future degradation of water quality. The size and location of the Stormwater Treatment Area(s) will be determined if treatment is required. New culverts will be constructed under Bee-Line Highway for up to 100 cfs deliveries to Loxahatchee Slough.

This estimate is based on very general information and relies on county-wide general knowledge. This is not a site specific component estimate. The component requires 40 acres of pasture/open land, required for widening an existing canal, with an amount of $10,000 per acre applied for a total lands and damages estimate of $1,420,000 for this 40 acres. The 40 acres consists of land required in widening the existing M Canal right-of-way. An additional approximately 340 acres is within the existing right-of-way of the M Canal, currently owned by Palm Beach County, which will be required. If the local sponsor has to acquire an interest from Palm Beach County for the 340 acres, that cost will be approximately $1,020,000 based on a estimated value of $3,000 per acre.

The number of affected ownership tracts is unknown, but is projected to be approximately 80 tracts. Based on this, the Federal administrative/acquisition cost is estimated to be $480,000, and the non-Federal administrative/acquisition cost is estimated to be $960,000. The number of residential and/or business relocations, mineral activity, and severance damages are unknown. The total real estate cost estimate for the probable and high-end costs is $4,290,000. This includes a contingency of 50 percent for the unknowns, and also assumes that the non-Federal sponsor will have to acquire an interest in the existing 340-acre M Canal from the County of Palm Beach.

The low-end estimated real estate cost of this component is $2,576,000. This assumes that the only acquisition needed for this component is the additional 40 acres to expand the canal's existing right-of-way, plus a 40 percent contingency. An amount of $10,000 per acre is estimated, for a total lands and damages estimate of $1,420,000. The Federal and non-Federal administrative/acquisition costs and the contingency are the same as in the estimated probable costs.

Component M6

Component M6 is a reservoir in the Water Preserve Area in Palm Beach County with a portion of the existing Hillsboro Canal incorporated into the reservoir. There will also be aquifer storage and recovery capacity of 75 million gallons per day and increased backpumping capacity. The purpose is to provide a water supply storage reservoir to supplement water deliveries to the Hillsboro Canal during the dry-season. The reservoir will be filled during the wet-season from excess water backpumped from the Hillsboro Canal. Water will be released back to the Hillsboro Canal to help maintain canal stages during the dry-season. If water is not available in the reservoir, existing rules for water delivery to this region will be applied. Aquifer Storage and Recovery capacity is being increased to improve water supply during dry seasons and droughts. Fifteen (15) 5 million gallons per day capacity aquifer storage and recovery wells will be added for a total of thirty (30) aquifer storage and recovery clusters for this alternative (total injection and recovery capacity is 150 million gallons per day or about 230 cfs). Water from the Site 1 Impoundment will be injected into the aquifer storage and recovery wells when stages in the impoundment are greater than 12.0 feet NGVD (0.5 feet of depth). Water will be recovered from the aquifer storage and recovery wells when stages in the Hillsboro Canal are less than 7.0 feet NGVD. There will be an inflow pump with a capacity of 700 cfs, which will be relocated to the eastern end of the Hillsboro Canal; an outflow structure with a capacity of 200 cfs at 4 feet of head; an emergency outflow structure with a capacity of 700 cfs; and thirty (30) – 5 million gallons per day aquifer storage and recovery wells.

There is an existing site of approximately 1,658 acres owned by South Florida Water Management District. The purchase price for this approximately 1,658 acres was $8,300,000. An additional 800 acres is required contiguous and south of the above acreage. The estimated price of this additional land is $12,000 per acre for a total value of $9,600,000. Total estimated probable land and damages costs are $17,900,000.

The number of affected ownership tracts is unknown, but is projected to be approximately 31 tracts. Based on this, the Federal administrative/acquisition cost is estimated to be $186,000 and the non-Federal administrative/acquisition cost is estimated at $425,000. The number of residential and/or business relocations, mineral activity, and severance damages are unknown. For both the probable and high-end cost estimates, a contingency of five percent is placed on the acquisition/administrative costs of the site already owned by South Florida Water Management District (currently estimated at $65,000). A contingency of 50 percent is placed on the 800-acre site value and the balance of the acquisition/ administrative cost estimate ($546,000) for this component. These contingencies are added to cover unknowns such as number of landowners, possible severance damages, outstanding mineral interests and possible relocation costs. Both the probable and high-end real estate cost estimates are the same for this component, $23,587,000.

The low-end estimated real estate cost of this component is reduced only by lowering the contingency to 40 percent on the 800-acre value and associated acquisition/administrative costs. The low-end estimate for this component is $22,573,000.

Component O6

Component O6 is located in the Water Preserve Area in Broward County. The purpose of this component is to reduce seepage from Water Conservation Areas 3A and 3B to improve hydropatterns within the Water Conservation Areas by allowing higher water levels in the borrow canals and longer inundation durations within the marsh areas that are located east of the Water Conservation Areas and west of US Highway 27. Seepage from the Water Conservation Areas and marshes will be collected and directed south into the Central Lake Belt Storage Area. This will maintain flood protection and the separation of seepage water from urban runoff originating in the C-11 Basin and Lake Okeechobee water supply deliveries. The L-37 and L-33 borrow canals will be operated to be held at higher stages as part of the Water Conservation Area 2 seepage collection and conveyance system (Component YY). Seepage collected in the L-37 and L-33 borrow canals and from the marsh areas will be directed into the Water Conservation Area 2 seepage collection and conveyance system and directed south into the Central Lake Belt Storage Area or directly to Northeast Shark River Slough. New levees will be constructed west of US Highway 27 from the North New River Canal to the Miami (C-6) Canal to separate seepage water from the urban runoff in the C-11 diversion canal (Component Q). The L-37 and L-33 borrow canals will be controlled at higher stages as will the marshes located east of the Water Conservation Areas. A divide structure will be added to the C-11 Canal west of US Highway 27 to maintain the separation of seepage water from urban runoff. Water from C-11 west will be diverted to the North Lake Belt Storage Area.

This component is in Broward County. The real estate involved here is a divide structure being added to the C-11 Canal just east of US-27 and new levee west of Highway 27. The real estate needs for the divide structure have not been identified or quantified, but the acreage estimate given for this component is 6,542 acres. However, approximately 3,185 acres lie west of Levee 37 and east of Levee 68A. As this land was once contained in the adjacent Water Conservation Area 3A, it was acquired for the prior project and is therefore not valued.

For the remaining 3,352 acres, the South Florida Water Management District has acquired approximately 2,360 acres at a cost of $44,683,000. For the remaining 992 acres remaining to be acquired, 982 acres is valued at $19,000 per acre based solely on what South Florida Water Management District has previously paid per acre for a total of $18,658,000.

The remaining approximately 10 acres required are located to the east of US Highway 27. The land to the east of US-27 appears to have a range from $15,000 to $26,500 per acre. Any land with frontage on US-27 has the potential of higher value due to the road frontage. The estimate value for this 10 acres is $26,000 per acre for a total of $260,000. Total estimated probable land and damages cost is $63,601,000 ($44,683,000 + $18,658,000 + $260,000).

The number of affected ownership tracts is unknown, but is projected to be approximately 250 tracts. Based on this, the Federal administrative/acquisition cost is estimated to be $1,500,000 and the non-Federal administrative/acquisition cost is estimated at $3,000,000. The number of residential and/or business relocations, mineral activity, and severance damages are unknown. For both the probable and low-end end cost estimates, a contingency of 25 percent is added to the total real estate cost estimate. The lower contingency reflects more accurate information received from South Florida Water Management District, and the costs paid to date by them for the land already purchased. The total probable/low-end real estate cost estimate for this component is $85,126,000.

The high-end estimated real estate cost of this component reflects a value of $20,000 per acre for the additional 982 acres required, and a value of $30,000 per acre for the 10 acres east of U.S. Highway 27 required for this component. The Federal and non-Federal administrative/acquisition costs are the same as those in probable/low end cost estimate. The contingency is also increased to 30 percent on the overall cost to reflect unknowns. The total estimated high-end cost of this component is $89,859,000.

Component Q5

Component Q5 is the Western C-11 Diversion Impoundment and Canal located in the Water Preserve Area in Miami-Dade and Broward Counties. The purpose of this component is to divert untreated runoff from western C-11 that is presently discharged into Water Conservation Area 3A through the C-11 Stormwater Treatment Area /Impoundment to the North Lake Belt Storage Area. Runoff in the western C-11 Canal that was previously backpumped into Water Conservation Area 3A will be diverted to the C-11 Stormwater Treatment Area/Impoundment and then to North Lake Belt Storage Area. If storage capacity is not available in the impoundment or North Lake Belt Storage Area, then the S-9 pump will be used for flood protection for the Western C-11 Basin, which pumps to Water Conservation Area 3A. To improve groundwater elevations in the eastern C-11 Basin, the S-9 seepage divide structure will be operated to maintain the western C-11 Canal stage at elevation 3.0 feet NGVD. The component will have: (1) a 2,500 cfs diversion canal west of U.S. 27 between C-11 and C-9 and 2,500 cfs conveyance capacity improvements to the C-9 Canal between S-30 and the North Lake Belt Storage Area; (2) an intermediate 2,500 cfs pump station in the C-11 Canal to direct runoff to the C11 Stormwater Treatment Area/Impoundment; (3) a 1,600-acre, Stormwater Treatment Area/Impoundment with a maximum depth of 4 feet; (4) a Seepage Collection canal and Pump for C-11 Stormwater Treatment Area/impoundment; and (5) a 2,200 cfs structure to discharge from the impoundment to C-11 west of US 27 to diversion canal.

This component will require a new canal with a width of 500 feet and a length of 46,569 feet for a total of 535 acres. Land involving frontage on SR-27 could have higher zoning and/or commercial possibilities influencing the value. Generally, land west of, and in near proximity to, SR-27 is estimated at $5,000 per acre in Broward County and assumed to have some agricultural possibilities. Information indicates that South Florida Water Management District has paid $5,000 per acre for this type of land. Therefore, 535 acres at $5,000 per acre yields $2,675,000

A 1,600-acre Stormwater Treatment Area is also required for this component. The indicated estimate for this land is in the range of $15,000 to $20,000 per acre. South Florida Water Management District has purchased approximately 497 acres at a total cost of $11,366,000 or approximately $22,869 per acre. The land is being estimated at a value of $22,900 per acre for this area due to its dynamics, for the probable/high-end cost estimate. Having then approximately 1,103 acres at a value estimate of $22,900 per acre yields $25,258,700. When added to the amount already paid by South Florida Water Management District, the total probable/high-end cost estimate for this 1,600 acre area is $36,625,000.

In addition, 400 acres will be needed for an additional canal. Employing the $20,000 per acre value as discussed above, the estimated cost of the 400 acres for the canal is $8,000,000 for both the probable/high-end and low-end cost estimate.

The number of affected ownership tracts is unknown, but is projected to be approximately 639 tracts. Based on this, the Federal administrative/acquisition cost is estimated to be $3,834,000 and the non-Federal administrative/acquisition cost is estimated to be $7,668,000. The number of residential and/or business relocations, mineral activity, and severance damages are unknown. For both the probable and high-end cost estimates, a contingency of 50 percent is added to the total real estate cost estimate (less the 497 acres already purchased by South Florida Water Management District), to reflect costs for unknowns. The total probable/high-end real estate cost estimate for this component is $82,520,000.

The low-end estimated real estate cost of this component is based on appraisal information. For the low-end cost, a value of $20,000 per acre for the 1,600 acres totals $32,000,000. The 400-acre canal is valued at $8,000,000 and the 535 acres is valued at $2,675,000. A contingency of 40 percent on the 535-acre area and associated acquisition/administrative costs, and 35 percent on the 2,000 acre area to be acquired and associated acquisition/administrative costs to reflect a total low-end real estate cost estimate of $73,323,000.

Component R4

Component R4 is the C-9 Stormwater Treatment Area/Impoundment located in the Water Preserve Area in Broward County. The purpose of this component is the treatment of water supply deliveries from North Lake Belt Storage Area to C-9, C-6/C-7 and C-2/C-4 Canals. The North Lake Belt Storage Area is used to capture runoff from western C-9 Basin and C-11 west by backpumping into the curtain walled reservoir area. The C-9 impoundment will provide treatment of runoff stored in North Lake Belt Storage Area, groundwater recharge within the basin and seepage control of Water Conservation Area 3 and buffer areas to the west. Water supply deliveries from North Lake Belt Storage Area to C-9, C-6/C-7 and C-2/C-4 Canals will be pumped into the C-9 STA/impoundment for treatment of the stormwater runoff stored in the North Lake Belt Storage Area. Seepage from C-9 impoundment will be collected and returned to the impoundment. The component will have an inflow structure with a capacity of 1,500 cfs pump (North Lake Belt Storage Area); a gravity outflow structure with 1,500 cfs capacity at 4 foot head. Discharge will be made from the C-9 impoundment to C-9, C-6/C-7 and C-2/C-4 Canals for water supply deliveries.

This component will require 2,500 acres, of which 1,505 acres have already been purchased by the South Florida Water Management District for a price of $29,174,000 or approximately $19,385 per acre. The general area appears to be prairie and trees with heavy quarry influence from rock mining. There was one sale in this area that occurred in 1989 for approximately $15,000 per acre. However, land to the north has sales for $20,000 per acre and higher. Applying a 3 to 4 percent Consumer Price Index to this one sale and considering the sales to the north, indicate a value in the $20,000 per acre vicinity. Broward County has a positive and rapid growth policy and available land is being developed. This area is desirable for residential development and the pressure to develop is high.

Applying a value of $20,000 per acre to the approximately 995 acres remaining to be acquired yields a total of $19,900,000. This added to the amount paid by South Florida Water Management District ($29,174,000) totals $49,074,000 for the lands and damages cost estimate.

The number of affected ownership tracts is unknown, but is projected to be approximately 145. Based on this, the Federal administrative/acquisition cost is estimated to be $870,000 and the non-Federal administrative/acquisition cost is estimated to be $1,740,000. The number of residential and/or business relocations, mineral activity, and severance damages are unknown. For both the probable and high-end cost estimates, a contingency of 50 percent to cover unknowns is added to the 995-acre value of $19,900,000 and the associated acquisition/administrative cost estimates. The total estimated probable/high-end real estate cost estimate is $62,939,000.

The low-end estimated real estate cost of this component is $58,437,000. This includes a contingency of 30 percent on the 995-acre value of $19,900,000 and the associated acquisition/administrative cost estimates added to the costs of lands already acquired by South Florida Water Management District ($29,174,000).

Component S6

Component S6 is the Central Lake Belt Storage Area located in the Water Preserve Area in Miami-Dade County. The purpose of the in-ground reservoir is to receive excess water from Water Conservation Areas 2B, 3A and 3B. The in-ground reservoir, Central Lake Belt Storage Area, with perimeter seepage barrier will allow storage of large quantities of water without groundwater seepage losses in this highly transmissive region. The water stored in the Central Lake Belt Storage Area will be provided to 1) Northeast Shark River Slough, 2) Water Conservation Area 3B, and 3) to supply flows to Biscayne Bay when available. Inflows from L-33 (see Component ZZ) will be through a 1,500 cfs pump. Inflow ceases when stages reach ~21.0 feet NGVD (16 feet above adjacent land elevation). Inflows from L-33 will be diverted to the Central Lake Belt Storage Area. Outflows for water deliveries are pumped through a polishing marsh cell prior delivery to Northeast Shark River Slough via L-30 and a reconfigured L-31 N (see component U). Deliveries of water to Northeast Shark River Slough to maintain inundation will occur when Northeast Shark River Slough dries below trigger levels and target hydroperiods simulations call for Northeast Shark River Slough to be inundated. The Central Lake Belt Storage Area delivers water to Water Conservation Area 3B through a polishing marsh cells via L-30 to inundate the eastern area of Water Conservation Area 3B to a 6 inch depth when triggers call for deliveries. This delivery occurs when Water Conservation Area 3B dries below 6 inches above ground, and target hydroperiods simulations indicate inundation in Water Conservation Area 3B. When available, outflows will be directed to Biscayne Bay through discharges to Snapper Creek at the Turnpike. Supply from the reservoir can be withdrawn for stages down to –15 feet NGVD (up to 36 feet of working storage & maximum head on seepage barrier). The reservoir will also have a subterranean seepage barrier around the perimeter to enable drawdown during dry periods and to prevent seepage losses. Inflow structures will consist of: (a) a 1,500 cfs pump from the L-33 borrow canal; (b) a 500 cfs structure at S-9 pump station to gravity discharge from Water Conservation Area 3A to L-33; and (c) a 700 cfs structure (Existing S-31) for Water Conservation Area 3B to the Central Lake Belt Storage Area via C-6 Canal. Outflow structures will consist of: (a) a 800 cfs pump to polishing cell to make deliveries to Northeast Shark River Slough and Water Conservation Area 3B; (b) a 500 cfs pump off L-30 to deliver to Water Conservation Area 3B; (c) a 300 cfs pump to make deliveries for Snapper Creek Canal; and (d) a 1,100 cfs structure at 0.5 feet head to provide regional system deliveries to Snapper Creek Canal via C-6 if Central Lake Belt Storage Area is out of water.

This component will require 5,770 acres of what appears to be primarily wetland prairies, melaleuca trees, and quarries from rock mining. It is estimated that roughly 1,400 acres of this component appears to have quarry lakes left from rock mining. Ownership of these large lakes appears to be more a liability than an asset unless there is consideration for possible residential development, which would assume the physical land characteristics to allow this. Sales indications for the remaining lands show a low of about $2,500 per acre, which are presumed to be wetlands. Other sales have occurred at approximately $5,000 per acre and these seem to be more in the speculative realm. Then added to this mix are properties that are assumed to be quarry related by proximity to developed and developing quarry mining operations in the $10,000 to $25,000 per acre range. It should also be noted that South Florida Water Management District has paid $55,000 for an acre that was permitted for rock mining. In this case the mineral rights were included with the sale and were of significant value.

It follows that the closer land is to the ongoing rock mining operations or interest, the higher the land value with an indicated range of $10,000 to $25,000 per acre. For rock mining lands permitted and waiting on mining to commence the indication is for as much as $55,000 per acre for fee title.

The land being identified by this component, where full fee ownership is to be acquired, appears to be primarily owned by large rock companies. The 620 acres to be acquired in full fee with all mineral rights is being estimated at the highest price per acre indicated of $55,000 per acre for a total value of $34,100,000, which applies to both the probable/low-end cost estimate and the high-end cost estimate.

More distant properties from the current rock mining operations appear to be bought for speculation and have sales between $2,500 and $5,000 per acre as previously mentioned. The South Florida Water Management District has estimated the high end at $7,500 per acre for this type of land. There are many unanswered questions in this area; exact amount of land now in quarry lakes, how much land is currently under permit, how much has potential for permitting, and the remaining portion, which lies in the more speculative category. The price currently being paid for speculative land dealing appears to be $5,000 per acre; however, because of uncertainties, the South Florida Water Management District's estimate of $7,500 per acre was utilized to calculate the probable and high/end estimate. Most of the land identified in this component appears to be owned by large rock mining companies. When buying from these large rock companies, the net effect would be the same as buying quarry lakes. However, based on the market and ignoring ownership and questions of ultimate use $7,500 per acre can be justified. Of the total 5,770 acres, 620 acres is to be acquired in full fee and 5,150 will be acquired without mineral rights and allowing the excavation of limestone. So, subtracting out the 1,400 acres of quarry lakes from this 5,150-acre area leaves 3,750 acres. Therefore, the 3,750 acres is valued at approximately $7,500 per acre yielding $28,125,000, based on the South Florida Water Management District's information. This cost estimate is used for the probable/low-end estimate. For the low-end estimate, a value of $5,000 per acre for the 3,750 acres will be used, based on appraisal information.

Very large quarry lakes are left after land has been rock mined. This land is being mined so intensely that the leavings are a honeycomb effect of lakes with connecting land bridges separating them. Where a lake has been formed, by mining or borrowing in the past, residential subdivisions have been developed around them. This does not look possible with the intense method of mining that is on-going in the subject area. After mining the value is estimated to be very minimal and can only be compared with wetland sales. Therefore, an estimated $500 to $1,000 per acre is concluded for mined out properties. For purposes of this estimate, a value of $1,000 per acre is used for mined out properties, or quarry lake acreage. As such, the low-end cost estimate of this portion of the component is $1,400,000. A value of $3,500, based on South Florida Water Management District 's recommendation, is used for the probable/high-end estimate of this component ($4,900,000),

Adding the $34,100,000 value estimate for fee value with mineral rights for the 620 acres, the $28,125,000 for value excepting mineral rights and the right to excavate for limestone removal for the 3,750 acres, and the $4,900,000 value estimate for quarry lakes for the 1,400 acres, the total probable/high-end lands and damages estimate for this component is $67,125,000.

The low-end lands and damages estimate would amount to $54,250,000.

The number of affected ownership tracts is unknown, but is projected to be approximately 116 tracts. Based on this, the Federal administrative/acquisition cost is estimated to be $696,000 and the non-Federal administrative/acquisition cost is estimated to be $1,392,000. The number of residential and/or business relocations and severance damages are unknown. For the probable/high-end cost estimates, a contingency of 45 percent is added to cover unknowns. For the low-end estimate a contingency of 50 percent is added. The total estimated probable/high-end real estate cost for this component is $103,359,000. The total estimated low-end real estate cost for this component is $84,507,000.

Component T6

Component T6 is an additional C-4 Structure located in the Water Preserve Area in Miami-Dade County. The purpose of the proposed structure will provide benefits. This structure would reduce regional system deliveries by diverting dry season stormwater flows to the C-2 Canal to increase recharge nearby several coastal wellfields. The East structure would divert dry season stormwater flows from the western C-4 Basin to the C-2 Canal to recharge the wellfields in the eastern C-2 Basin. It would have an operable lift-gate with 6.5 feet NGVD overflow and approximately 400 cfs capacity (final design specifications will be determined in detailed design and hydrologic and hydraulic modeling in the future) and would be located just downstream of the Miami-Dade-Broward Levee in the C-4 Canal.

This estimate is based on very general information and relies on county-wide general knowledge. This is not a site specific component estimate. The component will require acquisition of 2.0 acres of commercial/open land. A value estimate of $75,000 per acre yields $150,000 for the estimated lands and damages cost.

The number of affected ownership tracts is unknown, but is estimated at 10 tracts. Based on this, the Federal administrative/acquisition cost is estimated to be $60,000 and the non-Federal administrative/acquisition cost is estimated to be $120,000. The number of residential and/or business relocations and severance damages are unknown. For the probable/high-end cost estimate at contingency of 50 percent is added for a total estimated real estate cost of $495,000. The total estimated low-end real estate cost for this component is $446,000, which includes only a 35 percent contingency.

Component U6

Component U6 is the Bird Drive Recharge Area located in the Water Preserve Area - Miami-Dade County. The purpose is to captures runoff from the western C-4 Basin and accepts inflows from the West Miami-Dade Wastewater Treatment Plant to recharge groundwater and reduce seepage from the Everglades National Park buffer areas by increasing water table elevations east of Krome Avenue. The facility will also provide C-4 flood peak attenuation and water supply deliveries to the South Dade Conveyance System and Northeast Shark River Slough. Inflows from western C-4 Basin and the West Miami-Dade Wastewater Treatment Plant will be pumped into the proposed Recharge Area. C-4 runoff in excess of 200 cfs will be discharged eastward. Inflows from the West Miami-Dade Wastewater Treatment Plant will be continuous when the Recharge Area depth is equal to or less than 3 feet above ground. West Miami-Dade Wastewater Treatment Plant discharges will be to deep injection wells if the depth is greater than 3 feet. A seepage management system will be operated around the east and southern perimeters of the Recharge Area. Recharge Area outflows will be prioritized to meet 1) groundwater recharge demands, 2) South Dade Conveyance System demands and 3) Northeast Shark River Slough demands, when supply is available. Regional system deliveries will also be routed through the seepage collection canal system of the Bird Drive Recharge Area to the South Dade Conveyance System, which should reduce seepage from areas west of Krome Avenue. The inflow structure will be a 200 cfs pump (to be resized as needed) from C-4 and the outflow structure will be a gravity structure with 200 cfs capacity at 2 feet of head. There will also be a Seepage Collection System up to 500 cfs pump to control a seepage collection canal at 5.0 feet NGVD. Seepage is returned to Bird Drive Recharge Area. An 800 cfs pump to provide regional system deliveries to South Dade Conveyance System. An 800 cfs canal capacity, in addition to the canal required for the Bird Drive seepage collection system, will be constructed to pass the regional system deliveries to the South Dade Conveyance System. Approximately 5 miles of canal with 800 cfs capacity between Bird Drive seepage collection system to C-1W just east of Krome Avenue. Plans are to relocate S-338 east of Krome Ave. and delivery canal.

This component will affect approximately 2,877 acres. Information from South Florida Water Management District and sales analyzed puts the value from $8,000 to $10,000 per acre in this area, though South Florida Water Management District recommends a higher value per acre of $14,000. This area has the potential of increasing pressure to develop similar to the way this is happening in Broward County currently

Using the top of the current value range, $10,000 per acre, for 2,877 acres, yields a total lands and damages probable/low-end estimate total of $28,770,000. The high-end lands and damages estimate would be $40,278,000 using the South Florida Water Management District's recommendation of $14,000 per acre.

The number of affected ownership tracts is unknown, but is estimated to be 1,460. Based on this, the Federal administrative/acquisition cost is estimated to be $5,840,000 and the non-Federal administrative/acquisition cost is estimated to be $13,140,000. Because of the number of estimated tracts, the Federal administrative/acquisition cost is estimated at $4,000 per tract and the non-Federal administrative/acquisition cost is estimated at $9,000 per tract. The number of residential and/or business relocations and severance damages are unknown. For both the probable/low-end and high-end cost estimates a contingency of 50 percent is added. The total estimated real estate cost for the probable/low-end component cost is $71,625,000. The high-end total estimated real estate cost is $88,887,000 based on a per acre value of $14,000 per acre with the administrative/acquisition costs remaining the same as in the probable cost estimate and a 50 percent contingency.

Component W2

Component W2 is the Taylor Creek/Nubbin Slough Storage and Treatment Area located is either Okeechobee or St. Lucie Counties and is comprised of a total of 10,000 acres, with a Storage Reservoir of 5,000 acres at 10 feet maximum depth having an inflow pump with a capacity of 2,500 cfs and an outflow pump with a capacity of 1000 cfs, and a Stormwater Treatment Area of 5,000-acres at 4 feet maximum depth having an inflow pump with a capacity of 1,000 cfs (same structure as reservoir outflow) and an outflow pump with a capacity of 1,000 cfs. The purpose of the storage reservoir and stormwater treatment area is to provide flood protection, water quality treatment, estuary protection and water supply benefits. The component will be operated so that local runoff from the Taylor Creek/Nubbin Slough Basins is pumped into the 5,000-acre reservoir and then into the 5,000-acre stormwater treatment area. The stormwater treatment area will reduce phosphorus concentrations in the runoff from approximately 0.528 mg/l to 0.107 mg/l. Treated water will then be pumped into Lake Okeechobee when the lake stage is falling and is at least 0.5 feet below the bottom pulse release zone.

This component requires a storage reservoir and stormwater treatment area in the vicinity of Taylor Creek/Nubbin Slough, a small part of which appears to be in Okeechobee County and the larger part in Martin County. The mapping provided for this component was general in nature and did not give a detailed location for this 10,000-acre tract. The Martin County Property Assessor's Office states that this area is primarily cleared pasture and sales reflect a range of $1,500 to $1,800 per acre.

This 10,000-acre site is being estimated at $1,800 per acre for a value of $18,000,000 for the probable/low-end lands and damages cost estimate. South Florida Water Management District's recommendation of $3,000 per acre for a total of $30,000,000 is estimated for the lands and damages high-end cost estimate.

The number of affected ownership tracts is unknown, but is projected to be approximately 100. Based on this, the Federal administrative/acquisition cost is estimated to be $600,000 and the non-Federal administrative/acquisition cost is estimated to be $1,200,000, for both the probable/low-end and high-end costs. The number of residential and/or business relocations, mineral activity, and severance damages are unknown. For both the probable/low-end and high-end cost estimates, a contingency of 50 percent to cover unknowns is added. The total estimated real estate cost for the probable/low-end estimate is $29,700,000. The total estimated cost for the high-end estimate is $47,700,000.

Component X6

Component X6 is the C-17 Backpumping with the land required being located in Palm Beach County. The purpose is to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-17 Basin to the West Palm Beach Water Catchment Area and enhance hydroperiods in the Loxahatchee Slough. The component will be operated to capture excess C-17 Canal water to meet urban water supply demands in North Palm Beach Service Area. Water would be diverted through existing canals to a stormwater treatment area and ultimately to the West Palm Beach Water Catchment Area. The component will be designed to have a 200 cfs pump in the existing Northern Palm Beach County Improvement District Canal at its intersection with the Turnpike Canal to pull flows west and direct them south into the east Turnpike Canal. A culvert will be constructed under 45th Street (N/S) to connect the east Turnpike Canal. A 150 cfs capacity culvert and pump from the Turnpike Canal will direct flows into the proposed stormwater treatment area. There will be a 550-acre stormwater treatment area at 4 feet maximum depth with a 200 cfs culvert to connect the stormwater treatment area under Florida's Turnpike to allow nonrestrictive flows and a 100 cfs gravity discharge structure into West Palm Beach Water Catchment Area.

This site is a 550-acre Stormwater Treatment Area to be located west of the West Palm Beach Water Catchment Area. The property in this general area is reported to be underwater year round. Property records show sales from approximately $5,000 per acre to $21,000 per acre in this vicinity. Palm Beach County owns land in this area and appears to have paid an estimated $16,000 per acre for some of it.

However, land that is underwater year round or even most of the year should logically be valued in the lower range. However, as land delineation is not being accurately detailed at this stage of planning, the property is being valued at $12,500 (or mid-range) for the probable cost lands and damages estimate to total $6,875,000. The low-end estimate includes valuing the property at $5,000 per acre for a total of $2,750,000. The high-end estimate includes valuing the property at $21,000 per acre for a total of $11,550,000.

The number of affected ownership tracts is unknown, but is estimated to be two. Based on this, the Federal administrative/acquisition cost is estimated to be $12,000 and the non-Federal administrative/acquisition cost is estimated to be $24,000. The number of residential and/or business relocations and severance damages are unknown. For all three component costs, a contingency of 50 percent is added. The probable total estimated real estate cost is $10,367,000, the low-end is $4,179,000 and the high-end estimate is $17,325,000.

Component Y6

Component Y6 is the C-51 Backpumping to Water Catchment Area located in the Water Catchment Area in Palm Beach County. The purpose is to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-51 West Basin to the West Palm Beach Water Catchment Area and enhance hydroperiods in Loxahatchee Slough. The component will be operated to capture excess C-51 Canal water to meet urban water supply demands in the North Palm Beach County Service Area. Water would be diverted from C-51 to a water treatment area and then into the Water Catchment Area. A 600 acres at 4 feet maximum depth to be used for stormwater treatment. The S-155A structure will be relocated east of the intersection of Lake Worth.

This component also requires relocation of the S-155A structure east of the intersection of the Lake Worth Drainage District' s E-1 Canal and the C-51 Canal and increase the capacity of S-155A as necessary to pass the additional inflows, and improvement of conveyance between C-51 and the stormwater treatment area as necessary. A 450 cfs inflow pump will be constructed to the stormwater treatment area with a 100 cfs gravity discharge structure into West Palm Beach Water Catchment Area.

This site consists of 710 acres, located southeast of the West Palm Beach Water Catchment Area. As in component W6 above, properties in this area have sold in the broad range of $5,000 to $20,000 per acre. Palm Beach County owns large parcels of land in this area and appears to have paid approximately $16,000 per acre for some of it.

Depending on the boundary structure for this area, residential lands and developments could be impacted. Moving south toward Okeechobee Blvd. increases both the development potential and existing developed areas. Moving boundaries westward also puts the proposed component into existing and potential residential area, but this appears to not be affecting those areas.

The same value ranges as used above in component W6 are used here. The probable lands and damages estimate is at $8,875,000 using the mid-range value estimate of $12,500. The high-end lands and damages estimate totals $14,910,000 based on $21,000 per acre. The low-end lands and damages estimate values each acre at $5,000 for a total of $3,550,000.

The number of affected ownership tracts is unknown, but is estimated to be six. Based on this, the Federal administrative/acquisition cost is estimated to be $36,000and the non-Federal administrative/acquisition cost is estimated to be $72,000. The number of residential and/or business relocations and severance damages are unknown. For all three component costs, a contingency of 50 percent is added. The probable total estimated real estate cost is $13,475,000, the low-end is $5,487,000 and the high-end estimate is $22,527,000.

Component BB5

Component BB5 is the improvements to the Miami-Dade Broward County Levee/Pennsuco Wetlands located in the Water Preserve Area in Miami-Dade County. The purpose is to reduce seepage to the east from the Pennsuco Wetlands and southern Water Conservation Area 3B and enhance hydroperiods in the Pennsuco Wetlands. Also an improved Dade Broward Levee will enhance recharge to Miami-Dade County's Northwest Wellfield. Recharging the conveyance features of the Miami-Dade-Broward levee from the regional system deliveries provides recharge to Miami-Dade County's Northwest Wellfield. Treatment areas will be provided to meet all water quality standards required, if necessary. The existing Miami-Dade-Broward Levee will be constructed or improved to five-foot height with 2-foot top width while creating or improving existing conveyance to a capacity of up to 300 cfs. An 150 cfs bypass structure and canal from C-6 Canal to the Miami-Dade-Broward Levee will provide recharge from the regional system via the improved US Highway #27 borrow canal. A 150 cfs gravity structure in the Miami-

Dade-Broward Levee Borrow Channels will be constructed due west of the southern end of the Northwest Wellfield.

This component requires the acquisition of approximately 384 acres of open pastureland. There is a wide range of values indicated by the sales in this area. The sales form a range from approximately $2,300 per acre to $8,475 per acre. For the low-end cost estimate, the bottom of the range ($2,300) per acre is used to provide a total lands and damages estimate of $883,200. The high range (or $8,500) per acre provides the probable cost lands and damages estimate, which totals $3,264,000. South Florida Water Management District recommends a figure of $10,000 per acre. Using this per acre value yields the high-end lands and damages estimate of $3,840,000.

The number of affected ownership tracts is unknown, but is estimated to be 140. Based on this, the Federal administrative/acquisition cost is estimated to be $840,000 and the non-Federal administrative/acquisition cost is estimated to be $1,680,000. The number of residential and/or business relocations and severance damages are unknown. For all three cost estimates (high-end, probable and low-end) a contingency of 50 percent is added. The estimated probable total real estate cost is $8,676,000, the low-end estimate is $5,105,000 and the high-end estimate is $9,540,000.

Component CC6

Component CC6 is the Broward County Secondary Canal System improvements located in Broward County. The purpose is to increase pump capacity of existing facilities (from the 2050 Base Case), and construct additional canal and pump facilities for the Broward Secondary Canal System to provide recharge to wellfields located in central and southern coastal Broward County, to stabilize the salt water interface, and reduce storm water discharges to tide. The component will be operated so that when excess water is available in the basin, the water is pumped into the coastal canal systems to maintain canal stages. When local water is not sufficient to maintain canal stages, canals are maintained first from local sources and then from Lake Okeechobee and the Water Conservation Areas. Local sources include the Site 1 Impoundment (Component M) and the North Lake Belt Storage Area (Component XX). Secondary canals maintained are: 1) Broward County's C-2 from the Hillsboro Canal, 2) north secondary canal from C-13, 3) south secondary canal from C-13, 4) Turnpike canal south from C-12 Canal north from C-9 at levels as follows: (a) improve canal conveyance of secondary canal located east of the Florida Turnpike from the C-12 Canal south to the Fort Lauderdale Golf and Country Club and includes routing of water eastward to recharge the aquifer and help stabilize the saltwater interface at Ft. Lauderdale. Canal conveyance improvements may also be necessary for the Old Plantation Water Control District's eastern canal and in southeastern Broward County. Pump capacities and maintenance levels are as follows: (a) a 100 cfs pump from Hillsboro to Broward

County Secondary Canal (pump #1); (b) a 100 cfs pump from C-13 north to Broward County Secondary Canal; (c) a 100 cfs pump from C-13 south to Broward County Secondary Canal (pumps #2 and #3 described in the 2050 Base Case increased from 33 cfs to 100 cfs); (d) a 100 cfs pump on the east Turnpike canal withdrawing water from the C-12 Canal; and (e) a 150 cfs pump on the C-9 Canal for maintaining water in southeastern Broward County. Canal improvements and control elevations will be to improve east and west Turnpike canals and golf course lake system between C-12 and the North New River to achieve an average top width of 200 feet. The Turnpike canals shall be maintained at a minimum elevation of 4.0 feet NGVD. Also improvements for the canal/ lake systems in southeastern Broward County and the Orangebrook Golf Course to have an average canal top width of 30 feet. The southeastern Broward Canal system shall be maintained at a minimum elevation of 2.5 feet NGVD.

All three estimates are constant for this component. Approximately 245 acres will be required. The lands and damages estimate totals $740,000 (55 acres at $10,000 per acre plus 190 acres at $1,000 per acre).

The number of affected ownership tracts is unknown, but is estimated to be 30. Based on this, the Federal administrative/acquisition cost is estimated to be $180,000 and the non-Federal administrative/acquisition cost is estimated to be $360,000. The number of residential and/or business relocations and severance damages are unknown. For all three component costs a contingency of 50 percent is added. The probable, high-end and low-end total estimated real estate cost is $1,920,000.

Component FF4

Component FF4 is the construction of S-356 A & B Structures in Miami-Dade County. The purpose of these structures is to improve deliveries to Northeast Shark River Slough in Everglades National Park and reduce seepage to Lower East Coast Service Area 3. The structures will be operated to redirect S-357 outfall from L-31N to the mid-point of the Modified Water Deliveries mitigation canal northwest of the 8.5 Square Mile Area. The new 356 pumps will be operated to direct seepage collection from the Water Conservation Areas and water deliveries from Central Lake Belt Storage Area to Northeast Shark River Slough. The design of this component will require removal of the Modified Water Deliveries S-356 structure; relocation of the Modified Water Deliveries S-357 structure; adding S-356 A & B Structures (900 cfs each) at locations along modified L-31N between G-211 and Tamiami Trail; rerouting the L-31N borrow canal to east side of buffer cell; relocating L-31N to east side of buffer cell; backfilling a portion of L-31N where the levee is moved; and constructing a 5 foot levee along west side of existing lakes.

This area is located east of Levee 30 to Highway 997, extending from just south of the Tamiami Canal to just south of Kendall Drive. There appears to be no canal to inhibit access from the highway as has been the case on many of the previous components along this north south corridor. This highway could make this land more valuable if development were to push this far westward. A total of approximately 3,947 acres will be required.

In the absence of sales, the assessed value of land in the central segment of this component was $3,500 per acre. This area has 1,237 acres that is to be valued allowing the excavation of limestone, as the owners would retain the right to mine the property as is being done currently in this segment. Approximately 155 acres of the 1,237 acres is already mined and left in a quarry lake that appears under active mining operation currently. Using a value of $1,000 per acre for this 155 acres and valuing the remaining 1,082 acres at $3,500 per acre yields $3,942,000 for this central segment containing 1,237 acres. This $3,942,000 estimate is applied to the probable/high-end cost estimate and the low-end cost estimate.

Of the remaining 2,710 acres which would be acquired in full fee, 1370 acres lies to the north of the quarry lake and 1,340 acres lies to the south. Land in the northern segment showed sales ranging from $8,000 to $10,000 per acre, while land in the southern segment, sales ranged around $10,000 per acre. South Florida Water Management District estimated the per acre value of both the northern and southern segments at $20,000 per acre. For planning purposes, the low-end cost estimate for this 2,710 acres was valued at $10,000 per acre for a total of $27,100,000. The probable and high-end cost estimate was valued at $20,000 per acre for a total lands and damage estimate of $54,200,000.

For the probable and high-end cost estimate, the total lands and damages estimate is $58,142,000. The low-end cost estimate for lands and damages is $31,042,000.

The number of affected ownership tracts is unknown, but is estimated to be 528. Based on this, the Federal administrative/acquisition cost is estimated to be $3,168,000and the non-Federal administrative/acquisition cost is estimated to be $6,336,000. The number of residential and/or business relocations and severance damages are unknown. For the low-end cost estimate, a contingency of 50 percent is added. For the probable/high-end cost estimate, contingency of 40 percent is added. The low-end total estimated real estate cost estimate is $60,819,000. The probable/high-end real estate cost estimate is $94,704,000.

Component GG4

Component GG4 is the Lake Okeechobee Aquifer Storage and Recovery to be located in Glades and Okeechobee Counties. The purpose is to provide additional regional storage while reducing both evapotranspiration losses and the amount of land removed from current land use (e.g. agriculture) that would normally be associated with construction and operation of above-ground storage facilities (reservoirs); to increase the Lake's water storage capability to better meet regional water supply demands for agriculture, Lower East Coast urban areas, and the Everglades; to manage a portion of regulatory releases from the Lake primarily to improve Everglades hydropatterns, to meet environmental targets within the Water Conservation Areas, and to meet supplemental water supply demands of the Lower East Coast; to reduce harmful regulatory discharges to the St. Lucie and Caloosahatchee Estuaries; to maintain existing level of flood protection. The system will be operated so that water from Lake Okeechobee is pumped into the Lake Aquifer Storage and Recovery wells when the climate-based inflow forecast projects that the Lake water level will rise significantly above those levels that are desirable for the Lake littoral zone (15.25 - 14.85 feet NGVD). During the dry season, flow may be made back to the Lake from the aquifer storage and recovery wells either when the Lake water level is projected to fall to within three-quarters of a foot of the supply-side management line the same dry season, or below 11.75 feet NGVD the upcoming wet season. During the wet season, flow is allowed from the aquifer storage and recovery wells to the Lake when climate-based inflow forecast projects less than 1.5 million acre-feet of inflow during the next 6 months, and the Lake water level is either below 11.75 feet (NGVD) during the current wet season, or is projected to be in supply-side management during the upcoming dry season. There will be a total of 200, 5-million gallons per day aquifer storage and recovery wells and associated infrastructure.

This estimate is based on very general information and relies on county-wide general knowledge. This is not a site specific component estimate. The component is to be based on 300 acres of pasture/open land. A value estimate of $2,500 per acre yields $750,000 for the low-end lands and damages estimate. A value of $3,500 is provided for a probable/high-end lands and damages estimate totaling $1,050,000.

The number of affected ownership tracts is unknown, but is estimated to be 220. Based on this, the Federal administrative/acquisition cost is estimated to be $1,320,000and the non-Federal administrative/acquisition cost is estimated to be $2,640,000. The number of residential and/or business relocations and severance damages are unknown. For all the cost estimates, a contingency of 50 percent is added. The probable/high-end total estimated real estate cost is $7,515,000. The low-end real estate cost is $7,065,000.

Component KK6

Component KK6 is for additional structures in the Loxahatchee National Wildlife Refuge Internal Canal in Water Conservation Area 1 located in Palm Beach County which are to improve the timing and location of water depths in the Refuge. The two structures, one a L-7 borrow canal structure (consisting of a 1,500 cfs gravity structure at 0.5 foot head) and the other a L-40 borrow canal structure (consisting of a 1,500 cfs gravity structure at 0.5 foot head), would remain closed except to pass Stormwater Treatment Area 1 East and Stormwater Treatment Area 1 West outflow and water supply deliveries.

This estimate is based on very general information and relies on county wide general knowledge. This is not a site specific component estimate. The component will require 5.0 acres of pasture/open land. A value estimate of $10,000 per acre totals $50,000 for the probable, high-end and low-end lands and damages estimate.

The number of affected ownership tracts is unknown, but is estimated to be 10. Based on this, the Federal administrative/acquisition cost is estimated to be $60,000and the non-Federal administrative/acquisition cost is estimated to be $120,000. The number of residential and/or business relocations and severance damages are unknown. For all cost estimates, a contingency of 50 percent is added. The probable, high-end and low-end total estimated real estate cost is $345,000.

Component LL6

Component LL6 is the C-51 Regional Groundwater Aquifer Storage and Recovery to be located in Palm Beach County. This is a regional groundwater aquifer storage and recovery system, which will capture and store excess water during wet periods and recover the water for utilization during dry periods. The ability to use the recovered water during dry periods will increase regional water resources. Water will be captured and stored when water is being discharged out of S-155 to tide. Water will be recovered during dry periods based on canal elevations. Recoverable water is limited to 70 percent of injected water. This component consists of 34 well clusters located along the West Palm Beach Canal (C-51 Canal), each being composed of two (2) surficial aquifer wells and one Upper Floridan aquifer, aquifer storage and recovery well. The surficial aquifer wells will each have a 2.5 million gallons per day withdrawal capacity and be located in proximity to the canal so that the water withdrawn would result in the interception of water that would otherwise go to tide in wet periods. Each upper Floridan aquifer storage and recovery well will have a capacity of 5 million gallons per day (the total injection and recovery capacity of the aquifer storage and recovery system is 170 million gallons per day or about 264 cfs.). Water will be injected when stages in the C-51 Canal are above 8.0 feet NGVD. Water will be retrieved from the aquifer storage and recovery wells when canal stages are below 7.8 feet NGVD. Recovered water will be discharged to the C-51 Canal.

This estimate is based on very general information and relies on county wide general knowledge. This is not a site specific component estimate. The component will require acquisition of approximately 34 acres of commercial/open land. A value estimate of $100,000 per acre yields $3,400,000 for the low-end cost estimate. South Florida Water Management District recommends using a value of $150,000 per acre. Based on this, the high-end/probable cost lands and damages estimate is $5,100,000.

The number of affected ownership tracts is unknown, but is estimated to be 85. Based on this, the Federal administrative/acquisition cost is estimated to be $510,000 and the non-Federal administrative/acquisition cost is estimated to be $1,020,000. The number of residential and/or business relocations and severance damages are unknown. For all cost estimates, a contingency of 50 percent is added. The probable/high-end total estimated real estate cost is $9,945,000. The low-end total estimated real estate cost is $7,395,000.

Component QQ6

Component QQ6 is the decompartmentalization of Water Conservation Area 3 in Broward and Miami-Dade. The purpose is to remove most flow obstructions to achieve unconstrained or passive flow between Water Conservation Areas 3A and 3B and Northeast Shark River Slough and reestablish the ecological and hydrologic connection between these areas. Structural Changes will be to backfill the Miami Canal in Water Conservation Area 3 from the east coast protective levee to one to two miles south of the S-8 pump station to maintain flood discharge capability. Water supply deliveries previously made through the Miami Canal will be delivered through the North New River, and improved US 27 borrow canal (see Component SS); to remove the L-68A levees; to degrade the L-67C levee and backfill the adjacent borrow canal; to backfill the L-67A Canal from Tamiami Trail approximately 7.5 miles north; to relocate a single S-349 structure at the downstream end of L-67A Canal (downstream of the S-345 structures); to remove the L-29 levee and canal (south of Water Conservation Areas -3A and 3B) to restore sheetflow into Everglades National Park; to remove the L-28 and L-28 Tieback levees and borrow canals from L-28 Tieback south to L-29; to elevate Tamiami Trail (U.S. 41) through the installation of a series of bridges between L-31N and L-28 consist with conveyance capacities determined at I-75 and any increases required due to inflows downstream of I-75 and upstream of Tamiami Trail; to remove the S-344, S-343A and B and S-12 structures; to construct 8 passive weir structures along the entire length of L-67A to promote sheetflow during high flow conditions and locate the S-345s (component AA3) just downstream of the new termination of L-67A Canal. Operational Changes include 1) Operate Water Conservation Areas 2A import trigger using only 2A-N gage as the trigger rather than using average of 2A-N and 2A-17 gages; 2) The time series target at 2A-N was truncated at 1.25 ft above and 0.5 ft below land surface elevation; 3) The time series target at 3A-NE was truncated at 1.0 ft above and 0.5 ft below land surface elevation; 4) S-345 operations are now based on triggers at R33C26 and the NESRS-1 and NESRS-2 gages (the 3A-4 gage is no longer used); 5) S-349 structure operations are the same as the S-345's operations.

Approximately 18 acres of fee and 37 acres of temporary easements are required for this component. A total of 20 bridges will be constructed in a twenty-mile strip of Tamiami Trail (each one mile apart). Each bridge will be 1,000 feet in length and 40 feet in width (.9 of an acre is required in fee for each bridge for a total of 18 acres). It is unknown what title Florida Department of Transportation holds to the underlying lands currently comprising the Tamiami Trail, and the width of the existing right-of-way varies.

Additional temporary easements for construction of the bridges will be required. These easements will be either within the existing right-of-way of Tamiami Trail, within lands owned by the National Park Service or within lands owned by South Florida Water Management District. Lands owned by South Florida Water Management District may require a different estate then what the Water Management District currently owns.

The 18 acres required in fee is valued at $4,000 per acre for a total of $73,600. The 37 acres required as temporary easements are valued at $2,000 per acre for a total of $73,600. Total lands and damages cost estimate is $147,200.

The number of affected ownership tracts is estimated to be two, for a Federal acquisition/administrative cost estimate of $64,000 and a non-Federal acquisition/ administrative cost estimate of $108,000. These higher acquisition/administrative cost estimates include additional expenses for negotiating relocation contracts with the Florida Department of Transportation. The total estimated real estate cost for this component for the probable, high-end and low-end estimates is $479,000.

Component SS4

Component SS4 is designed to reroute Miami-Dade County Water Supply Deliveries in the Everglades Agricultural Area and Miami-Dade County from the Miami and Tamiami Canals and Water Conservation Area 3 to the North New River Canal due to the backfilling of the Miami Canal as part of the decompartmentalization of Water Conservation Area 3. The operation will send water supply deliveries from Lake Okeechobee to Miami-Dade County southeast through the North New River Canal in the Everglades Agricultural Area (L-20, L-19, L-18) to S-150. From S-150 send deliveries into L-38W and at the southern terminus of L-38W south through a 1,500 cfs pump to the borrow canal along the west side of US 27. The component will double the capacity of the North New River Canal south of the proposed Everglades Agricultural Area Storage Reservoir (see Component G3) to convey additional water supply deliveries to Miami-Dade County as necessary; will double the capacity of S-351 and S-150 to pass additional water supply deliveries to Miami-Dade County as necessary; will improve conveyance in the borrow canal on the west side of US 27 between L-38W and the Miami Canal as necessary to pass the additional flows.

This estimate is based on very general information and relies on county-wide general knowledge. This is not a site specific component estimate. The component requires 200 acres of residential land. A value estimate of $30,000 per acre yields

$6,000,000 for the low-end lands and damages cost estimate. A probable/high-end value of $50,000 is applied to total $10,000,000 for the lands and damages cost estimate.

The number of affected ownership tracts is unknown, but is estimated to be 400. Based on this, the Federal administrative/acquisition cost is estimated to be $2,400,000 and the non-Federal administrative/acquisition cost is estimated to be $4,800,000. The number of residential and/or business relocations and severance damages are unknown. For all the cost estimates, a contingency of 50 percent is added. The probable/ high-end total estimated real estate cost is $25,800,000. The low-end cost estimate is $19,800,000.

Component UU6

Component UU6 is for storage reservoirs in the St. Lucie River Estuary/C-23, C-24, C-25 Northfork and Southfork Basins. The storage reservoirs are to capture local runoff from the C-23, C-24, C-25 and Northfork and Southfork Basins of the St. Lucie River Estuary. The reservoirs will be designed for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. There will be one reservoir in each basin. A total of 39,000 acres at 8 feet maximum depth distributed as follows among these basins: C-23 – 8,400 acres, C-24 – 6,000 acres, C-25 - 12,800 acres; and Northfork – 11,800 acres. In the Southfork Basin storage requirements were met using 9,350 acres inundated to a depth of 4 feet.

This component includes the acquisition of approximately 48,350 acres of land in Martin (17,750 acres) and St. Lucie (30,600 acres) Counties. From a general evaluation of the areas, including land uses, it was determined that for the probable/low-end lands and damages cost estimate, a value of $5,800 per acre for the 30,600 acres located within St. Lucie County is reasonable (for a total of $177,480,000). The high-end cost estimate assumes that 30,000 acres in St Lucie County is prime citrus land valued at $7,500 per acre (total value estimate of $225,000,000) and the remaining 600 acres are residential land valued at $25,000 per acre (total value estimate of $15,000,000). The 17,750 acres in Martin County are valued at $6,000 per acre for the probable and high-end estimates ($106,500,000) and at $4,000 per acres for the low-end estimate ($71,000,000).

The number of affected ownership tracts is unknown, but is estimated to be 114. Based on this, the Federal administrative/acquisition cost is estimated to be $684,000 and the non-Federal administrative/acquisition cost is estimated to be $1,368,000. The number of residential and/or business relocations and severance damages are unknown. For all the cost estimates, a contingency of 50 percent is added. The total estimated real estate probable cost is $429,048,000, the low-end is $375,798,000 and the high-end estimate is $522,828,000.

Component VV6

Component VV6 is the Palm Beach County Agricultural Reserve Reservoir located in Palm Beach County. The purpose of the reservoir is to increase water supply for central and southern Palm Beach County by capturing and storing water currently discharge to tide. The reservoir will be filled during the wet-season from excess water pumped out of the western portions of the Lake Worth Drainage District (backpumped). Water will be released back to Lake Worth Drainage District to maintain canal stages during the dry-season. Regional water will be supplied to the Lake Worth Drainage District when water levels fall below 15.8' NGVD. Water will be back pumped into the reservoir when water levels are above 16.0 feet NGVD. Aquifer Storage and Recovery capacity is included to improve supply during dry seasons and droughts. Fifteen (15) 5-million gallons per day capacity aquifer storage and recovery wells (total injection and recovery capacity 75 million gallons per day or about 116 cfs) are included. Water from the reservoir will be injected when depths in the impoundment are above 1 foot. Water will be supplied from the reservoir before tapping water from aquifer storage and recovery systems. Specifically, the water supplied from the reservoir will be maximized (up to the outflow capacity) before water is supplied from aquifer storage and recovery storage. The reserve reservoir will consist of 1,660 acres, with a maximum depth of 12 feet (volume of 19,920 acre-feet), with an inflow pump capacity of 500 cfs (provided by two 250 cfs pumps), an outflow structure with a capacity of 500 cfs @ 4 feet head, and an emergency outflow structure with a capacity of 300 cfs.

The land required for this component (1,660 acres) lies west of Highway 441 in Palm Beach County. The aerials indicate that this land is used primarily for farming. Its location on Highway 441 could indicate a higher value due to its frontage. At the northern end of this area a sale indicates approximately $35,000 per acre. Other sales nearby have indicated $20,000+ per acre. However, the agricultural branch of the tax assessor's office feels a value of $12,000 per acre is indicated based on agricultural activity. This property is in the Agricultural Reserve Area of West Palm Beach, which dictates that property in this area will remain agricultural. This policy is very controversial and has been receiving a large amount of attention and it is not known if this usage is going to hold. South Florida Water Management District estimates a value of $25,000 per acre. For the probable/low-end lands estimate, a per acre value of $20,000 is applied to the 1,660 acres for a total of $33,200,000. The high-end estimate uses the $25,000 per acre recommended by South Florida Water Management District for a total of $41,500,000. Some improvement information was gathered for this component. There are an estimated 29 improvements in the area to be acquired which are valued at a total of $4,500,000.

It is estimated that 18 tracts will be affected for this component. As such, the Federal acquisition/administrative cost estimate is $108,000 and the non-Federal acquisition/administrative cost estimate is $216,000. Applying a cost of $23,000 per improved tract (18) for relocation expenses totals $414,000.

A contingency of 50 percent is applied to all costs estimates. The total estimated probable/low-end real estate cost is $57,657,000. The total estimated high-end cost is $70,107,000.

Component WW5

Component WW5 is the C-111N Spreader Canal located in South Miami-Dade County. The purpose of the spreader canal is to reduce wet season flows in C-111, improve deliveries to Model Lands and Southern Glades and decrease potential flood risk in the lower south Dade area. Water is pumped from C-111 and C-111E into a Stormwater Treatment Area prior to pumping through S-332E into C-111N to Southern Glades and Model Lands. S-197 and S-18C are removed and C-111 is backfilled. The component will increase S-332E to 500 cfs from 50 cfs (pump when available); relocate C-111N to southwest theoretical 440th street (approximately 1 section north); construct a culvert under US 1 and a culvert under Card Sound Road; build a Canal through triangle area of Model Lands, east of Card Sound Road; fill in C-111 south of confluence with C-111N to S-197; remove levees and access roads; completely backfill C-110; create a Stormwater Treatment Area in triangle land between C-111 and C-111E to clean water prior to putting in Model Lands.

The land required for this component lies south of Homestead and extends to the Manatee Bay and Middle Key area along the coast. The total land required is estimated at 12,415 acres. Using a sampling of sales in and around the delineated area, the northerly one-fifth of the area reflects sales as high as $5,000 per acre. Much of the land appears to be wetlands. The low-end of the wetland sales that were found are generally around $500 per acre. Other wetland sales have indicated $1,000 to $1,500 per acre. No structures appear to be in this area.

Approximately 3,000 acres of the site are being estimated at the upper end of the indicated range ($5,000 per acre) for a total of $15,000,000 for all three estimate levels (probable, high and low-ends). The remaining 9,415 acres are being estimated at $1,000 per acre (($9,415,000) for the low-end estimate, $1,250 per acre ($11,773,000) for the probable cost and $1,500 per acre ($14,123,000) for the high-end estimate.

Total probable land and damages cost estimate for the entire 12,415 acres is $26,773,000. For the low-end, land and damages costs are estimated at $24,415,000 and for the high-end at $29,123,000.

It is estimated that 396 tracts will be affected for this component. As such, the Federal administrative/acquisition cost estimate is $2,376,000 and the non-Federal administrative/acquisition cost estimate is $4,752,000.

A contingency of 35 percent is added to the probable cost estimate, which brings the total estimated probable real estate cost estimate to $45,766,000. A contingency of 40 percent is added to the low-end cost estimate, which brings the total estimated low/end real estate cost estimate to $44,160,000. A contingency of 50 percent is added to the high-end cost estimate, which brings the total estimated high/end real estate cost estimate to $54,376,000.

Component XX6

Component XX6 is the North Lake Belt Storage Area located in the Water Preserve Area in Miami-Dade County. This in-ground reservoir is to capture a portion of runoff from C-6, western C-11 and C-9 Basins. The in-ground reservoir with perimeter seepage barrier will allow storage of untreated runoff without concerns of ground water contamination. The stored water will be used to maintain stages during the dry season in the C-9, C-6, C-7, C-4 and C-2 Canals and to provide deliveries to Biscayne Bay to aid in meeting salinity targets. The component will be operated so that inflows from C-6 (west of the turnpike), western C-11, and C-9 Basin runoff are pumped and gravity fed into the in-ground reservoir. The inflow ceases when stages reach ~5.0 feet NGVD (0 feet above adjacent land elevation). Outflows for water supply are pumped to the C-9 Storm Water Treatment Area /Impoundment prior to delivery to the C-9, C-6, C-7, C-4 and C-2 Canals. Water from the reservoir can be withdrawn down to a stage of -15 feet NGVD (up to 20 feet of working storage & maximum head on seepage barrier). The following will be the prioritization of outflows: (1) if water levels in North Lake Belt Storage Area are from between +5.0 feet NGVD and 0.0 feet NGVD flows will be discharged to Biscayne Bay via the C-2 Canal; (2) if water levels in North Lake Belt Storage Area are from between –10 feet NGVD and 0.0 feet NGVD flows will be discharged to C-9, C-6, C-7, C-4 and C-2 Canals only to prevent salt water intrusion; (3) if water levels in North Lake Belt Storage Area drop to levels between –15 feet NGVD and -10.0 feet NGVD flows will be limited to discharge to the C-9 Canals only to avoid water shortage restrictions. The storage area is 4,500 acres with subterranean seepage barrier around perimeter to enable drawdown during dry periods, prevent seepage and to prevent water quality impacts. The inflow structures will be a 2,500 cfs gravity structure at 0.5 feet head from C-11W; a 600 cfs pump from C-9; a 300 cfs pump from C-6 west of divide structure. The outflow structures will be a 1,000 cfs pump to C-9 STA/Impoundment for treatment prior to deliveries to C-6, C-7, C-2, C-4 and C-9 to prevent saltwater intrusion in coastal canals. (Stormwater Treatment Area detention time requirements need to be addressed. Pretreatment in reservoir may reduce size requirements of treatment area). In the Canal: an 800 cfs canal capacity. Water supply discharges are routed to C-4/C-2 via a canal to be located east of the Snapper Creek Canal (Northwest wellfield protection canal system). Two 1,400 cfs delivery structures, one each at the new canal's confluence with C-6 and C-4. A total of 5,861 acres will be required for this component.

This component requires approximately 5,861 acres and has an irregular shape and therefore affects a wider diversity of lands. Approximately 1,200 acres are in existing quarry lakes. These quarry lakes were valued at $1,000 per acre for the probable, high-end and low-end cost estimates. The cost estimate for this 1,200 acres at $1,000 per acre yields $1,200,000.

The remaining 4,661 acres, includes a 350 acre canal that was subsequently added to this component during review of alternative D13R. Based strictly on sales information, for the probable/high-end cost estimate, it is assumed that acquisition of the full fee for this 4,661 acres would be required. South Florida Water Management District recommends $20,000 per acre value for this area. The fee is estimated at $20,000 per acre for a total of $93,220,000. The estimated probable and high-end real estate cost is $94,420,000 ($93,220,000 + $1,200,000).

For the low end cost estimate, this component was valued with approximately 3,344 acres of the remaining 4,661 acres of land (does not include 1,200 acres in quarry lakes) that would be acquired with mineral rights and limestone excepted and the landowner retaining the right to excavate the limestone and minerals and 1,317 acres that would be acquired with full fee title which includes the 350 acre canal. The 3,344 acres (not including the 350 acre canal) is valued at $12,000 per acre for the low-end cost estimate for a total of $40,128,000. The 350 acre canal is being estimated at $20,000 per acre for a low-end estimate of $7,000,000. .

The other land totaling 967 acres would be acquired with full fee title. Depending on where the mining permit stage is for property within these tracts, the values could be dramatically different. South Florida Water Management District has paid as much as $55,000 for one acre of permitted land. Based strictly on limited sales information for the area, a value of $20,000 per acre is being estimated for 567 acres for a total of $11,340,000) for and $12,500 per acre is applied to the remaining 400 acres for the low-end cost estimate for a total of $5,000,000. The total lands and damages for the low-end cost estimate is $64,668,000.

The number of affected ownership tracts is unknown, but is estimated to be 900. Based on this, the Federal administrative/acquisition cost is estimated to be $5,400,000 and the non-Federal administrative/acquisition cost is estimated to be $10,800,000. The number of residential and/or business relocations and severance damages are unknown. For the probable/high-end cost estimate, a contingency of 40 percent is added. For the low-end cost estimate, a contingency of 50 percent is added. The probable/high-end total estimated real estate cost is $154,868,000. The low-end real estate cost estimate is $121,302,000.

Component YY4

Component YY4 is designed to divert Water Conservation Area 2 flows to the Central Lake Belt Storage Area and is located in Broward County. The purpose is to capture excess in Water Conservation Area 2B; to reduce stages above desired target levels in Water Conservation Area 2B; and to divert water through improved L-37 and L-33 Borrow Canals to 1) Northeast Shark River Slough to meet targets or 2) Central Lake Belt Storage Area. Surface water in Water Conservation Area 2B above NSM will overflow through 3 structures along L-35 and L-35A to North New River Canal along with seepage from Water Conservation Area 2B and pumped to L-37. North New River Canal, L-37 and L-33 Borrow Canals will be improved to accept this additional flow along with the seepage collected from Water Conservation Area 3. This water will be pumped to Northeast Shark River Slough if the Slough is below target levels or into a lined reservoir south of the confluence of L-33 and the C-6 Canal referred to as the Central Lake Belt Storage Area. Construction will consist of the following: (1) 3-diversion structures with 120 cfs capacity @0.5 feet of head and 350 cfs capacity at 4.0 feet of head along the southern perimeter of Water Conservation Area 2B; (2) an intermediate 1,500 cfs pump station to divert overflow and seepage from NNR to L-37; (3) an inverted siphon with 1,500 cfs capacity to pass water supply deliveries from L-38 borrow canal to US 27 West borrow canal; (4) improved conveyance of L-37 and L-33 to 3,000 cfs to handle Water Conservation Area 2B flows plus seepage from Water Conservation Area 3; and (5) removal of S-9XN and S-9XS or improve structures to accommodate increased flows.

This estimate is based on very general information and relies on county wide general knowledge. This component requires the acquisition of approximately 835 acres which has not been delineated. A per acre value of $5,000 is applied which totals $4,175,000 for the probable, high-end and low-end lands and damages estimate.

The number of affected ownership tracts is unknown, but is estimated to be 250. Based on this, the Federal administrative/acquisition cost is estimated to be $1,500,000 and the non-Federal administrative/acquisition cost is estimated to be $3,000,000. The number of residential and/or business relocations and severance damages are unknown. For the probable/high-end cost a contingency of 50 percent is added to yield a total estimated real estate cost of $13,013,000. A contingency of 40 percent is added to the low-end estimate to total an estimated real estate cost of $12,145,000.

Component ZZ5

Component ZZ5 is designed to divert Water Conservation Area 3 flows to Central Lake Belt Storage Area. The structures will be located in the eastern levees of Water Conservation Area 3 in Broward and Miami-Dade Counties. The purpose is to capture excess in Water Conservation Area 3A and Water Conservation Area 3B to reduce stages above target stages in Water Conservation Area 3 and to divert water through modified structures at S-9 and S-31 to Central Lake Belt Storage Area via the L-33 borrow canal. The component will be operated so that when surface water in Water Conservation Area 3B exceeds target depths by 0.10 feet it will be diverted to the Central Lake Belt Storage Area via L-33. When surface water in Water Conservation Area 3A near S-9 exceeds target depths by 1.0 foot, water will be diverted to the Central Lake Belt Storage Area via L-33. Two outflow structures will be constructed (1) a 500 cfs structure at 2.0 feet of head (new structure) at S-9 (Water Conservation Area 3A) and (2) a 700 cfs structure (modify existing S-31 if necessary) (Water Conservation Area 3B).

This estimate is based on very general information and relies on county wide general knowledge and is not based on the delineation of a specific site. The component requires 2.0 acres of pasture/open land. A value of $12,500 is applied to the acreage to total $25,000 for the lands and damages estimate for all levels of cost.

The number of affected ownership tracts is unknown, but is estimated to be 10. Based on this, the Federal administrative/acquisition cost is estimated to be $60,000 and the non-Federal administrative/acquisition cost is estimated to be $120,000. The number of residential and/or business relocations and severance damages are unknown. For the probable/high-end cost a contingency of 50 percent is added to yield a total estimated real estate cost of $308,000. A contingency of 40 percent is added to the low-end estimate to total an estimated real estate cost of $277,000.

Component BBB6

Component BBB6 is the South Miami-Dade County Reuse (South District Reclaimed Water Treatment Plant) located in Southern Miami-Dade County. The existing South District Wastewater Treatment Plant located north of the C-1 Canal will provide wastewater treatment coupled with superior treatment technology to supply reclaimed water to the South Biscayne Bay and Coastal Wetlands Enhancement Project. The water will be provided throughout the year to augment water supply to the South Biscayne Bay and Coastal Wetlands Enhancement Project upon demand. This supplemental water will restore overland flow in the coastal area and recharge groundwater to enhance groundwater discharge to Biscayne Bay. Saltwater intrusion benefits to the southern part of Miami-Dade County are anticipated. The South District Wastewater Treatment Plant with superior treatment technology will be operated when the additional water is needed to supply the South Biscayne Bay and Coastal Wetlands Enhancement Project. When water is not needed, the South District Wastewater Treatment Plant will stop treatment beyond secondary treatment standards and will dispose of the secondary treated effluent into the existing deep injection wells. The South District Wastewater Treatment Plant will be designed to add on pretreatment and membrane treatment system to the existing secondary treatment facility. The plant will have a capacity of 131 million gallons per day. It is anticipated that phosphorus will be the constituent of concern in the reclaimed water. Therefore, the treatment will be designed to remove total phosphorous to acceptable levels. The South District Wastewater Treatment Plant will be located at, or in the vicinity of, the existing South District Wastewater Treatment Plant. The reclaimed water will be discharged to the C-1 Canal (Black Creek), upstream of S-21A, and then delivered southward towards the C-102 and C-103 Canals, and northward towards the C-100 Canal. The wastewater treatment facility will provide advanced treated water to L-31E. Flow southward in L-31E towards C-102 and C-103 shall be 202 acre-feet per day. Flow northward in L-31E towards C-100 shall be 200 acre-feet per day (through a canal extension). The combined inflow into L-31E shall be 402 acre-feet per day for every day of the simulation. Flows will reach C-102 and C-100 via modifications to L-31E. Operation of C-102 and C-103 shall be contingent upon Component FFF5.

This component consists of 200 acres in Miami-Dade County. It lies north of the Goulds Canal, east of the Florida Turnpike, south of Black Canal, and west of SW 9th Ave. This acreage is being estimated at $10,000 per acre. The total lands and damages estimate is constant for all levels of cost for this component is $2,000,000.

The number of affected ownership tracts is unknown, but is estimated to be 12. Based on this, the Federal administrative/acquisition cost is estimated to be $72,000 and the non-Federal administrative/acquisition cost is estimated to be $144,000. The number of residential and/or business relocations and severance damages are unknown. The probable/high-end and low-end cost estimates are all the same with a contingency of 50 percent and the total estimated real estate cost of $3,324,000.

Component CCC6

Component CCC6 is the Big Cypress/L-28 Interceptor Modifications with a purpose to alleviate over drainage in Northeast Big Cypress, Kissimmee Billy and Mullet Slough area and ensure that inflows meet applicable water quality standards. The system will be operated to reroute water from West and North Feeder Canals to wetlands in Northeast Big Cypress. It will allow flow along the south side of the West Feeder at designated locations and through a new S-190 Pump Station, while maintaining flood protection on Tribal lands and consistency with the Seminole Tribe's Conceptual Water Conservation System master plan. It will establish sheetflow south of the West Feeder Canal across the Native Area of the Big Cypress Reservation. It will establish sheetflow off the reservation in the Big Cypress National Preserve Addition. Pumps will be operated for approximate equalization of flows. Construction will consist of: degrading the levee, on the southwest side of the L-28 Interceptor Canal below the S-190 structure; backfilling the L-28 Interceptor Canal at a point, south of the Big Cypress Reservation boundary with Big Cypress National Preserve Addition; constructing a retaining levee on northeast side of L-28 Interceptor through the Big Cypress Seminole Reservation; construction of three pump stations and spreader canals to develop sheetflow along the south side of the West Feeder Canal. The pump station locations shall be adjacent to the discharge points from Water Resource Areas 1, 2 and 3 of the Seminole Conceptual Water Conservation System. The component also is designed to replace S-190 gated structure (existing capacity of 2,960 cfs) with a 1,460 cfs pump station. Construction of a North Feeder stormwater treatment area (1,100 acres at 4-foot maximum depth with an inflow pump station of 270 cfs and an outflow structure of 100 cfs). Construction of a West Feeder stormwater treatment area (800 acres at 4-foot maximum depth with an inflow pump station of 430 cfs and an outflow structure of 150 cfs. This component will be located in the Western Basin, Big Cypress Seminole Reservation, Big Cypress National Preserve Addition in Hendry and Collier Counties.

This component consists of two areas of land located in Hendry County, Florida. One of the areas has 800 acres and the other 1,100 acres for a total of 1,900 acres. From a discussion of agricultural values and uses in these general areas with the Hendry County Property Appraiser's Office, the most probable use is sugar cane. The estimate for this type of land is $2,500 per acre for a total lands and damages estimate of $4,750,000 for all three cost ranges.

The number of affected ownership tracts is unknown, but is estimated to be two. Based on this, the Federal administrative/acquisition cost is estimated to be $12,000 and the non-Federal administrative/acquisition cost is estimated to be $24,000. The number of residential and/or business relocations and severance damages are unknown. For the probable/low-end cost a contingency of 40 percent is added to yield a total estimated real estate cost of $6,700,000. A contingency of 50 percent is added to the high-end estimate to total an estimated real estate cost of $7,179,000.

Component DDD6

Component DDD5 is the Caloosahatchee Backpumping with Stormwater Treatment Area and is located in Hendry and Glades. The purpose is to capture excess C-43 Basin runoff to augment the regional system. These facilities will be designed to backpump excess water from C-43 to Lake Okeechobee after treatment through a Stormwater Treatment Area. This component operates after estuary and agricultural/urban demands have been met in the C-43 Basin and when water levels in the C-43 storage reservoir (Component D5) exceed 6.5 feet. When this situation occurs, water will be released from the reservoir and delivered to the Stormwater Treatment Area at the capacity of the backpumping/treatment system

(2,000 cfs). The Stormwater Treatment Area water is then backpumped to Lake Okeechobee. An additional requirement for the backpumping to take place is that Lake Okeechobee must be considered to have available storage, i.e. when its levels are below the pulse release zone line. The key components in the design are pumps and a stormwater treatment area. For the design it has been assumed that the Stormwater Treatment Area is located adjacent to Lake Okeechobee. Because it is not known where the reservoir will be located relative to the Stormwater Treatment Area, it has been assumed that water to be delivered to the Stormwater Treatment Area will be released from the reservoir to the Caloosahatchee River and then pumped from the River into the Stormwater Treatment Area. Since no pump to bring water from the lower basin (below S-78) to the upper basin has been included in the reservoir design and since most of the basin runoff is generated in the lower basin, a pump to bring the water from the lower Caloosahatchee Basin to the upper basin has also been included. The Stormwater Treatment Area has been included to meet the anticipated need to improve the quality of the water before it enters Lake Okeechobee. Finally, a pump station will be used to lift the water from the Stormwater Treatment Area to Lake Okeechobee. The following pumps will be required: (a) 1 pump of 2,000 cfs capacity to take water from the lower Caloosahatchee Basin to the upper Caloosahatchee Basin; (b) 1 pump of 2,000 cfs capacity to take water from the Caloosahatchee River into the Stormwater Treatment Area; and (c) 1 pump of 2,000 cfs capacity to discharge water from the Stormwater Treatment Area to Lake Okeechobee. The Stormwater Treatment Area will be comprised of approximately 5,000 acres and is proposed to achieve water quality improvements.

This component lies in Glades County and requires the acquisition of approximately 5,000 acres. The site is located west of Lake Okeechobee and consists mostly of sugar cane and pasture. For the probable cost lands and damages estimate, a value of $1,000 per acre ($2,500,000) is applied to half of the required 5,000 acres, assuming open pastureland. The balance of the acreage (2,500) is assumed to be sugar cane with a value per acre of $2,500, for a total of $6,250,000. The estimated probable land and damages costs are $8,750,000. The low-end estimate assumes the entire acreage to be pasture at a per acre value of $1,000 per acre for the entire 5,000 acre for a total estimated land and damages costs of $5,000,000. The high-end estimate values the entire acreage (5,000 acres) as sugar cane with a $2,500 per acre value, for a total estimated land and damages costs of $12,500,000.

The number of affected ownership tracts is unknown, but is estimated to be two. Based on this, the Federal administrative/acquisition cost is estimated to be $12,000 and the non-Federal administrative/acquisition cost is estimated to be $24,000. The number of residential and/or business relocations and severance damages are unknown. For all three levels of cost estimates a contingency of 50 percent is applied. The total estimated real estate probable cost is $13,179,000. The total estimated real estate low-end cost is $7,554,000, and the estimated total high-end cost is $18,804,000.

Component FFF5

Component FFF5 is the Biscayne Bay Coastal Canals located in Miami-Dade County. The purpose is to maintain higher stages in C-102 and C-103 for urban and environmental water supply with water provided from local sources. Wet season operation for C-102 between S-21A and S-195 (open at 2.2 feet NGVD, close at 2.0 feet NGVD) and for C-103 between S-20F and S-179 (open at 2.2 feet NGVD, close at 2.0 feet NGVD) will remain unchanged. Dry season operation of C-102, between S-21A and S-195, and C-103 between S-20F and S-179, will both change from opening at 1.4 feet NGVD and closing at 1.2 feet NGVD to opening at 1.6 feet NGVD and closing at 1.5 feet NGVD. A borrow canal (3.5 miles) will be constructed west of L-31E which directly connects the downstream reach of C-102 with C-103 to maintain levels in the lower reaches of C-103.

This component lies in Miami-Dade County and would require acquisition of approximately 350 acres, in three separate segments. The northerly delineated lands contain two of the segments and totals 200 acres. The southerly segment has 150 acres.

The land sales in these areas indicate a value of $10,000 per acre. The total value of the 350 acres is therefore estimated at $3,500,000, for all three levels of cost estimates.

The number of affected ownership tracts is unknown, but is estimated to be 15. Based on this, the Federal administrative/acquisition cost is estimated to be $90,000 and the non-Federal administrative/acquisition cost is estimated to be $180,000. The number of residential and/or business relocations and severance damages are unknown. For all three levels of component estimates a contingency of 50 percent is applied, yielding a total real estate cost estimate of $5,655,000 for this component

Component GGG6

Component GGG6 is the C-51 and Southern L-8 Reservoir located in the Water Preserve Area in Palm Beach County. The storage reservoir managed for the following environmental and water supply goals: (a) to reduce the number of events when discharges to the Lake Worth Lagoon exceed the desired daily average flow rate of 500 cfs; (b) to reduce the magnitude of events exceeding the desired flow rate of 500 cfs; (c) to reduce the average annual volume discharged to tide (over the S-155 structure) by detaining storm water runoff for subsequent environmental (routing from the West Palm Beach Water Catchment Area to the Northwest Fork of the Loxahatchee River) and water supply needs (providing water to the Lake

Worth Drainage District and the West Palm Beach Water Catchment Area); and to provide increased drainage to the C-51 Basin and the Southern L-8 Basin by lowering the average stages in the C-51 Canal. The reservoir will be filled, with excess water from the Southern L-8 Basin and the C-51 Basin, when flows over the S155 structure exceed 300 cfs during the wet-season from excess water in C-51 Canal and Southern L-8 (backpumped). Water will be released back to C-51 to help maintain canal stages during the dry-season. The reservoir will consist of 1,200 acres of usable area with a 100-foot deep, 2-foot thick slurry wall for seepage control along the approximate perimeter length of 6 miles (this depth assumes a surficial aquifer thickness of 170 feet, 20 feet of embankment and 10 feet of embedment of the slurry was into the confining layer). The reservoir will use have a total storage depth of 40 feet (30 below grade and 10 above grade). An inflow pump with a capacity of 1,500 cfs will be located at the reservoir, together with an emergency outflow structure with a capacity of 1,500 cfs to be operated when the water level exceeds the maximum operation depth of 40 feet by 2 feet. This component includes a 1,000 cfs pump at S-155A, which will be operated when flows through S-155 exceed 300 cfs, and there is capacity in the reservoir.

This component is in Palm Beach County, and lies north of the West Palm Beach Canal in the vicinity of Twenty Mile Bend. The component will require acquisition of 1,800 acres of land. The estimated land value is $10,000 per acre for a total probable/low-end lands and damages estimate of $18,000,000. South Florida Water Management District recommends a value of $15,000 per acre. Using this value, a total of $27,000,000 is estimated for the high-end lands and damages estimate.

The number of affected ownership tracts is unknown, but is estimated to be 13. Based on this, the Federal administrative/acquisition cost is estimated to be $78,000 and the non-Federal administrative/acquisition cost is estimated to be $156,000. The number of residential and/or business relocations and severance damages are unknown. For all levels of cost estimates a contingency of 50 percent is applied. The total estimated real estate cost for the probable/low-end is $27,351,000. The total estimated high-end cost is $40,851,000.

Component HHH6

Component HHH6 is the West Miami-Dade Reuse located in the Water Preserve Area in Miami-Dade County. The future West Miami-Dade Wastewater Treatment Plant, will be located immediately south of the Bird Drive Recharge Area and east of the relocated L-31 North Protective Levee, will provide wastewater treatment coupled with superior treatment technology to supply reclaimed water to the Bird Drive Recharge Area. The water will be supplied year round as needed to enhance groundwater recharge. Excess water, when available, will be sent as a second priority to the South Dade Conveyance System, to Northeast Shark River Slough as a third priority and to deep injection wells when there are no demands from the three designated priorities. The proposed reclaimed water production facility will be operated by Miami-Dade County and has the potential to discharge 100 million gallons per day. When all demands have been met, the West Miami-Dade Wastewater Treatment Plant will stop treatment beyond secondary treatment standards and will dispose of the secondary treated effluent into deep injection wells. Treatment will be biological nutrient-removal advanced wastewater treatment (AWT) followed by a superior treatment technology using iron salts to lower phosphorus to levels required for Everglades discharges. The iron salt coagulation system would be designed for a constant flow rate of 100 million gallons per day. The West Miami-Dade Wastewater Treatment Plant will pump superior, advanced treated water to the Bird Drive Recharge Area when the elevation of the Recharge Area is equal to or below 3 feet above natural ground at a rate of 155 cfs (100 million gallons per day).

This component will require 100 acres in Miami-Dade County, located at the southeast corner of State Road 997, Krome Ave., and Bird Drive. The estimated land value is $20,000 per acre for a total lands and damages estimate of $2,000,000, for all three cost estimate levels.

The number of affected ownership tracts is unknown, but is estimated to be 20. Based on this, the Federal administrative/acquisition cost is estimated to be $120,000 and the non-Federal administrative/acquisition cost is estimated to be $240,000. The number of residential and/or business relocations and severance damages are unknown. For this cost estimate a contingency of 50 percent is applied. The total estimated real estate cost for the probable, high-end and low-end is the same, $3,540,000

F.9 OTHER PROJECT ELEMENTS

After selection of the Initial Draft Plan, as set forth above, the Restudy Team developed a list of potential Other Project Elements that could not be evaluated during the iterative alternative plan formulation process. The list of Other Project Elements was developed by the Restudy Team from the Critical Projects list; the Governor's Commission Conceptual Plan, and nominations from Restudy Team members. After initial screening of a comprehensive list, the remaining Other Project Elements to be included in the Comprehensive Plan was developed. The Comprehensive Plan is comprised of the components of Alternative D13R and a select group of these Other Project Elements. For a more detailed discussion see Appendix A-5 entitled "Critical Projects" and Appendix A-6 entitled “Description of Other Project Elements. In the draft report there were eleven Other Project Element, eight of which included real estate with estimated real estate costs provided. Since the draft report, one (North New River Restoration) Other Project Element was deleted from inclusion in the final Comprehensive Plan. The North

New River Restoration Project was approved and will be funded as a Critical Project (see Appendix A-5). There were nineteen Other Project Elements recommended for inclusion into the final Comprehensive Plan. Of these nineteen Other Project Elements, sixteen were Critical Projects (see Appendix A-5). The nineteen Other Project Elements to be included in the Comprehensive Plan are: (1) Seminole Tribe Big Cypress Water Conservation Plan; (2) the Biscayne Bay Coastal Wetlands; (3) Melaleuca Eradication Project and other Exotic Plants; (4) the Protection and Enhancement of Existing Wetland Systems along the Loxahatchee National Wildlife Refuge, including the Strazulla Tract; (5) Pal Mar and Corbett Hydropattern Restoration; (6) Acme B Basin Discharge; (7) Lake Okeechobee Watershed Water Quality Treatment Facilities; (8) Miccosukee Water Management Plan; (9) Lake Okeechobee Tributary Sediment Dredging; (10) Lake Worth Lagoon Restoration; (11) Restoration of Pineland and Hardwood Hammocks in C-111 Basin; (12) Winsburg Farms Wetland Restoration; (13) Lake Istokpoga Regulation Schedule; (13) Southern Golden Gates Estate Restoration; (14) Southern Crew Project Addition; (15) Lake Trafford Restoration; (16) Henderson Creek/Belle Meade Restoration; (17) Lakes Park Restoration; (18) Florida Keys Tidal Restoration; and (19) Palm Beach County Wetlands-Based Water Reclamation. . Sixteen of these Other Project Elements require real estate that will be acquired for the particular Project Element, however, the full extent of the real estate required and the estimate costs have not been fully determined. The real estate cost estimates provided below are based solely on the estimated costs provided by the proponent of the Other Project Element. A description of the Other Project Elements that have been determined to include real estate and the project cost of the real estate are discussed below.

Lake Okeechobee Watershed Water Quality Treatment Facilities (Lake Okeechobee Water Retention/Phosphorous Removal)

Many of the wetlands in the Lake Okeechobee watershed have been ditched and drained for agriculture and flood control. The purpose of this project is to restore the hydrology of selected isolated and riverine wetlands in the region. A two-pronged approach will be taken in this project: (1) restoring hydrology of isolated wetlands by plugging the connection to drainage ditches; and (2) diversion of canal flows through constructed stormwater treatment areas to attenuate peak flows and retain phosphorus.

This feature includes two reservoir-assisted stormwater treatment areas and plugging of select local drainage ditches. The initial design of these reservoir-assisted stormwater treatment areas assume a 1,775 acre facility in the S-154 Basin in Okeechobee County and a 2,600 acre facility in the S-65D sub-basin of the Kissimmee River Basin in Highlands and Okeechobee Counties. The plugged drainage ditches will result in restoration of approximately 3,500 acres of wetlands throughout the Lake Okeechobee watershed basin. A total of 4,515 acres will be required which includes the reservoirs and interest in lands in the drainage ditches.

Participation by landowners will be voluntary. Non-standard perpetual flowage/conservation easement estates will be developed and discussed in subsequent design documents. It is estimated that the cost of lands for this OPE will be no greater than $14,448,000, which would include all land costs and administrative/acquisition costs (both Federal and non-Federal).

Lake Okeechobee Tributary Sediment Dredging

This project involves dredging sediments from 10 miles of primary canals within an 8-basin area that encompasses the most intense agriculture in the northern watershed of Lake Okeechobee. The sediment in these tributaries is an undesirable source of phosphorous that contributes to the excessive loading to Lake Okeechobee. Dredging would remove the sediment as a potential source of phosphorous loading to the lake. Dredge material disposal areas would have to been identified and real estate interest would have to be obtained. The amount of acreage required for dredge disposal sites has not been determined, but is estimated at 320 acres. No real estate cost estimate was provided by the proponent of this OPE. However for planning purposes it is estimated that the real estate costs would be $900,000, which would include all land costs and administrative/acquisition costs (both Federal and non-Federal).

Pal Mar and Corbett Hydropattern Restoration

This component involves the acquisition of 3,000 acres between the South Florida Water Management District's Pal-Mar Save Our Rivers Project (approximately 35,435 acres) and the State of Florida's J.W. Corbett Wildlife Management Area (approximately 60,000 acres) to extend the spatial extent of protected natural areas. The project will also provide hydrologic connections between the J.W. Corbett Wildlife Management Area and; (1) the Moss Property, (2) the C-18 Canal, (3) the Indian Trails Improvement District, and (4) the L-8 Canal. These connections would relieve the detrimental effects on native vegetation frequently experienced during the wet season. Pal-Mar is a large pine flatwood/wet prairie/depression marsh complex located in Palm Beach and Martin Counties, northeast of the J.W. Corbett Wildlife Management Area. Acquisition of this approximately 3,000 acres of privately owned parcel of land between Pal-Mar and J.W. Corbett Wildlife Management Area would form an unbroken 126,000-acre greenbelt, extending from the Dupuis Reserve (approximately 21,800 acres) near Lake Okeechobee across the J.W. Corbett Wildlife Management Area, and connecting with Jonathan Dickinson State Park (approximately 8,000 acres). The estimated real estate cost of this 3,000 acres is $8,000,000, which would include all land costs and administrative/acquisition costs (both Federal and non-Federal).

Acme Basin B Discharge

This project involves the construction of a wetland treatment area to treat Acme Basin "B" runoff discharged to the Loxahatchee National Wildlife Refuge. The remainder of the discharge will be sent to a temporary storage reservoir to attenuate peak flows until such time as the water can be discharged to one of two alternative locations: Palm Beach County Agricultural Reserve reservoir or the in-ground reservoir area located adjacent to the L-8 Canal. Depending upon which storage facility is most feasible for long term storage, improvements to existing canals and new or modified pump stations will be necessary. The wetland treatment area will be comprised of 310 acres and the temporary storage area will be comprised of 620 acres. Estimated real estate cost of this 930 acres is $8,500,000, which would include all land costs and administrative/acquisition costs (both Federal and non-Federal).

Lake Worth Lagoon Restoration

This Project involves three phases, which will lead to improved water quality and the restoration of Lake Worth Lagoon located in Palm Beach County. Phase I will examine both quantity and quality of bottom sediment accumulations within the C-51 Canal and downstream discharge area within the lagoon. Phase II will develop a plan and project plan to provide for sediment removal or capping that could include creating a series of sediment traps along the C-51 where sediment accumulations increase. Phase III will involve the removal of bottom sediments with the C-51 Canal as well as implementing a prototype project to either remove or cap the organic bottom layer within the lagoon. The elimination of these sediments form the C-51 discharge will provide for long-term improvements to the lagoon and ensure success of additional habitat restoration projects. Dredge material disposal areas would have to been identified and real estate interests obtained. The amount of acreage required for dredge disposal sites has not been determined. No real estate cost estimate was provided by the proponent of this OPE. However for planning purposes, it is estimated that the real estate costs would be $300,000 which would includes all land costs and administrative/acquisition costs (both Federal and non-Federal).

Protect and Enhance Existing Wetland Systems along Loxahatchee National Wildlife Refuge including the Strazulla Tract

This component involves the acquisition of 3,335 acres to expand the spatial extent of protected natural areas. This project will make a hydrological and ecological connection to the Loxahatchee National Wildlife Refuge. This land will act as a buffer between higher water stages to the west and agriculture lands to the east that must be drained. This increase in spatial extent will provide vital habitat connectivity for species that require large unfragmented tracts of land for survival. It also contains the only remaining cypress habitat in the eastern Everglades and one of the few remaining sawgrass marshes adjacent to the coastal ridge. This is a unique and endangered habitat that must be protected. This area provides an essential Everglades landscape heterogeneity function. The total real estate cost, including contingency, of this OPE is estimated to be $48,972,000, which would includes all land costs and administrative/acquisition costs (both Federal and non-Federal).

Biscayne Bay Coastal Wetlands

The ability of the Initial Draft Plan to provide hydrologic benefits to the southern Everglades is supported in large part by the Biscayne Bay Coastal Wetlands Component FFF. This component replaces freshwater inputs to the Biscayne Bay estuary that are reduced by the Initial Draft Plan (i.e., seepage control components along the protective levee and the capture of other discharges to tide). This OPE compliments Component BBB and is necessary to properly distribute the additional flows to the estuary. This project has five sub-components located in southeast Miami-Dade County, covering the southwest shoreline of Biscayne Bay from the Deering Estate at C-100C south to the Florida Power and Light Turkey Point Power Plant, generally along L-31E.

- **Sub-component 1 - Deering Estate Flowway** - Operation of this sub-component involves pumping water from the SW 160th Street ditch (a tributary to C- 100C) through property adjacent to the Deering Estate and ultimately into Cutler Drain which runs through the Deering Estate. The design involves; adding a 50 cfs pump station at end of SW 160th Street Canal, filling in mosquito ditches in coastal mangroves, and constructing weirs to delay water passage in old Cutler Drain.

- **Sub-component 2 - Cutler Wetlands** - Operation of this sub-component involves: (1) routing water south from C-100A to the Cutler Wetlands Proposal Area via a shallow distribution swale on the surface of the marl to C-100B, (2) pumping water from C-100B to a spreader swale, and (3) pumping water from C-100A south into a spreader swale to allow sheetflow to Biscayne Bay. Depending on water quality, flows may need to be routed through Stormwater Treatment Areas (STA). Design involves constructing; (1) a spreader swale from C-100A south to C-100B, (2) a levee west of the spreader swale, (3) a 200 cfs pump along the north end of the spreader swale at C-100A. If water quality dictates, the design may also involve construction of: (4) an STA adjacent to C-100B, (5) a 200 cfs pump adjacent to the STA and C-100B, and (6) a levee seepage canal along the north and southern end of the STA.

- **Sub-component 3 - L-31E Flowway** – The purposes of this sub-component are (1) to reestablish conditions for living oyster bars along shoreline of the bay and (2) to hydrologically isolate the Miami-Dade County landfill. A flow redistribution system will be created west of L-31E and existing wetlands will be restored in the area between L-31E and the western boundary of the redistribution system. A distribution swale with a western levee will be constructed along this boundary. The wetland area west of L-31E should be used for short-term, shallow ponding of water to maintain wetlands and help drive freshwater flow to the nearshore Bay out of the east bank of L-31E. Depending on water quality, flows may need to be routed through an STA. Design involves; (1) installation of culverts and risers under L-31E, (2) construction of a spreader swale east of L-31E, (3) backfilling Military Canal, (4) construction of a plug in C-100B, (5) construction of a canal west of the landfill to intersect with L-31E borrow canal, and (6) filling in mosquito ditches. If water quality dictates, the design may also involve construction of: (7) an STA from C-102 to C-103 and east of Homestead Air Force Base, (8) a seepage collection ditch on the western side of the STA, (9) construction of a 200-cfs pump at C-102 to the STA, and (10) construction of a 200-cfs pump at C-103 to the STA.

- **Sub-component 4 - North Canal Flowway** – The operation of this sub-component involves; (1) pumping available water from C-103 and the Florida City Canal to re-establish sheetflow across freshwater and coastal wetlands to Biscayne Bay. Depending on water quality, flows may need to be routed through an STA. Design involves: (1) construction of a 200-cfs pump on C-103, (2) construction of a 200 cfs pump on Florida City Canal, (3) installation of culverts and risers under L-31E, (4) construction of a delivery canal from C-103 south to North Canal, (5) construction of a spreader swale east of L-31E, (6) backfilling the North Canal east of SW 112 Avenue and (7) construction of a flowway south from the Florida City Canal from SW 127th Avenue to SW 107th Avenue. If water quality dictates, the design may also involve construction of: (8) an STA on the western edge of the coastal wetlands in between the C-103 and the Florida City Canal, (9) an STA associated with the flowway south of the Florida City Canal, and (10) construction of seepage management facilities around the STAs.

- **Sub-component 5 - Barnes Sound Wetlands** – Operation of this sub-component involves pumping available water from the Florida City Canal to a shallow east-west spreader canal. Depending on water quality, flows may need to be routed through an STA. Design involves construction of: (1) a 50-cfs pump at the Florida City Canal, (2) a new canal south from Florida City Canal to a shallow spreader swale along the edge of the coastal wetlands. If water quality dictates, the design may also involve construction of an STA and seepage management facility.

There are some general problems or considerations that apply to the entire area. These include existing ditches, which are extensive, the presence of exotic plants and animals, potential water quality problems, and land ownership constraints. The areas under review for restored sheet flow were extensively ditched early in the twentieth century. This cross ditching interferes with providing restored historic flow patterns. For these reasons, the ditches may need to be filled. In addition, the area would require an extensive and possibly ongoing invasive exotic plant removal program. Most of the lands to be acquired are under current acquisition efforts by the State of Florida, the South Florida Water Management District, and Miami-Dade County.

The total acreage required for this component is estimated to be 13,600 acres with an estimated real estate cost for this component of $200,000,000, which would include all land costs and all Federal and non-Federal administrative/acquisition costs.

Seminole Tribe Big Cypress Water Conservation Plan

This feature includes construction of water control, management, and treatment facilities in the central, western and eastern portion of the Big Cypress Reservation. The construction elements include conveyance systems, including major canal bypass structures, irrigation storage cells, and water resource areas. The features proposed are part of a larger project known as the Seminole Tribe Comprehensive Water Conservation Project. This project has been divided into two separate elements, with the western portion being an approved Critical Project.

The purpose of this feature is to improve the quality of water and runoff from phosphorus generating agricultural sources within the Reservation. The area is traversed by the L-28 and L-28I Canals and the North and West Feeder Canals, all of which were constructed as part of the C&SF Project. This comprehensive watershed management system is designed to achieve environmental restoration on the Reservation, the Big Cypress Preserve, and the Everglades Protection Area (EPA). In addition, the project will reduce flood damage and promote water conservation.

The removal of pollutants will be achieved using natural treatment processes in pretreatment cells and water storage areas. A phosphorus level of 50 ppb is the goal, which is the current level to be achieved by the stormwater treatment areas of the ECP. Should design performance levels for phosphorus become more stringent, this project has sufficient flexibility is designed to be able to incorporate additional alternative technology to meet stricter levels.

It is estimated that 3,800 acres will be required at a total estimated real estate cost of $5,735,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

Miccosukee Water Management Plan

This feature includes construction of a 900-acre wetland retention/detention area on the Miccosukee Tribe's Alligator Alley Reservation. The feature includes a pump station, levees, trenches and culverts to create the inflow and outflow facilities for the retention/detention area..

The purpose of this feature is to provide water storage capacity and water quality enhancement for waters which discharge into the Everglades Protection Area.

It is estimated that 900 acres will be required at a total estimated real estate cost of $1,718,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

Winsburg Farms Wetland Restoration

This feature includes the construction of a 175-acre wetland east of Loxahatchee Wildlife Preserve in Palm Beach County. The feature will reduce the amount of treated water from the Southern Region Water Reclamation Facility wasted in deep injection wells by further treating and recycling the water.

The purpose of this facility is to create a wetland from water, which would be normally lost to deep well injection and lost for any future beneficial use. The wetland will reuse a valuable resource, recharge the local aquifer system and create a new and ecologically significant wildlife habitat and extend the function of the nearby Wakodahatchee Wetland.

It is estimated that 175 acres will be required at a total estimated real estate cost of $4,140,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

Southern Golden Gate Estates Restoration

This feature includes a combination of spreader channels, canal plugs, road removal and pump stations in the Western Basin and Big Cypress, Collier County, south of I-75 and north of U.S. 41 between the Belle Meade Area and the Fakahatchee Strand State Preserve.

The purpose of this feature is to restore and enhance the wetlands in Golden Gate Estates and in adjacent public lands by reducing overdrainage. Implementation of the restoration plan would also improve the water quality of coastal estuaries by moderating the large salinity fluctuations caused by freshwater point discharge of the Fahka Union Canal. The plan would also aid in protecting the City of Naples' eastern Golden Gate wellfield by improving groundwater recharge.

A Federal Farm Bill grant has allocated $25,000,000 in funds to aid in acquisition of lands required for this project, therefore, no real estate funds are required in the implementation of this project.

Southern Crew Project Addition

This feature includes the acquisition and restoration of 4,670 acres of land, and replacement of the Kehl Canal Weir in southern Lee County, adjacent to Corkscrew Sanctuary.

The purpose of this feature is to: 1) re-establish historic flow patterns and hydroperiods on the project lands, as well as CREW and Corkscrew Sanctuary wetlands to the east; 2) restore historical storage potential of the Southern CREW lands; 3) reduce excessive freshwater discharges to Estero Bay during the rainy season; 4) decrease saltwater intrusion during the dry season; 5) reduce loading of nutrients and other pollutants to the Imperial River and Estero Bay; 6) increase aquifer recharge and water supply for an area frequently facing water restrictions during dry years; and 7) reduce flooding of homes and private lands west of the project area.

Hydrologic restoration of this land will include the following modifications: removal of existing road beds, removal of single family homes, removal of junk debris, filling of ditches, and removal of agricultural canals and berms. Other components within the plan include: replacement of the Kehl Canal weir, clearing and snagging on Imperial River, Estero River and Halfway Creek, and reconnection of Spring Creek and Halfway Creek under U.S. Interstate 75.

The total estimated real estate cost is $30,104,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

Lake Trafford Restoration

This feature includes a lakewide organic sediment removal to Lake Trafford near Ft. Myers, Florida. Lake Trafford has poor water quality, extensive muck accumulations, loss of native submergent plant communities, periodic aquatic weed infestations, and numerous moderate fish kills. Poor water quality is attributed to internal nutrient cycling from extensive organic much deposits throughout the lake basin.

The purpose of this feature is to preserve the headwaters of the Corkscrew Swamp and Camp Keais Strand. The water quality of the lake affects these wetland resources that have been targeted for protection. These wetlands drain into important estuarine systems such as Estero bay and Cape Ramono. Lake Trafford is an integral contributor to the sheet flow that traverses such areas as the CREW and the Southern Golden Gates Estates area. As the only major lake in southwest Florida, Lake Trafford provides a sanctuary during the dry season. The quality of the lake and the associated watershed affects important wildlife species and offers a sanctuary for migrating birds.

This OPE will require acquisition of a 449 acre temporary disposal area and pipeline with a total estimated real estate cost of $744,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

Henderson Creek/Belle Meade Restoration

This feature combines multiple individual elements to complement each other to form a larger-scale combined effect. This feature includes a 10-acre stormwater lake/marsh filtering system, four culverts under State Road 951; hydrologic restoration around Manatee Basin including culverts, ditching, removal of some roadbed; invasive, exotic plant removal, and a public access point and interpretive boardwalk; construction of a swale and spreader system; and removal of the Road-to-Nowhere. This southwest Florida feature is located in Collier County. The area known locally as Belle Meade is the primary drainage basin for the Henderson Creek estuary, which drains into Rookery Bay.

The purpose of this feature is to restore historic sheetflow to the estuary, treatment of stormwater, improve water quality and increase habitat value and wetland functions.

It is estimated that 125 acres will be required at a total estimated real estate cost of $1,029,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

Lakes Park Restoration

This feature includes the construction of a 40-acre marsh/flowway in an abandoned rock mine, removal of exotic vegetation, and planting native vegetation on 11 acres of uplands and 9 acres of littoral zone. This feature is located in the Lee County Lakes Regional Park, upstream of Estero Bay.

The purpose of this feature is to enhance surface water runoff quality by creating a meandering flowway with shallow littoral zones to enhance pollution removal and oxygen content, removing aquatic and upland exotic infestation while allowing public access into upland areas of improved native habitat. The restoration will provide immediate habitat and water quality benefits at Lakes Park and improve downstream conditions in Hendry County and the Estero Bay Aquatic Preserve.

It is estimated that 40 acres will be required at a total estimated real estate cost of $166,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

Florida Keys Tidal Restoration (OPE)

This feature includes the use of bridges or culverts to restore the tidal connection between Florida Bay and the Atlantic Ocean in Monroe County. The four locations are as follows: 1) Tarpon Creek, just south of Mile Marker 54 on Fat Deer Key (width 150 feet); 2) unnamed creek between Fat Deer Key and Long Point Key, south of Mile Marker 56 (width 450 feet); 3) tidal connection adjacent to Little Crawl Key (width 300 feet); and 4) tidal connection between Florida Bay and Atlantic Ocean at Mile Marker 57 (width 2,400 feet).

The purpose of this feature is to restore the tidal connection that was eliminated in the early 1900's during the construction of Flagler's railroad. Restoring the circulation to areas of surface water that have been impeded and stagnant for decades will significantly improve water quality, benthic floral and faunal communities, larval distribution of both recreational and commercial species (i.e. spiny lobster) and the overall hydrology of Florida Bay.

It is estimated that 5 acres will be required at a total estimated real estate cost of $51,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

Palm Beach County Wetlands Based Water Reclamation project

The Wetlands-Based Water Reclamation feature proposes to treat wastewater from the East Central Regional Wastewater Treatment Facility using Advanced Wastewater Treatment processes to remove nitrogen and phosphorus. This will then be followed up with superior treatment technology to remove phosphorus to approximately 50 parts per billion or less. This feature will consist of a 10 million gallons per day operation with 6 million gallons per day of the water discharged into approximately 1,500 acres of bermed marsh where it will be used to rehydrate the marsh as well as manage the hydroperiod and water quality of the wetland environment. The water will then be pumped to another marsh of approximately 300 acres surrounding the City of West Palm Beach wellfield. Infiltration of the water into the wellfield will occur as the wellfield pumps groundwater into the adjacent M Canal where it becomes surface water. The surface water in M Canal will flow towards Clear Lake, which is the surface water source of drinking water for the City of West Palm Beach. At the City's water treatment plant, the surface water will be treated to drinking water standards prior to entering the water supply distribution system for the City as well as the Town of Palm Beach and South Palm Beach. The remaining 4 million gallons per day of the

10 million gallons per day of reclaimed water will be routed from the Advanced Wastewater Treatment/superior treatment technology facility to residential lake systems surrounding both the City's wellfield and Palm Beach County's 8W Water Treatment Plant wellfield.

The purpose of the wetlands based water reclamation is to reduce the City's dependence on surface water from Lake Okeechobee during dry or drought events. In addition, approximately 2,000 acres of wetlands would be created or restored. Other benefits include aquifer recharge and replenishment, reduction of water disposed in deep injection wells and a reduction of stormwater discharge to tide.

It is estimated that 2,000 acres will be required at a total estimated real estate cost of $2,800,000, which includes all land costs and all Federal and non-Federal administrative/acquisition costs.

F.10 NON-FEDERAL SPONSOR-OWNED PROJECT LANDS

The South Florida Water Management District, the non-Federal sponsor for the Central & Southern Florida Project, owns a variety of interests in lands within different components of the Restudy Area. Some of the lands were acquired for the existing Central & Southern Florida Project, while other lands were acquired by the South Florida Water Management District utilizing Federal funds, State funds or Water Management District funds. Following is a discussion of lands owned by the South Florida Water Management District within the Initial Draft Plan's components. More detailed discussions and identification of lands and interests owned by the South Florida Water Management District will be provided in more detail in subsequent design documents as more detailed site information is determined.

In Component G5-Palm Beach Everglades Agricultural Area Storage Reservoir, the United States Department of Interior, U.S. Fish and Wildlife Service has contracted to purchase fee title to 45,000 acres, more or less, within the Everglades Agricultural Area. The funding for the purchase of this land will be provided by Interior from the Farm Bill account (Public Law 104-127, Section 390(a). The land will be conveyed to the South Florida Water Management District and could be utilized as part of this Component.

In Component M6-Site 1 Impoundment Water Preserve Area Palm Beach County, of the approximately 2,458 acres in this component, the South Florida Water Management District has acquired approximately 1,658 acres at a cost, (including most incidental costs) of $8,359,706.12. South Florida Water Management District has received Farm Bill funding for this purchase (50 percent Federal and 50 percent non-Federal). South Florida Water Management District also owns lands within the right-of-way of the Hillsboro Canal, which were acquired and certified for the existing Central and Southern Florida Project. The estate owned by South Florida Water Management District and the width of the existing right-of-way have not been determined and therefore may not be sufficient for construction of a pump station.

Component O4, the Water Conservation Area 3A and 3B Levee Seepage Management Water Preserve Area-Broward County. Of the approximately 6,542 acres required for this Component, South Florida Water Management District owns fee title to approximately 5,550 acres, 3,190 of which were acquired and certified for the existing Central and Southern Florida Project. The remaining 2,360 acres owned by South Florida Water Management District were purchased between 1991 and 1997. The Department of Interior, U.S. Fish and Wildlife Service, South Florida Water Management District, and Broward County participated in the purchase of approximately 1,051 acres with the Department of the Interior contributing $4,134,000 toward the purchase of these lands by means of a Grant. The South Florida Water Management District also owns the existing right-of-way of the C-11 Canal. The estate own by South Florida Water Management District in the C-11 Canal and the width of the existing right-of-way may not be sufficient for construction of a pump station.

In Component Q5 Western C-11 Diversion Impoundment and Canal Water Preserve Area Broward County, the South Florida Water Management District has purchased and owns fee title to approximately 497 acres of the C-11 Impoundment Area. The land was purchased for $11,366,000, which includes most incidental costs associated with acquisition. The South Florida Water Management District also owns the right-of-way of the L-33 and L-37 levees and borrow canals.

In Component R C-9 Stormwater Treatment Area/Impoundment Water Preserve Area, Broward County, the South Florida Water Management District owns fee title to approximately 1,505 acres within the impoundment area. The land was purchased for $29,174,000, which includes most incidental costs associated with the acquisition.

In other components, which are described below, the South Florida Water Management District owns some interest in canals, levees, borrow canals, and the Water Conservation Areas, which were certified for the existing Central and Southern Florida Project. Many structures (pump stations, levee, canal improvements) may be constructed within these existing right-of-way; however, the interest owned by South Florida Water Management District and the width of the existing right-of-way have not been reviewed and therefore may not be sufficient to allow the construction proposed in the Plan. For that reason, and because most structures and improvements have not been clearly defined, or specifically and precisely located, for planning purposes, Real Estate Division has assumed that the existing estates of the South Florida Water Management District and the width of the existing right-of-way are not sufficient for the planned improvements. The following provides a review of components where South Florida Water Management District owns an interest and a right-of-way, which were certified for the existing Central and Southern Florida Project:

In Component B2, South Florida Water Management District owns lands within the existing right-of-way of C-44.

In Component D5, South Florida Water Management District owns lands within the existing right-of-way of C-43.

In Component G6, South Florida Water Management District owns lands within the right-of-way of the Bolles and Cross Canals, Miami Canal; and North New River Canal

In Component K6, South Florida Water Management District owns the L-8 Canal right-of-way in this area; the right-of-way of the L-8 Tieback Levee and borrow canal; and the south leg of the C-18 Canal.

In Component M6, South Florida Water Management District owns the right-of-way for the Hillsboro Canal.

In Component O4, South Florida Water Management District owns the right-of-way for the C-11 Canal.

In Component Q5, South Florida Water Management District owns right-of-way in C-11 Canal.

In Component R4, South Florida Water Management District owns right-of-way in C-9 Canal.

In Component S 6, South Florida Water Management District owns the rights-of-way or an interest in land the L-33 borrow canal, L-30 levee and borrow canal, C-6 Canal, Snapper Creek Canal, and C-4 Canal.

In Component T6, South Florida Water Management District owns the right-of-way for the C-4 Canal.

In Component Y6, South Florida Water Management District own lands within the right-of-way of the C-51 Canal and the Existing E-1 Canal.

In Component BB4, South Florida Water Management District owns the right-of way for the Dade Broward Levee and the right-of-way for the C-4 Canal;

In Component FF4, South Florida Water Management District owns the right-of-way to the existing L-7 borrow canal structure and the L-40 borrow canal.

In Component KK4, South Florida Water Management District owns the right-of-way to the existing L-31N Levee and borrow canal.

In Component LL6, South Florida Water Management District owns the right-of-way to the existing C-51 Canal.

In Component QQ6, South Florida Water Management District owns the right-of-way to Miami Canal, L-68A levee, L-67A Canal, L67C levee, L-29 levee and canal.

In Component SS4, South Florida Water Management District owns the right-of-way for the North New River Canal and lands underlying the existing S-351 and S-150 structures.

In Component UU6, South Florida Water Management District owns rights-of-way for C-23 Canal, C-24 Canal and the St Lucie Canal.

In Component WW5, South Florida Water Management District owns the lands where the Stormwater Treatment Area and C-111N spreader canal will be located and owns the fee to lands underlying C-111, S-197, C-110 and S-18C. The lands underlying the Stormwater Treatment Area and the Southern Glades lands affected by this Component will be provided as an item of the C-111 Project Modifications.

In Component XX6, South Florida Water Management District owns the right-of-way for the C-11 Canal.

In Component YY4, South Florida Water Management District owns the right-of-way for the North New River Canal, L-37 and L-33.levees and borrow canals; and the lands underlying the S-9XN and S-9XS structures.

In Component ZZ5, South Florida Water Management District owns the lands underlying the S-9 structure and S-32 structure.

In Component CCC6, South Florida Water Management District owns right-of-way for L-28 levee and borrow canal and lands underlying S-190.

F.11 FEDERAL GOVERNMENT OWNED LAND

The only known Federal Government owned land within the study area is located along the south side of Tamiami Trail in Component QQ, which lands are owned or are being purchased by the Department of Interior, National Park Service for the Everglades National Park Expansion.

F.12 FARM BILL FUNDING OF LAND ACQUISITION

Pursuant to Section 390, Federal Agriculture Improvement and Reform Act of 1996, Public Law 104-127, the Department of Interior entered into a Grant to provide South Florida Water Management District with land acquisition funds. The Grant provides that South Florida Water Management District must provide matching funds. To date (end of May 1998), the Department of Interior has provided $29,367,066 to the South Florida Water Management District for land acquisition. South Florida Water Management District has matched the Department of Interior funding for land acquisition by providing $32,602,675 to date (May 1998). Of the figure of $61,969,741, approximately $51,611,723 has been applied toward the acquisition costs of 3853 acres lands within various components of the restudy. In Component M, 7.5 acres at a cost of $40,019, in Component VV6, 1658 acres at a cost of $8,359,706. In Component XX, 26 acres at a cost of $203,379. In Component S, 178 acres at a cost of $3,348,476. In Component R, 1036 acres at a cost of $20,122,669. In Component Q, 947 acres at a cost of $19,537,471.

Additionally, the Department of Interior has contracted to purchase fee title to 45,000 acres, more or less, within the Everglades Agricultural Area (Talisman Property). See discussion in Section F.8, Component G6.

F.13 NON-FEDERAL SPONSOR'S AUTHORITY TO PARTICIPATE IN PROJECT

The South Florida Water Management District was created by virtue of Florida Statutes, Chapter 373, Section 373.069. The South Florida Water Management District was created to further the State policy of flood damage prevention, preserve natural resources of the State including fish and wildlife and to assist in maintaining the navigability of rivers and harbors. (There are other enumerated purposes but they are not directly applicable to this project.) The South Florida Water Management District is specifically empowered to

> *Cooperate with the United States in the manner provided by Congress for flood control, reclamation, conservation, and allied purposes in protecting the inhabitants, the land, and other property within the district from the effects of a surplus or a deficiency of water when the same may be beneficial to the public health, welfare, safety, and utility. (Section 373.103)*

To carry out the above purposes, the South Florida Water Management District is empowered to:

...hold, control, and acquire by donation, lease, or purchase, or to condemn any land, public or private, needed for rights-of-way or other purposes, and may remove any building or other obstruction necessary for the construction, maintenance, and operation of the works; and to hold and have full control over the works and rights-of-way of the district.

The term *works of the district* is defined by Section 373.019 to be

...those projects and works, including, but not limited to, structures, impoundments, wells, and other water courses, together with the appurtenant facilities and accompanying lands, which have been officially adopted by the governing board of the district as works of the district.

Section 373.139 specifically empowers the Water Management District:

...to acquire fee title to real property and easements therein by purchase, gift, devise, lease, eminent domain, or otherwise for flood control, water storage, water management, and preservation of wetlands, streams and lakes, except that eminent domain powers which may be used only for acquiring real property for flood control and water storage.

F.14 EXISTING FEDERAL PROJECTS WITHIN STUDY AREA

Below is a listing of all the existing Federal Projects within the Study Area, for a more complete description of the Projects see Appendix K.

Rivers and Harbor Act of 1930-Miami River channel; improvements to Caloosahatchee River and Canal from Lake Okeechobee to Gulf of Mexico; improvements to Taylor Creek from Okeechobee City to Lake Okeechobee; Lake Okeechobee Levee and a channel from the south shore of the lake from Fisheating Creek to the St. Lucie Canal; improvements to the St. Lucie River channel; and protection works in the St. Lucie Canal for erosion control. Table K-1 lists the CR&LODA Project features incorporated into the C&SF Project.

Flood Control Act of 1948-created the Central and Southern Florida Project for Flood Control and Other Purposes. Table K-2 lists the project features authorized or authorized to be modified by the 1948 authorization.

Flood Control Act of 1954-act authorized the remainder of the Comprehensive Plan for the C&SF Project. Table K-3 lists project works authorized by the 1954 act.

Flood Control Act of 1958-authorized cost sharing and changes to the Comprehensive Plan. TableK-4 lists the project works authorized by the 1958 act.

Flood Control Act of 1960-authorized flood protection for the Nicodemus Slough area, Glades County, Florida. Table K-5 lists the project works authorized by the 1960 act

Flood Control Act of 1962-authorized modification and extension of the C&SF Project for flood control and major drainage. The 1962 authorization affected the following areas: a. West Palm Beach Canal; Boggy Creek; South Dade County; Shingle Creek; Cutler Drain Area of Dade County. Table K-6 lists the project works authorized by the 1962 act

Flood Control Act of 1965-authorized a new plan for Hendry County west of Levees L-1, 2, and 3 and flood protection for Southwest Dade County. Table K-7 lists the project works authorized by the 1965 act

Flood Control Act of 1968-authorized modification to the existing project for improved conservation and distribution of available water and extended flood protection. Table K-8 lists the project works authorized by the 1968 act.

River Basin Monetary Authorization and Miscellaneous Civil Works Amendments Act of 1970-provided funding for accelerated construction of borrow canal L-70, Canal C-308, Canal C-119W and pumping station S-326 to meet increased water requirements of Everglades National Park.

Kissimmee River Restoration Project-was authorized by the U.S. Congress in the Water Resources Development Act of 1992. The major components of the project include: 1) reestablishment of inflows from Lake Kissimmee that will be similar to historical discharge characteristics (headwaters component), 2) acquisition of approximately 85,000 acres of land in the lower Kissimmee Chain of Lakes and river valley and approximately 20,000 acres in the chain of Lakes (Lake Cypress, Lake Tiger, Lake Hatchineha; and Lake Kissimmee); 3) continuous backfilling of 22 miles of canal, 4) removal of 2 water control structures; and 5) recarving of 9 miles of former river channel.

Herbert Hoover Dike Study-study to determine whether strengthening of the Herbert Hoover Dike should be accomplished.

Lake Okeechobee Regulation Schedule-the Lake is regulated to provide flood control, navigation, and water supply for agricultural irrigation, municipalities and industry, Everglades National Park, regional groundwater control, and salinity control; enhancement of fish and wildlife; and recreation. Lake water levels are regulated by a complex system of pumps and locks managed by the Corps and the

South Florida Water Management District. Lake Okeechobee is currently operated under a regulation schedule known as the "Run 25", which utilizes a 15.65 - 16.75 foot range with four levels above this range. The zones of operation control discharge to outlets ranging from non-harmful to maximum rate of discharge. The Run 25 schedule was adopted in May 1992. An Environmental Assessment along with a Finding of No Significant Impact have been completed.

New Water Conservation Area 1 Regulation Schedule -Water Conservation Area 1 is located within the Arthur R. Marshall Loxahatchee National Wildlife Refuge in southeast Palm Beach County. The Water Conservation Area covers 143,085 acres. Lands within Water Conservation Area 1 are leased to the U.S. Fish and Wildlife Service by the South Florida Water Management District. The Water Conservation Areas perform a wide variety of functions including flood control, agricultural water supply, municipal water supply, fish and wildlife habitat enhancement, groundwater recharge, recreation, Everglades National Park water supply, and prevention of saltwater intrusion. Water Conservation Area 1 receives inflow via two pumping stations, a spillway (S-5A-S), and rainfall. The U.S. Fish and Wildlife Service has asked that a new regulation schedule be adopted to improve conditions within the Refuge. The improved schedule incorporates a flood stage that ranges between 15.75 feet and 17.5 feet. The water supply zone is between the range of 14.0 feet and 15.75 feet. The drought zone is 14.0 feet and no releases occur. Any Releases are also a function of Lake Okeechobee levels. This new schedule was designed to accomplish the following:

(1) allow higher water levels during wet years in the northern portion of the refuge.

(2) increase the hydroperiod of interior marshes of the refuge such that dryout does not occur on an annual basis.

(3) increase the proportion of the interior marsh of the refuge that serves as nursery areas for aquatic organisms.

(4) improve the timing of winter stage drawdown in the refuge to benefit wading birds.

(5) restore conditions in the refuge similar to those found when the area was used by snail kites for nesting.

(6) allow for storage of a greater quantity of water within the C&SF system during wet and normal rainfall years.

Everglades National Park Hole-in the Donut Restoration.

The Hole-in the Donut is a tract of land (approximately 10,000 acres) within Everglades National Park that was previously farmed and has now become overgrown with Brazilian Pepper trees. Research has shown that the only effective method for the elimination of the invasive Brazilian Pepper and the re-establishment of native wetland conditions is complete removal of the disturbed soil. Up to 4.8 million cubic yards of material is expected to be removed from this area (restoration area approximately 6,000 acres) over the next 15 – 20 years.

Modified Water Deliveries to Everglades National Park.

The Modified Water Deliveries to Everglades National Park Project was authorized by the Everglades National Park Protection and Expansion Act (Public Law 101-229). The purpose of the project is to provide for structural modifications to the C&SF Project to enable the restoration of more natural water flows to Shark River Slough in Everglades National Park. The project is being implemented by the Corps in conjunction with the acquisition of about 107,600 acres of land by the Department of Interior. Land acquisition for the levee, canal, and pump station for the flood mitigation system in the 8.5-square-mile area is underway.

This project is presently in the design and construction phase. The addition of water control structures and culverts will reestablish the natural distribution of water from Water Conservation Area 3A into Water Conservation Area 3B. Outlets from Water Conservation Area 3B (S-355A & B) will be constructed to discharge into Northeast Shark River Slough. An existing levee and canal (L-67 Extension) along the eastern edge of the existing Everglades National Park boundary will also be removed. A Miccosukee Indian camp will be floodproofed to avoid periodic flooding that would otherwise be caused by the project.

In order to prevent adverse flood impacts to the 8.5-square-mile residential area, the project includes the construction of a seepage levee and canal around the western and northern edges of the area and a pump station (S-357) to remove excess seepage water. These project features are designed to maintain the existing level of flood protection in the residential area after the Modified Water Deliveries to the Everglades National Park project returns water levels in Northeast Shark Slough to natural (slightly higher) levels. A second pump station (S-356) will be constructed to pump excess seepage water from the L-31N borrow canal and residential area into the L-29 borrow canal. This water will then flow through culverts under US Highway 41 into Northeast Shark River Slough.

The structural modifications were designed to provide for maximum operational flexibility so that as more is learned through the continued iterative testing program, the operation of the project can be adjusted accordingly.

C-111 Project.

Plan 6a, recommended in the Corps' General Reevaluation Report dated May 1994, will create the operational capability and flexibility to provide restoration of the ecological integrity of Taylor Slough and the eastern panhandle areas of the Everglades National Park and flood protection to the agricultural interests adjacent to C-111.

The C-111 Plan 6a will protect the natural values for a portion of the Everglades National Park, and will maintain flood damage prevention within the C-111 Basin, east of L-31N and C-111. The project, which consists of both structural and non-structural modifications to the existing project works within the C-111 Basin, will restore the hydrology in 128 square miles of Taylor Slough and its headwaters in the Rocky Glades. In addition, the hydroperiod and depths in 1,027 square miles of Shark River Slough are beneficially impacted by the higher stages in the Rocky Glades, resulting in a net increase in water volume within Shark River Slough.

Experimental Program of Water Deliveries to Everglades National Park

Authority for conducting the Experimental Program for Modified Water Deliveries to Everglades National Park expires upon completion of construction of the Modified Water Deliveries to Everglades National Park Project.

Everglades National Park and Everglades National Park Expansion- The Everglades National Park and Everglades National Park Expansion, owned or being acquired by the United States Department of Interior, National Park Service comprises 1,506,539 acres in Miami-Dade, Monroe and Collier Counties.

Big Cypress National Preserve and Addition-The Big Cypress National Preserve owned or being acquired by the United States Department of Interior, National Park Service, comprises 728,000 acres in Collier County.

Biscayne National Park is owned by the United States Department of Interior, National Park Service and lies in Miami-Dade and Monroe counties.

F.15 NAVIGATIONAL SERVITUDE

The navigational servitude will likely not be applicable to any components within the Restudy.

F.16 INDUCED FLOODING

At present, all components were valued as if fee title would be required. Whether there will be flooding induced by the construction or the operation and maintenance of the various components of the project has not been analyzed. No written analysis has been completed for any component, except for lands within Components O, and YY. These lands were acquired by the South Florida Water Management District as a result of adverse rulings in inverse condemnation actions.

F.17 ESTATES TO BE ACQUIRED

STANDARD ESTATES

Land values for all Components have valued as if fee title would be acquired. As additional data is obtained and provided, and as more definite plans and specifications are developed, lesser estates (in accordance with Chapter 12, ER 405-1-12) may be determined to be appropriate. The determination of the required estates will be addressed in future documents applicable to the different components. For the purposes of this document the following estates may be acquired:

1. FEE. The fee simple title to (the land described in Schedule A) /(Tracts Nos. ____, ____ and ___), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

2. FEE EXCEPTING AND SUBORDINATING SUBSURFACE MINERALS. The fee simple title to (the land-described in Schedule A) (Tracts Nos. ____, ____ and ____), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; excepting and excluding from the taking all (coal) (oil and gas) in and under said land and all appurtenant rights used in connection with the exploration, development, production and removal of said (coal), (oil and gas), including any existing structures and improvements; provided, however, that the said (coal) (oil and gas) and appurtenant rights so excepted and excluded are hereby subordinated to the prior right of the (United States and non-federal project sponsor) to flood and submerge the land as may be necessary in the construction, operation and maintenance of the project; provided further that any exploration or development of said (coal) (oil and gas) in and under said land shall be subject to Federal and State laws with respect to pollution of waters of the reservoir, and provided that the type and location of any structure, improvement and appurtenance thereto now existing or to be erected or constructed on said land in connection with the exploration and/or

development of said (coal) (oil and gas) shall be subject to the prior written approval of the representative of the non-federal project sponsor), or his duly authorized representative.

3. FEE EXCLUDING MINERALS (With Restriction on Use of the Surface). The fee simple title to (the land described in Schedule A) (Tracts Nos. ____, ____ and ____), subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; excepting and excluding from the taking all (coal) (oil and gas), in and under said land and all appurtenant rights for the exploration, development, production and removal of said (coal) (oil and gas), but without the right to enter upon or over the surface of said land for the purpose of drilling and extracting therefrom said (coal) (oil and gas).

4. FEE EXCLUDING MINERALS (With Restriction on Use of the Surface and Subordination to the Right to Flood). The fee simple title to (the land described in Schedule A) (Tracts Nos.____, ____ and ____), subject, however, to existing easements for public roads highways, public utilities, railroads and pipelines; excepting and excluding from the taking all (coal) (oil and gas) in and under said land and all appurtenant rights for the exploration, development, production and removal of said (coal) (oil and gas), but without the right to enter upon or over the surface of said land for the purpose of drilling and extracting therefrom said (coal) (oil and gas); provided, however, that the said (coal) (oil and gas) and appurtenant rights so excepted and excluded are subordinated to the prior right of the United States and the non-federal project sponsor to flood and submerge the land in connection with the operation and maintenance of the ____________ project.

5. FLOWAGE EASEMENT (Permanent Flooding). The perpetual right, power, privilege and easement permanently to overflow, flood and submerge (the land described in Schedule A) (Tracts NOS. ____, ____ and ____), (and to maintain mosquito control) in connection with the operation maintenance of the ________________ project as authorized by the Act of Congress approved _______________, and the continuing right to clear and remove any brush, debris and natural obstructions which, in the opinion of the representative of the United States in charge of the project, may be detrimental to the project, together with all right, title and interest in and to the timber, structures and improvements situate on the land (excepting _____________, (here identify those structures not designed for human habitation which the representative of the non-federal project sponsor determines may remain on the land)); provided that no structures for human habitation shall be constructed or maintained on the land, that no other structures shall be constructed or maintained on the land except as writing by the representative of the non-federal project sponsor in charge of the project, and that no excavation shall

be conducted placed on the land without such approval as to the may be approved in charge of the and no landfill location and method

6. FLOWAGE EASEMENT (Occasional Flooding). The perpetual right, power, privilege and easement occasionally to overflow, flood and submerge (the land described in Schedule A) (Tracts Nos.____, ____ and ____). (and to maintain mosquito control) in connection with the operation and maintenance of the __________ project as authorized by-the Act of Congress approved _____________, together with all right, title and interest in and to the structure; and improvements now situate on the land, except fencing (and also excepting _____________________ (here identify those structures not designed for human habitation which the non-federal project sponsor determines may remain on the land)) ; provided that no structures for human habitation shall be constructed or maintained on the land, that no other structures shall be constructed or maintained on the land except as may be approved in writing by the representative of the non-federal project sponsor in charge of the project, and that no excavation shall be conducted and no landfill placed on the land without such approval as to the location and method of excavation and/or placement of land-fill; the above estate is taken subject to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the landowners, their heirs and assigns, all such rights and privileges as may be used and enjoyed without interfering with the use of the project for the purposes authorized by Congress or abridging the rights and easement hereby acquired; provided further that any use of the land shall be subject to Federal and State laws with respect to pollution.

7. FLOWAGE EASEMENT (Portions of Land to be Subjected to Permanent Inundation and Portions to be Subjected to Occasional Flooding). The perpetual right, power, privilege and easement in, upon, over and across (the land described in Schedule “A”) (Tracts Nos. ____, ____ and ____) for the purposes set forth below:

a. Permanently to overflow, flood and submerge the land lying below elevation __________ (and to maintain mosquito control,) in connection with the operation and maintenance of the ___________ project for the purposes as authorized by the Act of Congress approved _______________, together with all right, title and interest in and to the timber and the continuing right to clear and remove any brush, debris and natural obstructions which, in the opinion of the representative of the non-federal project sponsor in charge of the project may be detrimental to the project.

b. Occasionally to overflow, flood and submerge the land lying above elevation _________ (and to maintain mosquito control,) in connection with the operation and maintenance of said project.

Together with all right, title and interest in and to the structures and improvements now situate on the land, except fencing above elevation ________ (and also excepting _______ (here identify those structures not designed for human habitation which the representative of the non-federal project sponsor determines may remain on the land)) provided that no structures for human habitation shall be constructed or maintained on the land, that no other structures shall be constructed or maintained on the land except as may be approved in writing by the representative of the non-Federal Project sponsor in charge of the project, and

8. CHANNEL IMPROVEMENT EASEMENT. A perpetual and assignable right and easement to construct, operate, and maintain channel improvement works on, over and across (the land described in Schedule A) (Tracts Nos.____, ____ and ____) for the purposes as authorized by the Act of Congress approved _____________, including the right to clear, cut, fell, remove and dispose of any and all timber, trees, underbrush, buildings, improvements and/or other obstructions therefrom; to excavate: dredge, cut away, and remove any or all of said land and to place thereon dredge or spoil material; and for such other purposes as may be required in connection with said work of improvement; reserving, however, to the owners, their heirs and assigns, all such rights and privileges as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

9. FLOOD PROTECTION LEVEE EASEMENT. A perpetual and assignable right and easement in (the land described in Schedule A) (Tracts Nos.____, ____ and ____) to construct, maintain, repair, operate, patrol and replace a flood protection levee, including all appurtenances thereto; reserving, however, to the owners, their heirs and assigns, all such rights and privileges in the land as may be used without interfering with or abridging the rights and easement hereby acquired; subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

10 ROAD EASEMENT. A perpetual and assignable easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and ____) for the location, construction, operation, maintenance, alteration replacement of (a) road(s) and appurtenances thereto; together with the right to trim, cut, fell and remove therefrom all trees, underbrush, obstructions and other vegetation, structures, or obstacles within the limits of the right-of-way; (reserving, however, to the owners, their heirs and assigns, the right to cross over or under the right-of-way as access to their adjoining land at the locations indicated in Schedule B); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines.

11. BORROW EASEMENT. A perpetual and assignable right and easement to clear, borrow, excavate and remove soil, dirt, and other materials from (the land described in Schedule A) (Tracts Nos. ____, ____ and ____); subject, however, to existing easements for public roads and highways, public utilities, railroads and pipelines; reserving, however, to the land-owners, their heirs and assigns, all such rights and privileges in said land as may be used without interfering with or abridging the rights. and easement hereby acquired.

12. TEMPORARY WORK AREA EASEMENT. A temporary easement and right-of-way in, on, over and across (the land described in Schedule A) (Tracts Nos. ____, ____ and ____), for a period not to exceed ______________, beginning with date possession of the land is granted to the United States, for use by the United States, its representatives, agents, and contractors as a (borrow area) (work area), including the right to (borrow and/or deposit fill, spoil and waste material thereon) (move, store and remove equipment and supplies, and erect and remove temporary

NON-STANDARD ESTATES

13. FEE EXCEPTING THE RIGHT TO EXCAVATE THE LAND FOR THE PURPOSE OF QUARRYING LIMESTONE, AND SAND. The fee simple title to (the land described in Schedule A) (Tracts Nos.____, ____ and ____), subject, however, to existing easements for public roads highways, public utilities, railroads and pipelines; excepting that excavation for the purpose of quarrying (limestone) (sand) shall be permitted, subject only to such approval as to the placement and disposal of overburden, if any, in connection with such excavation.

14. RELEASE OF SURFACE EXPLORATION RIGHTS

WHEREAS ________________ is the owner of certain (oil, gas, phosphate, etc.) and other mineral rights or reservations, together with the right of access to explore, prospect, exploit, develop and otherwise seek (oil, gas, phosphate, etc.) and other mineral deposits on the lands hereinafter described on Exhibit “A”; and

WHEREAS, a release and waiver of such rights of surface exploration has been requested of __________________ by the SOUTH FLORIDA WATER MANAGEMENT DISTRICT, and a valuable consideration for so doing has been paid by the SOUTH FLORIDA WATER MANAGEMENT DISTRICT.

NOW, THEREFORE, for and in consideration of the sum of ____________ Dollars and other good and valuable considerations paid by said SOUTH FLORIDA WATER MANAGEMENT DISTRICT,

________________________________ does for itself, its successors, heirs, and assigns, subject to existing mineral leases, if any, hereby waive and release to said SOUTH FLORIDA WATER MANAGEMENT DISTRICT, its successors and assigns, its rights of access to explore for (oil, gas, phosphate, etc.) and mineral deposits on the land described on Exhibit "A" situated in ____________ County, Florida.

EXPRESSLY RETAINING AND RESERVING, HOWEVER, all (oil, gas, phosphate, etc.) and mineral right reservations otherwise owned by _____________ in the land described on Exhibit "A", as to which the right of access for surface exploration is hereby released, and

EXPRESSLY RETAINING AND RESERVING SPECIFICALLY, the right to receive bonuses, rentals, royalties, and other payments to which it may be otherwise entitled by reason of the leasing, sale, or exploration of said (oil, gas, phosphate, etc.) and mineral rights.

F.18 ATTITUDE OF LANDOWNERS

The attitude of landowners within the project study area varies. Some are totally in favor of the project, while others are totally against the project or components of the project.

F.19 MINERALS

There are no known minerals in the project area, however, limestone is mined and quarried in portions of Components S and FF. The landowners will be allowed to continue to extract and excavate limestone in portions of these Components. The Non-Standard Fee estate will be utilized to acquire interests in these lands. Limestone, pursuant to Florida case law (<u>Florida Audubon Society v. Ratner</u>, 497 So.2d 672, (3rd D.C. App, Fla.) 1986, is not considered a mineral subject to a normal reservation of mineral rights or interests.

For other components within the recommended Comprehensive Plan, during subsequent design documents, the outstanding third party mineral interests will be more fully discussed. Conceptually, land costs could be reduced if the owners of the outstanding third party mineral interests were allow to retain the royalties, bonus, rentals and other payments that they may be entitled to by reason of the exploration of the minerals. This could be accomplished by the non-Federal sponsor securing from the owner of the outstanding third party mineral interest, a release of their surface exploration rights. The standard Release of Surface Exploration Rights is as set forth in the Non-Standard Estates, paragraph 21 above.

F.20 STANDING TIMBER AND VEGETATIVE COVER

Standing timber or other vegetative cover that has significant recreation or scenic value has not been identified at this time. It will be identified is subsequent design documents.

F.21 MITIGATION

Mitigation lands, if any, will be identified in subsequent design documents.

F.22 OUTSTANDING RIGHTS

Outstanding rights will be identified in subsequent design documents.

F.23 HAZARDOUS, TOXIC AND RADIOACTIVE WASTES (HTRW)

Phase I Hazardous, Toxic and Radioactive Waste (HTRW) Site Assessments were conducted in all subregions in conformance with the scope and limitations of ASTM Practice E 1527 and Engineer Regulation ER-1165-2-132. The findings and conclusions provided below reflect existing HTRW conditions based on database searches, aerial photography, review of available records, site inspections and interviews. These findings and conclusions are of existing conditions at this time. The project conditions assume that any HTRW found during any phase of the project would be remediated in accordance with local, state and federal laws. Therefore, it can be assumed that conditions at future construction sites will be contamination free or of low levels which would include de minimis conditions that generally do not present a material risk of harm to public health or the environment.

The assessment covered all Restudy sub-regions, within the general vicinity of proposed project features or existing features proposed for significant modification. Several site visits were conducted over the past few years, with the most recent survey having been performed during the week of 12 August 1998. The HTRW database search was performed on the entire area and it indicated that overall, the majority of the proposed new construction areas are free of hazardous and toxic waste. Most of these general features are proposed for remote and rural areas, and were farms, vacant land, or wildlife management areas. The most common type of HTRW, hydrocarbons, was found along state highways in which the majority of the gasoline stations had leaking underground storage tanks. The leaking underground storage tanks are found on roads crossing potential project lands at the Kissimmee River, Lake Okeechobee perimeter road, Upper East Coast roads, and Lower East Coast Roads.

Databases also revealed that several locations are National Priority Listed (NPL). Most of these NPL sites are due to past landfill operations. These sites are located in Palm Beach County, the Lower East Coast Lakebelt area in the vicinity of S-9 Structures and in Broward County south of Alligator Alley. Contaminated sites located on the perimeter of any proposed water storage area may be migrating or expanding into the project area. Any such sites would require further survey and specific evaluation prior to detailed design for Restudy features. Another feature of concern is the numerous landfills and waste handling facilities existing in the Lower East Coast sub-region. To the extent feasible, water storage areas should not be sited immediately adjacent to these known sites.

There are, in addition to identified sites, numerous undocumented tanks and landfills that may be present in future project areas which were not included in the database. These HTRW locations may be due to undocumented dumping or other HTRW operations. Within the agricultural areas there are numerous temporary pump sites and fuel storage areas. These makeshift portable tanks are not reported, and therefore are not presented in the HTRW database. In addition, pesticide/chemical mixing areas may also exist. Project implementation requires that any HTRW problems revealed during the real estate acquisition or actual project construction require full remediation

The database and Phase-1 assessment results are maintained at the US Army Corps of Engineers, Planning Division, as a series of maps and GIS overlays. It is not appropriate to include detailed information in this Programmatic Report and EIS. However, the data will be available to planners for consultation during development of specific project features, and is expected to aid in avoiding sites with major remediation needs.

F.24 RECREATION RESOURCES

There are no separable recreation lands required for this project.

F.25 RELOCATIONS OF ROADS, BRIDGES, UTILITIES/FACILITIES, TOWNS AND CEMETERIES

Based on available information, required relocations of roads, bridges, utilities, towns or cemeteries could not be identified. These will be accomplished in subsequent design documents.

F.26 CHART OF ACCOUNTS - RECOMMENDED COMPREHENSIVE PLAN

Alternative D-13R

O1	LAND AND DAMAGES	
01B	ACQUISITIONS	
01B20	BY LOCAL SPONSOR (LS)	$77,525,000
01B40	REVIEW OF LS	$38,055,000
01R	REAL ESTATE PAYMENTS	
01R10	LAND PAYMENTS	
01R1B	BY LS	$1,499,796,000
01R2	PL 91-646 ASSISTANCE PAYMENTS	
01R2B	BY LS	$414,000
TOTAL REAL ESTATE COST EXCLUDING CONTINGENCY		$1,615,790,000
CONTINGENCY (see note 2)		$605,645,000
	TOTAL FOR COMPREHENSIVE PLAN	$2,221,435,000

Note 1- These costs are not broke-out. Federal acquisition/admin costs are estimated at $6,000 per tract which are included in account 01B40 includes accounts 01A00, 01C40, 01E50, 01F40, 01G40, and 01M00. Non-federal acquisition admin costs included in account 01B20 includes accounts 01C20, 01E30, 01F20, 01G20, and 01G60.

Note 2 –Contingency on the components are shown on Table F-2. .

Real Estate costs for “Other Project Elements” were based solely on information provided from the proponents of the “Other Project Element” and have not been verified by Real Estate Division, Jacksonville District.

District Engineer, Jacksonville District
U.S. Army Corps of Engineers
P.O. Box 4970
Jacksonville, Florida 32232-0019

Dear Colonel Miller:

Subject: Local Sponsorship of the Central and Southern Florida Project Comprehensive Review Study

Restoration of the Everglades ecosystem, including Lake Okeechobee, the St. Lucie and Caloosahatchee estuaries and the provision of adequate water supplies for South Florida has been a priority of the South Florida Water Management District (SFWMD) for many years. While the Central and Southern Florida (C&SF) Project, first authorized in 1948, has provided tremendous benefits to the region, it has also contributed to a precipitous decline in the health of the Everglades and Florida Bay, Lake Okeechobee, Lake Worth Lagoon, as well as the St. Lucie and Caloosahatchee estuaries. In addition, the continuing and projected growth of the region increasingly will strain the ability of the existing project to provide water for agricultural and urban purposes. Clearly, a comprehensive and balanced approach for solving these problems is needed.

The Central and Southern Florida Project Comprehensive Review Study (the Restudy) provides the best opportunity for solving the region's environmental and water resource problems on a regional scale. Thus, we strongly support the Restudy, which we believe will provide the basis for a healthy, sustainable Everglades ecosystem and adequate future water supply for the region.

SFWMD supports approval of the Comprehensive Plan by Congress as a guideline, and as a basis for establishing federal support for the Plan. We encourage congressional authorization for a series of pilot projects that are necessary prior to construction of select components at the full scale. Authorization of pilot projects and a series of initial components will enable the Corps and SFWMD to continue to work together to meet the future water needs for all users in a timely manner.

Implementation of the Comprehensive Plan must not result in delay of the important projects that Congress has already approved. The Kissimmee River Restoration, Modified Water Deliveries, C-111, STA-1 East, and Critical Restoration Projects are already underway and are essential to Everglades Restoration. Any necessary delays to these projects should be minimized to the maximum extent possible.

Mailing Address: P.O. Box 24680, West Palm Beach, FL 33416-4680

Colonel Joe R. Miller
February 10, 1999
Page 2

Implementation of the Restudy will take many years. The recommended plan outlines the additional studies, pilot projects, and engineering, economic, and environmental analyses that must occur before construction. As these detailed analyses are completed for each project, a Project Cooperation Agreement will be prepared that specifies the scope of the project and the financial obligations of the federal government and the local sponsor.

As the implementation plan crystallizes, several outstanding issues of great importance to the SFWMD and the State of Florida must be adequately addressed. These issues are 1) capital projects cost share, 2) operation, maintenance and monitoring cost share, 3) permitting of Restudy Comprehensive Plan components and projects, 4) assurances to existing legal users, 5) provision of flood protection, 6) impacts to on-going projects, 7) water quality, and 8) scientific peer review. The attachment to this letter describes the issues and concerns of the SFWMD in more detail.

Ensuring strong support from the Governor and the State Legislature continues to remain a key goal. The 1998 session of the Florida Legislature documented the State's significant interest in the Restudy. The Florida Legislature must approve any projects that require state appropriations. In addition, the State of Florida Joint Legislative Committee on Everglades Oversight, which is charged with overseeing this agency's action relative to Everglades restoration projects, can provide oversight and review of the Restudy.

The SFWMD is a public corporation of the State of Florida and as such is legally capable of fulfilling the requirements of local sponsor for this project in accordance with Section 221 of the Flood Control Act of 1970 as amended (Public Law 91-611). This letter, while not legally binding on the SFWMD in any way, is intended to demonstrate our support for the Restudy.

The SFWMD looks forward to continuing our partnership with the Corps of Engineers in this important endeavor.

Sincerely,

Frank Williamson, Jr.
Chairman, Governing Board
South Florida Water Management District

Issues Associated with Implementation of the Restudy Comprehensive Plan

Capital Projects Cost Share

Specifying a 50/50 cost share for the initial capital project costs is appropriate at this conceptual stage in the implementation process. Numerous funding decisions will be necessary over the next 25 years as we progress into the detailed design and planning phase of implementation for the individual projects. Until project implementation is at hand, we should not rule out other cost share formulas that may be appropriate. As individual Project Implementation Reports are considered by Congress, it may be appropriate to seek a larger federal share of the capital costs. Flexibility to accomplish, under certain circumstances, a larger federal share must be preserved. It is also imperative that flexibility be preserved in determining the credits that can be received for lands already purchased. This flexibility is needed to assure that the amount credited equitably reflects the time value of the funds invested in land purchased in advance of the construction of components and the value of the land given its allowable uses at the time of purchase.

Operation, Maintenance and Monitoring Cost Share

The operations and maintenance costs present a similar dilemma. Estimates are at $175 million per year for operation, maintenance and monitoring of the projects contemplated in the draft Comprehensive Plan. This cost is over and above current operation, maintenance and monitoring costs. These projected costs are a significant issue for this agency and the State of Florida. The Plan contains a large number of components that together accomplish restoration of the South Florida ecosystem. In addition, a monitoring program will be a necessary component for providing information and data regarding the effects of changes to the South Florida ecosystem and for providing a basis for adjustments to the Comprehensive Plan in the future. While we are committed to working with the State Legislature and local interests to find solutions to this issue, increased federal funding of the operation, maintenance and monitoring of the Comprehensive Plan will be required. South Florida Water Management District pledges to work with the Corps, the United States Congress and the State Legislature to develop a fair and realistic mechanism and cost share allocation to fund the Comprehensive Plan’s OMM&R.

Permitting of Restudy Comprehensive Plan Components and Projects

Unprecedented projects, in terms of scope and purpose, are contained within the Comprehensive Plan. To put it simply, these projects do not fall within the traditional mold of projects that are subject to Federal and State agency permitting requirements.

Recent experiences with the Everglades Stormwater Treatment Areas and the C-111 Project (S-332D) demonstrate that there is serious uncertainty associated with the permitting of such projects. While maintaining agency permitting jurisdiction, there is a critical need to develop a formal process that requires each regulatory agency to provide reliable assurances concerning project permittability during its “up-front” plan review. Otherwise, substantial costs, delays and uncertainty in the outcome of permitting Restudy projects could result.

Assurances to Existing Legal Users

The SFWMD and the Corps should work with all stakeholders to develop appropriate water user assurances to be incorporated as part of the Comprehensive Plan authorizations. These water user assurances should be based on the following principles:

A. Physical or operational modifications to the C&SF Project by the Federal government or the SFWMD will not interfere with existing legal uses and will not adversely impact existing levels of service for flood management or water use, consistent with State and Federal law.

B. Environmental and other water supply initiatives contained in the Restudy shall be implemented through appropriate State (Chapter 373, F.S.) processes.

C. In its role as local sponsor for the Restudy, the SFWMD will comply with its responsibilities under State water law (Chapter 373, F.S.).

D. Existing Chapter 373, F.S. authority for the SFWMD to manage and protect the water resources shall be preserved.

Provision of Flood Protection

As a general principle, the Comprehensive Plan should not compromise or adversely affect levels of service for flood protection now provided by the C&SF Project. Furthermore, it is the South Florida Water Management District's intent to utilize the Project Implementation Report process to address any flood protection issues in the areas potentially affected by the Comprehensive Plan. This will not compromise the environmental goals of the plan, but instead will be an effective way to add economic benefit and public support.

Impacts to On-Going Projects

Implementation of the Comprehensive Plan must not result in delay of the important projects that Congress has already approved. The Kissimmee River Restoration, Modified Water Deliveries, C-111, STA-1 East, and Critical Restoration Projects are already underway and are essential to Everglades Restoration. Any necessary delays to these projects should be minimized to the maximum extent possible.

Water Quality

Water Quality remains a complex and in some cases unresolved issue in the Comprehensive Plan. The Comprehensive Plan effort must develop and propose specific solutions for dealing with the water quality implications resulting from increased water deliveries to the Everglades Protection Area, as well as inflows to Lake Okeechobee and the coastal estuaries.

A number of components in the Comprehensive Plan provide either direct or indirect water quality benefits. As the Comprehensive Plan progresses into more detailed planning and design for individual projects, improving water quality will need to remain a high priority in project design. It is critical that the SFWMD and the Corps work closely with other agencies with water quality regulatory responsibilities to design projects that will optimize water quality benefits.

The priority given to water quality components of the Comprehensive Plan, as well as how such components will be funded, regulated and operated, are issues that must be squarely addressed as soon as possible.

Scientific Peer Review

The South Florida Water Management District supports the establishment of an ongoing outside scientific review process as being developed by the South Florida Ecosystem Restoration Task Force as an essential component to ensure an effective adaptive management process for South Florida Ecosystem Restoration. Such peer review should in no way delay the Restudy process.

FINANCIAL CAPABILITY STATEMENT AND FUNDING PLAN

G.1 INTRODUCTION

This is the financial capability statement and funding plan submitted by the South Florida Water Management District (SFWMD) in support of its role as local sponsor for the Central and Southern Florida Project Comprehensive Review Study and the projects proposed for authorization in the Water Resources Development Act of 2000. The Comprehensive Plan is a general document that will be implemented over a long period of time. More detailed evaluations called Project Implementation Reports will be completed on individual components or groups of components to settle design, cost and timing issues. For these reasons the SFWMD's financial capabilities with respect to the Comprehensive Plan are discussed in general terms. At the same time, authorization is proposed for pilot projects and an initial set of the components of the Comprehensive Plan, and a continuing financial need for the adaptive assessment and monitoring efforts has been identified. Thus, more detailed financial capability statement and funding plan are provided for these pilot projects, components proposed for initial authorization and the adaptive assessment and monitoring efforts (monitoring program).

G.1.1 Participation of the South Florida Water Management District as Local Sponsor

The Central and Southern Florida Flood Control District (FCD) was created by the Florida Legislature in 1949 to serve the functions of local sponsor for the Central and Southern Florida (C&SF) Flood Control Project authorized by the U.S. Congress in 1948 to be constructed by the U.S. Army Corps of Engineers (USCOE). Upon completion of components, the FCD assumed operation and maintenance responsibility for project works.

The Florida Water Resources Act of 1972 modified the boundaries of the FCD and greatly expanded its responsibilities creating the South Florida Water Management District (SFWMD). The SFWMD is the local sponsor of the C&SF Project and the partner to USCOE in the development of the Central and Southern Florida Project Comprehensive Review Study (Restudy). The SFWMD's state mandated responsibilities include environmental protection and enhancement, water supply, flood protection and water quality protection. Thus, the mission of the South Florida Water Management District corresponds with the goals of the Restudy and the SFWMD is an appropriate partner to the USCOE for the implementation of the Restudy recommendations.

G.1.2 Statutory Authority for the South Florida Water Management District to Act as Local Sponsor

The SFWMD is authorized to enter into contracts with public agencies pursuant to section 373.083, Florida Statutes (F.S.). Furthermore, the SFWMD is authorized, under Section 373.103, F.S., to cooperate with United States in the manner provided by Congress for flood control, reclamation, conservation and allied purposes. In recent years the SFWMD has utilized its capabilities in this regard to be an effective local partner in several ongoing restoration efforts including the Kissimmee River Restoration, the C-111 South Dade Project and the C-51 West/STA-1 East project.

G.1.3 SFWMD Taxing and Fundraising Authority

The SFWMD is an independent special district under the Florida Constitution and the special district classification scheme established by general law. The SFWMD's powers and authority are established in provisions of Chapter 373, FS. The SFWMD's authority to impose fees and special assessments and to incur debt is based on the construction of the expressed powers provided in Chapter 373, F.S. In order for the SFWMD to tax or levy fees and assessments, it must first have statutory authority to do so. Because the SFWMD has no home rule power, it can only impose those fees and special assessments which have been expressly provided by law or which can reasonably be implied from an express grant of authority. Likewise, the SFWMD is limited by any specific legislative restrictions or conditions placed on its authority to impose fees or special assessments.

G.1.3.1 Expressly Granted Taxing Authority

The major taxing authority granted the SFWMD is the levying of ad valorem taxes. This taxing authority is subject to two caps on the total rates, a 1 mill cap contained in Florida's constitution and a legislatively mandated .8 mill cap. Within the total, the SFWMD levies three millage rates. The first is the SFWMD at large millage rate, which is levied against the value of all real and personal property within SFWMD boundaries. The second is the Okeechobee Basin millage rate, which is levied on property in fifteen of the sixteen counties (excludes the Big Cypress Basin, which consists of Collier County and a small portion of Monroe County). The third applies to the Big Cypress Basin. Lands within the SFWMD are, then, subject to the District at large millage levy and one of the two basin levies. There is also a statutory limit that no more than 40% of the levy can be for District purposes and 60% for basin purposes. This means that the maximum rate allowed by law for the District millage is 0.32 mills and 0.48 mills for either basin millage.

As a result of the Everglades Forever Act the SFWMD is also now levying an Agricultural Privilege Tax on agricultural properties within the Everglades Agricultural Area and the C-139 Basin. The schedule of rates for this tax is established in the Legislation. The funds from this tax are dedicated toward the completion of the Everglades Construction Project.

G.1.3.2 Expressly Granted Authority To Levy Fees And Assessments

The only fees that the SFWMD can impose are those prescribed by statute and administrative rule. In general the fees the SFWMD may impose relate to permits issued by the SFWMD or grants of rights for utilization of SFWMD rights of way. All permit fees must be based on and are limited to the costs incurred by the SFWMD in their issuance.

Two requirements for the imposition of special assessments in Florida are: 1) the property assessed must derive a special benefit from the improvement or service provided; and 2) the assessment must be fairly and reasonably apportioned among the properties that receive the special benefit. There must exist a “logical relationship” between the service provided and the benefit to property. The District has specific authorization to impose special assessments within stormwater system benefit areas for water quality benefit except on property subject to an Agricultural Privilege Tax. There are many informational requirements regarding the extent to which parcels contribute to the need for water quality management programs that must be met in order to develop and implement the fair apportionment required for the implementation of special assessments.

G.1.3.3 Expressly Granted Authority to Issue Bonds and Incur Debt

The SFWMD can issue bonds and incur debt to finance its operations under specified circumstances. Bonds payable from its ad valorem revenues can be issued with the approval of the electorate. The SFWMD can also issue bonds, but without the requirement for approval of the electorate, when the Legislature authorizes the SFWMD a new taxing source or transfers a portion of existing state tax revenues to the SFWMD for its use for SFWMD purposes. For example, funds appropriated in the Water Management Lands Trust Fund created in section 373.59, F.S., are distributed to the SFWMD and have been pledged for the payment of SFWMD bonds issued for land acquisition.

G.2 OVERALL SFWMD FINANCIAL CAPABILITY STATEMENT AND FUNDING PLAN FOR THE RESTUDY

This section discusses in general terms the strategy that the SFWMD intends to implement to complete its obligation as local sponsor for the Restudy. To understand the reasons for the proposed strategy, it is important to understand both the recent and the anticipated future growth in the SFWMD’s responsibilities and consequent funding needs.

G.2.1 Recent SFWMD Experience with Funding Responsibilities

In recent years the SFWMD has been charged with or undertaken the implementation of many significant projects that have greatly increased its spending and consequently its funding responsibilities. These tasks have included the restoration of the Kissimmee River and the completion of the Everglades Construction Project. The Everglades Construction Project is required under the Everglades Forever Act (EFA), passed by the Florida Legislature in 1994. The EFA required the SFWMD to construct six stormwater treatment areas to clean stormwater runoff from farms in the Everglades Agricultural Area (EAA). The total cost of the ECP was estimated at $796 million over 20 years in the 1998 Everglades Annual Report and it is one of the largest environmental restoration activities ever undertaken in the United States. As the agency responsible for implementing this statute, much of the actual expense of the project has fallen on the SFWMD. The increased funding required to meet these and other expanding obligations has increased the burden on the existing fund raising capabilities of the SFWMD granted by the state. The district's principal taxing authority is to levy ad valorem taxes. To some extent the ad valorem taxes have been raised to meet the expanding responsibilities. For instance, a special .1 mill levy within the Okeechobee Basin is dedicated to the ECP. Other major sources of additional funds for meeting these responsibilities have been inter-governmental transfers and new dedicated taxes. The intergovernmental transfers have included significant transfers by the state of Florida to the SFWMD for land acquisition, as well as transfers of federal money, including “Farm Bill” money, which have also been used for land purchases. A special tax on agricultural land users in the EAA, which is called an Agricultural Privilege tax, has been an additional source of funds dedicated to the completion of the ECP. Agricultural Privilege taxes are also collected from lands in the C-139 Basin.

G.2.2 Expected Future Increases in Funding Responsibility

Funding the local sponsor’s share of the cost of the Restudy, will be an increase in SFWMD funding responsibility of an unparalleled magnitude. However, this is not the only expanded or additional responsibility that the SFWMD will have to assume in the upcoming decades. A second major task and funding responsibility will be for the completion of phase two of the ECP. This additional effort to improve the quality of water going into the EPA is necessary because the facilities completed under the first phase of the ECP may not be able to meet the water quality standards that will be promulgated by the Florida Department of Environment Protection (FDEP). Recent changes to the state constitution have clearly established that polluters will be primarily responsible for the payment of efforts to clean up the pollution entering the EPA. However, SFWMD funds, in addition to payments by the polluters, may be required to achieve the desired water quality standards. Because the standard, the means to achieve the standard and the sources of funding are all yet to be identified, the amount of funding by the SFWMD can not be determined at this time. The SFWMD is also expecting that the additional feasibility studies recommended as part of the Restudy Comprehensive Plan will result in additional recommended expenditures. In addition, as the local sponsor for the C&SF Project, the SFWMD has responsibility for the rehabilitation, repair and replacement of major project facilities as they reach the ends of their useful lives. Because the SFWMD does not have established funds set aside for these purposes, the upcoming expenses in this area also represent significant future funding obligations. Finally, there are expected to be significant increases in O&M costs associated with the expanded facilities and operations. The cumulative impact of all of these funding needs calls for the development of an overall funding strategy. The strategy for funding the local sponsor's financial obligations for the Restudy will be an important component of the overall implementation strategy.

G.2.3 SFWMD Overall Funding Strategy to Meet Existing and Future Responsibilities

In anticipation of these greatly expanded funding needs, the SFWMD is currently developing a funding strategy. The strategy will include but not be limited to the following:

1) Operate efficiently to obtain maximum value from funds received,
2) Make full use of existing tax authority,
3) Use fees and assessments when the projects or programs confer special benefits or assist in alleviating water quality problems for which contributors to the problem may have responsibility for the solution,
4) Implement cost sharing agreements with other Florida public entities when there is a mutuality and commonality of interest or responsibility,
5) Seek an expansion of direct financial assistance from the State of Florida in the land acquisition area,
6) Seek legislative authorization for additional taxing authority or the dedication of a portion of state revenues and
7) Make appropriate use of bonding to enhance the capabilities of funding authority to meet the temporarily higher spending needs associated with the Restudy and other Capital Improvement Projects.

Each of these components of the proposed strategy is now discussed in turn in a way that highlights its applicability to the funding of the Restudy.

G.2.3.1 Operate Efficiently To Obtain Maximum Value From Funds Received

The SFWMD recognizes that the more cost effectively it can discharge its normal and continuing responsibilities the larger the amount from its funding capabilities that can be made available to fund capital improvement responsibilities such as the Restudy. To this end the SFWMD has and will continue to streamline processes and reprioritize programs.

G.2.3.2 Make Full Use Of Existing Tax Authority

The principal source of funds and the major taxing authority of the SFWMD is to levy ad valorem taxes. As was discussed above, there are several important limitations placed upon the millage that the SFWMD can levy. In fiscal year 1998 the total millage levied by the SFWMD was 0.697 mills for the Okeechobee Basin and 0.662 mills to the Big Cypress Basin. The SFWMD's governing board can, under its existing authority, raise the total millage up to legislative limits of 0.8 mils. In addition, with legislative authorization, the millage rates could be raised up to the full 1 mill limit contained in Florida's constitution. Any increases beyond that level would require modifications to Florida's constitution.

The SFWMD may, as part of its efforts to fund the Restudy and its other emerging obligations, request legislative authorization to raise the millage to the 1 mill constitutional cap and to remove the limitations on the basin and district-wide proportions. Most of the future additional obligations are district-wide in nature. For instance, the ecosystem restoration being provided by the Restudy is of district-wide benefit, even when the particular ecosystem restoration components are located in the Okeechobee or Big Cypress Basin. Thus, the SFWMD expects to use a district-wide assessment for the funding of Restudy components not covered by other elements of its funding strategy. The SFWMD recently estimated the additional revenue that would have been available for its Fiscal Year 1999 budget if the full 1 mill of taxing authority were used as $89.1 million dollars. The comparable additional revenue that would have been available if taxes were raised to the .8 mill legislative cap was estimated as $29.8 million dollars.

An important consideration in looking at funding sources, is whether the sources are likely to grow over time due to the effects of inflation and economic growth. The SFWMD's experience with the value of taxable property is that it has continued to grow significantly over time. In the period from 1989 to 1999 the average annual growth rate in assessed values was 5.5%. This was due both to the addition of new structures and higher valued land uses and to the increase in values of existing properties. The expected growth of the South Florida population and economy indicate that the capability of ad valorem taxes at any given millage rate to help support projects such as the Restudy will be increasing over time.

G.2.3.3 Make Appropriate Use Of Fees And Assessments

In looking at alternative funding sources, one of the important considerations is the extent to which the benefits of the project component accrue to specific entities or property. This would occur, for instance, when a project includes facilities to bring water from regional system canals to secondary canals that serve to recharge specific well fields. It would also occur when projects or specific facilities included in those projects serve to increase flood protection within specific sub-basins. A second rationale for the use of alternative funding sources is the extent to which there are contributors to a specific water quality problem that the project is designed to solve. The use of alternative funding sources for financing the components that serve to solve pre-existing problems could be directly implemented when they are consistent with the Constitution and existing law. The SFWMD would seek additional authorization from the Florida legislature if this source is deemed appropriate for certain project components and additional authorization is needed.

G.2.3.4 Seek And Implement Cost Sharing Opportunities

Cost sharing opportunities arise when there is a mutuality or commonality of interest or responsibility between the activities of the SFWMD and those of local governments. For instance, many counties within the SFWMD have in the past pursued the purchase of environmentally sensitive lands and have joined with the SFWMD and the state of Florida in such efforts. In the past counties have also participated with the SFWMD in the construction of secondary drainage/recharge facilities, one example being the secondary canal system improvements in coastal Broward County being completed as part of the SFWMD's Interim Plan for Water Supply for the Lower East Coast. Local governments have also partnered with the SFWMD in the retrofit of stormwater management systems, an example of this being stormwater management projects in Miami-Dade County implemented as part of SWIM plans for Biscayne Bay.

Recently, as a result of evaluations undertaken for the SFWMD by the Government Services Group, twenty (20) Restudy components were identified as having the potential for cost sharing. In many cases only some of the facilities and not the whole component may be applicable for cost sharing. Most of the components potentially suitable for cost sharing fall into one of several categories: 1) they enhance environmental resources that are of great local interest, 2) they directly enhance flood protection, 3) they recharge areas that protect wellfields from salt water intrusion or 4) they improve water quality in an area in which an existing entity such as a drainage district can be a conduit for the recovery of costs.

G.2.3.5 Seek An Expansion Of Direct Financial Assistance From The State Of Florida In The Land Acquisition Area

The financial assistance provided in the land acquisition area through the Preservation 2000 Trust Fund, the Conservation and Recreation Lands Trust Fund (CARL) and the Water Management Lands Trust Fund has played a major role in the successful participation of the SFWMD in restoration programs. In recent years the total additions to the Preservation 2000 and Water Management Lands Trust Funds allocated to the SFWMD has provided a base level of funding of about $41 to $46 million per year. In individual years $26 to $27 million in allocations to the SFWMD were made to the Preservation 2000 Trust Fund while $14 to $19 million were allocated to the SFWMD in the Water Management Lands Trust Fund. In several recent years there have been special allocations that have significantly increased this amount. In 1996 the SFWMD received a special allocation from the Preservation 2000 Trust of $24 million to assist with land purchases for the Everglades East Coast Buffer. In 1998 about $14 million from the Conservation and Recreation Lands Trust Fund was used, principally to purchase lands as part of the Indian River Lagoon and Atlantic Ridge ecosystem projects.

The legislative authorization for the sale of bonds to support the Preservation 2000 programs will expire in 2000. It is expected that legislation authorizing a similar program to continue this effort will be enacted. The SFWMD will support the continuation of these programs and will point out the importance of increasing the dollar participation to assist in meeting the expanded obligations for land purchases under the Restudy and other ecosystem restoration and enhancement efforts. Flexibility in the use of the funds, such as allowing them to be used to support the construction of reservoirs and not just the purchase of lands, will also be important in the implementation of the Restudy.

G.2.3.6 Seek And Utilize Additional Taxing Authority Or Dedicated State Funding

It is expected that to meet all of its future obligations, the SFWMD will have to receive additional taxing authority or dedication of state funding. In this case there are many options from which the legislature can choose. One option would be for the state to authorize the SFWMD to levy parcel property taxes to fund certain facilities that provide services for specific areas. The Agricultural Privilege Tax, which is levied on a per acre basis for agricultural land uses within specific basins, is an example of this type of levy. Another option would be to dedicate a portion of state revenue from selected sources for funding specific projects that are of statewide benefit. State Documentary Stamp Taxes are a source, portions of which have been dedicated to land acquisition programs, but some of which could be dedicated to the funding of capital projects which serve statewide purposes. Alternatively a portion of state sales tax revenues could be dedicated to fund specific project components. Providing the water management districts authority to levy fees for consumptive use permits or water withdrawals is another alternative source of funding for water management related activities throughout Florida. There also may be some potential for State Department of Transportation funds to be used when implementation of the component requires highway improvements for which the state has responsibility.

G.2.3.7 Make Appropriate Use Of Bonding Capabilities

Bonding is not an original revenue source, but it is an important tool when spending needs temporarily exceed revenue generation capabilities and there is a willingness to utilize future revenues to meet the present spending needs. Because the spending needs generated by the Restudy will be spread out over more than 20 years, the potential benefits of bonding as a means of balancing the timing of spending and income will be limited unless the bonds issued are repaid beyond that period.

G.3 SFWMD FINANCIAL CAPABILITY STATEMENT AND FUNDING PLAN FOR PILOT PROJECTS, THE COMPONENTS FOR WHICH AUTHORIZATION IS REQUESTED AND MONITORING

This section discusses the financial capabilities of the SFWMD to fund the pilot projects, the components proposed for authorization in the Water Resources Development Act of 2000 and the monitoring program.

G.3.1 Funding Needs of the Pilot Projects, the Components for Which Authorization is Requested and the Monitoring Program

The funding needs of the pilot projects, the components for which authorization is requested and the monitoring program have been developed based on the timing and cost of those components as presented in the implementation plan. These total first costs and the timeframes for the expenditures are presented in ***Table G-1***. Additional details on the costs and the timing of expenditures for each individual component are provided in the Implementation Plan which is part of this plan. ***Table G-1*** shows that the total estimated first cost (planning, design, land purchase and construction) of the pilot projects and components for which authorization is being requested as well as the monitoring program is $1.2 billion in 1998 dollars and has a proposed expenditure schedule extending through 2012.

G.3.2 SFWMD Plan for Funding the Pilot Projects, the Components for Which Authorization is Requested and the Monitoring Program

At this time the SFWMD plan for funding for the pilot projects, the components proposed for initial authorization and the monitoring program is presented in terms of several scenarios. This will help demonstrate the SFWMD's capabilities under a variety of approaches that may be selected. All scenarios will require legislative action. This may include a continuation or expansion of SFWMD allocations from state programs such as Preservation 2000. Adjustments to the programs, so that funds can be spent on surface facilities associated with lands (such as reservoirs) and not just the lands themselves, may also be necessary. The granting of authority for the SFWMD to increase its ad valorem tax rates beyond

TABLE G-1
EXPENDITURE SCHEDULE FOR PILOT PROJECTS, COMPONENTS RECOMMENDED FOR AUTHORIZATION AND MONITORING PROGRAM

Year	PROPOSED EXPENDITURE ($1999)
1999	$4,792,334
2000	$15,257,469
2001	$60,317,389
2002	$214,669,882
2003	$206,260,050
2004	$106,004,085
2005	$89,074,279
2006	$148,069,171
2007	$145,017,440
2008	$124,659,933
2009	$76,569,505
2010	$7,025,194
2011	$167,308
2012	$33,974
Total	$1,197,918,013

present legislative limits and the relaxation of present restrictions of basin and district-wide caps on assessments may also be necessary. It appears that none of the scenarios will require voter approval of bond issues. The designs of the components and the functionality built into the designs, which will be determined in the Project Implementation Reports, will clarify the potential for cost sharing of the local sponsor share with other South Florida government agencies and the state of Florida. Furthermore, many options, in addition to those presented in these scenarios, are available to legislature when they consider how best to support the funding of the Restudy. Thus, it is too early to specify a single direction and the scenario approach has been taken. In developing the scenarios certain baseline assumptions regarding borrowing costs, interest rates and inflation were developed. In addition, for each scenario specific assumptions were developed regarding the proposed funding sources. These include initial amounts, starting and ending years and expected escalation over time.

G.3.2.1 Baseline Assumptions for the Development of Funding Scenarios

In order to develop the alternative future funding scenarios, it was necessary to make baseline projections of price level escalation, growth in tax bases, and real and nominal interest rates.

Recently the historical inflation rates for most broad indices of prices and costs have been at about 3%. A reasonable baseline assumption is that this rate will continue into the future. It is significant that this rate was selected as the cost escalation factor for the legislation dealing with mitigation costs for the Lake Belt mining. The 3% estimate is a good base assumption to use for price level inflation including costs of the components, inflationary effects on taxable sales and property values and the inflationary component of the nominal interest rate.

Interest rates that might either be paid or earned are frequently analyzed in terms of a real rate of return and an inflationary component. Real rates of return for fairly low risk investments such as treasury bonds have historically approximated 2%.

Together the proposed projection of inflation of 3% and the real rate of return of 2% give a nominal interest rate of 5%. This rate is proposed for use as the rate at which SFWMD surplus funds will earn interest and as the rate that the SFWMD will have to pay on funds that it borrows. Using the same interest rate for earnings and payments will make the analysis neutral with regard to the SFWMD's borrowing capabilities. The SFWMD will not attempt to show that it has the financial resources to meet its obligations by borrowing funds on which it could earn more interest than it paid.

A related general assumption is the cost of borrowing. When the funding balances in any evaluation become significantly negative and persist for several years, this indicates that the funding problem can not be addressed by means of short-term adjustments to spending schedules. However, the problem can be addressed by long-term financing, bonding. There are costs associated with the bonding including underwriting, bond insurance and the creation of a debt service reserve account. The latter, by far the largest component, is unique in that interest is earned on the account and the funds in the account are eventually returned to the borrower and can in fact be used to make the final payment on the bonds. Because these costs net out in the long-run and the remaining borrowing costs are relatively small, in the scenario evaluations these costs are assumed to be zero. The spreadsheet model developed and used to evaluate the funding scenarios can evaluate scenarios including borrowing costs when they are specified as a percent of the funding deficit in each year.

With one exception the local sponsor share is the 50% established in WRDA-96. The exception results from previous land acquisition agreements that affect the

EAA Storage and Conveyance component, Phase 1 of which is a component proposed for initial authorization. This is discussed in 10.6.5 of the main report. The net result is that the SFWMD cost share for this component is $36,000,000 ($1998) greater than its normal 50% share. This is handled by proportionally increasing the SFWMD funding obligations for this component to make the new total $36,000,000 more than half of the cost cited for this component in the Implementation Plan.

Escalations in tax yields over time are assumptions associated with the scenarios. However, it is useful here to discuss assumptions that can be used, especially for the property tax base. A reasonable baseline escalation in the property tax base is 5%. In the long run, it is likely that the price inflation in housing and property costs will approximate the overall inflation rate, the baseline assumption for which is 3%. Added to this would be an escalation to cover structural improvements and changes of lands to higher value uses that are due both to the increased population/economic growth and to the accumulation of wealth by the population. Projecting additions to the property tax base due to growth is appropriate considering that the Restudy also projects significant population growth. Historically the SFWMD's ad valorem property tax base has grown at 5.5% per annum. This rate has held over both the past 5 and the past 10 years (1994-1999 and 1989-1999 respectively). The proposed 5% rate is, thus, somewhat conservative compared to the historical rate.

G.3.2.2 Formulation And Evaluation Of Funding Scenarios

The revenue sources the SFWMD anticipates using to fund the local sponsor portion of costs for the programs under discussion are:

1) credits for lands already purchased,
2) funds from the existing Preservation 2000 programs and its successor program which is now being considered by the Florida Legislature
3) ad valorem tax proceeds,
4) cost shares obtained from local governments and private interests, and
5) special fees and assessments.

Three funding scenarios are presented below. Key assumptions are presented in ***Table G-2*** while results are presented in ***Table G-3*** and ***Figures G-1 – G-3***. The spreadsheets that contain the analyses are presented as Attachments 1 through 3.

The SFWMD recognizes that, during the timeframe of the implementation of the pilot projects and components proposed for authorization, additional spending is anticipated on Restudy components covered by programmatic authority and additional authorizations. In the implementation plan, total Restudy costs for land, construction and monitoring through 2010 are about $4 billion, much more than the $1.2 billion included in the schedule being evaluated here which includes only the pilot projects, initial authorization components and monitoring. Furthermore operations and maintenance costs will have to be met and will gradually increase as components are completed. O&M costs for the initial authorization components are approximately $20 million ($1998). Other water management and restoration programs are also likely to expand. For these reasons, all of the scenarios were constructed using conservative assumptions to assure that some leeway was provided for these other expenditures.

The major conservative elements incorporated into the development of the scenarios are:

1) All scenarios are developed so that SFWMD debt financing will not be required. Scenarios that would have required SFWMD debt financing would limit the ability to fund Restudy components in the period after 2010.
2) Funds from state land acquisition programs and ad valorem taxes are raised only through 2010 even though some construction takes place through 2012.
3) The funds from state land acquisition programs consider only revenues from the Preservation 2000 fund and its successor program. The SFWMD also receives funds from the Water Management Lands Trust Fund and the CARL program. Much of the additions to the Water Management Lands Trust Fund over the next 10 years will be devoted to servicing of debt and the maintenance of properties already purchased. However, some funds will be available for land purchases (for example $8.6 million in 1997 and $1.7 million in 1998 were so spent) and the fund had a balance of $23 million at the end of fiscal 1998. CARL funds used by the SFWMD for the purchase of lands totaled $55.8 million in the last four fiscal years (1995–1998). Also SFWMD's balance in the Preservation 2000 Trust Fund at the end of fiscal 1998 was $53 million and the proposed funding does not include the use of any of these funds.
4) In the scenarios, the assumed share of Preservation 2000 funds devoted to the pilot projects and initial authorization components varies from 50% to 85%. Room is always left for some of the funds to be applied to other Restudy and non-Restudy efforts.
5) In developing the successor program to the Preservation 2000 program the legislature will consider a wide range of options for increasing the overall program amount and changing the rules and procedures for the allocation of the funds. At present the SFWMD typically receives less than 10% of the program allocations. Two of the scenarios limit future funding to recent historical levels while the third uses the historical high allocation as the average for the future.
6) With legislative authorization, the maximum increase in District ad valorem funding from fiscal 1999 levels would be slightly over .3 mills. The scenarios assume increases of .075 to .15 mills, which will leave

significant room for the funding of other Restudy and non-Restudy construction or operation and maintenance costs from ad valorem taxes.

G.3.2.2.1 Scenario 1

G.3.2.2.1.1 Formulation of Scenario 1

Scenario 1 represents a balanced reliance on state assistance, ad valorem taxes and cost sharing/fees and assessments. First of all, scenario 1 includes credits for lands already purchased which will be utilized for these components ($67,655,000). Scenario 1 is somewhat conservative regarding the availability of funds from Preservation 2000 and its successor program. It assumes that from 1999 to 2010 the funds available are $27,000,000 which is close to levels received by the SFWMD in past years when significant special allocations were not made to the SFWMD to assist with land purchases. On the other hand it assumes that the SFWMD uses 85% of the funds to support the pilot projects and components for which authorization is requested. It is conservative regarding the funding available from ad valorem sources in that only slightly more than .1 mill is dedicated to implementation of this part of the Restudy. If other SFWMD future funding needs can be met within the 1999 millage rates, the SFWMD would not require legislative authorization raising its maximum millage rate in order to provide these funds. This represents about a third of the potential revenues available from the actual 1999 millage rate to the 1 mill constitutional cap. Since legislative action would not necessarily be required, the funds from this source begin in 2000. Scenario 1 also includes the “middle” preliminary assessment of revenues that will be available from cost sharing/fees and assessments. SFWMD staff recently completed this assessment. Overall, the estimated $28 million ($1998) for cost sharing/fees and assessments represents about 13% of the local sponsor’s cost for the components to which the alternative funding sources apply.

G.3.2.2.1.2 Evaluation of Scenario 1

Revenues from the major funding sources for Scenario 1, which are estimated only through 2010, are adequate to provide the full local share. Funding balances remain positive throughout the period except for 2008 when a funding deficit of $1.35 million occurs. This is indicated by the statistics summarized in ***Table G-3*** and by the fact that the current funding balance, plotted in ***Figure G-1***, remains positive throughout the period except for 2008. Since the funding balance becomes significantly positive by 2010, slight modifications to the spending schedule would permit the funding balance to remain positive throughout the implementation. This demonstrates that Scenario 1 is one approach by which the SFWMD could meet its obligations for the funding of the pilot projects, the components for which authorization is being requested and the monitoring program.

G.3.2.2.2 Scenario 2

G.3.2.2.2.1 Formulation of Scenario 2

Scenario 2 places a relatively heavy reliance on state assistance and on cost shares/fees and assessments and decreased reliance on ad valorem taxes. First of all, Scenario 2 includes credits for lands already purchased which will be utilized for these components ($67,655,000). Regarding state assistance, it focuses on funds from the current Preservation 2000 program and the expected successor program. The present program will provide funds for 1999 and 2000. For these years it is assumed that the allocations are $27,000,000, the same as in Scenario 1. For years 2001 to 2010 Scenario 2 assumes that the successor program makes $51,000,000 per year available to the SFWMD. This is the level of funding received in 1996 when a special allocation was made for the purchases of land in the East Coast Buffer. In all years, it is assumed that 75% of the funds are used to support the pilot projects and components in the initial authorization package. Scenario 2 is conservative regarding the funding needed from ad valorem sources. Only .075 mills are dedicated to the implementation of this portion of the Restudy. Since legislative action would not necessarily be required, the funds from this source begin in 2000. This represents about a quarter of the potential revenues available from the actual 1999 millage rate to the 1 mill constitutional cap. Scenario 2 also includes the “optimistic” preliminary assessment of revenues that will be available from cost sharing/fees and assessments. SFWMD staff recently completed this preliminary assessment. Overall, the estimated $44.8 million ($1998) from these sources represents 21% of the local sponsor’s cost for the components to which the alternative funding sources apply.

G.3.2.2.2.2 Evaluation of Scenario 2

Revenues from the major funding sources for Scenario 2 through 2010 are adequate to provide the full local share. Funding balances remain positive throughout the period. This is indicated by the statistics summarized in ***Table G-3*** and by the fact that the current funding balance, plotted in ***Figure G-2***, remains positive throughout the period. This demonstrates that Scenario 2 is a second approach by which the SFWMD could meet its obligations for the funding of the pilot projects, the components for which authorization is being requested and the monitoring program.

G.3.2.2.3 Scenario 3

G.3.2.2.3.1 Formulation of Scenario 3

Compared to Scenarios 1 and 2, Scenario 3 relies more heavily on ad valorem revenues. First of all, Scenario 3 includes credits for lands already purchased which will be utilized for these components ($67,655,000). Scenario 3 is very conservative regarding funds from the Preservation 2000 program and its successor. It assumes that allocations to the SFWMD in both programs is at $27,000,000 per year and that only 50% of the available funds are utilized to support the implementation of this portion of the Restudy. The scenario plans for significant revenue from ad valorem sources. Specifically it is assumed that .15 mills of ad valorem taxing authority are dedicated to Restudy implementation. This is about one-half of the ad valorem funds that could be generated if rates were increased from their 1999 historical levels to the constitutional maximum. Since legislative action would be required to raise the rates this full amount, the ad valorem contributions begin in 2001. Scenario 3 also includes the “middle” preliminary assessment of revenues that will be available from cost sharing/fees and assessments. SFWMD staff recently completed this preliminary assessment. Overall, the estimated $28 million ($1998) for cost sharing/fees and assessments represents 13% of the local sponsor’s cost for the components to which the alternative funding sources apply.

G.3.2.2.3.2 Evaluation of Scenario 3

Revenues from the major funding sources for Scenario 3 through 2010 are adequate to provide the full local share. Funding balances remain positive throughout the period. This is indicated by the statistics summarized in ***Table G-3*** and by the fact that the current funding balance, plotted in ***Figure G-3***, remains positive throughout the period. This demonstrates that Scenario 3 is a third approach by which the SFWMD could meet its obligations for the funding of the pilot projects, the components for which authorization is being requested and the monitoring program.

TABLE G-2
SUMMARY OF ASSUMPTIONS FOR FUNDING SCENARIOS

Funding Component	Scenario 1	Scenario 2	Scenario 3
Credits for Lands Already Purchased	$67,655,000, this is the best available estimate of the cost of lands that the SFWMD owns and for which it can receive credit toward the funding of the Restudy initial authorization components and pilot projects. Credits for each component for which lands have been purchased are credited as cost reductions in the years during which real estate acquisition is scheduled for these components in the Implementation Plan.	$67,655,000, this is the best available estimate of the cost of lands that the SFWMD owns and for which it can receive credit toward the funding of the Restudy initial authorization components and pilot projects. Credits for each component for which lands have been purchased are credited as cost reductions in the years during which real estate acquisition is scheduled for these components in the Implementation Plan.	$67,655,000, this is the best available estimate of the cost of lands that the SFWMD owns and for which it can receive credit toward the funding of the Restudy initial authorization components and pilot projects. Credits for each component for which lands have been purchased are credited as cost reductions in the years during which real estate acquisition is scheduled for these components in the Implementation Plan.
Funds from State Land Acquisition Programs	$22,950,000 for 1999 through 2010. The underlying assumption is that the SFWMD receives $27,000,000 per year from the present Preservation 2000 program and its successor program each year and uses 85% for the Restudy Initial Authorization Components and Pilot Projects	$20,250,000 for 1999 and 2000 and $38,250,000 for 2001 through 2010. The underlying assumption is that the SFWMD receives $27,000,000 per year from the present Preservation 2000 program in 1999 and 2000 and $51,000,000 per year from the Preservation 2000 successor program from 2001 through 2010. In each case it uses 75% for the Restudy Initial Authorization Components and Pilot Projects.	$13,500,000 for 1999 through 2010. The underlying assumption is that the SFWMD receives $27,000,000 per year from the present Preservation 2000 program and its successor program and uses 50% for the Restudy Initial Authorization Components and Pilot Projects.
Ad valorem Tax Proceeds	$31,290,000 starting in 2000 continuing to 2010, escalating at 5% per annum. Assumes full yield of ad valorem taxing authority from 1999 millage up to the .8	$22,758,750 starting in 2000 continuing to 2010, escalating at 5% per annum. Assumes .075 mills of ad valorem taxing authority is dedicated to Restudy Initial	$45,517,500 starting in 2001 and continuing to 2010, escalating at 5% per annum. Assumes full yield from .15 mills of ad valorem taxing authority is dedicated

Funding Component	Scenario 1	Scenario 2	Scenario 3
	mill legislative cap is dedicated to Restudy Initial Authorization Components, Pilot Projects and Monitoring. This is slightly more than .1 mills.	Authorization Components, Pilot Projects and Monitoring.	to Restudy Initial Authorization Components, Pilot Projects and Monitoring.
Cost Sharing/ Special Fees and Assessments	$2,973,833 starting in 2000 and continuing till 2009, escalating at 3% per annum to match the expected cost inflation. This is a "middle" preliminary estimate developed by District staff by individually evaluating each of the components identified in the report "Funding the Central and Southern Florida Restudy" as having the potential for cost sharing/fees and assessments. Under this estimate, cost sharing, fees and assessment would cover about 13% of the local sponsor cost for these components.	$4,758,132 starting in 2000 and continuing till 2009, escalating at 3% per annum to match the expected cost inflation. This is an "optimistic" preliminary estimate developed by District staff by individually evaluating each of the components identified in the report "Funding the Central and Southern Florida Restudy" as having the potential for cost sharing/fees and assessments. Under this estimate, cost sharing, fees and assessment would cover about 21% of the local sponsor cost for these components.	$2,973,833 starting in 2000 and continuing till 2009, escalating at 3% per annum to match the expected cost inflation. TABLE G-3
SUMMARY STATISTICS SHOWING
FUNDING CAPABILITIES RELATIVE TO NEEDS[A]

Funding Result	Scenario 1	Scenario 2	Scenario 3
Projected 2012 Current Dollar Funding Balance	$85 million	$147 million	$119 million
Years with Cumulative Funding Deficits and Maximum Deficit	One year, maximum deficit of $1.35 million	No deficits	No deficits
1999 Present Value of Available Funds Less Required Expenditures	$47 million	$77 million	$65 million

[a] Three performance statistics are summarized in Table G-3. A positive value for the "Projected 2012 Current Dollar Funding Balance" implies that the funding in the scenario is capable of meeting the projected funding needs by the year of completion of the components for which authorization is being requested (in this case 2012). "Years with Cumulative Funding Deficits and Maximum Deficit" give some indication of the extent to which debt financing is needed to meet the funding obligations. Not having deficits indicates that the revenue sources are adequate to "pay-as-you-go" to meet the funding needs. Having a positive "1999 Present Value of Available Funds Less Required Expenditures" is simply another way of indicating the extent to which the funding scenario is capable of meeting the projected funding needs by the year of completion of the components as a group.

APPENDIX H

WATER QUALITY

Appendix H is the water quality appendix for the Draft Feasibility Report and Programmatic Environmental Impact Statement (PEIS). As such, it includes both existing conditions and environmental effects water quality information. Specifically, Appendix H is a detailed expansion of water quality aspects of Section 2 (*Historic Condition*), Section 3 (*Existing Conditions*), and Section 8 (*Environmental Effects*) of the report. Appendix H also includes Attachments A-F.

H.1 REGIONAL SYSTEM

H.1.1 INTRODUCTION

As previously indicated in this PEIS, the study area of the C&SF Restudy Project is divided into ten designated study regions. These regions are as follows: the Kissimmee River Region, Lake Okeechobee, Upper East Coast (UEC) and Indian River Lagoon (IRL) (which for this water quality review includes the St. Lucie River subregion and the Indian River Lagoon subregion), Everglades Agricultural Area (EAA), Water Conservation Areas (WCAs) (which here include the Loxahatchee National Wildlife Refuge subregion, WCA-2A/2B subregion, and WCA-3A/3B subregion), Lower East Coast (LEC) and Biscayne Bay (which here includes the Loxahatchee River Aquatic Preserve (LRAP=Preserve) subregion, Lake Worth subregion, and Biscayne Bay subregion), Everglades National Park (ENP=Park) and Florida Bay (which here includes the Shark River Slough/Taylor Slough subregion, Florida Bay subregion, Whitewater Bay subregion, and Ten Thousand Islands subregion), Florida Keys, Big Cypress Region, and Caloosahatchee River Region. These regions are depicted in ***Figure H.1.1-1***. Subregions were reviewed for some regions due to their importance to the region, size, and/or unique or different water quality characteristics within the region.

The suite of water quality parameters of concern in the study area consisted of metals, pesticides, nutrients, biologicals, physical parameters, and other parameters. These are listed in ***Table H.1.1-1***. These parameters are subsequently described in detail in Section H.1.4 and Attachment A. From this list of parameters, several "key" parameters of concern were selected for each region and considered subregions (see Section H.1.6). Baseline water quality data were compiled for key parameters for individual regions (see Section H.1.7) and for additional "other" parameters for those regions (see Section H.1.7 and Attachment B).

TABLE H.1.1-1

Suite of Water Quality Parameters of Concern in the Study Area of the C&SF Restudy Project	
Metals	Mercury, Copper, Cadmium, Lead, Zinc, Arsenic, and Tributyltin (TBT)
Pesticides	DDT and Derivatives, Atrazine, Simazine, Ametryn, Endosulfan Compounds, Ethion, Bromacil, 2,4-D, Aldecarb, and Fenamiphos
Nutrients	Phosphorus, Nitrite/Nitrate, and Ammonia/Unionized Ammonia
Biologicals	Fecal Coliforms and Pathogens, and Chlorophyll-*a*
Physical	pH, Dissolved Oxygen, Conductivity, Turbidity, Oil & Grease, Temperature, and Salinity
Other Parameters	Polycyclic Aromatic Hydrocarbons (PAHs), Dioxins and Furans, Sulfate, Chloride, Polychlorinated Biphenyls (PCBs), and Volatile Organic Carbons (VOCs)

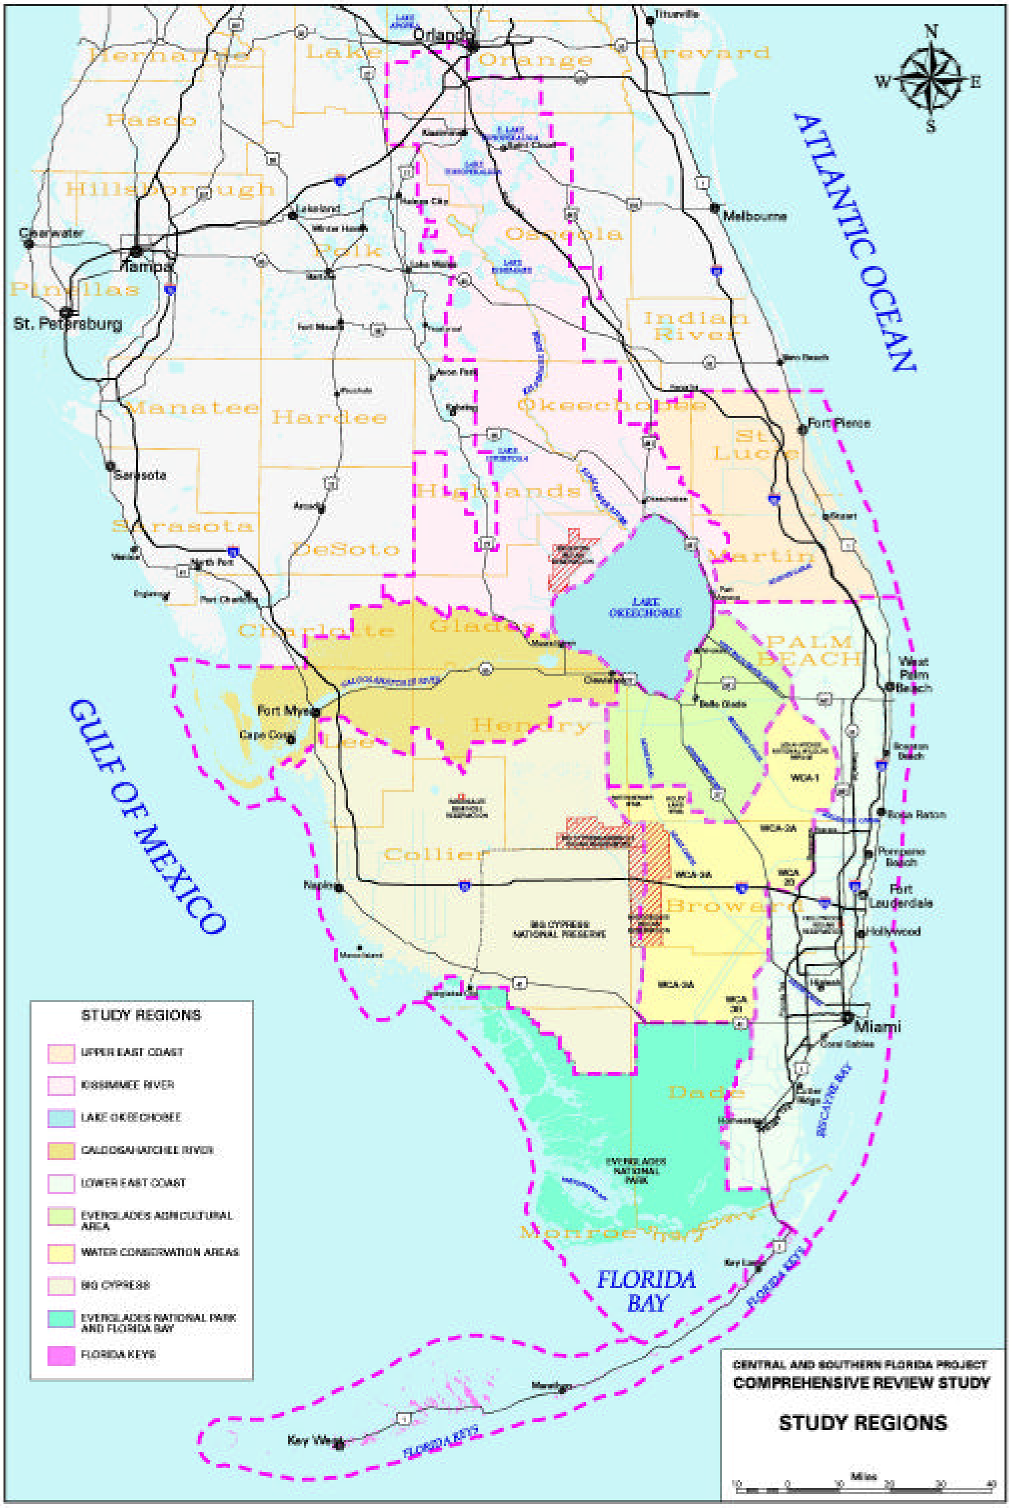

Figure H.1.1-1. Base map of the study area of the C&SF Restudy Project showing the ten regions of the Restudy as designated in this PEIS.

Water quality concerns have been identified for several of these parameters. Accordingly, both water quantity and water quality actions will be fully considered in the hydrologic restoration of South Florida via the Restudy PEIS.

Significant published references important to the description and/or data compilation of the ten regions and considered subregions include Boyer and Jones (1998), SFWMD (1998a, 1998b, 1992a, 1992b, 1982), USEPA (1996a;1998: draft), FDEP (1996), USGS (1996a), Limno-Tech (1995), Woodward-Clyde Consultants (1994), and USACE (1991). In addition, several reference citations were obtained via the EXTONET website (EXTONET, 1998: internet) searched in 1998. Also, unpublished data (1991-1997) were obtained from a SFWMD database (1998: unpublished) through 1998 personal communication with the SFWMD (M. Slayton) and were reduced to means and medians by a USEPA contractor. Unpublished pesticides data (1992-1997) were also obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Published data, as opposed to more recent but raw sampling data, were chiefly used for data compilation. Reliance on published data, resulted in the typical period of record for the data being from the late 1980's to the early 1990's. However, the specific period of record ranged from 1973 to 1997 and included some recent (1996-1998) published references such as those listed above. The established baseline year for the PEIS is 1995.

In addition to the narrative presented in Section 3, the current baseline water quality conditions of the ten regions of the study area are further discussed in the following narrative. An overview of historic water quality conditions is presented for comparison in Attachment E, which also supplements historic information presented in Section 2 (*Historic Condition*).

Kissimmee River Region

In general, the 305(b) report (FDEP, 1996) states the water quality trends for the basin are stable at forty sites, declining in Arbuckle Creek and Lake Underhill, and improving in Lake Tohopekaliga, Lake Kissimmee, and the Kissimmee River. The worst reported water quality conditions occurred in Reedy Creek and Bonnet Creek, while the best water quality conditions were observed in Lake Conway, Crooked Lake, and the Butler Chain of Lakes. Health advisories recommending the limited consumption of largemouth bass because of mercury have been issued for Lakes Kissimmee, Toho, East Toho, and Istokpoga.

Water quality in the channeled part of the river between Lake Kissimmee and Lake Okeechobee varies from north to south. From Lake Kissimmee to near Lake Okeechobee, where the channel flows mostly through unimproved rangeland, water quality was characterized as fairly good. As the river nears Lake

Okeechobee, however, cattle and dairies grow more numerous. Along the channel, water rich in nutrients and Biochemical Oxygen Demand (BOD) flows quickly to Lake Okeechobee, exacerbating eutrophication.

Lake Okeechobee

According to the 1996 305(b) report (FDEP, 1996) for Lake Okeechobee, the major pollution sources for the lake include runoff from ranch and dairy operations in the north where pollution has elevated phosphorus and coliform bacteria concentrations and created a continuous algal bloom. In the south, historic back-pumping of runoff from row crops and sugar cane has elevated nutrient and pesticide levels. The back-pumping has mostly ceased but still occurs when water in the primary canal of the Everglades Agricultural Area (EAA) reaches 13 feet (flood-control levels). As a result, depending on location and seasonal rainfall or drought, the lake receives varying amounts of nutrients, substances creating BOD, bacteria, and toxic materials. Other pollutants include high levels of total dissolved solids, unionized ammonia, chloride, color, and dissolved organic chemicals. The lake's Total Phosphorus (TP) levels have doubled in the last decade.

Biological sampling indicated variability but generally indicated eutrophic conditions. In recent years, several widespread algal blooms (one covering about 100 square miles) and at least one major fish kill (all of which were widely publicized) launched the environmental community and governmental agencies into intense investigation and analysis of the lake's problems. The Lake Okeechobee Technical Advisory Committee, formed to assess the situation and recommend solutions, determined that phosphorus from dairies and agriculture was a major cause of the noxious algal blooms and that levels should be reduced by 40 percent. A secondary cause of increased phosphorus may be the flooding of hundreds of acres of perimeter wetlands after the SFWMD decided in the late 1970's to raise the lake's water level. The higher level also reduced valuable fish-spawning grounds and waterfowl feeding and nesting habitat.

The Florida Steel Superfund site exists two miles northwest of Indiantown in Martin County. It consists of a 150-acre former steel mill that operated from 1970 to 1982. The USEPA has identified heavy metals, including arsenic, cadmium, and lead in the dust and ground water. PCBs have also been found at various locations. Adjacent wetlands are threatened by migrating contamination.

In general, the water quality trends for the lake are stable at six sites, improved at two sites, and degraded at two sites. The best water quality observations were noted for the flow entering Fisheating Creek and along the west near wetlands. The worst water quality conditions occurred in the south by agricultural areas, and to the northeast by Taylor Creek, Nubbin Slough and the St. Lucie Canal. The reported major pollution sources in this basin were dairies and agriculture. A generalized assessment of the lake shows the lake as having fair water quality conditions, except for Myrtle Slough which was shown to have poor water quality, and the extreme south-southwest section of the lake where good water quality conditions are described by the 305(b) report (FDEP, 1996).

Upper East Coast and Indian River Lagoon

Most pollutants found in surface waters along the Upper East Coast come from storm water (FDEP, 1996). Any water quality problems in these areas can be exacerbated by the extensive network of canals, which tend to diminish water quality and lower dissolved oxygen levels which in turn may lead to fish kills. In general, the 1996 305(b) report states that water quality in the northeastern basin is relatively good. The major problems in the basin are found near Port St. Lucie. Five-Mile and Ten-Mile creeks, which receive citrus grove runoff, have poor water quality with high pesticide levels that may be harming the North Fork of the St. Lucie River and Estuary. Water quality in the North Fork improves downstream of the confluence of Five-Mile and Ten-Mile creeks but, along with the main stem, is still affected by runoff from construction sites and urban development along the river in Port St. Lucie.

In general, the worst water quality conditions in the Upper East Coast Basin are reported in the St. Lucie River and the canals leading from the Everglades Agricultural Area. In general, the water quality indices for the areas west of the Indian River Lagoon and approximately centered on Port St. Lucie are reported as poor. The major sources of pollution in this basin are urban runoff, agriculture, boat discharge, and sewage overflows. Although the Savannas State Preserve, a 15-mile-long freshwater marsh between Ft. Pierce and Stuart, has fairly good water quality, mercury concentrations in fish tissue were high enough to warrant a no-consumption advisory for largemouth bass.

Water quality in the south section of the Indian River Lagoon was rated as fair by a National Estuary Program technical report (Woodward-Clyde Consultants, 1994). The best water quality conditions were identified in the areas south of Ft. Pierce; the worst in Belcher Canal. The main water quality issues in this segment of the basin were urban runoff, sewage discharge, freshwater discharge, rangeland runoff, and citrus runoff.

Everglades Agricultural Area

The 1996 305(b) report (FDEP, 1996) for the EAA states that the L-8, West Palm Beach, Hillsboro, North New River, and Miami canals from Lake Okeechobee to the L4-L7 canals; which roughly define the EAA; have poor water quality with extremely high nutrient and low dissolved oxygen levels. Other problems include pesticides, BOD, bacteria, and suspended solids. Agricultural runoff and overflow or seepage from sugar mill retention ponds also contribute pollutants. In addition, between the L-8 and West Palm Beach canals, biosolids-spreading operations may cause pollution. Fish kills occur periodically in the West Palm Beach Canal after heavy rains due to drainage from the Chemair Spray hazardous waste site. Canals bordering the Water Conservation Areas generally have very low dissolved oxygen levels typical of marsh waters. Nutrient levels at the marsh perimeter are elevated, probably from the breakdown of organic debris as well as agricultural drainage. To date, the FDEP has identified four major violations of Class III criteria caused by nutrients including imbalances of aquatic flora and fauna, dominance by nuisance species, diminished biological integrity, and low levels of dissolved oxygen. Controversy has been considerable over agriculture's effect on water quality in Lake Okeechobee, the canals, the Water Conservation Areas (WCAs), and Everglades National Park (ENP=Park). In the WCAs as well as the Park, cattails have been replacing the predominant native sawgrass community.

In general, the 1996 305(b) report rates water quality in the EAA as fair in the areas southeast of the lake, and poor in the areas south of the lake. The worst water quality conditions are reported for the canals from the EAA.

Water Conservation Areas

The 1996 305(b) report (FDEP, 1996) generalizes the water quality conditions in the WCAs as ranging from poor to good. The conditions for WCA-1 are rated as fair throughout the basin, with the exception of the northern area, which is shown to have poor water quality. The ten-year trend for WCA-1 shows no change for the areas currently described as having fair water quality. Interestingly, the ten-year trend shows water quality conditions have improved in the areas currently described as having poor water quality.

The 1996 305(b) report classifies water quality conditions as good in the northernmost areas of WCA-2 transitioning to a fair condition throughout most of the remainder of the basin. Poor water quality conditions are shown to exist along the L-38E canal. The ten-year trend analysis indicates that conditions have improved in the easternmost section of WCA-2A, and generally have not changed throughout the remainder of the basin.

The 1996 305(b) report classifies water quality conditions in WCA-3B as poor. The conditions in WCA-3A are rated as fair north of the county line, and are rated as good on the south side of the line. The ten-year trend does not show significant changes have occurred in the basin.

A health advisory recommending no consumption of largemouth bass because of mercury content has been issued for WCA-2A and -3A, and portions of ENP. An advisory has also been issued for limited consumption in WCA-1 and portions of the Park.

Lower East Coast and Biscayne Bay

The 1996 305(b) report for the Lower East Coast states that good-to-fair water quality was found throughout the Loxahatchee Basin. A small section of the North Fork of the Loxahatchee River has low dissolved oxygen levels. Waters in Jonathan Dickinson State Park have high coliform bacteria counts. In the last decade, seagrass beds in the estuarine portion of the Loxahatchee River have declined dramatically. Jupiter Sound has good water quality and a healthy biological community.

Lake Worth has good water quality near the inlet and mostly good water quality north of the inlet; however, water quality degrades to the south, especially where the West Palm Beach Canal enters the lake. Water quality improves again at the South Lake Worth Inlet and near Boca Raton Inlet.

Ft. Lauderdale is particularly plagued with water quality problems from urban runoff and wastewater treatment discharges. The westernmost stations on the canals often have the worst water quality from agricultural runoff. Canals are often choked with weeds that must be mechanically removed or treated with herbicides. An FDEP study of major Miami-Dade County canals in 1985 showed poor water quality, low biological diversity, and many exotic plants and animals.

The most serious problems confronting the Miami River are chronic and acute coliform bacteria contamination and heavy metal and organic pollution in sediments. The metal pollution in the sediments ranks among the highest in Florida. Chronic contamination results from illegal sewer connections to storm water pipes, leaking pipes and joints, and broken pipes. Acute contamination occurs when raw sewage flows from either emergency overflows or manholes.

In Miami-Dade, Broward, and Palm Beach counties, ten major public drinking-water wellfields have shown petroleum contamination, including the cities of:

- Riviera Beach
- Delray Beach
- Hallandale
- Dania
- Deerfield Beach
- North Miami Beach
- Miami Springs' Preston Wellfields
- Ft. Lauderdale's Peele-Dixie Wellfield

- Fort Lauderdale's Executive Airport Wellfield

Major petroleum assessments and cleanups are also in progress at Port Everglades, Miami International Airport, and Homestead Air Force Base, among others.

Biscayne Bay, although polluted by canal discharges and port activities, has fairly good water quality because of flushing from the Atlantic Ocean, especially south of Key Biscayne. Much of the bay is blanketed with seagrasses, which are associated with high levels of biological diversity. A potential threat is increased turbidity from resuspended spoil from the bay's bottom. Boat traffic, shoreline development, and pollutants from the Miami River also threaten the bay. High nitrogen concentrations have been measured in some of the canals that flow into Biscayne Bay from the agricultural area of southeastern Miami-Dade County. Another threat is from agricultural pesticides. A system that calculated pounds applied per acre of drainage area per year ranked Biscayne Bay as the second worst estuary in the U. S. for intensity of per-unit application of the more hazardous pesticides (Pait et al. 1992)

Everglades National Park and Florida Bay

As reported in the 1996 305(b) report (FDEP, 1996), the water quality conditions in the ENP were fair throughout the inland areas, and good along the coastal areas. The ten-year trend analysis presented in the report shows that water quality conditions in the ENP have been stable during the period of 1985 to 1995, except for the southeast corner (in the area of Taylor Slough) where water quality conditions reportedly have improved. The 1997 Everglades Annual Report (SFWMD, 1998b) indicates that phosphorus concentrations entering the Park are lower than the interim and long-term limits established by the 1992 Settlement Agreement. The annual report also states that significant increases in pesticide concentrations in water and sediment were not evident for the period 1996 to 1997. However, field studies have detected the presence of endosulfan and other pesticides in Florida Bay, especially near the C-111 basin (Scott et al. 1994; Scott et al. 1995). No significant trends in annual average mercury concentrations in water, sediment, or fish have been observed for the past five years. The annual report indicates that outflow concentrations of total mercury and methylmercury are less than inflow concentrations and upstream reference site concentrations; that total mercury concentrations are below Class III standards; and that outflow concentrations in largemouth bass are much less than the reference site and the Florida “limited consumption” action level of 0.5 mg/L. Although the Florida Department of Health and Rehabilitative Services recommends no consumption of largemouth bass throughout most of the eastern two thirds of the Park, this recommendation is being modified to a recommendation of limited consumption for the southeast east corner of the Park.

Some parts of Florida Bay have experienced a massive seagrass and mangrove die-off in the late 1980's and early 1990's. Researchers estimate that 9,880 acres of seagrass have died and another 66,690 acres have been affected to a lesser extent. The problem likely stems from a lack of flushing from hurricanes, high water temperatures, and high levels of salinity (recorded as high as 70 ppt (SFWMD, 1998b)). Chlorophyl-*a* levels in the bay generally were higher in the western areas (>1.0 ppb) than in the eastern portion of the basin (<1.0 ppb). Mercury contamination in seatrout collected from Florida Bay also is reported to be a cause for concern.

Florida Keys

According to the 1996 305(b) report (FDEP, 1996), the island waters open to the Atlantic or Gulf as having good water quality; however, many man-made canals and marinas have water-quality problems that are exacerbated by decreased flushing. A 1986 205(j)study in the Keys indicated that most pollution came from the following sources (excerpted: FDEP, 1996):

- Wastewater plants and small "package plants" discharging to poorly flushed, man-made waterways;
- Thousands of septic tanks and cesspools;
- Marinas lacking facilities to pump out waste from boats;
- Fish processors;
- Storm water runoff, especially into the canals.

The general water quality index for the Keys is reported to be good by the 305(b) report. The water quality trends indicate one site is stable. The worst water quality conditions are found in the urban canals and marinas. The best conditions are found in the open ocean and bay waters. Major pollution sources in the Keys are construction, septic tanks, marinas, live-aboard vessels, and storm water runoff.

Big Cypress Region

The general water quality indices for this basin range from good in the western portion of the basin to fair conditions in the east (FDEP, 1996). Water quality trends indicate there are five stable sites and two improving sites located in the Everglades west coast basin. There were no recently sample poor sites in this basin. The major sources of pollution include hydrologic modifications and agriculture.

Caloosahatchee River Region

A 1988-1989 study reported in the 1996 305(b) report (FDEP, 1996) showed that the upper portions of the region near Lake Okeechobee frequently violated dissolved oxygen standards and had high conductivity and nutrient levels from low flows and agricultural drainage (mostly sugar cane). Nine-Mile Canal, which drains agricultural fields, has very poor water quality. Pollution-tolerant species dominated biological samples. Although no algal blooms were seen during the sample period, they have been reported.

Although wastewater discharges remain a problem, the estuary is presently more seriously affected by high-nutrient waters from the river and tributaries, and storm water runoff from cities. Nutrient and chlorophyll levels are high, and small algal blooms occur regularly. The Orange River, a tributary entering the Caloosahatchee below the locks, is a favored wintering place for manatees because a nearby power plant discharges warm water. A fish kill and clam die-off occurred in 1990 because of high-temperature water discharges and low dissolved oxygen levels.

In general, good water quality conditions exist in the central portions of the basin. The best water quality indices are reported for Orange Creek. Water quality indices decline to fair in the easternmost area of the basin; specifically in the areas north and west of Lake Hicpochee; in the westernmost area of the basin, specifically around Trout Creek; and in the tidal areas of the Caloosahatchee River. Poor water quality indices were shown for the areas south and southeast of Lake Hicpochee, for the Daughtrey Creek sub-basin. Billy Creek, in the western portion of the basin, is reported as having the worst water quality in the basin. Overall, the monitoring stations were stable at three sites, and worse at one site. Major pollution sources were reported to be hydrologic modifications, agriculture, and urban areas, specifically Fort Myers.

H.1.2 WATER QUALITY REGULATIONS AND STANDARDS APPLICABLE TO REGION

Several federal, State and Tribal regulations and standards are relevant to the C&SF Restudy region. Summaries of the Federal Clean Water Act, the State of Florida Everglades Forever Act, and the Seminole Tribe of Florida Tribal Water Code and the Miccosukee Tribe of Indians of Florida Environmental Protection Code are presented in this section. Additional federal and State regulations and standards are presented in Attachment C**.**

H.1.2.1 Federal Regulations and Standards

H.1.2.1.1 Federal Clean Water Act

The Federal Clean Water Act (CWA) is the principle statute governing the quality of the Nation's waterways. The Act was initially called the Federal Water Pollution Control Act upon its inception in 1948. Since 1948, the Act has been amended on a regular basis. Major amendments were enacted in 1961, 1966, 1970, 1972, 1977, 1981, and 1987. It was reauthorized in 1991. The 1977 Amendments gave the Act its current name.

Prior to the 1972 Amendments, the Act relied largely on the States for achieving water pollution control. The 1972 Amendments, however, gave the Act a new regulatory and enforcement approach and created a strong federal enforcement program. These amendments were the federal government's response to a growing awareness that reform was needed—as evidenced by ready examples of water pollution. The 1972 Amendments declared that "the objective of this Act is to restore and maintain the chemical, physical, and biological integrity of the Nation's waters." National goals of the elimination of the discharge of pollutants into the Nation's waters by 1985, and that all waters be safe for fishing and swimming by 1983, were established.

The new approach combined the setting of state water quality standards based on desired water use objectives with the establishment of individual facility effluent limitations. The use of discharge permits was established to require point source dischargers to be in compliance with technology-based standards. Large sums of money were made available for construction grants for municipal sewage treatment plants which would aid municipalities in reaching compliance. In addition, Section 404 created a new permitting program to regulate the discharge of dredged material into waters of the U.S., including wetlands.

More specifically, states are authorized to develop ambient water quality standards and water quality management plans. States must determine maximum daily allowable pollutant loads for waters where the desired water quality cannot be met with technology-based standards. The States must then establish effluent limits and compliance schedules for point source dischargers to assure the attainment of the desired water quality.

Pursuant to Section 402 of the CWA, National Pollutant Discharge Elimination System (NPDES) permits are required for all new and existing point sources from which pollutants are discharged to navigable waters. Permits stipulate the amount of pollutant permitted to be discharged, compliance schedules for dischargers who cannot meet current standards, and monitoring, testing and reporting requirements. Effluent limitations are to be imposed and enforced in NPDES permits by several means. They are:

- Best Practicable Control Technology (BPT) - an average of the best treatment technology currently available.
- Best Available Technology Economically Achievable (BAT) - applies to toxic pollutants.
- Best Conventional Pollution Control Technology (BCT) - applies to conventional pollutants.
- Best Management Practices (BMPs) - designed to minimize the discharge of toxic and hazardous substances.

New pollution sources in an industry must meet a separate set of standards, called New Source Performance Standards (NSPS). These standards limit the discharge of pollutants by new sources based on Best Available Demonstrated Control Technology (BDT). The storm water permit program attempts to reduce pollutants to the maximum extent practicable for municipalities, and to technology-based requirements for industry. Immediate corrective actions must be taken when a discharge contributes to a violation of a water quality standard, or is a significant contributor of pollutants to the Nation's waters.

A discharge monitoring report must be submitted regularly by the NPDES permittee, providing a summary of the discharger's records on a monthly or quarterly basis. Periods of legal non-compliance would require the submission of a quarterly report stating the cause and period of non-compliance, the expected return to compliance, and plans to reduce the chance of future non-compliance. Non-compliance involving the discharge of toxic pollutants, a threat to drinking water, or injury to human health requires that the USEPA be notified within 24 hours. Intentional non-compliance may be allowed if necessary to prevent loss of life or serious property damage. Temporary non-compliance due to factors beyond reasonable control of the permittee must be promptly reported.

Two classes of pretreatment standards exist for new and existing industrial users who discharge to Publicly Owned Treatment Works (POTWs). Categorical pretreatment standards are intended to control toxic pollutants in specific industries and to prevent interference with the effective treatment of sewage. General pretreatment standards prohibit interference, fire or explosion hazards, corrosivity, solid or viscous obstructions, and heat sufficient to inhibit biological activity at POTWs.

Nonpoint Source (NPS) pollution is discussed under Section 303 (regulatory) and Section 319 (voluntary) of the CWA. States are to establish planning bodies to develop area-wide pollution control plans and identify waters which are unlikely to comply with state standards without additional nonpoint source controls. NPDES permits cannot be issued where the permit may conflict with an approved plan.

Specific to the State of Florida, the USEPA has recently (May 1, 1995) authorized the State of Florida to administer the NPDES Permit Program for all operational NPDES permits (except for federal facilities) with USEPA oversight. Coverage for storm water (construction) NPDES permitting in Florida is regulated via a General Permit issued by the USEPA on September 25, 1992.

Section 404 of the CWA regulates discharges of dredged and/or fill material into waters of the United States, including wetlands, through permits issued by the USACE. The USEPA is authorized to comment on these permits, elevate unaddressed concerns, and in certain cases, issue a determination that a site is not suitable for the discharge of dredged and/or fill material. Under regulations developed by the USEPA, permit applicants are required to first avoid, minimize, then mitigate the effects of their projects on wetlands. The relative significance of the functions and values of the wetland, and the availability of alternative sites must be considered. The CWA promotes the functional replacement of any unavoidable project wetland losses through wetland enhancement, restoration and/or creation, or the purchase of wetlands for their preservation in perpetuity.

Discharges of oil or hazardous substances in quantities that may be harmful to waters of the United States are prohibited. The cleanup of spills are provided for and Spill Prevention, Control and Countermeasure (SPCC) plans are required. Over 300 substances have been defined as hazardous by the Clean Water Act.

H.1.2.1.2 Other Federal Regulations and Standards

In addition to the CWA, the Federal Safe Drinking Water Act is relevant to the water quality of the study area. A summary of this statute is provided in Attachment C**.** In addition, Section H.1.4.1 presents USEPA and/or State of Florida aquatic life criteria for several of the suite of water quality parameters identified in Section H.1.1 that are of concern in the study area. USEPA human health risk criteria are also presented for some parameters.

H.1.2.2 State of Florida Regulations and Standards

H.1.2.2.1 Everglades Forever Act

The State of Florida's Everglades Forever Act (EFA), Florida Statute 373.4592, was passed in 1994 by the Florida Legislature. In addition to legislative findings that the Everglades ecosystem was a unique ecological treasure which is "endangered as a result of adverse changes in water quality, and in water quantity, distribution, and timing of flows" and that "waters flowing into the Everglades contain excessive levels of phosphorus," the legislature also stated their intention to "preserve natural values in the Everglades while also maintaining the quality of life for all residents of South Florida, including those in agriculture, and to minimize the impact on South Florida jobs, including agricultural, tourism, and natural-resource related jobs..."

The EFA sets out an iterative process to lead towards restoration of the Everglades. The first step is set out in Section 373.4592(4). The EFA mandates a comprehensive program ("Everglades Program") of scientific research, monitoring, construction, implementation of agricultural BMPs, regulation, and funding to achieve the State's objectives for Everglades restoration and protection. The principal elements of the Everglades Program include:

- construction and operation of the Everglades Construction Project (ECP) which is to consist of six large-scale Stormwater Treatment Areas (STAs) designed to treat EAA runoff prior to discharge to the Everglades;

- implementation of agricultural BMPs in the Lake Okeechobee drainage basin, the EAA, and the C-139 Basin (west of the EAA);

- extensive research and monitoring activities to determine numerically the concentration at which total water column phosphorus creates an imbalance in natural populations of aquatic flora and fauna in the Everglades.

The FDEP is to initiate administrative rule-making adopting the numeric phosphorus criterion no later than December 31, 2001. If, however, FDEP has not adopted a numeric phosphorus criterion by December 31, 2003; the legislature determined a default concentration of 10 parts per billion (ppb) for waters in the Everglades Protection Area (EPA). Section 373.4592(2)(h) of the Act defines the EPA as consisting of the Arthur R. Marshall Loxahatchee National Wildlife Refuge; Water Conservation Areas 1, 2A, 2B, 3A, and 3B; and Everglades National Park. Furthermore, in addition to numerically interpreting the State's narrative nutrient water quality standard for phosphorus in the Everglades, the EFA requires that all other water quality standards applicable to the EPA and EAA canals be evaluated. Research necessary to complete this evaluation is to be completed by December 31, 2001. By 2003, the SFWMD must submit a prompt modification to incorporate proposed changes to the ECP to achieve compliance with the new phosphorus criterion and other State water quality standards by December 31, 2006.

Construction of the ECP is to be completed by October 1, 2003. Construction of the first STA (STA6-Section 1) was completed in October 1997. After a brief start-up period, full operation of STA6-Section 1 began in December 1997. Construction of STA1 West and Inflow and Distribution Works, STA2, and STA5 is scheduled to be completed by January 1, 1999. Construction of the largest STA,

STA 3/4, is scheduled to begin after January 1, 1999 and is to be completed by October 1, 2003. By December 31, 2006, the ECP is to be operated to achieve compliance with all applicable State water quality standards, including the numeric phosphorus criterion. Furthermore, by that same date, all other existing (and future) SFWMD-controlled structures discharging water into the EPA (the so-called "Non-ECP Structures") are to be operated to achieve compliance with all applicable State water quality standards. The SFWMD has already developed schedules and strategies for evaluating these structures and for implementing water quality improvements where necessary.

H.1.2.2.2 State Water Quality Regulations

In addition to the EFA statute, additional State of Florida water quality regulations and standards are discussed in Attachment C**.** These regulations and standards are the:

- Florida Statutes 373 (Water Resources) and 403 (Environmental Control)
- Surface Water Standards
- Beneficial Use Classifications (Class I-V)
- Ground Water Standards
- Drinking Water Standards.

H.1.2.3 Tribal Water Codes

H.1.2.3.1 Seminole Tribe of Florida Tribal Water Code

The Seminole Tribe of Indians, being a federally-recognized Tribe of Indians, has the right under federal law to set water quality standards for its tribal lands. The Seminole Tribe has enacted a Tribal Water Code which includes water quality standards for controlling both point and nonpoint sources of pollutants for the Big Cypress and Brighton Reservations, last amended on March 13, 1998. The Code, which is applicable to the Big Cypress Reservation, has been approved by the USEPA. Currently, the USEPA is reviewing the latest revision.

The water quality standards state that all Reservation surface waters be free from substances that (excerpted: Tribal Code):

- settle to form objectionable deposits
- float as debris, scum, oil or other matter forming nuisances
- produce objectionable color, odor, taste, or turbidity
- cause injury to or are chronically toxic to, or produce adverse physiological responses in humans, wildlife, plants, or fish and other aquatic life
- are unsuitable for aquatic life propagation and maintenance
- support balanced indigenous populations of aquatic life.

Moreover, the Tribe has enacted two additional standards for a special class of waters called Class II-A waters. These standards state that Class II-A waters be free from substances that "disturb, injure or in any way jeopardize the continued existence of the unique diverse plant and wildlife used in the religious ceremonies and customs of the Tribe; or impair the biological community as it naturally occurs in the designated area due to physical, chemical or hydrologic changes."

The Tribal Council has adopted the goals and policy in the CWA. In particular, the Tribal Council endorses the national goal of the elimination of the discharge of pollutants into the Nation's waters; protecting fish, shellfish, and wildlife; providing for recreation in and on the water; the elimination of the discharge of toxic pollutants in toxic amounts; and the development of nonpoint sources of pollution control.

In addition to the declaration of goals and policy in the CWA, the Tribal Council has adopted its own water quality policies. These include (excerpted: Tribal Code):

- protecting water quality to pursue economic development;
- conserve the habitat of culturally important fish, wildlife, and plant life in order to provide for hunting, fishing, and other traditions;
- prohibit the degradation of groundwater because groundwater is important for human consumption and because it is costly and difficult to restore contaminated groundwater;
- protect the values and functions of wetlands and provide appropriate mitigation measures for unavoidable adverse impacts.

The Seminole Tribe has established these policies in order to protect the health and welfare of the Tribe's members and others within the Reservation; provide appropriate protection for aquatic life and wildlife; protect aspects of the natural environment important for carrying out traditional cultural activities; and ensure that development activities be carried out.

The Tribe has adopted a narrative criterion for nutrients and phosphorus. The USEPA has reviewed and approved this criterion in fiscal year 1997 (FY97).

H.1.2.3.2 Miccosukee Tribe of Indians of Florida Environmental Protection Code

The Miccosukee Tribe of Indians, being a federally-recognized Tribe of Indians, has the right under federal law to set water quality standards for its tribal lands. According to the Tribe, "(t)he ecological integrity and ultimately the very survival of the Miccosukee Tribe's lands in the Everglades are threatened by the inflow of water containing excess nutrients, especially phosphorus. In order to preserve the unique flora and fauna of Tribal lands, and to preserve the natural balances of Tribal lands", the Miccosukee Tribe established the Miccosukee Tribe of Indians Water Quality Standards. These standards were adopted by the Tribe on December 19, 1997, and amended on March 4, 1998. Currently, the USEPA is conducting a formal review of the water quality standards.

The standards call for all Reservation surface waters to be free from substances other than natural ones that (excerpted):

- settle to form objectionable deposits;
- float as solids, oil and grease;
- cause objectionable color, odor, taste, nuisance conditions, turbidity, temperature, salinity, dissolved solids, chlorides, pH, dissolved oxygen levels, and bacteriological quality;
- affect biological integrity and nutrient concentrations; or
- are toxic substances or pathogens.

The Tribe finds that excessive nutrients (including total phosphorus) constitute one of the most severe water quality problems threatening the Everglades. The Tribe's policy is (excerpted):

> *"to limit the introduction of nutrients from anthropogenic sources into waters of the Tribe. Particular consideration shall be given to the protection from further nutrient enrichment of waters which are presently high in nutrient concentrations or sensitive to further nutrient concentrations and to further nutrient loadings. It is the intent of the Miccosukee Tribe to prevent adjacent water users from using Tribal waters or vegetative communities within Tribal jurisdiction as a biological filter with respect to nutrient removal. These water quality standards take into consideration the water quality standards of downstream waters and provide for the attainment and maintenance of downstream waters. The Miccosukee Tribe's waters in the areas of the North Grass, South Grass, and Gap (WCA-3A) shall have a nutrient standard consistent with natural oligotrophic levels (including a total phosphorus limitation of 10 parts per billion of water). The most stringent nutrient standards will be applied to the most upstream reaches of the Tribal waters."*

The Miccosukee Tribe's Class III-A waters have a nutrient standard that is protected by a TP criterion of 10 ppb. For Class III-B waters, the Tribe has adopted a narrative criterion.

The objective of the Miccosukee Tribe's Water Quality Standards is to "provide that contamination that may result from the use of water shall not lower the quality of the water below that which is required for recreation and protection and propagation of fish, shellfish, wildlife, and native plants consistent with preservation of the Everglades Ecosystem within Water Conservation Area 3-A and Everglades National Park." The Miccosukee Tribe's Water Quality Standards have been enacted to establish goals for specific water bodies on the Miccosukee Reservation, to assign uses to water bodies for which protection is required, and to prescribe water quality criteria needed to meet and sustain those uses. The standards aim to protect threatened and endangered species listed by the U.S. Fish and Wildlife Service (USFWS), to promote the health, social welfare, and economic well-being of the Miccosukee Tribe, to provide a legal basis for regulatory controls, and to provide a basis for the Clean Water Act Section 401 certification. An overriding concern, in addition to the above-mentioned agenda items, is the desire to assure that the degradation of existing water quality does not occur.

The standards apply to all Tribal Reservation surface waters within the exterior boundaries of the Tribe's Reservation, including water situated wholly or partly within, or bordering upon Tribal Reservation lands. The standards shall be the basis for regulatory enforcement against discharges so as to protect the water within the Reservation.

The Tribe hopes to accomplish these goals by incorporating the standards into a permitting and management process for point and nonpoint source discharges, by using the standards to determine when a designated use is threatened, and by using current treatment technologies to control point sources and BMPs to control nonpoint sources of pollution. The Tribe recognizes the need to mediate regulatory actions with the technological progress and the social and economic well-being of Tribal members. No compromise will be allowed, however, when it comes to protecting human health or the preservation of the Everglades.

H.1.2.3.3 1992 Settlement Agreement

In 1988, the federal government filed a lawsuit against the SFWMD and the FDEP, alleging that water discharged into Everglades National Park and the Loxahatchee National Wildlife Refuge violated State water quality standards. In particular, the lawsuit alleged that the farm runoff from the EAA contained excessive levels of nutrients such as phosphorus that were causing imbalances in natural populations of flora or fauna, a violation of State Class III water quality standards.

The lawsuit was settled in 1991, with the parties agreeing that the ecological integrity, and ultimately the survival, of the Park and the Refuge are threatened by inflows of water containing excess nutrients. The settlement agreement, which the federal court entered as a Consent Decree in 1992, requires several affirmative steps to remedy these problems. First, it requires the state parties to achieve interim and long-term phosphorus concentration levels and limits in the Park and

Refuge. Second, the parties agreed that phosphorus loads discharged from the EAA will be reduced by approximately 80% to the WCAs and the Park, and by 85% to the Refuge as compared to mean levels measured from 1979 to 1988. Third, the state parties agreed to construct Stormwater Treatment Areas (STAs) to remove phosphorus from farm runoff before it enters the WCAs. Fourth, the state parties agreed to initiate a regulatory program requiring the use of BMPs in the EAA that are designed to reduce phosphorus levels in farm runoff. Fifth, the parties agreed to take all actions within their authority necessary to provide adequate flows to meet water quantity, distribution, and timing needs of the Park and Refuge. Finally, the parties agreed to a research and monitoring program, and specifically agreed to numerically interpret the narrative Class III nutrient water quality criteria.

In 1993 and 1994, the federal and State governments agreed to augment the program required by the Consent Decree, primarily by increasing the size and number of STAs and delineating the process for the State to establish a numeric Class III nutrient water quality criterion for phosphorus. The Florida Legislature passed the Everglades Forever Act in 1994, F.S. 373.4592, to authorize the implementation of the augmented program. In 1995, the parties moved the Court to modify the Consent Decree to accommodate the new program and the revised deadlines associated with it. The motion, which the Court has not yet ruled upon, asked the Court to modify the deadlines in the Consent Decree to require compliance with the phosphorus interim levels and limits in the Refuge to 1999 and in the Park to 2003; require the load reductions for the Refuge by 1999 and for all of the WCAs by 2003; and require the STAs to be completed between 1997 through 2003.

H.1.2.4 Federal Monitoring

H.1.2.4.1 United States Geological Survey

The United States Geological Survey (USGS) has conducted extensive long-term monitoring of surface water and ground-water quality at hundreds of locations throughout the South Florida ecosystem. This monitoring has included water physical parameters, nutrients, ions, metals, pesticides and other organic compounds. An overview of available information on surface water and ground water quality for water bodies throughout the ecosystem is provided in USGS (1996b). In 1993, the USGS initiated a National Water Quality Assessment (NAWQA) Program effort in South Florida. This effort includes analysis of historical data, surface and ground-water assessments, and ecological studies. Sampling includes streambed sediment, game fish, surface water and ground water (USGS, 1996b). Ongoing ecosystem studies include extensive Everglades mercury geochemical cycling research, including work on methylmercury degradation, dissolved organic carbon-mercury interactions, sulfur cycling, mercury accumulation and processes in peat, biological uptake of mercury, and ground water-surface water exchange (USGS, 1996c).

H.1.2.4.2 United States Environmental Protection Agency

The Regional Environmental Monitoring and Assessment Program (REMAP) initiated in 1993 is the only system-wide monitoring of the freshwater Everglades ecosystem (USEPA, 1996). This program monitors nutrient, phosphorus, mercury, water management, and habitat indicators. This information is important for assessing ecosystem health and tracking the effectiveness of the Restudy and other efforts directed at ecosystem protection or restoration. This monitoring should continue using the Environmental Monitoring and Assessment Program (EMAP) design with revisions to include compliance monitoring, and fixed or process study stations. It is important to continue monitoring water, soil/sediment, periphyton, and fish in order to develop a time series which will allow a trend analysis in the future to provide for the assessment of changes in the system due to management and restoration actions. In addition, future monitoring will also determine plant biomass estimates across the system and make quantitative habitat assessments and food chain analyses to support a mercury cycling model of the ecosystem. A comparative ecological risk assessment will be completed in order to better understand and control ecosystem threats. This monitoring is designed to compliment the USGS site-specific Everglades mercury process research.

H.1.2.4.3 United States Army Corps of Engineers

The USACE has historically conducted water quality monitoring at key locations throughout South Florida. Monitoring efforts have been undertaken around Lake Okeechoobee, the Loxahatchee National Wildlife Refuge, Water Conservation Areas (WCAs), and the Upper St. Johns portion of the C&SF project. Water quality data including field parameters, nutrients, metals, pesticides, and inorganic constituents, are available from those programs. Funding and manpower considerations have changed the scope of this program several times in the last several years from long term operation-and-maintenance efforts to more short term synoptic studies associated with specific events or projects. As part of a long term effort, the USACE continues to maintain several water quality monitoring stations at: 1) inflows to the Everglades National Park (ENP), 2) stations required for operation of some of the features of the Modified Water Deliveries to the ENP project, and 3) in the Upper St. Johns Project.

H.1.2.4.4 United States Department of the Interior

The USDOI has several water quality monitoring programs underway within its South Florida units. Monitoring objectives are many, and may include: 1) determine water quality conditions; 2) determine water quality trends; 3) determine the presence of external water quality threats; 4) determine the effect of various land uses on water quality; 5) determine the effect of C&SF Project water management practices on water quality; 6) determine the effectiveness of water quality control measures such as agricultural BMPs; 7) assess compliance with water quality standards, the Everglades Forever Act, various Memoranda of Agreement, and the 1992 Settlement Agreement; 8) aid in development of new water quality criteria; and 9) guide resource management decisions directed at protecting or restoring ecology and aquatic resources.

Since 1994, the SFWMD and USFWS have been monitoring 14 interior marsh stations within Loxahatchee National Wildlife Refuge for nutrients, physical parameters, ions, and metals. A similar long-term joint National Park Service (NPS within the USDOI) and SFWMD monitoring program has been in place since about 1985 at nine interior marsh stations within the ENP. The SFWMD also monitors the quality of water at about 50 WCA water control structures. Some of these structures discharge into the Park or Refuge and have been monitored since the 1970's. Water quality within the Big Cypress National Preserve has been monitored cooperatively with SFWMD since 1994 at 14 marsh stations. The SFWMD, Miami-Dade County, and Florida International University (FIU) are all involved in long-term water quality monitoring at over 90 stations within Biscayne National Park. More detail about the above monitoring programs can be found in SFWMD (1998a).

In addition to the above efforts, other collaborative efforts with the USDOI include extensive monitoring performed by FIU. A large amount of other historic water quality data and publications also exist for these areas. For example, the USGS began monitoring water quality within the ENP in 1953. Historic data were collected by USGS, SFWMD, USDOI, or various universities. In addition, periodic special studies or research efforts have gathered additional water quality data throughout these USDOI units such as information on pesticides, mercury, or phosphorus impacts.

H.1.2.4.5 General

Because of the historical impacts and the difficulty in finding a concise, yet comprehensive, water quality data set addressing the entire system, phosphorus has been the Restudy's primary focus. Understanding is incomplete about the types, concentrations and loads of pollutants that are causing ecological problems and likely to create future ecological problems at critical locations. This lack of understanding exists in spite of a significant collective monitoring effort. A number of different agencies routinely collect large quantities of water quality data in the region, yet these data are seldom collected in conjunction with important events such as agricultural pesticide and fertilizer applications, major storm water discharges or pumping activities. Many monitoring programs are localized efforts collecting data at fixed locations at scheduled times which are then stored in databases and seldom used. When pollution impacts do become evident, existing monitoring efforts are often unable to identify the source or cause of the impacts. A detailed water quality monitoring program that is well coordinated among the collecting agencies is necessary to adequately ensure that water quality considerations are included in the stages of the design process for project features.

H.1.2.5 State of Florida Monitoring

State of Florida water quality monitoring is conducted by the FDEP and the SFWMD. Monitoring includes surface water, ground water and atmospheric deposition. Florida counties also have various monitoring programs.

References used to develop this water quality monitoring section were SFWMD (1998a), the FDEP internet website searched in 1998 (FDEP, 1998: internet), and 1998 personal communication with the SFWMD (R. Pfeuffer). Figures and tables incorporated in this section and Attachment D were excerpted from SFWMD (1998a), which was coordinated with the District (G. Germain: SFWMD, 1998 personal communication).

H.1.2.5.1 Surface Water

The FDEP's water quality monitoring, assessment, and data management responsibilities and authorities are promulgated in the State of Florida's 1983 Water Quality Assurance Act (Section 373.026, F.S.), Section 403.061 F.S., and State Water Policy (Section 62-40.540, F.A.C.). In addition, the USEPA has delegated the state additional responsibilities pursuant to the Federal Clean Water Act (CWA).

Historically, FDEP has pursued an ambient monitoring strategy of fixed station networks to characterize water quality. Monitoring efforts were expanded with the initiation of the Surface Water Ambient Monitoring Program. Started in 1991, SWAMP was an effort to revitalize monitoring programs at FDEP to better address federal (305[b] reporting requirements) and state water quality management and assessment requirements. An important component of SWAMP was an effort to formalize biological assessment protocols.

SWAMP was intended as an interagency collaborative effort to better coordinate Florida's monitoring efforts. It also was FDEP's primary surface water quality monitoring program and central repository for surface water quality data. SWAMP had a three-tiered approach with the following goals for each tier:

- Water Chemistry Status Network - The objective of status monitoring was to define the existing conditions of a waterbody and provide background information to support other programs. The initial program was short lived, from 1991-1994, however, during this time the program added over 500 new watersheds for evaluation in the 1994 and 1996 305(b) assessments. FDEP selected waterbodies for monitoring based on two criteria. The first was their identification by the 1990 and 1992 305(b) assessments as having poor, fair, or unknown water quality. The second criterion applied to the selection process was a lack of recent data. This was defined as no new data over the preceding five years. For waterbodies classified as unknown, priority was given to areas with expected threats or impairments. Presently, the Division of Water Facilities Integrated Water Resource Monitoring Network is incorporating the concepts of status monitoring into its design.

- Water Chemistry Trend Network - Designed to determine trends in surface water quality and to determine adequate sampling frequency. Expanded historical permanent and fixed station networks.
- Special SWAMP Projects - Designed as problem-specific or waterbody-specific monitoring programs.

The stated overall program goal of SWAMP was to provide information to the public, elected officials, and FDEP managers about the health of Florida's waterbodies; whether they meet standards and criteria; and the occurrence of changes in quality in a technically sound, timely manner; in an easily understandable format using water chemistry, sediment, and biological data.
SWAMP's stated objectives were (excerpted: FDEP, 1998: internet):

- Identifying and documenting the existing condition of the State's surface waters through a status network;
- Determining support of State water quality criteria;
- Identifying changes in water quality over time of significant waterbodies through a trend network;
- Documenting potential problem areas;
- Establishing stream and lake eco-region reference sites for comparison purposes;
- Collecting biological data at eco-region references sites to establish preliminary biological integrity measurement techniques; and
- Providing information for management, legislators, other agencies, and the general public primarily through 305(b) reporting.

The SWAMP Program ended in 1996 with the merger of FDEP’s ground water and surface water monitoring programs. Elements of SWAMP have been incorporated into FDEP’s Integrated Water Resource Monitoring Program (IWRM) and basin management framework.

IWRM uses a three tiered approach to integrate monitoring to address point and nonpoint sources of pollution, BMPs, pesticides, habitat area, atmospheric deposition, land use/land cover, and the interactions of surface and ground waters.

It will be conducted on a rotating five-year basin cycle, where 20% of the State's basins are monitored intensively during year one, while the remaining 80% would be monitored at a less intense level. During year two, a second and different 20% would be intensively monitored, and the remaining 80% would be monitored at a less intense level. This would continue for five years until 100% of the state was intensively monitored, and then the cycle could begin again.

The first tier of IWRM will provide a broad assessment of the status of Florida’s water resources. It is not designed to identify causes of pollution, monitor compliance of point sources, or allow a thorough detailed understanding of an ecosystem. The second tier is directed to supporting providing more detailed information about a basin. Information generated from this tier can be used for development of Total Maximum Daily Loads (TMDLs: also see Section H.1.5.1.2), identify waterbodies for more detailed studies, and potentially identify water bodies for restoration and rehabilitation. The third tier is directed toward monitoring that supports regulatory programs, such as compliance and enforcement monitoring.

The SFWMD has the responsibility to manage water and related resources for the benefit of the public and to stay updated with the needs of the C&SF Restudy region. The District uses various approaches to protect water quality, including monitoring, testing and researching those water quality parameters related to the District's operations, land management activities, and regulatory functions. The general scope of the water quality monitoring programs currently managed by the District include monitoring points in lakes, rivers, canals, wetlands, dairies, the intracoastal waterway, estuaries, rainfall, and water control structures. The SFWMD Department of Water Resources Evaluation (WRE) is responsible for collecting and maintaining a database of surface water quality and hydrologic information. Specific goals related to water quality monitoring programs administered by WRE include the following (excerpted FDEP, 1998: internet):

- To provide water quality data and evaluations from a network of sampling stations to support water resource management decision-making;
- To optimize the efficiency of data collection monitoring networks, and ensure data accuracy through rigorous quality control; and,
- To develop and maintain a water quality database to provide efficient data access.

There are 40 major water quality monitoring programs that incorporate 991 sampling locations within the SFWMD region, including the following (excerpted: SFWMD, 1998a):

- Surface Water Improvement and Management (SWIM) Act of 1987.
- Permits issued by the Florida Department of Environmental Protection (FDEP), and the Environmental Protection Agency (EPA) [USEPA].

- Memorandum of Agreement (MOA) between the Everglades National Park (PARK), the District, and the United States Army Corps of Engineers (COE).
- MOA's between the District and the Miccosukee and Seminole Indian Tribes of Florida.
- MOA between the District, the United States Department of Agriculture, and the Environmental Protection Agency [USEPA].

Depending on the specific program and/or parameter, the sampling frequencies range from weekly to biannually. In addition, some sampling is conducted only during storm events. The parameters analyzed include basic inorganics (e.g., nutrients, cations, anions and metals), organics (e.g., pesticides and their derivatives, and base neutral/acid extractable and purgeable compounds), and physical parameters (e.g., temperature, dissolved oxygen, pH, specific conductance, etc.).

The areal extent of the SFWMD surface water quality monitoring program is shown in ***Figure H.1.3.2.1-1***. The SFWMD monitored water quality parameters are listed in ***Table H.1.3.2.1-1***, the pesticides analyzed for surface water and sediments listed in ***Table H.1.3.2.1-2,*** and the priority pollutants analyzed for surface water and sediments are listed in ***Table H.1.3.2.1-3***.

The 40 individual monitoring programs are grouped together under 24 main networks with 22 geographic areas and two (pesticide and atmospheric deposition) District-wide monitoring programs. The 24 geographic networks are (excerpted: SFWMD, 1998a):

1. Upper Kissimmee Chain of Lakes and Tributaries
    a. Upper Kissimmee River Chain of Lakes
    b. Tributaries of the Upper Kissimmee
2. Kissimmee River
    a. Kissimmee River
    b. Tributaries of the Kissimmee River
3. Arbuckle Creek
4. Lake Istokpoga
5. Lower Kissimmee River Basin
6. Taylor Creek/Nubbin Slough
7. Indian River Lagoon
8. St. Lucie Estuary
9. Upper and Lower East Coast
10. Works of the District Compliance Monitoring
11. Lake Okeechobee
    a. Inflows and Outflows
    b. Limnetic and Littoral Zones
12. Caloosahatchee River
13. Everglades Nutrient Removal
14. Holey Land
    a. Permitted Inflows and Outflows
    b. Interior Marsh Sites
15. Everglades Protection Area
16. Big Cypress Seminole Indian Reservation
17. Water Conservation Areas Inflows and Outflows
18. Biscayne Bay Monitoring
19. Everglades National Park
    a. Inflows and Outflows
    b. Interior Monitoring
20. Routine Pesticide Monitoring Network
21. Precipitation Monitoring Network
22. Manatee Bay/Long Sound
23. South Florida Estuarine Monitoring Network
24. Big Cypress National Preserve

The locations of sampling sites within most of these networks are depicted in Figures D-1 through D-28 in Attachment D. In addition, the two District-wide monitoring programs (the Routine Pesticide Water and Sediment Monitoring Program and the Atmospheric Deposition Monitoring Program) are discussed below.

The SFWMD Routine Pesticide Water and Sediment Monitoring Program is depicted in ***Figure H.1.3.2.1-2***. As discussed in Section H.1.5.2.1.3.2, the only long-term pesticide monitoring in the C&SF Restudy project area is being conducted by the SFWMD (R. Pfeuffer: SFWMD, 1998 personal communication). The District has maintained a pesticide monitoring program in South Florida since 1984. The pesticide monitoring network includes sites designated in the Everglades National Park Memorandum of Agreement, the Miccosukee Tribe Memorandum of Agreement, the Lake Okeechobee Operating Permit, and the Non-ECP Structure Permit. The monitoring provides data to determine the condition or changes in the quality of water being delivered to Lake Okeechobee, ENP, the WCAs, and Florida Bay. Additional pesticide residue data are collected to determine water quality conditions at the major water control structures throughout the District. The data collected for each sampling event provide information on potential short-term, acute environmental effects for any of the compounds detected. An indication of possible fish toxicity, bioaccumulation for wildlife, or human health impacts can also be inferred from the data. The program has been dynamic over time, as concerns arise about pesticide use within the District, to accommodate sampling for new pesticides and the addition of sampling sites to the network. The current monitoring program consists of analyses for 66 pesticides at 37 sites within District boundaries. This set of compounds includes chemicals currently utilized in the associated agricultural areas, chemicals regulated by Florida's Surface Water Quality Standards (F.A.C. 62-302), and restricted-use pesticides.

The SFWMD also maintains a District-wide Atmospheric Deposition Monitoring Program. This program is related to water quality given the air deposition of mercury and other contaminants in South Florida on waterbodies and upland areas prone to storm water runoff. The location of sampling stations for this program are presented in ***Figure H.1.3.2.1-3***.

H.1.2.5.2 Ground Water

In 1983, the Florida Legislature passed the Water Quality Assurance Act, a portion of which required the FDEP to "establish a ground water quality monitoring network designed to detect or predict contamination of the state's ground water resources" (Florida Statutes, Chapter 403.063). To facilitate this effort, the act requires that the FDEP work cooperatively with other federal and state agencies, including the five Water Management Districts and other government agencies in the establishment of the network.

The goal of the Ground Water Quality Monitoring Network (GWQMN) is to provide scientifically defensible, statewide information on the important chemical and physical characteristics of water from the three major aquifer systems of the State. The objectives of the program are (excerpted: FDEP 1998: internet):

- To establish the baseline water quality of major aquifer systems in the state
- To determine significant trends in ground water quality
- To detect and predict changes in ground water quality resulting from the effects of various land use activities and potential sources of contamination
- To disseminate to the Department, local governments and the public, water quality data and interpretations generated by the network.

FDEP is the lead agency in the network, determining goals and strategies, setting priorities and coordinating the effort. Contracts were developed with the five Water Management Districts and other government agencies to carry out most of the necessary field work. The network consists of two major sub-networks, each of which has unique monitoring priorities and goals. These are (excerpted: FDEP, 1998: internet):

- Background Network - designed to help define background water quality through a network of approximately 1700 wells that tap all major potable aquifers within the state;
- VISA (Very Intense Study Area) Network - designed to monitor the effects of various land uses on ground water quality within aquifers in selected areas.

The Background Network is designed to help define background water quality through a network of over 1,700 wells that tap the three aquifer systems in the state. The first sampling of each well in the network involves the measurement of a comprehensive set of field and chemical parameters. These analyses, combined with historical data, can be used to estimate background ground-water quality. In this case, background water quality refers to water quality in an area of the aquifer which is representative of the general ground-water quality of the region, and is not designed to be associated with degradation from contamination sources.

After the initial samples are collected and analyzed, background monitoring wells are periodically sampled for a standard list of aquifer characterizing parameters, as well as an extended group or series of parameters, that can act as indicators of contamination or degradation. These extended parameter groups are pesticides, trace metals, volatile organic compounds (VOCs), and base neutral acid extractables (BNAs).

H.1.3 REGIONAL WATER QUALITY PARAMETERS AND POLLUTANTS OF CONCERN

H.1.3.1 Listing of General Regional Parameters of Concern

A suite of water quality parameters of concern in the study area was identified in Section H.1.1. These metal, nutrient, biological, physical, and other water quality parameters are listed in Table H.1.4.1-1. This table further presents USEPA and/or State of Florida acute and/or chronic criteria for freshwater and/or saltwater aquatic life for several of the suite of water quality parameters of concern. The State of Florida criterion was listed in the absence of a USEPA aquatic criterion or if the State of Florida criterion was more stringent than the USEPA criterion. In addition, USEPA human health risk criteria are also presented for some parameters. The table was developed from updates of USEPA (1986) and also references the State of Florida F.A.C. 62-302 for State pesticide criteria.

With the exception of the mercury, phosphorus, and pesticides parameters which are described below, the rest of the suite of water quality parameters area also listed in ***Table H.1.4.1-1*** (plus the terms "bioaccumulation" and "biomagnification") and are described in detail in Attachment A.

H.1.3.2 Description of Major Regional Parameters of Concern

Mercury, phosphorous, and pesticides are considered three of the most important water quality parameters in the region. They are described below in detail.

Table H.1.4.1-1.

Water Quality Parameters of Concern for the Ten South Florida Regions in the Study Area of the C&SF Restudy Project, Showing USEPA and/or State of Florida Aquatic Life Criteria and/or USEPA Human Health Risk Criteria (Modified From Updates of USEPA, 1986)

H.1.3.2.1 Mercury

Mercury cycles between the atmosphere, land and water undergoing a series of complex chemical and physical transformations. These scientific issues were addressed in the *Mercury Study Report to Congress* (USEPA, 1997) which provided the following summary (excerpted):

> *Mercury cycles in the environment as a result of natural and human activities. The amount of mercury released into the biosphere has increased since the beginning of the industrial age. Most of the mercury in the atmosphere is elemental mercury vapor, which circulates in the atmosphere for up to a year, and hence can be widely dispersed and transported thousands of miles from likely sources of emission. Most of the mercury in water, soil, sediments or plants and animals is in the form of inorganic mercury salts and organic mercury (e.g. methylmercury). The inorganic form of mercury, when either bound to airborne particles or in a gaseous form, is readily removed from the atmosphere by precipitation and is also dry deposited. As it cycles between the atmosphere, land, and water, mercury undergoes a series of complex chemical and physical transformations, many of which are not completely understood.*
>
> *Mercury accumulates most efficiently in the aquatic food web. Predatory organisms at the top of the food web generally have higher mercury concentrations. Nearly all of the mercury that accumulates in fish tissue is methylmercury.*
>
> *Fish consumption dominates the pathway from human and wildlife exposure to methylmercury. The Mercury Report to Congress (USEPA, 1997) supports a plausible link between anthropogenic releases of mercury from industrial and combustion sources in the United States and methylmercury in fish. However, these fish methylmercury concentrations also result from existing background concentrations of mercury (which may consist of mercury from natural sources, as well as*

mercury which has been re-emitted from the oceans or soils) and deposition from the global reservoir (which includes mercury emitted by other countries). Given the current scientific understanding of the environmental fate and transport of this element, it is not possible to quantify how much of the methylmercury in fish consumed by the U.S. population is contributed by U.S. emissions relative to other sources of mercury (such as natural sources and re-emissions from the global pool).

The typical U.S. consumer eating fish from restaurants and grocery stores is not in danger of consuming harmful levels of methylmercury from fish and is not advised to limit fish consumption. The levels of methylmercury found in the most frequently consumed commercial fish are low, especially compared to levels that might be found in some non-commercial fish from fresh water bodies that have been affected by mercury pollution. While most U.S. consumers need not be concerned about their exposure to methylmercury, some exposures may be of concern. Those who regularly and frequently consume large amounts of fish -- either marine species that typically have much higher levels of methylmercury than the rest of seafood, or freshwater fish that have been affected by mercury pollution -- are more highly exposed. Because the developing fetus may be the most sensitive to the effects from methylmercury, women of child-bearing age are regarded as the population of greatest interest.

Cost-effective opportunities to deal with mercury during the product life-cycle, rather than just at the point of disposal, need to be pursued. A balanced strategy which integrates end-of-pipe control technologies with material substitution and separation, design-for-environment, and fundamental process change approaches is needed. In addition, international efforts to reduce mercury emissions as well as greenhouse gases will play an important role in reducing inputs to the global reservoir of mercury.

Description

Mercury in South Florida

Since the initial detection of elevated levels of mercury in freshwater fish in 1989 (Ware *et al.*, 1990), it has become increasingly apparent that South Florida has an extensive mercury contamination problem. The State of Florida has issued human health fish consumption advisories due to mercury contamination that either ban or restrict the consumption of largemouth bass and other freshwater species from over two million acres encompassing the Everglades and Big Cypress

National Preserve. The maximum concentrations found in largemouth bass (4.4 mg/kg) and bowfin (over 7 mg/kg) collected from the Everglades are the highest concentrations found in Florida to date. Mercury contamination has also been found at levels of concern in largemouth bass throughout Florida's surface waters (Lange *et al*., 1993). Mercury accumulation through the food web may reduce the breeding success of wading birds (Frederick and Spalding, 1994) and the viability of the endangered Florida panther (Roelke *et al*., 1991). For additional background information on the mercury issue affecting the Everglades, USACE (1996) may be referenced.

The sources, distribution, magnitude, transport, transformations and pathways of mercury through the Everglades ecosystem are poorly understood. Among the possible mercury sources in South Florida are natural mineral and peat deposits (Rood *et al*., 1995), and atmospheric deposition from global, regional and local (e.g., fossil-fuel-fired electrical generating plants, municipal waste incinerators, and medical waste incinerators) sources. Although there are multiple interactions among these sources and several possible pathways for mercury transport and bioaccumulation through the Everglades ecosystem, none of these individual sources appear to adequately explain the vast area of contamination.

The issues of mercury contamination of Everglades biota are extremely complex. Various hypotheses have been put forward to account for the apparent susceptibility of the Everglades to mercury impacts, including:

- High historical accumulations of readily methylatable mercuric ion in the downstream sediment attributable to the historical oxidation of peat in the EAA;
- A high mobilization rate of readily methylatable mercuric ion from the sediment associated with the dry-wet cycles in the EAA and some locations in the WCAs;
- A high atmospheric deposition flux of methylatable mercuric ion from local, regional, and global sources;
- A high rate of net methylation of mercuric ion associated with high concentrations of conducive factors in water and sediment pore water;
- A high bioavailable fraction of methyl mercuric ion;
- The absence of a freeze-thaw cycle and high average annual temperatures that accelerate aquatic metabolic processes;
- High bioaccumulation and biomagnification factors resulting from the complex aquatic and terrestrial food webs;
- The interaction of mercury methylation and bioaccumulation with water quality gradients in total phosphorus, total organic carbon and sulfate; or
- Combinations of the above.

Each of these hypotheses is the subject of intensive scientific investigation under the multi-agency South Florida Mercury Science Program (SFMSP, 1996). In order to guide the development of this integrated scientific approach for understanding mercury contamination in the South Florida ecosystem, USEPA Region 4 developed seven policy-relevant assessment questions to be addressed by the SFMSP (USEPA, 1993; 1996a; 1998: draft):

(1) Magnitude - What is the magnitude of the problem(s) in the Everglades?
(2) Extent - What is the extent of the problem(s)?
(3) Trend - Is the problem(s) getting better, worse, or staying the same?
(4) Cause - What factors are associated with or causing the problem(s)?
(5) Source -What are the sources contributing to the causes and what is the importance of different sources to the problem(s)?
(6) Risk - What are the risks to different ecological systems and species from the stressors or factors causing the problem)s)?
(7) Solutions - What management alternatives are available to ameliorate or eliminate the problem(s)?

Understanding South Florida mercury risks, sources and bioaccumulation, and identifying management appropriate actions has been the subject of an extensive interagency scientific effort (USEPA, 1996a; USGS, 1996c).

Potential Sources and Transport Pathways of Mercury to the Everglades

The sources, distribution, and pathways of transport and transformation of mercury through the South Florida ecosystem are beginning to be understood. Mercury has been sequestered in the vast deposit of oligotrophic, circumneutral Everglades peat over its approximately 5,000 years of natural accumulation. Oxidation and subsidence of these soils following drainage, perhaps enhanced by agricultural cultivation and fertilization, maybe mobilizing this geochemical mercury reservoir. The thousands of miles of man-made canals in the Everglades, with their typically low oxygen concentrations, may provide a primary locale for methylation of mercury and serve as a conduit for its transport through the system in a dissolved form or in association with organic matter. Possible external mercury sources include atmospheric deposition from global background; and deposition resulting from local atmospheric emissions such as fossil-fuel electric power plants, waste incinerators, and paint and agricultural operations.

It is believed that there are six primary transport pathways of mercury species and biogeochemical factors in the Everglades system that warrant consideration in the initial conceptual model of mercury transport:

(1) direct wet and dry atmospheric deposition of soluble and particle-bound mercury species;
(2) exchange of mercury vapor across the air:water interface with and without plant-mediated transport;
(3) plant-mediated mercury vapor deposition;
(4) canal transport of Lake Okeechobee releases and EAA storm water runoff;
(5) ground-water transport of Lake Okeechobee, EAA, and WCA seepage to interior marsh discharge zones;
(6) release from the sediment reservoir.

Atmospheric Deposition

Significant quantities of mercury cycle through air, water and solid phases of the global environment. Mercury cycling through the atmosphere is estimated at about 6 million kilograms/year (Fitzgerald 1986, 1989; Porcella *et al.*, 1992), and additional research indicates that this amount has increased at about 1.5 percent per year over the North Atlantic Ocean (Slemr and Langer, 1992). Deposition of atmospheric mercury has increased since 1850 in lake sediments taken in mid-continental North America (Swain *et al.*, 1992). The rate closely parallels that documented for greenhouse gases, which suggests dependence of both quantities on industrial inputs. Within this global background, regional areas exist which may exhibit higher atmospheric concentrations due to the proximity of urban or industrial activity. The entire southeast coast of Florida is an urban area inhabited by about 6 million people. The operation of solid waste incinerators and fossil-fuel power plants has increased significantly since 1940 (Newman, 1992), presenting the prospect that regional atmospheric mercury might have increased similarly over this same time period.

The predominant wind directions in southeast Florida are from the east-southeast, which cause air masses to be transported from above the Atlantic Ocean, westward over the urban area and across the Everglades. There are many mercury emission sources in the urban areas along the east coast. Mercury is emitted into the atmosphere as a mixture of gases and particulates. As the mercury from individual sources mixes together, the mass of air containing mercury may be transported over the Everglades where it is then potentially deposited through a variety of mechanisms. The most likely mechanism is through wet deposition, with the mercury being washed out by rainfall. The other mechanisms are dry deposition with particulates dropping into the Everglades and gaseous mercury coming into contact with the water or vegetation. The speciation of mercury emissions from local sources and atmospheric chemistry, must be evaluated to determine the depositional contributions to the Everglades ecosystem. The atmospheric mercury flux was monitored across the South Florida peninsula by the Florida Atmospheric Mercury Study (FAMS). The emissions from three atmospheric point sources located in the urban area (municipal waste incinerator, medical waste incinerator and a coal-fired cement kiln) were monitored and modeled by the South Florida Atmospheric Mercury Monitoring Pilot Study (SOFAMMS).

A summary of the general findings of the FAMS, SOFAMMS, and other atmospheric studies are listed below.

- The average annual mercury emissions for South Florida (0.48 kg/m^2/yr) are three times higher than the state average (KBN, 1992; Baker and Roberson, 1994; KBN, 1994).
- Mercury in precipitation in South Florida is twice as high as in other rural areas of North America (W. Landing: Florida State University (FSU), 1995 personal communication).
- Point source monitoring in the urban area showed mercury concentrations in rain at three to five times levels found in industrial areas near the Great Lakes (Dvonch *et al*., 1995).
- Local sources in the urban area are emitting mercury primarily as ionic mercury. In this form, the mercury is capable of rapid deposition to nearby areas (J. Keeler, University of Michigan, 1997 personal communication).
- The contribution from local anthropogenic sources of mercury in wet deposition into the Everglades has been estimated to range from 30 percent (W. Landing: FSU, 1997 personal communication) to 100 +/- 18 (Dvonch, 1998) percent.

Using the mean annual rainfall rate for the Everglades of 53 inches (SFWMD, 1992) and a volume- and spatially-weighted average total mercury concentration in Everglades rainfall of about 13 micrograms/cubic meter (J. Guentzel: FSU, 1995 personal communication), it can be calculated that about 150 kg per year of mercury are being deposited by rainfall for the remnant Everglades. Dustfall would further contribute to mercury atmospheric deposition.

Water Discharge From the Everglades Agricultural Area

Surface flow of water may be an important transport mechanism which moves sediment, phosphorus, and inorganic and organic mercury off the EAA via canals to the downstream WCA and the ENP. Mercury loading to the public Everglades was estimated from bi-weekly monitoring of water samples that were collected at S-5, S-6, S-7 and S-8; the structures bordering the EAA; during 1994, 1995, and 1996 (USEPA, 1998: draft). Sampling at these four structures was used to estimate the mass transport of mercury through the canal system from the EAA to the publicly-owned system downstream. The loading of total mercury in the water flowing south through the structures was estimated at 0.5 to 0.6 kg during the dry season and 1.3 to 2.7 kg during the wet season. Annual estimates of total mercury loadings from the EAA ranged from 1.8 to 3.3 kg/yr. Estimates of the loading of methylmercury flowing through the structures was 0.1 to 0.2 kg during the dry season and 0.2 to 0.4 kg during the wet season. Annual estimates of methylmercury loading from the EAA ranged from 0.3 to 0.6 kg/yr. Potential mercury transport through levee seepage, ground-water movement, or particle transport has not been assessed; however, it is clear that water transport of mercury from the EAA into the public Everglades is much less significant than that deposited from the air.

Water Quality Patterns

The methylation of inorganic mercury to its bioaccumulated form methylmercury occurs under a unique set of environmental conditions. These conditions include anoxia (Matilianen, 1995), moderate sulfate concentrations (Gilmour *et al*., 1993), moderate dissolved organic carbon concentrations (Driscoll *et al*., 1995; 1997), and low pH and/or alkalinity concentrations (Rudd 1995; Rudd *et al*., 1997). In general, oligotrophic, rather than eutrophic, aquatic ecosystems have mercury contamination problems. Wetlands are particularly conducive to mercury methylation (Rudd *et al*., 1997; Zillioux *et al*., 1993). In general, southern and southeastern aquatic ecosystems under fish consumption advisories have these water quality characteristics (Southern States Mercury Task Force, 1997). The FDEP, SFWMD, USEPA and USGS, along with other agencies and universities, have been and are continuing to actively study the South Florida mercury contamination problem. USEPA (1996a; 1998: draft) has been monitoring mercury conditions throughout the Everglades and Big Cypress in fish, water, soil, and periphyton. The USGS has been conducting extensive Everglades mercury geochemical cycling research, including work on methylmercury degradation, carbon-mercury interactions, sulfur cycling, mercury accumulation and processes in peat, and biological mercury uptake (USGS, 1996c). The SFWMD has been investigating mercury behavior in the Everglades Nutrient Removal (ENR) Project, a research project similar to the STAs, constructed and managed to remove phosphorus.

Mercury Measurement

Due to the extremely low ultra trace levels of total mercury (THg) and methylmercury (MeHg) occurring in water, clean sampling and analytical techniques must be used to make valid measurements. Total and methylmercury concentrations in water are reported in nanograms per liter (ng/L, which equates to parts per trillion: ppt). Total and methylmercury concentrations in soil and periphyton are reported in g/kg (parts per thousand: ppt). Tissue concentrations of total mercury in mosquitofish are reported in µg/kg (ppb) while largemouth bass and other top aquatic predators are reported in mg/kg (parts per million: ppm) indicating the extremely efficient bioaccumulation of mercury up the aquatic food chain.

H.1.3.2.2 Phosphorus

Phosphorus is a nutrient that often controls primary productivity in aquatic systems. It occurs naturally in water bodies throughout the world. Elevated phosphorus loading to water bodies often results in biological changes. These effects may include increased primary productivity, loss of water column dissolved oxygen, algal blooms, and changes in biodiversity. This may result in the loss of a water body's usefulness for recreation or as habitat for wildlife.

Description

Phosphorus exists in a dissolved or solid state. The source and ultimate depository for it is in sediments. Water concentrations are reported in milligrams per liter (mg/L), which equates to parts per million (ppm), or micrograms per liter (µg/L), which equates to parts per billion (ppb). Unpolluted fresh waters tend to be relatively low in total phosphorus with almost no detectable inorganic phosphorus. For example, in unimpacted Everglades wetlands, the long-term surface water total phosphorus concentration has an average of 10 µg/L or less (Walker, 1995). Phosphorus has been identified as a primary cause of eutrophication and in recent years has been the focus of intense management efforts. Natural sources of phosphorus to surface waters include wet and dry atmospheric deposition and ground water. Excess phosphorus enters natural systems as a result of many human activities, with runoff (urban, agriculture, construction, development), sewage, and sewage treatment effluents being chief among them. At this time, there are no Florida numeric water quality standards for phosphorus.

H.1.3.2.3 Pesticides

Florida's economy is anchored to a large extent on the year-round growing season that allows agriculture to flourish. A key to agricultural success is the ability to protect the agricultural crop from pests such as insects, weeds, fungi, bacteria, etc. through the use of pesticides. In addition to the use of pesticides to control agricultural pests, Florida also uses pesticides to battle the aquatic weed problem which is so pervasive in Florida waterways. Movement of surface water and use of these waters could be severely impacted, were it not for the use of aquatic herbicides. Another key use of pesticides in Florida involves mosquito control—both for nuisance and public health. Mosquito control districts in Florida utilize both larvacides and adulticides to control this pest, which is so prevalent in the state. Application of these pesticides may be either by ground or air and are many times adjacent to centers of high population as well as sensitive environments where the mosquito is breeding. Lastly, it should be remembered that Florida's population and its tourism industry has grown tremendously over the recent years.

Many of the attractions (e.g., theme parks, golf courses) rely on pesticides to ensure that these properties do not succumb to pests that are pervasive in the Florida climate and thus remain attractive to residents and visitors.

Pesticides are registered by the USEPA after extensive testing results have been submitted by the registrant regarding impacts on human health and the environment. Once registered by the USEPA, a pesticide must be used in accordance with the registered label, as prescribed by the USEPA. When used in accordance with the label directions, the USEPA does not expect that any unreasonable adverse effects on either human health or the environment will occur. This does not mean, however, that adverse effects do not happen. The USEPA has a requirement that registrants must report these adverse effects to the Agency so determinations about future registration and/or labeling requirements can be made.

An extensive array of pesticides is being applied to (or persists in) South Florida waters, sediments and/or soils. These pesticides include those in the following sections.

Description

DDT and Derivatives

DDT (dichlorodiphenyltrichloroethane) is no longer registered for use in the United States, although it is still used in other (primarily tropical) countries. It is in USEPA Toxicity Class II. It is moderately toxic and was banned from use in the United States in 1972, barring a public health emergency (e.g., outbreak of malaria).

DDT is an organochlorine insecticide used mainly to control mosquito-borne malaria; use on crops has generally been replaced by less persistent insecticides. It was extensively used during the Second World War among Allied troops and certain civilian populations to control insect typhus and malaria vectors. It was extensively used as an agricultural insecticide after 1945. DDT was banned for use in Sweden in 1970 and in the United States in 1972.

Technical grade DDT is actually a mixture of three isomers of DDT, principally the p,p'-DDT isomer (ca. 85%), with the o,p'-DDT and o,o'-DDT isomers typically present in much lesser amounts.

DDT may be slightly toxic to practically non-toxic to birds. In birds, exposure to DDT occurs mainly through the food web through predation on aquatic and/or terrestrial species having body burdens of DDT, such as fish, earthworms and other birds.

There has been much concern over chronic exposure of bird species to DDT and effects on reproduction, especially eggshell thinning and embryo deaths. The mechanisms of eggshell thinning are not fully understood. It is thought that this may occur from the major metabolite, DDE, and that predator species of birds are the most sensitive to these effects.

DDT is very highly toxic to many aquatic invertebrate species as well as to fish species. In addition to acute toxic effects, DDT may bioaccumulate significantly in fish and other aquatic species, leading to long-term exposure. This occurs mainly through uptake from sediment and water into aquatic flora and fauna, and also fish.

The reported bioconcentration factor for DDT is 1,000 to 1,000,000 in various aquatic species. Bioaccumulation may occur in some species at very low environmental concentrations. Bioaccumulation may also result in exposure to species which prey on fish or other aquatic organisms (e.g., birds of prey).

DDT is very highly persistent in the environment, with a reported half-life of between 2-15 years. It is immobile in most soils. Routes of loss and degradation include runoff, volatilization, photolysis and biodegradation (aerobic and anaerobic). Breakdown products in the soil environment are DDE and DDD, which are also highly persistent and have similar chemical and physical properties.

Due to its extremely low solubility in water, DDT will be retained to a greater degree by soils and soil fractions with higher proportions of soil organic matter. It may accumulate in the top soil layer in situations where heavy applications are (or were) made annually. Generally, DDT is tightly absorbed by soil organic matter, but it (along with its metabolites) has been detected in many locations in soil and ground water where it may be available to organisms. This is probably due to its high persistence. Although it is immobile or only very slightly mobile, over very long periods of time it may be able to eventually leach into ground water, especially in soils with little soil organic matter.

Numerous references searched in 1998 from the web site of the University of Oregon's Extension Toxicology Network (EXTONET, 1998: internet) were used to compile this DDT and derivatives description. These references were: Augustijn-Beckers *et al.* (1994), the Agency for Toxic Substances and Diseases Registry (ATSDR)/U.S. Public Health Service (1994), Meister (1992), the Royal Society of Chemistry Information Services (1991), the World Health Organization (WHO) (1989), USEPA (1989a), Hudson, *et al.* (1984), and Johnson and Finley (1980).

Atrazine

Atrazine is a selective triazine herbicide used to control broadleaf and grassy weeds in corn, sorghum, sugarcane, pineapple, Christmas trees and other crops, and in conifer reforestation plantings. It is also used as a non-selective herbicide on non-cropped industrial lands and on fallow lands. A shelf life of three years can be expected under environmental conditions in unopened, undamaged original containers.

Atrazine is only slightly toxic to birds, fish and other pond or stream life and is noted as being non-toxic to bees.

Atrazine is moderately-to-highly mobile in soils, especially where soils have low clay or organic matter content. Because it does not absorb strongly to soil particles and it has a lengthy soil half-life, it is expected to have a high potential for ground-water contamination, even though it is only moderately soluble in water. Atrazine, however, is not normally found below the first foot of soil, even after years of continuous use.

Atrazine is not very water soluble. Chemical hydrolysis, followed by biodegradation, may be the most important route of disappearance from aquatic environments. Hydrolysis is rapid under acidic or basic conditions, but is slower at neutral pHs. Addition of humic material increases the rate of hydrolysis. Atrazine is not expected to strongly adsorb to sediments.

The Florida Department of Agriculture and Consumer Services (FDACS) is currently reviewing a copy of a registrant's drinking water well survey which encompassed 52 wells in the south Florida area predominated by sugarcane production. The registrant has also supplied FDACS with a report on atrazine in shallow ground water associated with sod production in Florida. This pesticide will be addressed by Florida in the Pesticide State Management Plan (PSMP) as required by the USEPA.

Relevant references for this Atrazine section searched from EXTONET (1998: internet) were Meister (1992), U.S. Department of Agriculture, Soils Conservation Service (USDA/SCS) (1990), Weed Science Society of America (WSSA) (1989), and USEPA (1988a).

Simazine

Simazine is a selective triazine herbicide. It is used to control broad-leaved weeds and annual grasses in field, berry fruit, vegetable and ornamental crops, on turfgrass, and in orchards and vineyards. At higher rates, it is used for nonselective weed control in industrial areas. Before 1992, simazine was used to control submerged weeds and algae in large aquariums, farm ponds, fish hatcheries, swimming pools, ornamental ponds, and cooling towers.

Simazine is persistent and does not adsorb strongly to soil particles (K_{oc} = 138 g/mL). In combination with a lengthy soil half-life, these factors suggest that simazine is likely to contaminate ground water. Its tendency to leach is limited by its low solubility in water (6.2 µg/mL). Simazine is subject to decomposition by ultraviolet radiation, but this effect is small under normal field conditions. Loss from volatilization is also insignificant. In soils, microbial activity probably accounts for decomposition of a significant amount of simazine. Simazine has little if any lateral movement in soil, but can be washed along with soil particles.

The average half-life of simazine in ponds where it has been applied is 30 days, with the actual half life dependent on the level of algae present, the degree of weed infestation, and other factors.

Simazine has been found in surface water in 16 states and in ground water in 8 states. The maximum levels detected were 1,300 µg/L in surface water and 800 µg/L in ground water.

A drinking water well survey of 47 wells was conducted by a registrant and results were provided to FDACS. This pesticide must also be addressed by Florida under the PSMP.

Literature consulted through an EXTONET (1998: internet) search in 1998 to develop this Simazine description was Meister (1992), USDA/SCS (1990), WSSA (1989), and USEPA (1988b).

Ametryn

Ametryn is a selective herbicide used to control annual broadleafs and grassy weeds. Possible crop uses in Florida include grapefruit, orange, sugarcane and corn. This herbicide is a member of the Triazine chemical family and inhibits photosynthesis and other enzymatic processes.

Ametryn is only slightly toxic to birds and bees, moderately toxic to fish and mollusks and highly toxic to crustaceans.

Ametryn's half life in soils is 70 to 250 days, depending on the soil type and weather conditions. Loss from the soil is principally by microbial degradation. Ametryn moves both vertically and laterally in soil due to its high water solubility. Because it is persistent, it may leach as a result of high rainfall, floods, and furrow irrigation.

In a study of surface and ground-water contaminants in the U.S., ametryn was found in six states, in very few surface water samples and in 4% of the ground-water samples. The maximum concentration found was 0.1 µg/L in surface water and 450 µg/L in ground water.

Information for this ametryn summary was compiled from an EXTONET (1998:internet) search in 1998. References used were the Royal Society of Chemistry Information Systems (1994), Meister (1992), Briggs (1992), USEPA (1989b), USEPA (1987a), and Thompson (1982).

Endosulfan Compounds

Endosulfan is a chlorinated hydrocarbon insecticide of the cyclodiene subgroup which acts as a contact poison in a wide variety of insects and mites. It can also be used as a wood preservative. It is used primarily on food crops like tea, fruits, vegetables, and on grains.

The commercial product is made up of a mixture of two separate parts (isomers): the alpha and beta configurations.

Endosulfan does not easily dissolve in water. It does stick to soil particles readily. Transport of this pesticide is most likely to occur if endosulfan is attached to soil particles in surface runoff. Large amounts of endosulfan can be found in surface water near areas of application. It has also been found in surface water throughout the country at very low concentrations and has been detected in the air at minute levels. It is not expected to pose a threat to ground water.

In raw river water at room temperature and exposed to light, both isomers disappeared in four weeks. A breakdown product first appeared within the first week. The breakdown in water is faster (five weeks) under neutral conditions than at more acidic conditions (five months). Under strongly alkaline conditions the half life of the compound is one day.

The two isomers have different degradation times in soil. Under neutral conditions, the half life for the alpha isomer is 35 days, and 150 days for the beta isomer. These two isomers will persist longer under more acidic conditions. The compound is broken down in soil by fungi and by bacteria.

The breakdown product, endosulfan sulfate, has been observed in several field studies involving plants. The sulfate is more persistent than the parent compound, accounting for 90% of the residue in 11 weeks. Sulfate formation increases as temperatures increase. However, sunlight may play a role in the reaction, perhaps in starting the process. On most fruits and vegetables, 50% of the parent residue is lost within three to seven days.

An interagency study, funded by the USEPA, is ongoing in south Miami-Dade county to assess the impact endosulfan might have on local waters. Pesticide detection data collection from monitoring programs and surface water studies is still ongoing. Mitigation strategies, including retrofitting of open irrigation wells, additional monitoring at particular structures where multiple detections have been reported, and minimizing runoff have been addressed. NOAA is also continuing to work on an ecotoxicological assessment of endosulfan and other potential endocrine-disrupting chemicals on living marine resources in Florida Bay (Scott et al. 1994; Scott et al. 1995).

References reviewed through an EXTONET (1998: internet) search in 1998 for the development of this description of endosulfan were Howard (1991), U.S. Department of Health and Human Resources (USHHR) (1990), and the National Research Council Canada (1975).

Ethion

Ethion is an organophosphate pesticide used to kill aphids, mites, scales, thrips, leafhoppers, maggots and foliar feeding larvae. It may be used on a wide variety of food, fiber and ornamental crops, including greenhouse crops, lawns and turf. Ethion is often used on citrus and apples. It is mixed with oil and sprayed on dormant trees to kill eggs and scales. Ethion may also be used on cattle. It is available in dust, emulsifiable concentrate, emulsifiable solution, granular and wettable powder formulations.

Ethion adsorbs strongly to soil particles and it is nearly insoluble in water. It is therefore unlikely to leach or contaminate ground water. In open waters, it is likely to adsorb to suspended particles and bottom sediments.

Ethion is very highly toxic to freshwater and marine fishes and to freshwater invertebrates.

Several references used via an EXTONET (1998: internet) search in 1998 to prepare this description for ethion: Meister (1992), Howard (1991), USDA/SCS (1990), USEPA (1989c), Worthing (1987), Van Driesche (1985), USEPA (1984: unpublished), Hartley and Kidd (1983), and Clayton and Clayton (1981).

Bromacil

Bromacil is one of a group of compounds called substituted uracils. These materials are broad spectrum herbicides used for nonselective weed and brush control on non-cropland; as well as for selective weed control on a limited number of crops, such as citrus fruit and pineapple. The herbicide is preferably sprayed or spread dry on the soil surface just before, or during, a period of active weed growth.

Bromacil binds, or adsorbs, only lightly to soil particles (K_{oc} = 32 g/mL), is soluble in water, and has a relatively lengthy soil half-life (60 days). For these reasons, bromacil is expected to move (leach) quite readily through the soil and it can contaminate ground water. The amount of leaching is dependent on the soil type and the amount of rainfall or irrigation water. The potential for bromacil to leach and contaminate ground water is greatest in sandy soils. In regular soils, it can be expected to leach to a depth of 2-3 ft. Bromacil was found in Florida's ground water at 300 parts per billion (ppb). Bromacil should not be used near drinking water reservoirs or in well recharge areas because of its mobility in soil. Directions and precautions listed on product labels must be followed to minimize potential bromacil movement into ground water.

Studies conducted in 1995 indicated that bromacil was present in wells around the Lake Wells ridge area. Although the detections were less than the guidance concentration, the State promulgated a rule which limited the use of this pesticide in certain areas.

The reference used for this bromacil description accessed through an EXTONET (1998: internet) search in 1998 was USEPA (1988c).

2,4-D

The herbicide 2,4-D is a chlorinated phenoxy compound that functions as a systemic herbicide and is used to control many types of broadleaf weeds. There are many forms or derivatives (esters, amines, salts) of 2,4-D and these vary in solubility and volatility. This compound is used in cultivated agriculture, pasture and rangeland applications, forest management, home and garden situations, and for the control of aquatic vegetation.

The 2,4-D herbicide was a major component (about 50%) of the product *Agent Orange* used extensively throughout Vietnam. However, most of the problems associated with the use of Agent Orange were associated with a contaminant (dioxin) in the 2,4,5-T component of the defoliant. The association of 2,4-D with Agent Orange has prompted a vast amount of study on the herbicide.

The herbicide is slightly toxic to wildfowl. Some formulations of this pesticide may be highly toxic to fish.

Despite its short half life in soil and in aquatic environments, the compound has been detected in ground-water supplies in at least five States and in Canada. It has also been detected in surface waters throughout the U.S. at very low concentrations.

Although recently-manufactured 2,4-D technical acids have consistently been free of dioxin contamination, the amine and ester products may have measurable levels of some forms of dioxin. According to a study of 2,4-D manufactured in Canada, 8 were positive of the 26 amine samples tested. The levels ranged from 5 ppb to nearly 500 ppb. Several different forms of dioxin were present in the different products. All but one of 21 ester samples were positive.

References relevant for this section on 2,4-D were available through an EXTONET (1998: internet) search made in 1998. They were: Howard (1991), USEPA (1987b), and the National Research Council Canada (1978).

Other Pesticides

Arsenic (Pesticides-Derived)

A study is under review by FDACS in which shallow monitor wells at municipal golf courses in Miami-Dade County were tested for pesticides. Thirty wells on five golf courses were sampled. The focus of the study was: fenamifos, metribuzin, MSMA (total arsenic), prodiamine and chlorothanlonil. Samples indicated the presence of arsenic (MSMA) in shallow ground water, with several wells above the draft Mean Contaminant Level (MCL) of 50 µg/L.

Aldicarb

Aldicarb is used as a systemic insecticide, acaricide, and nematicide. It is applied to soils to control insects, mites and nematodes on citrus, cotton, dry beans, peanuts, sorghum, soybeans, and pecans. The registrant, due to monitor well detections, filed a 6(a)(2) report with USEPA in 1996 regarding adverse effects.

Fenamiphos

Fenamiphos is a systemic nematicide used to control the major genera of nematodes attaching many field, vegetable, fruit, turf, and ornamental crops. Elevated levels of fenamiphos sulfoxide led the registrant to submit label changes to USEPA to prohibit use at selected counties in the Central Ridge area of Florida.

H.1.4 GENERAL OVERVIEW OF CURRENT REGIONAL WATER QUALITY CONDITIONS

H.1.4.1 Ground-Water Conditions

H.1.4.1.1 Introduction

Ground water in South Florida consists of the surficial Biscayne aquifer and the Floridan aquifer. Both are critical to the ecology and economy of South Florida.

The Biscayne aquifer has been classified as a Sole Source Aquifer under the Safe Drinking Water Act based on the aquifer's susceptibility to contamination and the fact that it is a principal source of drinking water. The aquifer underlies an area of about 4,000 square miles and is the principal source of water for all of Miami-Dade and Broward Counties and the southeastern part of Palm Beach County in southern Florida. Major population centers that depend on the Biscayne aquifer for water supply include Boca Raton, Pompano Beach, Fort Lauderdale, Hollywood, Hialeah, Miami, Miami Beach and Homestead. The Florida Keys also are supported primarily by water from the Biscayne aquifer that is transported from the mainland by pipeline.

The Biscayne aquifer fluctuates in direct and rapid response to variations in recharge (precipitation), natural discharge, and pumpage from wells. Natural discharge is by seepage into streams, canals, or the ocean, and by evaporation or transpiration by plants.

The Floridan aquifer system is one of the most productive aquifers in the world. The aquifer underlies an area of about 100,000 square miles in southern Alabama, Georgia, South Carolina, and Florida. The Floridan is a multiple-use aquifer system. Where it contains freshwater, it is the principal source of water supply. In several places where the aquifer contains saltwater, such as along the southeastern coast of Florida, treated sewage and industrial wastes are injected into it. Near Orlando, drainage wells are used to divert surface runoff into the Floridan. South of Lake Okeechobee, the aquifer contains saltwater. Some of this saltwater is withdrawn for industrial cooling purposes and some is withdrawn and converted to freshwater by desalinization plants. Desalinization is especially important in the Florida Keys, which have no other source of freshwater except that which is imported by pipeline.

H.1.4.1.2 Ground-Water Contamination

Because the Biscayne aquifer is highly permeable and is at or near the land surface in many locations, it is readily susceptible to ground-water contamination. Because of the high permeability of the aquifer, most contaminants are rapidly flushed. Major sources of contamination are saltwater encroachment and infiltration of contaminants carried in canal water. Additional sources include direct infiltration of contaminants, such as chemicals or pesticides applied to or spilled on the land; or fertilizer carried in surface runoff; leachate from landfills, septic tanks, sewage-plant treatment ponds; and wells used to dispose of storm water runoff or industrial waste. Most disposal wells are completed in aquifers containing saltwater that underlie the Biscayne aquifer, but they are a potential source of contamination where they are improperly constructed. Numerous hazardous waste sites (e.g., Superfund and Resource Conservation and Recovery Act [RCRA] sites) have been identified in the area underlain by the Biscayne aquifer. Remedial action to cleanup existing contamination is underway at many of these sites. Waste management practices at these sites are generally monitored to prevent further contamination.

As indicated above, Superfund sites can contribute to ground-water quality degradation through the leaching of site pollutants into ground water (as well as to surface water quality degradation through storm water runoff). The USEPA has completed environmental evaluations which indicate that 24 sites in the general Restudy area pose environmental threats which warrant inclusion on the National Priorities List (NPL). No additional federal cleanup action is necessary at 295 sites. Evaluations continue to be conducted by the USEPA at an additional 225 sites. The evaluation process includes a ground water component to insure protection of the ground water resources in the southern Florida area. The Superfund Program has made significant progress towards environmental cleanup in South Florida since the creation of the program in 1980.

The majority of the sites in the South Florida area are in Miami-Dade and Broward Counties followed by Polk, Palm Beach and Orange Counties. (Urban areas of these counties are located within regions designated in this PEIS as the “Lower East Coast and Biscayne Bay” region, and the “Kissimmee River Region”.) Miami-Dade and Broward Counties currently have 10 and 7 NPL sites, respectively. Although each site poses unique environmental threats, trichloroethylene (TCE) and vinyl chloride are generally identified as contaminants of concern in ground water at these sites. Both of these organic compounds are carcinogens associated with degreasing agents which have enforceable drinking water standards (3 ppb for TCE and 1 ppb for vinyl chloride).

To address area-wide, ground-water contamination in the Miami area, the Superfund Program assisted the City of Miami in the construction of 64 air stripping towers for TCE/vinyl chloride remediation. The Superfund program is currently in the process of developing remediation options to protect the Peele-Dixie Wellfield in Broward County.

The RCRA facilities which Treat, Store and/or Dispose (TSDs) of hazardous waste may contribute to ground-water contamination through past spills and poor waste management practices resulting in the leaching of pollutants into the subsurface. There are approximately 22 TSDs in the general Restudy area, seven (7) of which are in operation. Fourteen of the 22 TSDs are undergoing either closure or post-closure care and the remaining TSD has not yet been permitted. Eleven (11) of the 21 operating, closing, or post-closure-care TSDs required investigation of potential contamination. The investigation of the TSDs included a ground-water component to evaluate potential ground-water contamination and to ensure protection of the ground-water resources in the South Florida area through containment and treatment of the contaminated ground water.

The majority of the RCRA TSDs in the South Florida area: Palm Beach, Broward and Miami-Dade Counties, with 5, 4 and 4 TSDs, respectively; followed by Orange and Monroe Counties with 3 and 2, respectively; and one facility each in Highland, Lee, Osceola and Polk Counties (these counties are located within regions designated in this PEIS as the “Kissimmee River Region,” “Caloosahatche River Region,” “Everglades Agricultural Area,” “Water Conservation Areas,” “Big Cypress Region,” “Lower East Coast and Biscayne Bay” and/or “Everglades National Park and Florida Bay”). As with Superfund sites, though each facility presents unique environmental threats, Non-Aqueous Phase Liquids (NAPLs) and TCE and its daughter products, particularly vinyl chloride, are of greatest concern with respect to ground-water contamination. This is due to the prevalence of these contaminants, the difficulty of remediating and preventing further degradation of the ground water, and the toxicological effects of the contaminants.

In addition to the 22 TSDs in the general Restudy area, there are approximately 450 large quantity hazardous waste generators and 9,000 small quantity generators in the area. These generators are regulated through RCRA by addressing the hazardous waste management standards of the generators. Though it is possible that these generators may contribute to ground-water contamination, data do not exist to confirm this.

H.1.4.2 Surface Water Conditions

H.1.4.2.1 Major Regional Water Quality Concerns

Perhaps the three most important water quality parameters of concern in the C&SF Restudy region are mercury, phosphorus, nitrates, and pesticides. These are discussed below from a regional perspective.

Mercury

Several scientific efforts are underway that are focused at understanding how and why mercury bioaccumulates in Everglades biota. Numerous factors have been implicated as having some influence on mercury cycling within the Everglades marsh system. Among the key factors are complex inter-relationships involving sulfate, sulfide, phosphorus, oxygen, carbon, calcium, peat chemical characteristics, periphyton biomass, macrophyte biomass, biodilution, and aquatic food web structure. At present there is no scientific consensus as to which of these factors dominate, and whether the dominant factors are constant throughout all habitats within the 4,000 square mile Everglades ecosystem. No single factor can explain the mercury concentrations observed in Everglades fish or wildlife. Scientific efforts and the current leading hypotheses and findings can be found in: USEPA (1998: draft); Ambrose *et al*. (1998: in prep); USGS (1996c); and Gilmour *et al*. (1998).

The USEPA (1998: draft) review of mercury water quality conditions in selected portions of the project area considers canal versus marsh areas. It also specifically compares existing mercury conditions in the ENP, WCAs, Big Cypress National Preserve and EAA regions based on the draft results from the South Florida Ecosystem Assessment (REMAP) project. This system-wide (4,000 square mile) research and monitoring project of the Everglades ecosystem was conducted to address mercury contamination, eutrophication, habitat alterations, and hydropattern modification issues (USEPA, 1998: draft). This project strongly supports the federal and State Everglades restoration efforts and will provide a means to evaluate present and future management actions. This project is focused on the ecological risk assessment process and is guided by a set of policy relevant questions. A statistical Environmental Monitoring and Assessment Program (EMAP) survey design was used to select 200 canal and 500 marsh sampling stations, a quarter of which were sampled during successive wet and dry seasons from 1993-96. These data allow quantitative estimation of the relative risk to the ecological resources from multiple interacting environmental threats. The greatest threat to the Everglades ecosystem is to assume that these issues are independent. REMAP strongly supports the federal and State Everglades restoration efforts and will provide a means to evaluate present and future management actions. This effort compliments the mercury biogeochemical research being conducted by the USGS (1996c).

Bioaccumulation and Biomagnification

Wet deposition is thought to be the primary mechanism by which mercury emitted to the atmosphere is transported to surface waters and land, although dry deposition may also contribute substantially. Once deposited, mercury enters aquatic and terrestrial food chains and wetland environments are particularly conducive to the methylation of mercury (Zillioux *et al*., 1993 and Rudd *et al*., 1997). Mercury concentrations increase at successively higher trophic levels as a result of bioconcentration, bioaccumulation and biomagnification. Of the various forms of mercury in the environment, methylmercury has the highest potential for bioaccumulation and biomagnification. Predators at the top of these food chains are potentially at risk from consumption of methylmercury in contaminated prey. The available information shows that piscivorous (fish-eating) birds and mammals are particularly at risk from mercury emissions. This risk is likely to be greatest in areas that receive high levels of mercury deposition, although local and regional factors can substantially impact the amount of total mercury that is translocated from watersheds to waterbodies and undergoes chemical transformation to the methylated species (USEPA, 1997).

Frederick *et al*. (1997) studied the effects of methylmercury exposure on the health, reproduction and survival of wading bird populations in the Florida Everglades. The concern for wading birds arose because this group of animals are, by virtue of their high metabolism and position in the food chain, at high risk of mercury exposure. Concern has also derived from the extreme reduction in breeding numbers in the Everglades observed during the past four decades, and the view that increased breeding numbers is a key goal for the restoration of the ecosystem. Most of these studies were carried out in WCA-3 where the vast majority of the wading bird nesting has occurred in recent decades. Frederick *et al*. (1997) found significant differences in the blood and feather mercury concentrations in great egret chicks among colonies within WCA-3, with samples from a colony in north-central WCA-3 consistently showing the highest mercury values. The distribution among colonies seemed to match the geographic distribution of mercury concentrations in mosquitofish reported by USEPA (1996a; 1998: draft).

Results from both field and laboratory studies showed the cumulative effects of mercury on juvenile and post-fledging birds at levels of mercury intake common in the Everglades (0.33 - 0.75 mg/kg), are likely to result in reduced survival of offspring through reduced body mass, decreased red cell numbers, increased lethargy, increased susceptibility to disease, and increased time to capture fish (Frederick *et al*., 1997); however, they were not able to estimate the magnitude of population level effects.

The risk of mercury contamination to the Florida panther was considered by USEPA (1997). All of the panther's range falls within an area of high mercury deposition. Mercury levels found in tissues obtained from dead panthers are similar to levels that have been associated with frank toxic effects in other feline species. The most highly exposed individuals have been those in the east Everglades which have preyed more intensively on raccoons. The State of Florida has taken measures to reduce the risk to panthers posed by mercury by trying to increase the availability of deer which are not a part of the aquatic food chain. Raccoons frequently feed at or near the top of aquatic food webs and can accumulate substantial tissue burdens of mercury. An evaluation of the risk posed by mercury to the Florida panther is complicated by the possible impacts of other chemical stressors, habitat loss, and in-breeding.

Recent research in the Everglades ecosystem has clearly demonstrated the Bioaccumulation Factors (BAFs) for methylmercury in fish for trophic level 3 (prey fish, mosquitofish) (USEPA, 1998: draft) and level 4 (top predator, e.g., largemouth bass) (Lange *et al.* 1993) are nominally 10^5 or 10^6. However, the Everglades BAFs are strongly influenced by the gradients in total phosphorus, total organic carbon and sulfate entering the system from the north. This results in an inverse relationship in the median BAFs for mosquitofish ranging from 0.6 x 10^5 in WCA-1 to 8.5 x 10^5 in southern ENP. The risk of exposure to higher trophic levels in the system increases to the south. USEPA (1997) estimated a species-specific Wildlife Criteria (WC) for methylmercury over several selected avian and mammalian wildlife. A final WC was then calculated as the lowest mean of WC values for each of the two taxonomic classes (birds and mammals). The final WC for methylmercury was based on individual WC values calculated for mammalian species, and was estimated to be 50 picograms (pg) methylmercury/L in water. Median methylmercury concentrations in water for the Everglades marsh range from 0.538 to 0.151 ng/L or 10 to 3 times higher, respectively, than this proposed criterion. However, high methylmercury concentrations in water are not bioaccumulated into fish due to biodilution and associated changes in the food chain. The stimulatory effects of TP in this system on the methylating microbes is a key component, for it is apparent when the fertilizing effect is minimal in southern ENP the available methylmercury declines in both the water and biota.

Phosphorus

Historically, South Florida waters were low-nutrient waters (i.e., an oligotrophic system). Due to anthropogenic activities, including the ditching and draining of wetlands and the expansion of agricultural practices employing fertilizers, waterbodies from the Kissimmee River southward have become nutrient-enriched to various degrees. This is due to water body receipt of agricultural runoff from such land uses as pastures, truck farming, and sugar cane fields. The Everglades Agricultural Area (EAA) is one such area of farming, although the farming areas surrounding Lake Okeechobee in general have contributed to elevated nutrients in the Kissimmee River, Lake Okeechobee, the Caloosahatchee River, and the Everglades. In addition, urban storm water runoff is another potential source of phosphorus to the Everglades or South Florida coastal systems. Elevated phosphorus loading of waterbodies and the resulting increased water phosphorus concentrations (eutrophication) may have various ecological effects. These effects may include increased primary productivity, loss of water column dissolved oxygen, algal blooms, and changes in vegetation and biodiversity. The significance of such phosphorus loading may be the reduction or loss of water body habitat and/or recreational value.

The nutrient of greatest ecological concern in South Florida is phosphorus. In general, the trend for phosphorus concentrations is a decrease from north

(Kissimmee River and EAA) to south (ENP) since the major anthropogenic sources are in the agricultural areas. Nutrient removal from marsh water is due to the natural water quality treatment processes associated with South Florida wetlands, notably the Everglades. According to the Florida SWIM Plan (SFWMD, 1997), the highest average concentrations of phosphorus for 1990 to 1994 are in water discharged from the Lower Kissimmee River (S-65D basin = 770 ppb), Taylor Creek/Nubin Slough (S-154 basin = 610 ppb), and the EAA (East Beach Drainage District = 560 ppb) the EAA. The lowest concentrations (about 10 ppb) are reported for marsh stations within the ENP (USGS (1996d)). The Florida EFA specifies that a yet-to-be-established numeric phosphorus criterion is to be established for the Everglades by the State of Florida and then approved by the USEPA (no later than December 31, 2003), or a default level of 10 ppb will be implemented. Currently, six (6) Stormwater Treatment Areas (STAs), which are established by the EFA and total 44,000 acres, are being implemented by the SFWMD as part of the USACE Everglades Construction Project (ECP). These STAs are designed to reduce phosphorus levels in agricultural runoff, in addition to the agricultural BMPs being implemented. A research project similar to the STAs, the Everglades Nutrient Removal (ENR) Project, is currently functioning and reducing phosphorus levels to less than 30 ppb. Additional STA treatment (Phase 2) would be needed to reduce concentrations to levels in the range of the 10 ppb default level.

Region-Specific Conditions

The following summary presents a brief description of the current phosphorus conditions in portions of the study area of C&SF Restudy Project:

Kissimmee River Region

The Kissimmee River is the major tributary to Lake Okeechobee and is a major source of lake phosphorus. The major external source of phosphorus in this region is dairy farms and beef cattle farms (SFWMD, 1989). A dairy buy-out program and other efforts are underway to reduce the river phosphorus load. Average phosphorus concentration in the Kissimmee River Basin has been consistently below the target concentration of 0.18 mg/L since June 1991. (ref: SFWMD, 1998a)

Lake Okeechobee

Phosphorus targets for each Lake tributary basin were established in the 1989 Lake Okeechobee Interim Surface Water Improvement and Management (SWIM) Plan (SFWMD, 1989). These targets were set up to reduce phosphorus loading to the lake. Under this SWIM Plan, each basin must either not exceed a total phosphorus (TP) concentration of 0.18 mg/L or maintain its 1989 discharge concentration, whichever is less. Over the past decade, several programs have been initiated to reduce phosphorus loads to Lake Okeechobee. These programs include agricultural BMPs, dairy buy-outs, a regulatory program for non-dairy use of lands, and limiting backpumping to the lake from the EAA. These programs have reduced the phosphorus load from a five-year moving average annual load of about 600 metric tons in the early 1980's to about 450 tons in the mid-1990's. The TP load has not reached target levels, however, since the mid-1990's, load remains about 100 metric tons above the target load. Additional reduction measures may be required. (Refs: SFWMD, 1989; 1998)

Upper East Coast and Indian River Lagoon

Based on the 1996 305(b) report (FDEP, 1996), the average TP concentration in the St. Lucie River within the Upper East Coast region was 0.15 mg/L in the south Fork, 0.31 mg/L in the north, and 0.2 mg/L in the estuary. Woodward-Clyde (1994) report that the mean TP concentration in the south Indian River Lagoon (IRL) was 0.034 mg/L (with a standard deviation of 0.02 mg/L) for the period of 1989 to 1991, while the maximum and minimum concentrations for the same period were 0.18 mg/L and 0.004 mg/L, respectively. (Refs: FDEP, 1996; Woodward-Clyde, 1994).

Everglades Agricultural Area

The EAA is a major source of external phosphorus loading to the Everglades Protection Area (EPA). A program of agricultural BMPs and STAs has been implemented by the State of Florida in order to decrease the load of phosphorus passing from the EAA into the Everglades. The goal of the BMP program is a 25% annual total phosphorus reduction from the EAA relative to a base period, 1979-1988 (pre-BMP implementation in the EAA). The first years during which all lands within the EAA had fully implemented BMPs were 1996 and 1997. According to SFWMD, from 1995 to 1997, the EAA BMP program resulted in a three-year average phosphorus load reduction of 51%, with an annual TP reduction statistical variability of plus or minus 18%. (SFWMD, 1997)

Water Conservation Areas

Eutrophication due to anthropogenic phosphorus poses a long-term threat to the oligotrophic Everglades marsh, including the Everglades Water Conservation Areas WCAs). Walker (1995) summarized phosphorus data from 1973-1991 which clearly shows a gradient with high phosphorus concentrations of 100 to 250 ppb at WCA inflows from the EAA, decreasing downstream to below 10 ppb at remote marsh stations within the ENP. Phosphorus impacts that have been documented in the WCAs include effects on microbial populations, major changes in periphyton species composition, reduced algal species diversity, increases in algal growth rates, loss of water column dissolved oxygen, increases in soil phosphorus concentrations, and marsh vegetation changes such that cattails replace sawgrass. A major focus of the BMP and STA program mentioned above is preventing further phosphorus impacts in the WCAs. (SFWMD, 1992a)

Lower East Coast and Biscayne Bay

Biscayne Bay is a shallow subtropical estuary with an urban watershed. Much of the bay has been designated as a national park. The bay receives storm water and surface water runoff delivered by flood control canals along the urban Lower East Coast. Phosphorus levels are low to moderate in the central and southern bay and are slightly higher in the northern bay. (SFWMD, 1994)

Everglades National Park and Florida Bay

Environmental problems occurring recently in Florida Bay include sea grass die-offs, sponge die-offs, and algal blooms. Extensive data exist on Florida Bay nutrient sources and the relationships of nutrients to sea grass die-offs and algal blooms. Much uncertainty remains as to the relative importance of internal nutrient cycling versus external nutrient sources. Once the sources are clearly understood, mechanisms for controlling the nutrient sources and sinks must be identified. Considerable research and monitoring is directed at understanding these Florida Bay nutrient issues. (Boesch *et al.*, 1997)

Florida Keys

Adjacent to the Florida Keys land mass are a variety of marine environments, including sea grass meadows, mangrove islands, and extensive living coral reefs. These environments support rich biological communities. Water quality plays a critical role in the preservation of these sensitive natural resources. Among the phosphorus-related water quality concerns in the Keys are: septic leachate from on-site disposal systems, sewage discharges from live-aboard vessels, discharges from sewage treatment plants, and storm water runoff. Federal, State and local officials are working to implement identified corrective actions for these anthropogenic sources of nutrient loading. (USEPA, 1996b)

Big Cypress Region

The Big Cypress Swamp was set aside as a national preserve (Big Cypress National Preserve) in order to assure the preservation, protection and conservation of the natural, hydrologic, floral and faunal, and recreational values of the watershed. This wetland system receives much of its surface water from outside its political boundary. As such, the Big Cypress Swamp depends upon upstream areas for surface water. A recent analysis of available water quality data, including phosphorus, did not indicate any clear problems within the Preserve. However, expanding agricultural operations upstream in the Big Cypress watershed presents a continual and potentially serious threat to the integrity of the quality of waters entering the Preserve. (Ref: USDOI, 1996).

Caloosahatchee River Region

Urban land use can be an important influence on water quality. The USGS (1996a) reports that urban storm water runoff from Fort Myers and La Belle have contributed significant amounts of nutrients to the Caloosahatchee River. (Ref: USGS, 1996a). Agricultural land uses (citrus, ranch, and fruit and vegetables) in the basin also contribute point and non-point sources of pollution to basin waters.

Pesticides

The South Florida region is unique in that a very large and sensitive ecosystem exists in the midst of an evergrowing urban population and an extensive and intensive agricultural production area. A variety of pesticides are used in this area for a number of different reasons. Major uses are ground and/or aerial applications related to agricultural production, mosquito control, aquatic plant growth in local waterways, golf course maintenance, and homeowner lawn and vegetation maintenance.

Pesticides used in the above situations are effective in controlling the pest at hand; however, the use of pesticides may also pose possible threats to the sensitive ecosystems in Florida due to the intense year-round agriculture, coupled with the shallow water tables and the ever-increasing urban sprawl that demands an increasing supply of quality water.

Three major areas of agricultural production are present in South Florida:

(1) Miami-Dade County (which, relevant to agriculture, is located in the region designated in this PEIS as the Lower East Coast and Biscayne Bay);

(2) the agricultural areas surrounding Lake Okeechobee (consisting of Palm Beach, Hendry, Glades and Martin Counties, which, relevant to agriculture, are located in the regions designated in this PEIS as the Kissimmee River Region, Upper East Coast and Indian River Lagoon, Lower East Coast and Biscayne Bay, Everglades Agricultural Area, Big Cypress Region, and Caloosahatchee River Region);

(3) Collier County (which is located in the regions designated in this PEIS as the Big Cypress Region and the Caloosahatchee River Region).

Miami-Dade County ranks among the top counties in winter vegetable production in the U.S. and is number one in tropical fruit production. Agriculture in the four EAA counties include sugar cane and truck farming. Collier County has approximately one-third of its land utilized for agricultural purposes. Pesticide transport to the ENP (which is the region designated in this PEIS as the Everglades National Park and Florida Bay) from these three major agricultural areas can occur through hydrological connection to the Park from all three areas.

Pesticide Monitoring and Other Studies

The only long-term pesticide monitoring in the C&SF Restudy project area is being conducted by the SFWMD (R. Pfeuffer: SFWMD, 1998 personal communication). The District has maintained a pesticide monitoring program in South Florida since 1984. The pesticide monitoring network includes sites designated in the Everglades National Park Memorandum of Agreement, the Miccosukee Tribe Memorandum of Agreement, the Lake Okeechobee Operating Permit and the Non-ECP Structure Permit. The monitoring provides data to determine the condition or changes in the quality of water being delivered to Lake Okeechobee, ENP, and the WCAs and Florida Bay. Additional pesticide residue data are collected to determine water quality conditions at the major water control structures throughout the District. The data collected for each sampling event provide information on potential short-term, acute environmental effects for any of the compounds detected. An indication of possible fish toxicity, bioaccumulation for wildlife, or human health impacts can also be inferred from the data. The program has been dynamic over time, as concerns arise about pesticide use within the District, to accommodate sampling for new pesticides and the addition of sampling sites to the network. The current monitoring program consists of analyses for 66 pesticides at 37 sites within District boundaries. This set of compounds includes chemicals currently utilized in the associated agricultural areas, chemicals regulated by Florida's Surface Water Quality Standards (F.A.C. 62-302), and restricted-use pesticides.

SFWMD pesticide monitoring data for 1992-1997 are presented in Table H.1.5.2.1.3.2-1. Data are for monitoring sites in various areas in South Florida, including regions and subregions designated in this PEIS (e.g., St. Lucie River, Indian River Lagoon, Everglades Agricultural Area, Caloosahatchee River). This table discusses changes in the rate of pesticide detections at monitoring sites between 1992 and 1997 in the context of a flexible monitoring program that is frequently adjusted to define the types and amounts of pesticides entering the South Florida environment. It should be noted that the existing Florida Criteria for Surface Water Quality Classifications, F.A.C. Section 62-302.530, does not list many contemporary pesticides such as ametryn, atrazine, hexazinone, bromacil, norflurazon, and simazine. These six pesticides rank in the top 10 for number of detections between 1992 and 1997. For pesticides not specifically listed, the acute or chronic toxicity criteria under Surface Waters, Minimum Criteria (F.A.C. 62-

302.500) are utilized. The acute and chronic toxicity standards are calculated as one-third and one-twentieth, respectively, of the amount lethal to 50% of the test organisms in 96 hours, where the 96-hour LC50 (i.e., Lethal Concentration for 50% of the test subjects) is the lowest value which has been determined for a species significant to the indigenous aquatic community (F.A.C. 62-302.200). It is noted, however, that finding LC50 data for aquatic species indigenous to South Florida aquatic ecosystems can be difficult.

A snapshot of the SFWMD pesticides monitoring program is presented by Miles and Pfeuffer (1997). This publication describes the results of the monitoring program between November 1991 through June 1995, while estimating pesticide usage during this same period in the South Florida area. Sugarcane, citrus and vegetable crops comprise the major crops in this area, based on acreage, with approximately 428,000, 213,000 and 155,000 cultivated acres, respectively. This accounts for all of Florida's sugarcane and approximately 38% of the citrus and 42% of the vegetables. Estimated pesticide usage in the area was approximately 14,590 tons per year, which exceeded a USEPA estimate of 10,500 tons per year. The difference is most likely related to the large amount of agricultural area in the SFWMD. Of the 14,590 tons of pesticides used in this area, approximately 38% were insecticides, 20% were herbicides, 19% were fungicides and nematicides, and 24% were fumigants. Atrazine, ametryn, bromacil, simazine, and norflurazone were the most frequently detected pesticides in surface water samples, while DDE, DDD and ametryn were the most frequently detected in the sediment samples. Previous pesticides work in this general area was conducted by Scheidt (1989) who identified a total of 88 compounds (including 41 insecticides, 29 herbicides, 15 fungicides and 3 fumigants) as being used in agricultural production in this area.

In addition, monitoring of ground water for pesticides by the FDACS has been ongoing since the early 1980's. FDACS seeks to maximize the probability of identifying pesticide residues in existing drinking water wells by:

- concentrating efforts on pesticides identified as being mobile and known to be used in Florida agricultural production

- selecting counties that possess significant agricultural production overlying susceptible soils and ground-water hydrology

- carefully targeting the wells sampled based on documented historical use of one or more of the listed pesticides.

During 1983-1987, FDACS monitored 897 wells in 21 counties for aldicarb and its metabolites, aldicarb sulfone, and aldicarb sulfoxide. Twenty-four of the wells were positive for aldicarb and/or one of its metabolites. A Collier County study conducted by FDACS in 1986-87 reviewed pesticide use in an area where tomatoes and other vegetables were major crops, with citrus also becoming a major crop. Only bromacil was reported above the level of detection and was found in a citrus grove.

NOAA is also working on an ecotoxicological assessment of endosulfan and other potential endocrine-disrupting chemicals on living marine resources in Florida Bay (Scott et al. 1994; Scott et al. 1995).

H.1.4.2.2 Regional 303(d) Impaired Waters

Section 303(d) of the Federal Clean Water Act and the USEPA Water Quality Planning and Management Regulations (40 CFR Part 130) require states to develop Total Maximum Daily Loads (TMDLs) for their water bodies that are not meeting designated uses under technology-based controls for pollution. The TMDL process establishes the allowable loadings of pollutants or other quantifiable parameters for a water body based on the relationship between pollution sources and instream water quality conditions, so that states can establish water-quality-based controls to reduce pollution from both point and nonpoint sources and restore and maintain the quality of their water resources. The Section 303(d) list, which is prepared every two years, is based on priority water bodies identified as part of the Florida Surface Water Improvement and Management (SWIM) Act and data from the 1996 FDEP 305(b) report (FDEP, 1996).

The SWIM Act directed the state to develop management and restoration plans for preserving or restoring priority water bodies. The legislation designated a number of SWIM water bodies. The SWIM water bodies in Southwest Florida are Tampa Bay, Rainbow River, Crystal River/Kings Bay, Lake Panasoffkee, Charlotte Harbor, Lake Tarpon, Lake Thonotosassa, Winter Haven Chain of Lakes, and Sarasota Bay. In South Florida the water bodies are Lake Okeechobee/Kissimmee River, Biscayne Bay, Indian River Lagoon, Everglades/East Everglades/Holey Land/Rotenberger, Upper Kissimmee Chain of Lakes, and the Florida Keys. For all of the water bodies listed above except the Upper Kissimmee Chain of Lakes and the Florida Keys, the SWIM plan has been approved and the SFWMD has begun restoration.

Impaired Section 303(d) Waters

Table H.1.5.2.2.2-1 presents the regions and associated waters (waterbodies/water segments) that are listed as impaired on the 1998 Section 303(d) list pursuant to Section 303(d) of the CWA. Over 160 waterbodies/water segments within the study area are so listed. The table lists both the nomenclature of the regions as designated in Section 303(d)of the CWA, as well as the corresponding regions (or parts of regions) as designated in this PEIS. These regions and corresponding regions are: Kissimmee River Basin (PEIS: Kissimmee River

Region), Lake Okeechobee (PEIS: Lake Okeechobee), Caloosahatchee River Basin (PEIS: Caloosahatchee River Region), Everglades-West Coast or Big Cypress (PEIS: Big Cypress Region and Everglades National Park and Florida Bay), and Southeast Florida Basin (PEIS: Upper East Coast and Indian River Lagoon, Everglades Agricultural Area, Water Conservation Areas, Lower East Coast and Biscayne Bay, Everglades National Park and Florida Bay, and Florida Keys). Specific water quality concerns are discussed below for each of these regions. It may be noted that portions of the ENP are located in both the Everglades-West Coast or Big Cypress region and the Southeast Florida Basin presented in the 1996 305(b) report.

Table H.1.5.2.2.2-1
Constituents of Section 303(d) Concern for Regions in South Florida.

Region § 303(d) and (PEIS)	Number of Water Segments listed on § 303(d) list	Primary Constituents of Concern
Kissimmee River Basin (Kissimmee River Region)	25	DO, nutrients, and coliforms
Lake Okeechobee (Lake Okeechobee)	12	nutrients, DO, coliforms
Caloosahatchee River Basin (Caloosahatchee River Region)	8	nutrients, coliforms, DO, Biochemical Oxygen Demand (BOD)
Everglades-West Coast or Big Cypress (Big Cypress Region and Everglades National Park and Florida Bay)	13	nutrients, DO, and BOD
Southeast Florida Basin (Upper East Coast and Indian River Lagoon, Everglades Agricultural Area, Water Conservation Areas, Lower East Coast and Biscayne Bay, and Everglades National Park and Florida Park)	87	nutrients, DO, mercury, BOD, coliforms
Florida Keys (Florida Keys)	1	NA

Kissimmee River Basin (PEIS: Kissimmee River Region)

The major land uses in the Kissimmee River Basin are agriculture, rangeland and urban development. The pollution sources are hydrologic modification, dairies, and ranching. Water quality in the river between Lake Kissimmee and Lake Okeechobee varies from north to south. From Lake Kissimmee to near Lake Okeechobee, water quality is fairly good. As the river approaches Lake Okeechobee, cattle and dairies grow more numerous. Along the channel, water rich in nutrients and BOD flows quickly to Lake Okeechobee, exacerbating eutrophication. Recently, efforts were made to restore parts of the river to its natural, meandering course by strategically placing weirs in the channel. In those sections, the river has returned to its original floodplain, effectively re-creating the buffering wetlands.

Land purchases, design plans, and monitoring continue toward the restoration goal of 32,000 acres. The governor supports a multimillion-dollar plan to return the Kissimmee River to its natural state, but funding has not been fully established. In 1992, President George Bush allocated $5 million for restoration. Plans included backfilling part of the canal, excavating some of the channel, and raising the regulated levels of the upper basin's lakes to allow more natural water flows. The USACE has prepared an Environmental Impact Statement (EIS) on the restoration of the Kissimmee River. The USACE, together with the SFWMD, have initiated project construction.

Twenty-five water segments in the Kissimmee Basin are listed on the 1998 Section 303(d) list. Several water segments are slated for TMDL development in 1999. The TMDL scheduled to be developed is for phosphorus only. The segments include: Chandler Slough, S-65D, Oak Creek, and a southern segment of Kissimmee River. The SFWMD has completed a Pollutant Load Reduction Goal (PLRG) for nutrients for these segments (*Note*: a PLRG is similar to a TMDL and will ultimately be transformed into a TMDL).

Lake Okeechobee (PEIS: Lake Okeechobee)

The major land uses in the Lake Okeechobee Basin are agriculture, wetlands, and improved pasture. The major pollution sources are dairies and agriculture. In recent years, several widespread algal blooms and at least one major fish kill launched the environmental community and governmental agencies into intense investigation and analysis of the lake's problems. The SFWMD has initiated a number of biological, chemical, and ecological research studies, and plans are being submitted to stem lake pollution. An FDEP dairy rule requires BMPs for dairies. By 1991, all 52 dairies in the Lake Okeechobee drainage basin had to sell and remove their cattle or else comply with the rule.

Lake Okeechobee benefitted from Florida's Everglades Forever Act because about 20 tons of phosphorous, 500 tons of nitrogen, and a number of other pollutants were diverted from the lake annually. Despite these efforts, phosphorus limits established for the lake by the legislature in 1992 have not been met. SFWMD research indicates that because the lake's phosphorus is internally recycled and a vast reservoir of the nutrient is stored in lake sediments as well as lake wetland and canal sediments, phosphorus may not reach acceptable levels for many decades or even a century. New actions will be needed to reduce pollution where tributaries enter the lake.

TMDLs for phosphorus are slated to be developed for all 12 listed water segments in Lake Okeechobee in 1998. The SFWMD has completed a PLRG for nutrients for all segments.

Caloosahatchee River Basin (PEIS: Caloosahatchee River Region)

The major land uses in the Caloosahatchee River Basin are rangeland, agriculture, wetlands, and urban development. The major pollution sources are hydrologic modification, agriculture, and urban areas.

The upper portions of the river near Lake Okeechobee frequently violate DO standards and has high conductivity and nutrient levels from low flows and agricultural drainage. Nine-Mile Canal, which drains agricultural fields, has very poor water quality, and pollution-tolerant species dominate biological samples. Water quality improves down-river near Alva where the river has more natural tributaries and old channels. The estuary portion of the river is affected by high-nutrient waters from the river and tributaries and storm water runoff from cities. Nutrient and chlorophyll levels are high, and small algal blooms occur regularly.

Eleven water segments in the Caloosahatchee River Basin are listed as high or low priorities on the 1998 Section 303(d) list.

Big Cypress Region (PEIS: Big Cypress Region and Everglades National Park and Florida Bay)

The major land uses in the Big Cypress region are wetlands, agriculture, rangeland, and urban development. The major pollution sources are hydrologic modification and agriculture.

The western half of the Tamiami Canal is threatened or moderately impaired from nutrients, algal and weed growth, and pesticides. Canals draining urban areas are also affected by urban runoff and septic tank leachate. Naples Bay and parts of Estero Bay are threatened or moderately impaired. Lake Trafford near Immokalee, which is severely impaired from agriculture, urbanization and septic tank runoff, experiences algal blooms, weed growth, and occasional fish kills. The basin's most disturbing, ecologically destructive problem is severely altered freshwater flows from drainage canals with inadequate or nonexistent control structures. The canals cause excess fresh water to drain into the estuaries in the wet season and increase saltwater intrusion in the dry season. The bays at the mouth of the main canals are the most seriously threatened. The drought of the last few years has severely stressed the region's plants and animals. The potential for widespread, disastrous fires is great. Water-use restrictions have been implemented in much of the basin.

Fourteen low priority waters are listed in the Big Cypress region on the 1998 Section 303(d) list.

Southeast Florida Basin (PEIS: Upper East Coast and Indian River Lagoon, Everglades Agricultural Area, Water Conservation Areas, Lower East Coast and Biscayne Bay, and Everglades National Park and Florida Bay)

Ninety-five waters in the Southeast Florida Basin are listed on the 1998 303(d) list. Several of the water segments are slated for TMDL development in the next couple of years. They are: the North New River Canal, West Palm Beach Canal, M canal, 715 Farms, S-3, South Bay, East Beach, L-8. Bessey Creek is slated for 1999, and C-24, North St. Lucie, St. Lucie, and C-25 are slated for TMDL development in the year 2000.

The major land uses are wetlands, agriculture, and urban development. The major pollution sources are urban runoff, agriculture, boat discharges, and sewage overflows.

Some basin-wide generalizations can be made. On the heavily urbanized eastern coast, most pollution comes from storm water. Most wastewater treatment plants either use deep-well injection or ocean outfalls, but where they do discharge to surface waters, water quality is usually degraded. Intensive agricultural development affects the western portions of the basin, particularly south of Lake Okeechobee. In the southern basin, between the agricultural and urban areas, lie the WCAs which are vast diked wetlands used for aquifer recharge. Although these areas absorb some nutrients, the canal water quality depends heavily on water quantity.

The extensive network of canals has diminished water quality. DO levels are often low, with fish kills resulting. Controversy has been considerable over agriculture's effect on water quality in the Southeastern Florida Basin. To date, FDEP has identified four major violations of Class III criteria caused by nutrients: imbalances of aquatic flora and fauna, dominance by nuisance species, diminished biological integrity, and low levels of DO.

Ninety-five high or low priority waters are listed in the Southeast Florida Basin on the 1998 Section 303(d) list.

Upper East Coast and Indian River Lagoon

Water quality in the northeastern basin is relatively good. The major problems are found near Port St. Lucie. Five-Mile and Ten-mile creeks, which receive citrus grove runoff, have poor water quality with high pesticide levels that may be harming the North Fork of the St. Lucie River and Estuary. Along the Savannas State Preserve concentrations of mercury in fish tissue were high enough to warrant a no-consumption advisory for largemouth bass. Uncontrolled storm water runoff may also be harming the water quality, plant communities, and biological diversity. An addendum to the Indian River Lagoon SWIM Plan contains projects that will improve the situation.

Everglades Agriculture Area

The L-8, West Palm Beach, Hillsboro, North New River, and Miami canals from Lake Okeechobee to the L4-L7 canals, which roughly define the EAA, have poor water quality with extremely high nutrient and low DO levels. Other problems include pesticides, BOD, bacteria, and suspended solids. Fish kills occur periodically in the West Palm Beach Canal after heavy rains drain from the Chemair Spray hazardous waste site.

Water Conservation Areas

Canals bordering the Water Conservation Areas generally have very low DO levels typical of marsh waters. Nutrient levels at the marsh perimeter are elevated, probably from the breakdown of organic debris as well as agricultural drainage.

Lower East Coast and Biscayne Bay

Farther east, the North New River Canal joins the South Fork of the New River near Fort Lauderdale. The Miami Canal joins the Miami River near Miami. Both rivers are in heavily urbanized areas and have been channeled and bulkheaded. Several major Class I Solid Waste Disposal Facilities are located along major canal systems, including: the North Miami-Dade, South Miami-Dade, Lantana, and Martin County landfills, as well as Glades Road Resources Recovery of Miami-Dade and Munisport Landfill. All have the potential to pollute surface waters.

The most serious problems confronting the Miami River are chronic and acute coliform bacteria contamination and heavy metal and organic pollution in sediments. Chronic contamination results from illegal sewer connections to storm water pipes, leaking pipes and joints, and broken pipes. Acute contamination occurs when raw sewage flows from either emergency overflows or manholes. The Miami River's bacterial problems and their impact on Biscayne Bay have been a concern since the 1940s. In 1984, the Miami River Management Committee was established to develop a coordinated plan for improving the river. The committee was able to raise funds that were used to improve storm water outfalls, establish a state and local pollution control enforcement program, monitor pollution controls, and rank drainage basins for retrofitting.

Fort Lauderdale is particularly plagued with water quality problems from urban runoff and historical wastewater treatment discharges. The westernmost stations on the canals often have the worst water quality from agricultural runoff. Canals are often choked with weeds that must be mechanically removed or treated with herbicide. An FDEP study of major Miami-Dade County canals in 1985 showed poor water quality, low biological diversity, and many exotic plants and animals.

Twenty federal Superfund hazardous waste sites exist in the basin. About 50 more sites contaminated by heavy metals, solvents, or pesticides will need assessment and remediation. Although the sites will mostly affect ground water, they all have the potential to affect surface waters (and ground waters are near the land surface in many urban locations of the LEC). In addition, Miami-Dade, Broward, Palm Beach, Okeechobee, and St. Lucie counties contain about 5,150 petroleum-contaminated sites. They also contain approximately 10,000 regulated petroleum facilities, all of which have the potential for contamination.

In Miami-Dade, Broward, and Palm Beach counties, ten major public drinking-water well fields have shown petroleum contamination, including the cities of Riviera Beach, Delray Beach, Hallandale, Daniea, Deerfield Beach, and north Miami Beach, as well as Fort Lauderdale's Peele-Dixie Wellfield, Miami Springs' Preston Wellfields, and Fort Lauderdale's Executive Airport Wellfield. Major petroleum assessments, and cleanups are also in progress at Port Everglades, Miami International Airport, and Homestead Air Force Base, among others.

Biscayne Bay, although polluted by canal discharges and port activities, has fairly good water quality because of flushing from the Atlantic Ocean, especially south of Key Biscayne.

Everglades National Park and Florida Bay

Some parts of Florida Bay have experienced a massive seagrass and mangrove die-off in the late 1980's and early 1990's. Fisheries have declined as a result. Researchers estimate that 9,880 acres of seagrass have died and another 66,690 acres have been affected. The problem likely stems from a lack of flushing from hurricanes, high water temperatures, high levels of salinity, and disruptions in the quantity and quality of freshwater flows to the bay from channelized mainland waterways.

No water segments in Florida Bay are listed on the 1998 Section 303(d) list.

Florida Keys (PEIS: Florida Keys)

The major land uses are urban development, recreation, and sportfishing. The major pollution sources are wastewater plants, septic tanks, marinas lacking facilities to pump out waste from boats, fish processors, and storm water runoff.

For years the City of Key West discharged raw sewage directly to the ocean. The FDEP and the USEPA issued a consent order requiring that a treatment facility be built. It began operating in 1989 and appears to be functioning well.

The coral reefs on the ocean side have been damaged by careless divers, boat anchors, and several commercial ship groundings and spills. To protect the reefs and the Everglades, the State is attempting to block offshore oil drilling and to move shipping channels farther offshore. The Florida Marine Research Institute (FMRI) and National Oceanic and Atmospheric Administration (NOAA) are carrying out an extensive monitoring and assessment project in the Keys.

No water segments in the Florida Keys are listed on the 1998 Section 303(d) list.

H.1.5 APPROACH TO BASELINE WATER QUALITY DATA COMPILATION

A suite of baseline water quality parameters potentially affected by the existing conditions of the study area were introduced in Section H.1.1 and described in Section H.1.4 (mercury, phosphorus, and pesticides) and in Attachment A**.** A subset of these parameters of potential concern were considered key degraded parameters for the study area. Those considered "key" for each of the ten regions designated in this PEIS and are presented below by region in ***Table H.1.6-1***. These key parameters were selected based on the perceived relevance to the regions and study area and the reasonable availability and accessibility of published data. As such, the parameters associated with each region varied and data were not provided for the entire suite of parameters considered in Section H.1.1.

Water quality data compilations were provided for the "key" parameter subsets as well as for additional "other" parameter subsets. Data for key parameters are detailed below by region in Section H.1.7, while data for other parameters are detailed by region in Attachment B**.**

The established baseline year for this PEIS is 1995. Baseline water quality conditions described in this section were primarily taken from SFWMD, FDEP, and USEPA references. Data in published references were chiefly relied upon, as opposed to more recent but raw sampling data. The notable exception to this approach was the SFWMD raw database (SFWMD, 1998: unpublished) used to compile water quality data for the Florida Bay and Whitewater Bay (subregions of

Table H.1.6-1. Listing of Key Water Quality Parameters Considered Degraded in the Study Area of the C&SF Restudy Project.

South Florida Region / Subregion	Key Water Quality Parameters Considered Degraded in the Study Area
Kissimmee River Region	TP, No_x, DO
Lake Okeechobee	TP, NO_x , chlorophyll-*a*, turbidity, chloride
Upper East Coast & Indian River Lagoon St. Lucie River	TP, pesticides, DO, mercury and other heavy metals, NO_x , salinity
Indian River Lagoon	TP, pesticides, NO_x , turbidity, salinity, heavy metals, coliforms
Everglades Agricultural Area	TP, pesticides, mercury, NO_x , DO, conductivity
Water Conservation Areas Loxahatchee Natl Wildlife Refuge WCA 2A/2B WCA 3A/3B	 TP, DO, conductivity, mercury, NO_x TP, DO, conductivity, mercury, NO_x TP, DO, conductivity, mercury, NO_x
Lower East Coast & Biscayne Bay Loxahatchee River Aquatic Preserve Lake Worth Biscayne Bay	 TP, DO, mercury, NO_x, coliforms, salinity TP, NO_x , DO, turbidity, heavy metals, VOCs, salinity, coliforms TP, NO_x , DO, TBT, heavy metals, coliforms VOCs

Florida Keys	TP, NO_x , DO, turbidity, chlorophyll *a*, coliforms
Big Cypress Region	TP, NO_x , DO
Caloosahatchee River Region	TP, pesticides, NO_x , DO, conductivity, coliforms

DO = Dissolved Oxygen
NO_x = Nitrite/Nitrate Nitrogen
TP = Total Phosphorus
TBT = Tributyltin
VOCs = Volatile Organic Compounds

the Everglades National Park and Florida Bay region designated in this PEIS). This database (1991-1997) was made available by the SFWMD through personal communication (M. Slayton, SFWMD) in 1998 and was reduced to means and medians by a USEPA contractor. In addition, summarized pesticide monitoring data (1992-1997) were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Reliance on published data resulted in the typical period of record for the data being from the late 1980's to the early 1990's. However, the specific period of record ranged from 1973 to 1997 and included some very recent publications such as the USEPA mercury data (USEPA, 1998: draft), the SFWMD Everglades data (SFWMD, 1998b), and the Florida International University Florida Keys data (Boyer and Jones, 1998).

Data interpretations made in the following water quality data sections and in Attachment B discussing "trends" and "significance" were non-statistical observations. They were based on the data in the reference cited, which may or may not have been statistically treated.

H.1.6 REGIONAL DATA SUMMARIES

H.1.6.1 Kissimmee River Region

References used to compile the Kissimmee River Region data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were SFWMD (1998a**,** 1982) and USACE (1991).

H.1.6.1.1 Key Region-Specific Water Quality Parameters

Key water quality parameters for the Kissimmee River Region are considered to be phosphorus nitrite/nitrate, and dissolved oxygen (see Table H.1.6-1). Data for these parameters are detailed below.

Phosphorus

Total phosphorus (TP) concentrations in the main drainages of the Kissimmee Valley ranged between less than detectable and 2.46 mg/L and generally increased from north to south. Along the river channel itself (C-38), TP ranged from 0.025 to 0.50 mg/L, reflecting decreasing water quality conditions resulting from intensive land uses, primarily agricultural, in more southerly sub-basins. TP concentrations at structure S-65E, the last water control structure on C-38 approximately 7 miles north of Lake Okeechobee, vary from 0.011 to 0.441 mg/L, averaging 0.109 mg/L. Orthophosphate or Soluble Reactive Phosphorus (SRP) ranged from 0 to 90% of TP, averaging about 60% at the S-65E structure. Increases in phosphorus concentration from north to south are associated primarily with the increase in SRP concentrations to the south. Areas of increased phosphorus levels along C-38 correspond to areas downstream of the tributaries displaying the highest phosphorus concentrations.

Nitrite/Nitrate

Mean nitrite/nitrate (NO_x) concentrations for six sampling stations along the Kissimmee River for the period from 1973-1978 averaged between 0.032 and 0.058 mg/L. More recent NO_x data for the river averaged 0.107 mg/L, ranging between undetectable and 1.369 mg/L. There was not a steady increase in concentrations north to south (downstream) but significantly higher values are found in the extreme southern end of C-38, with the rest of the river showing very similar low average values.

Dissolved Oxygen

Low DO levels along C-38 constitute a primary water quality concern for the Kissimmee River Basin. DO decreased during periods of low flow during both wet and dry seasons, with average concentrations falling below 3.0 mg/L. During periods of high discharge, the water column was well mixed. Seasonal patterns were also present, with wet season (May - October) DO values at the top and bottom of the water column lower on average (4.4 mg/L and 2.7 mg/L, respectively) than dry season values (7.1 and 6.1 mg/L, respectively), possibly as a result of high temperatures during the wet period of the year. Averages at sites along the length of the river ranged from 38 mg/L to 5.8 mg/L, with no apparent trend from north to south.

H.1.6.1.2 Other Region-Specific Water Quality Parameters

Data for other water quality parameters for the Kissimmee River Region are detailed in Attachment B. These parameters are pH, conductivity, turbidity, and oil and pesticides.

H.1.6.2 Lake Okeechobee

References used to compile Lake Okeechobee water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were SFWMD (1998a), FDEP (1996), James *et al.* (1995), and Pfeuffer (1989). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

H.1.6.2.1 Key Region-Specific Water Quality Parameters

Key water quality parameters for Lake Okeechobee are considered to be phosphorus, nitrite/nitrate, chlorophyll-*a*, turbidity, and chloride (see Table H.1.6-1). With the exception of chloride, data for these parameters are detailed below.

Phosphorus

Phosphorus concentrations reported in the 1996 305(b) report (FDEP, 1996) ranged from 0.03 mg/L to 0.14 mg/L within the lake, with an overall mean concentration of 0.065 mg/L for the lake (for the period of 1990 to 1995). TP conditions in the basin were generally worse than those observed in the lake as shown below:

S-135 (current 1990-1995)	TP=0.08 mg/L
S-135 (historic 1980-1995)	TP=1.25 mg/L
Lettuce Creek	TP=0.40 mg/L
Myrtle Creek	TP=0.28 mg/L

Data collected and reported by the SFWMD (1998a) summarizes the TP concentrations entering the lake at thirty-five locations. During the period of period from 1989 to 1991, the mean TP concentrations entering and leaving the lake ranged from a low of 0.48 mg/L to a high of 0.545 mg/L. SFWMD (1998a) data for limnetic and littoral zone monitoring stations indicated the in-lake mean TP concentrations ranged from a low of 0.0099 mg/L to a high of 0.194 mg/L for the same period of time.

James *et al.* (1995) analyzed historical trends in the lake and reported that the mean TP concentration for the period of 1973 to 1992 was 0.080 mg/L, with an associated standard deviation of 0.032 mg/L. The median concentration for the lake was reported as 0.076 mg/L, with minimum and maximum values of 0.027 mg/L and 0.193 mg/L, respectively.

The three databases are not sufficient to develop trend analyses; however, the stations reporting the highest values within the SFWMD (1998a) database do not correspond to the monitoring zone reporting the highest TP concentration in the 1996 305(b) report. This may be attributed to the greater number of monitoring stations within the SFWMD (1998a) than those reported in the 305(b) report.

Nitrite/Nitrate

Data collected and reported by the SFWMD (1998a) summarizes the NO_x concentrations entering the lake at thirty-five locations. During the period from 1989 to 1997, the mean NO_x concentrations entering and leaving the lake ranged from a low of 0.0274 mg/L to a high of 1.596 mg/L. SFWMD (1998a) data for limnetic and littoral zone monitoring stations indicated the in-lake mean NO_x concentrations ranged from a low of 0.0108 mg/L to a high of 0.1964 mg/L for the same period of time. The SFWMD (1998a) report did not attempt to correlate the inflow, outflow, and in-lake NO_x concentrations, nor can a similar relationship be developed using the 1996 305(b) report.

James *et al.* (1995) reported that the mean NO_x concentration for the period of 1973 to 1992 was 0.130 mg/L, with an associated standard deviation of 0.113 mg/L. The median concentration for the lake was reported as 0.106 mg/L, with minimum and maximum values of 0.004 mg/L and 0.618 mg/L, respectively.

Chlorophyll-*a*

The mean chlorophyll-*a* concentration in the lake for the period of 1973 to 1992 was 23.9 mg/m^3, with an associated standard deviation of 8.4 mg/m^3 (James *et al*., 1995). The median concentration for the lake was reported as 23.1 mg/m^3, with minimum and maximum values of 4.9 mg/m^3 and 52.8 mg/m^3, respectively.

Turbidity

The 1996 305(b) report (FDEP, 1996) shows in-lake turbidity concentrations ranged from a high of 24.8 mg/L to a low of 2.0 mg/L. There were no apparent trends in the lake related to turbidity. The turbidity of water in the lake basin were generally lower than those observed in the lake, ranging from 3.7 mg/L in Myrtle Slough to 4.5 mg/L at S-135.

According to James *et al*. (1995), the mean turbidity concentration for the period of 1973 to 1992 was 20.5 mg/L, with an associated standard deviation of 14.4 mg/L. The median concentration for the lake was reported as 16.8 mg/L, with minimum and maximum values of 0.6 mg/L and 85 mg/L, respectively.

> (Note: Units for turbidity data for Lake Okeechobee were inadvertently reported in FDEP (1996) as "mg/L" as opposed to "NTU". This was apparently was also the case for James *et al*. (1995)).

H.1.6.2.2 Other Region-Specific Water Quality Parameters

Data for other water quality parameters for Lake Okeechobee are detailed in Attachment B. These parameters are pH, dissolved oxygen, ammonia/unionized ammonia, conductivity, temperature, and pesticides.

H.1.6.3 Upper East Coast and Indian River Region

The discussion of the Upper East Coast (UEC) region was divided into two subregions of interest: the St. Lucie River and the Indian River Lagoon.

H.1.6.3.1 St. Lucie River Subregion

References used to compile the St. Lucie River subregion water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were FDEP (1996) and Woodward-Clyde (1994). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the St. Lucie River subregion are considered to be phosphorus, pesticides, dissolved oxygen, mercury and other heavy metals, nitrite/nitrate, and salinity (see Table H.1.6-1). With the exception of nitrite/nitrate and salinity, data for these parameters are detailed below.

Phosphorus

The average TP concentration in the St. Lucie River was 0.15 mg/L in the south Fork, 0.31 mg/L in the north, and 0.2 mg/L in the estuary.

Pesticides

Table H.1.5.2.1.3.2-1 (see Section H.1.5.2.1.3.2) lists the pesticides detected at Monitoring Site S80 of the SFWMD pesticide monitoring program, which is the only monitoring location draining into the St. Lucie River (R. Pfeuffer: SFWMD, 1998 personal communication). During this time period (1992-1997), nine pesticides were detected. Of the four detections of ethion at Site S80, three (4/6/92, 7/27/92, 11/2/92) exceeded the 48-hour LC_{50} of 0.06 µg/L, reported for *Daphnia magna*, a sensitive indicator species for aquatic macroinvertebrate. The fourth detection (8/18/97) exceeds the chronic toxicity level (0.003 µg/L) for *D. magna*, calculated according to promulgated procedure (F.A.C. 62-302.200). At this level, long-term exposure can cause impacts to the macroinvertebrate populations. Although detected, endosulfan residues have not exceeded the Florida Criteria for Class III Waters (F.A.C. Section 62-302.530).

Dissolved Oxygen

The mean DO level for the river was 4.7 mg/L in the south Fork, 5.5 mg/L in the north, and 6.3 mg/L in the estuary.

Mercury and Other Heavy Metals

For the heavy metal mercury, some general mercury data from USEPA (1998: draft) were provided in sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the St. Lucie River subregion are detailed in Attachment B. These parameters are pH, conductivity, and turbidity.

H.1.6.4 Indian River Lagoon Subregion

The reference used to compile the Indian River Lagoon (IRL) subregion water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B was Woodward-Clyde (1994). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the IRL subregion are considered to be phosphorus, pesticides, nitrite/nitrate, turbidity, salinity, heavy metals, and coliforms (see Table H.1.6-1**.** With the exception of coliforms, data for these parameters are detailed below.

Phosphorus

The mean TP concentration in the south IRL was 0.034 mg/L (with a standard deviation of 0.02 mg/L) for the period of 1989 to 1991. The maximum and minimum concentrations for the same period were 0.18 mg/L and 0.004 mg/L, respectively.

Pesticides

Based on FDEP and SFWMD data from ongoing monitoring programs, C-25 in the IRL is known to transport pesticides into the estuary and offshore. Specifically, bromacil, chlorpyrifos ethyl, ethion, diuron, hexazinone, malathion, metalaxyl, norflurazon, dicofol, 2,4-D, and simazine pesticides were detected in water samples taken from C-25. Moreover, 12 state water quality standards violations have been documented for malathion and ethion from 1992 to 1997 (R. Pfeuffer: SFWMD, 1998 personal communication). For sediments, the pesticides dicofol, diuron, ethion, and p,p'-DDE were found in C-25 sediments, while diuron and ethion at probable toxic levels have also been documented.

Nitrite/Nitrate

The mean NO_x concentration in the south IRL was 0.15 mg/L for the period of 1989 to 1991.

Turbidity

The mean turbidity concentration in the south IRL, as reported in FDEP(1996), was 3.17 mg/L (with a standard deviation of 1.63 mg/L) for the period of 1989 to 1991. The maximum and minimum concentrations for the same period were 7.7 mg/L and 1.0 mg/L, respectively.

(Note: Units for turbidity were inadvertently reported in FDEP (1996) as “mg/L” as opposed to “NTU”.)

Salinity

The mean salinity of the south IRL was 24.5 ppt (with a standard deviation of 4.88 ppt) for the period of 1989 to 1991. The maximum and minimum concentrations for the same period were 37 ppt and 10 ppt, respectively.

Heavy Metals

For the heavy metal mercury, some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the IRL subregion are detailed in Attachment B. These parameters are dissolved oxygen and PAHs.

H.1.6.5 Everglades Agricultural Area

References used to compile the Everglades Agricultural Area (EAA) water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were FDEP (1996), USACE (1996), Limno-Tech (1995), and SFWMD (1992a). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

H.1.6.5.1 Key Region-Specific Water Quality Parameters

Key water quality parameters for the EAA are considered to be phosphorus, pesticides, mercury, nitrite/nitrate, dissolved oxygen, and conductivity (see Table H.1.6-1). Data for these parameters are detailed below.

Phosphorus

Water quality in the EAA is considered poor with respect to phosphorus concentrations. Phosphorus in the EAA waters constitutes a significant water quality problem, and is a primary focus of agricultural BMPs and storm water runoff cleanup efforts. The high phosphorus concentrations result from a combination of oxidation and mineralization of the peat soils and fertilizer use.

Discharges from several EAA basins monitored between 1979 and 1988 averaged 0.169 mg/L (volume-weighted concentration) TP, ranging between 0 .067 and 0.232 mg/L. Orthophosphate makes up the majority of TP. The lowest values were generally associated with minor discharge volumes and did not greatly affect the mean value. The phosphorus-laden water is discharged to the WCAs and is back-pumped to Lake Okeechobee, and has been a primary source of eutrophication for both areas.

Pesticides

Pesticides monitoring data for the EAA is presented in Table H.1.5.2.1.3.2-1 (see Section H.1.5.2.1.3.2) for 1992-1997. Seven monitoring sites were sampled by the SFWMD (1998 personal communication, R. Pfeuffer). During this period (1992-1997), 18 pesticides were detected with nine being detected only once. Only endosulfan (sum of endosulfan alpha and beta) was found to exceed its Class III criterion of 0.056 µg/L. Exceedances occurred at site L3BRS on 1/27/93 (0.063 µg/L). The only diazinon detection at Monitoring Site S2 (0.34 µg/L, 8/8/95) exceeded the acute and chronic toxicity levels for *Daphnia magna* (0.3 and 0.04 µg/L, respectively), a sensitive indicator species for aquatic macroinvertebrates, calculated according to promulgated procedure (F.A.C . 62-302.200). At these levels, exposure can cause impacts to the macroinvertebrate populations. The only diazinon detection at Site S4 (1.9 µg/L, 1/26/93) exceeded the 48-hour LC_{50} of 0.06 µg/L, reported for *D. magna*. At these levels, exposure can cause impacts to the macroinvertebrate populations. The only chlorpyrifos ethyl detection at Site S6 (0.023 µg/L, 4/17/96) exceeded the calculated chronic toxicity level for *D. magna* (0.005 µg/L). The only parathion methyl detection at Site S8 (0.022 µg/L, 10/11/95) exceeded the calculated chronic toxicity level for *D. magna* (0.007 µg/L).

Mercury

Some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Nitrite/Nitrate

Nitrate concentrations were found to range up to 2.4 mg/L in studies of EAA water quality conducted in the 1940's. Mean NO_X concentrations for the period 1977-1989 at four major pump stations draining the EAA ranged from 0.771 to 1.21 mg/L, primarily nitrate. These elevated values are derived primarily from the biological oxidation and mineralization of organic muck soils.

Dissolved Oxygen

DO levels in EAA waters often violate Class III water quality standards, averaging between 3.2 mg/L and 4.9 mg/L for four major pump stations sampled between 1977 and 1989.

Conductivity

EAA waters tend to have relatively high specific conductance due to contact with underlying limestone bedrock in the canal system that drains the basin. Long-term average conductivities at four major pump stations draining the EAA ranged from 788 µmhos/cm to 1,241 µmhos/cm. The data sets were relatively consistent with coefficient of variation values ranging between 25% and 36%.

H.1.6.5.2 Other Region-Specific Water Quality Parameters

Data for other water quality parameters for the EAA are detailed in Attachment B**.** These parameters are pH, temperature, ammonia/unionized ammonia, and turbidity.

H.1.6.6 Water Conservation Areas

Discussion of the Water Conservation Areas (WCAs) region was divided into three subregions of interest: the Loxahatchee National Wildlife Refuge (LNWR), the WCA-2A/2B, and the WCA-3A/3B.

H.1.6.6.1 Loxahatchee National Wildlife Refuge Subregion

References used to compile the LNWR water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were FDEP (1996), Limno-Tech (1995), and SFWMD (1992b). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the LNWR are considered to be phosphorus, dissolved oxygen, conductivity, mercury, and nitrite/nitrate (see Table H.1.6-1). With the exception of nitrite/nitrate, data for these parameters are detailed below.

Phosphorus

The mean TP concentration collected at thirty-three stations in the LNWR was 0.063 mg/L for the period from 1979 to 1993. The lowest mean concentration observed at any station in the LNWR was 0.11 mg/L, while the highest concentration was 0.171 mg/L. The lowest concentration observed in the basin was 0.001 mg/L and the highest observation was 0.494 mg/L.

Dissolved Oxygen

The mean DO concentration collected at thirty-three stations in the LNWR was 4.8 mg/L for the period from 1979 to 1993. The lowest mean concentration observed at any station in the LNWR was 2.6 mg/L, while the highest concentration was 7.7 mg/L. The lowest concentration observed in the basin was 0.1 mg/L and the highest observation was 10.7 mg/L.

Conductivity

The mean specific conductance value collected in the LNWR was 937.1µmhos/cm for the period from 1979 to 1993. The mean conductivity values observed in the LNWR ranged from 90.3 µmhos/cm to 1418.9µmhos/cm.

Mercury

Some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the LNWR are detailed in Attachment B**.** These parameters are ammonia/unionized ammonia, pH, turbidity, temperature, and pesticides.

H.1.6.6.2 Water Conservation Area 2A/2B Subregion

References used to compile the WCA-2A/2B subregion water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were FDEP (1996), Limno-Tech (1995), and SFWMD (1992b). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the WCA-2A/2B subregion are considered to be phosphorus, dissolved oxygen, conductivity, mercury, and nitrite/nitrate (see Table H.1.6-1). With the exception of nitrite/nitrate, data for these parameters are detailed below.

Phosphorus

The mean TP concentration collected in the WCA-2A basin was 0.061 mg/L, and in the WCA-2B basin was 0.021 mg/L, for the period 1979 to 1993. The lowest mean concentration observed at any station in the WCA-2A basin was 0.010 mg/L and in the WCA-2B basin was 0.018 mg/L, while the highest concentration was 0.245 mg/L in WCA-2A and 0.025 mg/L in WCA-2B. The lowest concentration observed in the WCA-2A basin was 0.001 mg/L and in the WCA-2B basin was 0.001 mg/L, while the highest observation was 4.190 mg/L in WCA-2A and 0.148 mg/L in WCA-2B.

Dissolved Oxygen

The mean DO concentration collected in WCA-2A was 3.1 mg/L, and in WCA-2B was 4.3 mg/L, for the period from 1979 to 1993. The lowest mean concentration observed at any station in WCA-2A was 1.2 mg/L, while the lowest level observed in WCA-2B was 3.0 mg/L. The highest mean DO concentration observed in WCA-2A was 5.0 mg/L, and in WCA-2B was 5.2 mg/L. The lowest concentration observed in the WCA-2A basin was 0.0 mg/L and the highest observation was 12.4 mg/L. The lowest DO concentration recorded in the WCA-2B basin was 0.3 mg/L, while the highest was 12.2 mg/L.

Conductivity

The mean specific conductance value collected in WCA-2A was 1,157.5 µmhos/cm, and in WCA-2B was 892.1 µmhos/cm, for the period from 1979 to 1993. The mean specific conductance values observed in WCA-2A ranged from 752.5 µmhos/cm to 2,720 µmhos/cm, and in WCA-2B ranged from 861 µmhos/cm to 931.7 µmhos/cm.

Mercury

Some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced

H.1.6.6.3 Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the WCA-2A/2B subregion are detailed in Attachment B**.** These parameters are ammonia/unionized ammonia, pH, turbidity, temperature, and pesticides.

H.1.6.6.4 Water Conservation Area 3A/3B Subregion

References used to compile the WCA-3A/3B subregion water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were FDEP (1996), Limno-Tech (1995), and SFWMD (1992b). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the WCA-3A/3B subregion are considered to be phosphorus, dissolved oxygen, conductivity, mercury, and nitrite/nitrate (see Table H.1.6-1). With the exception of nitrite/nitrate, data for these parameters are detailed below.

Phosphorus

The mean TP concentration collected in the WCA-3A basin was 0.032 mg/L, and in the WCA-3B basin was 0.013 mg/L, for the period from 1979 to 1993. The lowest mean concentration observed at any station in the WCA-3A basin was 0.004 mg/L and in the WCA-3B basin was 0.006 mg/L, while the highest concentration was 0.211 mg/L in WCA-3A and 0.031 mg/L in WCA-3B. The lowest concentration observed in the WCA-3A basin was 0.001 mg/L and in the WCA-3B basin was 0.002 mg/L, while the highest observation was 0.593 mg/L in WCA-3A and 0.435 mg/L in WCA-3B.

Dissolved Oxygen

The mean DO concentration collected in WCA-3A was 4.8 mg/L, and in WCA-3B was 3.7 mg/L for the period from 1979 to 1993. The lowest mean concentration observed at any station in WCA 3A was 1.7 mg/L, while the lowest level observed in WCA-3B was 1.9 mg/L. The highest mean DO concentration observed in WCA-3A was 8.8 mg/L, and in WCA-3B was 9.4 mg/L. The lowest concentration observed in the WCA-3A basin was 0.1 mg/L and the highest observation was 15.4 mg/L. The lowest DO concentration recorded in the WCA-3B basin was 0.0 mg/L, while the highest was 12.2 mg/L.

Conductivity

The mean specific conductance value collected in WCA-3A was 718.4 µmhos/cm, and in WCA-3B was 686.4 µmhos/cm, for the period from 1979 to 1993. The mean conductivity values observed in WCA-3A ranged from 240 µmhos/cm to 1,096.7 µmhos/cm, and in WCA-3B ranged from 460.9 µmhos/cm to 794.3 µmhos/cm.

Mercury

Some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the WCA-3A/3B subregion are detailed in Attachment B. These parameters are ammonia/unionized ammonia, pH, turbidity, temperature, and pesticides.

H.1.6.7 Lower East Coast Region

The discussion for the Lower East Coast (LEC) region was divided into three subregions of interest: the Loxahatchee River Aquatic Preserve (LRAP), Lake Worth Lagoon, and Biscayne Bay.

H.1.6.7.1 Loxahatchee River Aquatic Preserve Subregion

References used to compile the LRAP subregion water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were FDEP (1996) and SFWMD (1980).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the LRAP are considered to be phosphorus, dissolved oxygen, mercury, nitrite/nitrate, coliforms, and salinity (see Table H.1.6-1). With the exceptions of nitrite/nitrate, coliforms and salinity, data for these parameters are detailed below.

Phosphorus

The mean TP concentration in the estuarine section of the river was 0.03 mg/L.

Dissolved Oxygen

The mean DO concentration for the estuarine section of the river was 6.5 mg/L.

Mercury

Some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the WCA-3A/3B subregion are detailed in Attachment B**.** These parameters are pH, conductivity, and turbidity.

H.1.6.7.2 Lake Worth Subregion

References used to compile the Lake Worth subregion data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were SFWMD (1998a) and FDEP (1996). Water quality data were for canal stations near Lake Worth that influence its water quality, as opposed to Lake Worth itself.

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the Lake Worth subregion are considered to be phosphorus, nitrite/nitrate, dissolved oxygen, turbidity, heavy metals, VOCs, salinity, and coliforms (see Table H.1.6-1)**.** With the exceptions of VOCs, salinity and coliforms, data for these parameters are detailed below.

Phosphorus

The SFWMD (1998a) reports the mean TP concentration recorded at the S-44 structure on the C-17 canal was 0.0726 mg/L, where the minimum and maximum TP concentrations were 0.021 mg/L and 0.284 mg/L, respectively. The mean TP concentration recorded at the S-155 structure on the C-51 canal was 0.1108 mg/L, where the minimum and maximum TP concentrations were 0.029 mg/L and 0.384 mg/L, respectively.

Nitrite/Nitrate

According to the SFWMD (1998a), the mean NO_x concentration recorded at the S-44 structure on the C-17 canal was 0.1887 mg/L, where the minimum and maximum NO_x concentrations were 0.004 mg/L and 1.98 mg/L, respectively. The mean NO_x concentration recorded at the S-155 structure on the C-51 canal was 0.2447 mg/L, where the minimum and maximum TP concentrations were 0.004 mg/L and 1.768 mg/L, respectively.

Dissolved Oxygen

The 1996 305(b) report (FDEP, 1996) shows the mean DO concentration measured at for the West Palm Beach Canal was 4.6 mg/L.

Turbidity

The 1996 305(b) report (FDEP, 1996) shows the mean turbidity concentration measured for the West Palm Beach Canal was 16.8 mg/L.

(Note: Units for turbidity data for the Lake Worth subregion were inadvertently reported by FDEP (1996) as “mg/L” as opposed to “NTU”.)

Heavy Metals

For the heavy metal mercury, some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the Lake Worth subregion are detailed in Attachment B. These parameters are pH and conductivity.

H.1.6.7.3 Biscayne Bay Subregion

References used to compile the Biscayne Bay subregion data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were FDEP (1996), SFWMD (1995a), and Uhler (1993).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the Biscayne Bay subregion are considered to be phosphorus, nitrite/nitrate, dissolved oxygen, tributyltin (TBT), heavy metals, coliforms, and VOCs (see Table H.1.6-1). With the exceptions of coliforms and VOCs, data for these parameters are detailed below.

Phosphorus

The mean TP concentrations measured in Biscayne Bay ranged from 0.006 mg/L to 0.171 mg/L. The median TP concentrations ranged from 0.003 mg/L to 0.181 mg/L. TP concentrations changed significantly at nine monitoring stations: two stations indicated an increasing trend while TP concentrations decreased at seven other stations. The two stations showing increasing trends were associated with Goulds Canal and Aerojet Canal. Most of the decreasing trends were observed in the North Bay including Biscayne Canal.

Nitrite/Nitrate

The mean NO_x concentration observed for the Bay ranged from 0.01 to 3.58 mg/L. NO_x concentrations changed significantly at ten stations: increasing at seven and decreasing at three others. All increasing trends were observed in the tributaries to the Bay including Arch Creek, Miami Canal, Wagner Creek, Black Creek, Goulds Canal, and Military Canal.

Dissolved Oxygen

The mean DO concentrations, as measured at 1.0 meter below the surface, ranged from 1.6 mg/L to 8.0 mg/L.

Tributyltin (TBT)

TBT was sampled from oyster flesh (*Crassostrea virginica*) at several U.S. east coast sites (from Maine to Florida) at NOAA stations (Uhler *et al.*, 1993) as part of the NOAA National Status and Trends Mussel Watch Project. Three sample sets were taken, one each in 1989-1990, 1988-1989, and 1987-1988. Four Florida stations were sampled, including two stations within the Lower East Coast and Biscayne Bay region designated in this PEIS: North Miami (Maule Lake) and Biscayne Bay (Gould's Canal). In the most recent sampling (1989-1990), TBT, dibutlytin (DBT) monobutyltin (MBT), and total butyltin (Total) were analyzed. TBT at the North Miami site in 1989-1990 was 3.35 µg/l, while the Total was 4.42 µg/l. TBT at the Biscayne Bay site during this period was 4.03 µg/l, while the Total was 5.93 µg/l. The Total for the 1988-1989 sampling at the North Miami site was 7.66 µg/l. No Total data were recorded for the other two sample sets or for the Biscayne Bay site in general. These concentrations were the highest recorded for the sampled four Florida stations and the east coast stations in general.

Heavy Metals

For the heavy metal mercury, some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the Biscayne Bay subregion are detailed in Attachment B. These parameters are ammonia/unionized ammonia and salinity.

H.1.6.8 Everglades National Park and Florida Bay

The Everglades National Park and Florida Bay region is divided into four subregions of interest: Shark River Slough/Taylor Slough, Florida Bay, Whitewater Bay, and Ten Thousand Islands. These four subregions are discussed below.

H.1.6.8.1 Shark River Slough/Taylor Slough Subregion

References used to compile the Shark River Slough/Taylor Slough subregion data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were SFWMD (1998a), FDEP (1996), and Limno-Tech (1995). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the Shark River Slough/Taylor Slough subregion are considered to be phosphorus and mercury (see Table H.1.6-1). Data for these parameters are detailed below.

Phosphorus

Analysis of data (SFWMD, 1998a) for four sites in Shark River Slough and one in Taylor Slough indicated that TP concentrations ranged from 0.003 mg/L to 0.546 mg/L for the period 1985 to 1997. The mean TP concentrations ranged from 0.0067 mg/L to 0.0403 mg/L for the same time period.

Limno-Tech (1995) found a median TP concentration of 0.011 mg/L after analyzing 1,685 records at five stations (period of record was 1979 to 1993). The same report shows the mean TP concentrations in this basin ranged from 0.007 mg/L to 0.053 mg/L.

Mercury

Some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the Shark River Slough/Taylor Slough subregion are detailed in Attachment B. These parameters are nitrite/nitrate, ammonia/unionized ammonia, pH, dissolved oxygen, conductivity, turbidity, temperature, and pesticides.

H.1.6.8.2 Florida Bay Subregion

The references used to compile the Florida Bay subregion water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were SFWMD (1998b) and a SFWMD raw database (SFWMD, 1998: unpublished) made available through personal communication in 1998 (M. Slayton, SFWMD). The database for the period of record from 1991-1997 was then reduced to means and medians by a USEPA contractor and divided into an east basin and west basin data set. The dividing line between the two sub-basins was just east of Whipray Basin. In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the Florida Bay subregion are considered to be salinity, phosphorus, mercury, and chlorophyll-*a* (see Table H.1.6-1). Data for these parameters are detailed below.

Salinity

The mean salinity were higher in the west basin than in the east basin. The mean concentration in the east basin was 21.4 ppt for the period of record, with a corresponding standard deviation of 10.3 ppt. The median salinity level in the east basin was 23.3 ppt, with minimum and maximum values of 0.01 ppt and 53 ppt, respectively. The 53 ppt maximum is well about normal seawater (35 ppt).

The mean salinity concentration in the west basin was 33.3 ppt for the period of record, with a corresponding standard deviation of 6.2 ppt. The median salinity value in the west basin was 33.5 ppt, with minimum and maximum values of 8.7 ppt and 63 ppt, respectively.

Phosphorus

The mean total phosphorus concentrations were higher and showed greater variability in the west basin than the east basin. The mean concentration in the east basin was 0.0095 mg/L for the period of record, with a corresponding standard deviation of 0.0047 mg/L. The median phosphorus concentration in the east basin was 0.0082 mg/L, with minimum and maximum values of 0.001 mg/L and 0.04 mg/L, respectively.

The mean phosphorus concentration in the west basin was 0.0204 mg/L for the period of record, with a corresponding standard deviation of 0.0157 mg/L. The median phosphorus concentration in the west basin was 0.016 mg/L, with minimum and maximum values of 0.003 mg/L and 0.13 mg/L, respectively.

Mercury

Some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Chlorophyll-*a*

The mean chlorophyll-*a* concentrations were higher and showed greater variability in the west basin than the east basin. The mean value in the east basin was 0.71 mg/m^3 for the period of record, with a corresponding standard deviation of 0.4341 mg/m^3. The median chlorophyll-*a* level in the east basin was 0.7 mg/m^3, with minimum and maximum values of 0.02 mg/m^3 and 4.07 mg/m^3, respectively.

The mean chlorophyll-*a* level in the west basin was 2.07 mg/m^3 for the period of record, with a corresponding standard deviation of 1.91 mg/m^3. The median chlorophyll-*a* concentration in the west basin was 1.32 mg/m^3, with minimum and maximum values of 0.1 mg/m^3 and 11.6 mg/m^3, respectively.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the Florida Bay subregion are detailed in Attachment B**.** These parameters are nitrite/nitrate, ammonia/unionized ammonia, dissolved oxygen, turbidity, temperature, and pesticides.

H.1.6.8.3 Whitewater Bay Subregion

The reference used to compile the Whitewater Bay subregion water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Appendix I was a SFWMD raw database (SFWMD, 1998: unpublished) made available through personal communication with the SFWMD in 1998 (M. Slayton, SFWMD). The database for the period of record from 1991-1997 was then reduced to means and medians by a USEPA contractor. In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameters for the Whitewater Bay subregion are considered to be salinity, phosphorus, mercury, and chlorophyll-*a* (see Table 3.1.10.5.3-1). Data for these parameters are detailed below.

Salinity

The mean concentration in the bay was 13.8 ppt for the period of record (1991-1997) with a corresponding standard deviation of 9.0 ppt. The median salinity level in the bay was 11.9 ppt, with minimum and maximum values of 0.3 ppt and 35 ppt, respectively.

Phosphorus

The mean concentration in the bay was 0.024 mg/L for the period of record, with a corresponding standard deviation of 0.0118 mg/L. The median phosphorus concentration in the bay was 0.022 mg/L, with minimum and maximum values of 0.0007 mg/L and 0.094 mg/L, respectively.

Mercury

Some general mercury data from USEPA (1998: draft) were provided in Sections H.1.4.2.1 and H.1.5.2.1.1, with additional draft or published mercury data sources also being referenced.

Chlorophyll-*a*

The mean value in the bay was 3.4 mg/m^3 for the period of record, with a corresponding standard deviation of 2.6 mg/m^3. The median chlorophyll-*a* level in the bay was 2.6 mg/m^3, with minimum and maximum values of 0.3 mg/m^3 and 17.8 mg/m^3, respectively.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the Whitewater Bay subregion are detailed in Attachment B. These parameters are nitrite/nitrate, ammonia/unionized ammonia, dissolved oxygen, turbidity, temperature, and pesticides.

H.1.6.8.4 Ten Thousand Islands Subregion

The 1996 305(b) report (FDEP, 1996) was the reference used to compile the Ten Thousand Islands water quality data for the key water quality parameter discussed below and other water quality parameters discussed in Attachment B**.** In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

Key Subregion-Specific Water Quality Parameters

Key water quality parameter for the Ten Thousand Island subregion is considered to be salinity (see Table H.1.6-1)**.** In lieu of salinity data, conductivity data are provided below.

Salinity/Conductivity

No salinity data were reported in the 1996 305(b) report (FDEP, 1996). However, a related parameter, conductivity, was presented. The mean specific conductivity level recorded at the referenced station was 41,250 µmhos/cm.

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the Ten Thousand Islands subregion are detailed in Attachment B**.** These parameters are phosphorus, nitrite/nitrate, pH, dissolved oxygen, conductivity, turbidity, and pesticides.

H.1.6.9 Florida Keys

The reference used to compile the Florida Keys water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were Boyer and Jones (1998) and FDEP (1996).

H.1.6.9.1 Key Region-Specific Water Quality Parameters

Key water quality parameters for the Florida Keys are considered to be phosphorus, nitrite/nitrate, dissolved oxygen, turbidity, chlorophyll-*a*, and coliforms (see Table H.1.6-1). With the exceptions of chlorophyll-*a* and coliforms, data for these parameters are detailed below.

Phosphorus

The mean TP concentrations ranged from 0.01 mg/L in Harrison Canal to 0.13 mg/L in Blackwater Sound and 0.14 mg/L in Barnes Sound.

Nitrite/Nitrate

The median NO_x concentrations for surface segments 1, 2, 4, 5, 6, 7 and 9 ranged from 0.09 µM to 0.26 µM. The maximum NO_x concentrations for the same segments ranged from 0.55 µM to 4.57 µM, while the minimum concentrations ranged from 0.0 µM to 0.03 µM.

Dissolved Oxygen

The mean DO concentrations for the Keys basin ranged from 5.5 mg/L at Marathon to 8.4 mg/L at Plantation Key. The mean DO value for all reported stations was 6.8 mg/L.

Turbidity

According to the 1996 305(b) report (FDEP, 1996), the mean turbidity results for the Keys basin ranged from 1.0 mg/L at Plantation Key, Harrison Canal, and Barnes Sound to 2.2 mg/L at Marathon.

(Note: Units for turbidity data for the Florida Keys were inadvertently reported by FDEP (1996) as “mg/L” as opposed to “NTU”.)

H.1.6.9.2 Other Region-Specific Water Quality Parameters

Data for other water quality parameters for the Florida Keys are detailed in Attachment B. These parameters are ammonia/unionized ammonia, pH, conductivity, temperature, and salinity.

H.1.6.10 Big Cypress Region

The reference used to compile the Big Cypress Region water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were FDEP (1996) and the U.S. Department of the Interior/ National Park Service (USDOI/NPS: 1996).

H.1.6.10.1 Key Region-Specific Water Quality Parameters

Key water quality parameters for the Big Cypress Region are considered to be phosphorus, nitrite/nitrate, and dissolved oxygen (see Table H.1.6-1). With the exception of dissolved oxygen, data for these parameters are detailed below.

Phosphorus

TP concentrations ranged from below detection limits to 0.11 mg/L and averaged 0.02 mg/L for the period from 1969-1970. For the period from 1966-1980, TP ranged from 0.006 to 0.14 mg/L, averaging 0.03 mg/L.

Nitrite/Nitrate

Total nitrites and nitrates ranged from 0.004 mg/L to 0.25 mg/L.

H.1.6.10.2 Other Region-Specific Water Quality Parameters

No other water quality parameters for the Big Cypress Region are detailed in Attachment B.

H.1.6.11 Caloosahatchee River Region

The references used to compile the Caloosahatche River Region water quality data for the key water quality parameters discussed below and the other water quality parameters discussed in Attachment B were SFWMD (1998, 1980) and FDEP (1996). In addition, summarized pesticide data were obtained through 1998 personal communication with the SFWMD (R. Pfeuffer).

H.1.6.11.1 Key Region-Specific Water Quality Parameters

Key water quality parameters for the Caloosahatchee River Region are considered to be phosphorus, pesticides, nitrite/nitrate, dissolved oxygen, conductivity, and coliforms (see Table H.1.6-1)**.** With the exception of coliforms, data for these parameters are detailed below.

Phosphorus

TP values were widely variable over the basin, with the lower values more likely being associated with relatively undeveloped areas. Primarily agricultural drainages tended to have higher values. Samples from 19 sites in the basin collected in 1978 and 1979 averaged 0.108 mg/L with a standard deviation of 0.289. Orthophosphate accounted on average for 61% of TP in those samples. Data for four sites in the basin from the late 1970's and early 1980's to 1994 averaged 0.200 mg/L, with one site draining a basin near Lake Okeechobee averaging double the other sites. The maximum value recorded, 1.737 mg/L, was also from this site. The next highest value was 0.495 mg/L, and low values for the four sites ranged between 0.039 and 0.157 mg/L. Orthophosphate accounted for 64% of TP on average, but at the site with the highest values accounted for 71% of TP. Orthophosphate averaged 55% of TP at the other sites. Average sample values increased at two of the four sites for data collected between 1989 and 1991, with an overall mean of 0.265 mg/L. Orthophosphate accounted for 64% of TP on the average for these samples.

Pesticides

SFWMD pesticides monitoring data exists for the Caloosahatchee River Region (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2). Three monitoring sites have been sampled by SFWMD. During this period (1992-1997), 12 pesticides were detected with four being detected only once (R. Pfeuffer: SFWMD, 1998 personal communication). The only detection of ethion at CR33.5T, (0.035 µg/L, 6/5/95) exceeded the acute toxicity level (0.02 µg/L) reported for *Daphnia magna*, a sensitive indicator species for aquatic macroinvertebrate, calculated according to promulgated procedure (F.A.C. 62-302.200. At this level, short-term exposure can cause impacts to the macroinvertebrate populations. The remainder of pesticides detected did not exceed any numeric or calculated F.A.C. 62-302 criteria.

Nitrite/Nitrate

NO_x concentrations in the basin showed no clear pattern of change down the basin toward the west. Concentrations at several sites sampled in 1978 and 1979 ranged from less than detection to 1.133 mg/L, with an average sampling site mean of 0.206 mg/L. Mean values for NO_x at four sites in the basin for data from the late 1970's and early 1980's to 1994 averaged 0.208 mg/L, with individual site means ranging between 0.125 mg/L and 0.303 mg/L. Minimum values were below detection limits and maximum values ranged between 0.69 mg/L and 1.113 mg/L. The highest values were associated with an agriculturally developed area.

Dissolved Oxygen

DO concentrations varied widely over the planning area and seasonally at the various sites sampled. For all data, the mean DO was 5.2 mg/L with a standard deviation of 1.8 mg/L. Mean saturation level for the area was 60%, with a standard deviation of 21%.

Conductivity

Specific conductance varied greatly with season, and was also associated with saltwater mixing near the coast and rainfall dilution effects. The mean conductance over the planning area was 1,201 µmhos/cm with a standard deviation of 1,094 µmhos/cm.

Other Region-Specific Water Quality Parameters

Data for other water quality parameters for the Caloosahatchee River Region are detailed in Attachment B. These parameters are pH, turbidity, and temperature.

H.3 LIST OF ACRONYMS AND ABBREVIATIONS

% - Percent

ATSDR - Agency for Toxic Substance and Disease Registry

BAF - Bioaccumulation Factor

BAT - Best Available Technology Economically Achievable

BCF - Bioconcentration Factor

BCT - Best Conventional Pollution Control Technology

BMP - Best Management Practice

BOD - Biochemical Oxygen Demand

BPT - Best Practicable Control Technology

C - Canal (e.g., C-25)

Cd - Cadmium (elemental)

Cu - Copper (elemental)

CWA - Clean Water Act

CWAA - Clean Water Act Amendments

DBT - Dibutyltin

DDD - a DDT derivative (metabolite)

DDE - a DDT derivative (metabolite)

DDT - Dichlorodiphenyltrichloroethane

DNA - Deoxyribonucleic Acid

DO - Dissolved Oxygen

EAA - Everglades Agricultural Area

ECP - Everglades Construction Project

EFA - Everglades Forever Act

EMA - Ecosystem Management Areas

EMAP - Environmental Monitoring and Assessment Program

ENP (= Park) - Everglades National Park

EPA - Everglades Protection Area

EXTONET - Extension Toxicology Network

FAC - Florida Administrative Code

FAMS - Florida Atmospheric Mercury Study

FDACS - Florida Department of Agriculture and Consumer Services

FDEP (=Department) - Florida Department of Environmental Protection

Fe - Iron (elemental)

FMRI - Florida Marine Resource Institute

FS - Florida Statute

FSU - Florida State University

ft - feet

FY - fiscal year

g/ml - Grams Per Milliliter

GWQMN - Groundwater Quality Monitoring Network

Hg - Mercury (elemental)

IRL - Indian River Lagoon

IU - International Units

kg/yr - Kilograms Per Year

K_{OC} - Soil Organic-Carbon Coefficient

L - Levee (e.g., L-67)

LC50 - Lethal Concentration for 50% of test subjects

LEC - Lower East Coast (Region)

LNWR - Loxahatchee National Wildlife Refuge

LRAP - Loxahatchee River Aquatic Preserve

MBT - Monobutyltin

MCL - Maximum Contaminant Level

MDN - National Mercury Deposition Network

MeHg - Methylmercury

mg/L - Milligrams Per Liter

MOA - Memorandum of Agreement

MPN - Most Probable Number

MSL - Mean Sea Level

MSMA - Monosodium Methanearsonate

NAWQA - National Water Quality Assessment Program

NEP - National Estuary Program

NEPA - National Environmental Policy Act

NFWMD - Northwest Florida Water Management

ng TBT - Sn/Kg - Dry weight TBT measurement nanograms per kilogram

ng Sn/L (ppt) - Nanograms of Tin per Liter of Water ng/L - Nanograms Per Liter

NH_3 - Ammonia

NOAA - National Oceanic and Atmospheric Administration

NO_x - Nitrogen Oxides (Air Quality)

NO_x - Nitrites (NO_3) and Nitrates (NO_4) (Water Quality)

NPDES - National Pollutant Discharge Elimination System (permit)

NPL - National Priorities List

NPS - Non-Point Source (pollution)

NSPS - New Source Performance Standards

NTU - Nephelometric Turbidity Units

PAH - Polycyclic Aromatic Hydrocarbon

Pb - Lead (elemental)

PCBs - Polychlorinated Biphenyls

PEIS - Programmatic Environmental Impact Statement

pH - Hydrogen Ion Concentration

PLRG - Pollutant Load Reduction Goal

POTW - Publicly Owned Treatment Works

ppb - Parts Per Billion

ppm - Parts Per Million

ppq - Parts Per Quadrillion

ppt (= $^0/_{00}$) - Parts Per Thousand (salinity) ppt - Parts Per Trillion

PSMP - Pesticide State Management Plan

PVC - Polyvinyl Chloride

RCRA - Resource Conservation and Recovery Act

REMAP - Regional Environmental Monitoring and Assessment Program

S - Structure (e.g., S-9)

SDWA - Safe Drinking Water Act

SFMSP - South Florida Mercury Science Program

SFWMD - South Florida Water Management District

SJRWMD - St. John's River Water Management District

SO_4 - Sulfate

SOFAMMS - South Florida Atmospheric Mercury Monitoring Pilot Study

SPCC - Spill Prevention, Control and Countermeasure

SRP - Soluble Reactive Phosphorus

SRWMD - Suwanee River Water Management District

STA - Stormwater Treatment Area

SWAMP - Surface Water Ambient Monitoring Program

SWFWMD (=District) - Southwest Florida Water Management District

SWIM - Surface Water Improvement and Management Act

TBT - Tributyltin

TCDD - 2, 3, 7, 8-tetrachloro-dibenzo-p-dioxin

TCE - Trichloroethylene

THg - Total Mercury

TOC - Total Organic Carbon

TP - Total Phosphorus

TSD - Treat, Store and/or Dispose

UEC - Upper East Coast (Region)

UIC - Underground Injection Control

USACE - U.S. Army Corps of Engineers

USDA/SCS - U.S. Department of Agriculture, Soil Conservation Service

USDOI - U.S. Department of the Interior

USDW - Underground Sources of Drinking Water

USEPA - U.S. Environmental Protection Agency

USFWS - U.S. Fish and Wildlife Service

USGS - U.S. Geological Survey

USHHR - U.S. Department of Health and Human Resources

WCA - Water Conservation Area (WCA-1, WCA-2, WCA-2A, WCA-2B, WCA-3)

WHO - World Health Organization

WMD - Water Management District

WRE - Water Resources Evaluation

WSSA - Weed Science Society of America

Zn - Zinc (elemental)

°C - Centigrade

°F - Fahrenheit

µg/kg - Micrograms Per Kilogram

µg/L - Micrograms Per Liter

µg/ml - Micrograms Per Milliliter

µgSn/L (ppb) - Micrograms of Tin per liter of water

µgTBT-Sn/L - Micrograms of TBT Tin Per Liter

µgTBT-Sn/kg (ppb) - Dry weight TBT measurement - micrograms per kilogram

µM - Micromole (typically converted to mg/L or ppb)

µmhos/cm - Micromhos Per Centimeter

ATTACHMENT A
ADDITIONAL PARAMETER DESCRIPTIONS

In addition to mercury, phosphorus, and the suite of pesticides described in Appendix H, descriptions of the remaining water quality parameters potentially affected by the existing conditions of the C&SF study area are presented below. These are grouped as metals, biologicals, nutrients, physical parameters, and other parameters.

H-A.1 METALS

Metals can be released to the environment through natural processes such as volcanic activity and the weathering of soil and rock. Metals are also released to the environment through anthropogenic activities such as mining, smelting, plating, and other activities that involve the extraction or processing of metals. Some metals, such as iron, calcium, and zinc are essential human micro-nutrients. However, other metals, such as arsenic, mercury, and lead may be highly toxic and can cause serious human health effects (Goyer, 1991). Effective treatment of water resources contaminated with heavy metals may usually be accomplished by binding the metals to particulates and removing the particulates from the water stream through sedimentation, flocculation and filtration processes (Laws, 1993). A discussion of specific metals that may be contaminants in aquatic environments is presented in the following sections.

H-A.1.1 Copper

Copper is a reddish metal that is naturally occurring in rock, spoil, sediment, and air. Copper also occurs naturally in plants and animals, and is an essential nutrient for humans and animals. Several human enzymes require copper in order to function properly in the body. Forms of anemia can result from copper deficiency. Copper is commonly found in the U.S. penny, electrical wires, and some water pipes. Copper is also a component of some metal alloys, such as brass and bronze. Copper may additionally be found in natural and anthropogenic compounds, the most common of which is copper sulfate. Copper compounds are commonly used in agriculture to treat plant diseases and as a water treatment (ATSDR, 1990).

Copper can enter the body through ingestion, inhalation, and dermal contact. A common route of exposure is through the ingestion of drinking water that becomes contaminated through standing in copper and brass plumbing pipes and fixtures. Once in the body, some of the copper is absorbed by the bloodstream, but control mechanisms limit the amount that can be absorbed. Excess copper is removed from the body in urine and feces (ATSDR, 1990; Goyer, 1991).

Much of the copper that is found in the environment is strongly bound to particulates, and is not easily able to affect human health. Less tightly bound copper, such as copper that forms water soluble compounds, can more easily affect human health, but even these compounds tend to quickly bind to particulates when released to the environment (ATSDR, 1990). Therefore, sedimentation, flocculation, and filtration can be very effective methods of removing copper from water resources.

Although an essential human micro-nutrient, at very high concentrations copper can have serious human health effects. Mild copper poisoning can result in nausea and vomiting, while very high concentrations may result in damage to the liver and kidneys, and in some cases, death. Copper is not believed to be a human carcinogen (ATSDR, 1990; Goyer, 1991).

Additional information on copper may be found in the USEPA Fact Sheet entitled *EPA Facts About Copper* (USEPA, 1992a).

H-A.1.2 Iron

Iron is a relatively abundant element in the universe. It is the fourth most abundant element by weight that makes up the crust of the earth. The pure metal is very reactive chemically and rapidly corrodes. Iron is hard, brittle, and is generally used in industrial settings to produce alloys, including steel. Iron found in the environment may be the result of natural processes or from human activity surrounding its extraction from ore and subsequent industrial uses (CST, 1997(internet)).

Iron most readily enters the body through ingestion and inhalation. Typically, iron is poorly absorbed in the digestive tract. The body requires a relatively long period of time to replenish depleted stores of iron. Average absorption of dietary iron is 8-10% of the total intake. The “heme” form of iron, found in flesh foods (e.g. beef, liver), is more rapidly absorbed at a rate of approximately 10-30% of dietary uptake. Most of the iron absorbed by the body is bound by the protein transferrin, and is transported to the bone marrow where it can be used to create red blood cells. Iron concentrations in the body are highly regulated to maintain homeostasis (Goyer, 1991; Haas, 1998).

Iron is necessary for the formation of red blood cells and the transport of oxygen in blood. Iron also plays a role in DNA synthesis, in the functioning of neurotransmitters, and in several other essential biochemical processes. A deficiency of iron can result in a form of anemia. Because of the human body’s iron requirements and its internal regulation of iron, iron toxicity is relatively rare. Most cases of iron toxicity involve cases of accidental ingestion of large amounts of dietary supplements by children, excess dietary iron by adults, and in individuals who have a genetic inability to process iron or receive frequent blood transfusions. Acute iron toxicity may result in vomiting, while chronic iron toxicity can result in liver damage. Ingestion of iron from water systems is not typically a pathway that results in iron toxicity (Brookes, 1997(internet); Haas, 1998; Goyer, 1991).

H-A.1.3 Cadmium

Cadmium is a naturally occurring element in the earth's crust. Its pure form is a soft silvery-white metal. Cadmium is most commonly found in the environment as a compound. Cadmium can also be released to the environment as a by-product of smelting operations involving zinc, lead, or copper. Cadmium has a variety of industrial uses, but because of its non-corrosive properties its main use is in electroplating and galvanizing. Cadmium is also used as a pigment in paints, a component of batteries, and in plastics. Cadmium in the environment may be either naturally occurring or a waste product of human industrial activities (ATSDR, 1993).

Cadmium can be absorbed by the body through ingestion or inhalation, but is poorly absorbed through dermal contact with contaminated material. Only a fraction of the cadmium ingested approximately 1-5% is actually absorbed by the bloodstream. The remainder is excreted. The absorption rate of cadmium through inhalation is considerably higher, approximately 30-50%. Once absorbed by the body, cadmium binds very strongly to soft bodily tissues, particularly the kidneys, and tends to accumulate in the body over time. The half-life for eliminating cadmium from the body is estimated to be approximately 30 years (ATSDR, 1993; Goyer, 1991).

Inhalation of cadmium can lead to diseases of the lung. The level of impairment corresponds to the length of exposure and the amount inhaled. Inhalation can cause chronic bronchitis, which may lead to obstructive lung disease, and ultimately emphysema with prolonged exposure. Accumulation of cadmium in the body through ingestion of contaminated water or soil or through inhalation can also cause damage to the kidneys. Cadmium interferes with calcium metabolism and, as a result, can cause skeletal problems, such as bone pain and osteoporosis. Recent studies also suggest that cadmium may play a role in the development of essential hypertension. Cadmium is believed to be a probable human carcinogen (Goyer, 1991).

Additional information on cadmium may be found in the USEPA Fact Sheet entitled *EPA Facts About Cadmium* (USEPA, 1992b).

H-A.1.4 Lead

Lead is a naturally occurring metal that is found within the earth's crust in small quantities. In its metallic form, lead is unable to dissolve in water or burn. Lead salts, which are formed when lead combines with other chemicals, are soluble in water. Most of the lead that exists in the environment is the result of anthropogenic activities. The concentration of lead in the environment has declined significantly since the ban of leaded gasoline. Presently, lead is used in the manufacture of batteries, electronics, and various types of ammunition (ATSDR, 1997; Goyer, 1991).

Lead can enter the body through inhalation or ingestion. Dermal absorption of lead is not a significant pathway of exposure. Almost all of the lead that is inhaled into the lungs is absorbed and transported to other parts of the body. In adults, lead is not well absorbed from the digestive tract, and only small amounts of the lead ingested in contaminated food or water is transported to other parts of the body. However, the digestive tracts of children are able to absorb much more lead from ingestion of contaminated food, soil, water, paint chips, and other contaminated media. Children are also more sensitive to the effects of lead. Therefore, lead contamination of water systems is of much greater concern for children than for adults (ATSDR, 1997; Goyer, 1991).

Lead is stored in the body, primarily in bone, but is also stored in the brain and in neural tissues. The half life of lead in bone is approximately 20 years. Age, nutrition, body burden (i.e., the amount already stored in bodily tissues), and exposure duration can influence the absorption and excretion of lead (Goyer, 1991).

In recent years a great deal of medical research has focused on the adverse health effects associated with exposure to lead. Some studies have observed changes in certain blood lead enzymes and children's neurological development at concentrations that suggest that a threshold level of effect may not exist. Based upon sufficient animal evidence, lead is considered to be a probable human carcinogen. Rodent studies have shown a statistically significant increase in renal tumors with subcutaneous and dietary exposure to soluble lead salts. However, the human carcinogenicity data that is available at this time is inadequate to demonstrate that similar effects occur in humans (ATSDR, 1997).

Additional information on lead may be found in the USEPA Fact Sheet entitled *EPA Facts About Lead* (USEPA, 1992c).

H-A.1.5 Zinc

Zinc is a bluish-white, lustrous metal that is brittle at normal temperatures. Zinc has many industrial uses, such as a component of alloys (e.g., brass). Large quantities of zinc are used to create die-castings for heavy industry, and are often used to galvanize other metals to prevent corrosion. Zinc is ubiquitous in the environment and is found in virtually all foods, in water, and in air. Zinc is an essential human micro-nutrient that is required for the proper functioning of more than 70 human enzymes. Zinc deficiency can result in a variety of symptoms depending upon age and developmental factors (ATSDR, 1994).

Humans are exposed to zinc in small amounts on a daily basis. Zinc is almost universally present in our food, water, and air. Absorption of zinc through the skin is relatively inefficient and is not generally an important pathway of exposure. Inhalation of zinc fumes appears to produce the most severe health effect - temporary neurologic impairment. Ingestion of zinc in water or dietary supplements at many times the recommended daily allowance is needed to produce toxic effects. Therefore, zinc poisoning is not very common. Excess zinc is typically removed from the body in urine and feces (ATSDR, 1994; Goyer 1991).

A common route of exposure is through ingestion of drinking water or other liquids that are stored in galvanized metal containers, flow through galvanized pipes, or are contaminated from industrial waste sites or sources. Symptoms include vomiting and diarrhea (ATSDR, 1994).

Additional information on zinc may be found in the USEPA Fact Sheet entitled *EPA Facts About Zinc* (USEPA, 1992d).

H-A.1.6 Arsenic

Arsenic is an element that occurs naturally in the environment but may increase to toxic levels as a result of anthropogenic activities. Concentrations in soils typically range from 0.1 to 40 ppm, with an overall average of 2 ppm (Bohn *et al.*, 1985). Its natural occurrence is due to the presence and weathering of minerals found in local geologic settings, and from volcanic emissions. Major anthropogenic sources of arsenic result from the combustion of fossil fuels and petroleum-based products, metal and non-metal smelting processes, and glass manufacturing, all of which generally disperse to low concentrations over large areas via atmospheric deposition. Localized high concentrations of arsenic can occur in and near industrial sites where arsenic-containing waste products were improperly disposed with respect to present standards (Bohn *et al.*, 1985). Prevalent use of arsenic in our society includes use as an additive in pressure treated wood and in agricultural pesticides. Arsenic can therefore enter the aquatic environment through nonpoint-source runoff, point source discharges, and atmospheric deposition.

Elemental arsenic does not occur in nature nor is it readily contributed by anthropogenic activities to the environment. More commonly, arsenic is found in one or both oxidation states, As^{+3} or As^{+5}, which are typically found in combination with oxygen as arsenite (AsO_2^{-1}) and arsenate (AsO_4^{-3}) anions. The two oxidation states are relatively stable in natural environments; but may be converted to either depending on the redox conditions (and the presence of catalysts) in the environment (Pourbaix, 1958). The two anions are tightly bound in soils and sediments to organics, clays, iron and aluminum oxides, and sulfides; thereby reducing their mobility into surface waters (Bohn *et al.*, 1985). However, at high soil concentrations or at low pH (< 3.5), the arsenic ions may be mobilized and released into surface waters or taken up by plants and animals.

Human exposure is principally through ingestion of food and water that contain the arsenic ions or organic complexes. To a lesser degree, human exposure from inhalation of fugitive dust (e.g., wind-blown soils) containing arsenic complexes can occur. The body absorbs most ingested arsenic. At normal exposures, absorbed arsenic is converted to less-toxic forms that are excreted from the body as wastes. At high exposures, arsenic can accumulate in the body and result in a variety of acute toxicological effects such as nausea, diarrhea, reduced blood production, and liver and/or kidney damage. Elevated exposures can also increase the risk of cancer in the liver, kidneys, and lungs. Arsenic is also toxic to aquatic life causing acute toxicity (i.e., mortality) to freshwater test species in the range from 0.8 to 97 mg/l (ppm) for soluble arsenate. Long-term exposures result in toxicological effects at much lower concentrations. To protect aquatic life and drinking water supplies, the Florida Department of Environmental Protection (FDEP) promulgated numeric surface water quality criteria for arsenic of 50 µg/L (as total arsenic) and 36 µg/L (as As^{+3}).

Additional information on arsenic may be found in the USEPA Fact Sheet entitled *EPA Facts About Arsenic* (USEPA, 1992e).

H-A.1.7 Tributyltin (TBT)

Tributyltin (TBT) is not a compound in its own right, but only a constituent part of molecules in this class of organotin substances. Commercial products are typically available as bis(tributyltin) oxide (TBTO), acetate (TBT-OAc), halides (TBTF, TBTCl), and as a copolymer with methylmethacrylate (TBTM). Industrial applications of TBT compounds followed the recognition of its biocidal properties, first noted in the 1950s. Although present applications include molluscicides, stone preservation, and disinfectants; the most important usage remains in wood preservatives and anti-fouling paints. The main use of tributyltin compounds, with direct introduction to water, is as anti-fouling agents on ships, boats, docks, and cooling towers. There are other known uses, such as material preservatives (textiles, paper, leather, electrical equipment), joinery wood preservatives, remedial wood preservatives, wood preservative stains, and slimicides.

Butyltin species are not produced biologically, and therefore their environmental presence is due to anthropogenic (manmade) input. TBT has been found in power plant discharges, and sewage treatment plant influents and effluents. Dibutyltin and monobutyltin compounds are also used as stabilizers for polyvinyl chloride (PVC), and can therefore be found in industrial plant discharges through the leaching of organotin-stabilized PVC pipe.

For the aquatic environment, tin-based anti-fouling paint represents the most important source of TBT. For a given location, the highest concentrations of TBT are generally found close to drydock and shipyard facilities where TBT-based paints are stripped from ships and yachts. However, anti-foulant paints work by slow release of a toxin that forms a thin veneer around the hull, thereby repelling nuisance organisms in the water. Thus, TBT continually leaches from vessels using this anti-fouling agent.

Organotins are measured by extraction from the medium (water, sediment, tissues) followed by analysis through a separation technique that does not destroy the chemical forms. This usually involves liquid chromatography, gas chromatography, or cold trapping techniques. Results are expressed in a variety of ways, but usually in units expressed as parts per trillion (ppt) or parts per billion (ppb). For example, tributyltin in water may be reported as micrograms of tin per liter of water, µg Sn/L (ppb). TBT may be reported as nanograms of tin per liter of water, ng Sn/L (ppt). It also may be reported as µg TBT-Sn/L, indicating the form measured. TBT in sediments and tissues will be reported on a dry-weight basis, that is, µg TBT-Sn/kg (ppb) or ng TBT-Sn/kg (ppt).

TBT antifouling paints are applied to inhibit the growth of barnacles, tubeworms, algae and seaweed, and other fouling target organisms, which slow a vessel's movement through the water. Non-target species which appear to be highly sensitive to TBT include bivalves molluscs (oysters, clams, scallops and mussels), gastropods (snails), and fish.

Once released into the environment, TBT appears to be removed from the water column principally by adsorption to lipids (fats) and particulate matter and through assimilation and metabolism by plants and animals. From its octanol-water partition coefficient, TBT partitions to particulate organic matter in suspended sediments in marine and fresh waters. The binding of a polar molecule such as TBT is a function both of its hydrophobicity, associated with the bulky butyl groups, and its polarity, and on this basis organic carbon content of sediments may not be the only control on adsorption. Sediment particle size, or more correctly surface area of the sediments, is likely to be important. Differences in TBT degradation rates between the dissolved and particulate phases, can also be important.

In deeper anoxic sediments, the sediment-to-interstitial water ratio is high. Also, the diffusion of pore water, especially in clayey sediments, is slow. The persistence of TBT in deeper, anoxic sediments is considerably longer than in surface sediments. Half lives in surficial sediments may range from 360-775 days. In anaerobic sediments, the half-life appears to be in the order of tens of years, possibly prolonged by limited biotic degradation activity. Because TBT is rapidly adsorbed into suspended particles, it accumulates in the sediments where degradation rates are very slow. TBT has been detected in sediments deposited nearly 20 years ago. Since TBT is not completely adsorbed to particulate matter, slow release into the overlying waters may occur for a long time, facilitated by bioturbation, or resuspension by storms or dredging.

Organotin compounds are more toxic than inorganic tin compounds, with the triorganotin compounds being the most toxic. However, within the class of triorganotin compounds there are considerable variations in toxicity with the nature of the organic subtituents. For insects, trimethyltin compounds are the most toxic; for mammals, the triethyltin compounds; for Gram-negative bacteria, the tri-n-propyltin compounds; for Gram-positive bacteria—yeasts, fungi and fish—the tri-n-butyltin compounds. Triphenyltin compounds are particularly toxic to phytoplankton.

TBT concentrations can cause disturbances to aquatic organisms. Specifically, contamination levels in excess of the values provided below are likely to induce disturbances for the following organisms (De Mora, 1996):

>0.4 ng TBT-Sn/L effects on phytoplankton and zooplankton

>0.8 ng TBT-Sn/L effects on calcification anomalies in oysters (*Crassostrea gigas*)

>8 ng TBT-Sn/L effects on reproduction of *C. gigas*

0.4-4 µg TBT-Sn/L effects on fish reproduction

0.4-40 µg TBT-Sn/L modification of fish behavior (avoidance response, rheotaxis)

>200 µg TBT-Sn/L effects on exuviation (molting) of crustacean species

In regard to the control of TBT, the U.S. has enacted the Organotin Antifouling Paint Control Act of 1988, which prohibits use of TBT paints on vessels less than 25 meters (82 feet) in length, and requires a maximum daily leach rate of 4 µg TBT/cm^2/day on all vessels larger than 25 m in length (Champ and Seligman, 1996). All anti-foulings must be registered, and since March 1, 1990, TBT-based anti-fouling paints can only be purchased and applied or removed by certified pesticide applicators. Similar regulations have been enacted by most countries throughout the world.

Specific to Florida, it should also be noted that an Interagency TBT Working Group was formed in 1988, consisting of representatives from the FDEP, the Florida Department of Agriculture and Consumer Services, and the Governor's Office of Planning and Budgeting, to provide a thorough review of statewide TBT issues. The group recommended that Florida:

- determine the amount of TBT in water, sediments and shellfish
- develop water quality standards for TBT compounds
- review the registration of TBT compounds
- work with the USEPA in its special review of organotin
- review marina permitting to consider potential TBT loading and overall environmental effects
- distribute information on the proper use and disposal of TBT paints and current TBT regulations.

TBT is most likely to be found in sediments and waters associated with marinas, harbors, and ports, particularly in harbors with large vessel traffic; and with ship/boat refurbishing facilities.

H-A.2 BIOLOGICALS

H-A.2.1 Fecal Coliforms and Pathogens

A variety of pathogens and parasites that pose human health concerns may be present in surface and ground water from their contamination with fecal matter from treated and untreated domestic wastewater and nonpoint source runoff from agricultural sources (e.g., cattle, hog, and chicken farms). According to Craun (1988), approximately 75 percent of waterborne disease outbreaks during the period from 1971 to 1985 were the result of untreated or inadequately disinfected or filtered surface and ground water. This indicates the importance of adequate water treatment (e.g., disinfection and filtration) in the prevention of transmission of waterborne diseases.

The variety of pathogens and parasites that can be found in domestic and agricultural wastewaters can be grouped into four major categories:

1. bacterial pathogens including *Salmonella*, *Shigella*, virulent strains of *E. coli* (e.g., 0157:H7), *Campylobacter*, and *Yersinia* that cause gastrointestinal (enteric) infections such as typhoid, shigellosis and cholera;

2. viral pathogens comprised of at least 140 different types of enteric viruses causing diseases such as gastroenteritis, hepatitis, meningitis and respiratory infections;

3. protozoan parasites such a *Giardia lamblia*, *Cryptospridium*, *Entamoeba histolytica* and *Naegleria* that cause gastrointestinal ailments (diarrhea, nausea, loss of appetite, and low-grade fevers), amoebic dysentery, and amoebic meningoencephalitis; and

4. helminth (nematode and trematode worms) parasites that infect the gastrointestinal system causing a variety of enteric ailments (Bitton, 1994).

Monitoring surface and ground water for all of the above pathogens is not practical or economical. To identify the potential for pathogens to be present and determine safety of drinking waters, two bacterial groups are most commonly monitored. These are total coliforms and fecal coliforms.

Total coliforms are a group of aerobic and facultative anaerobic, rod-shaped, Gram-negative bacteria that ferment lactose at 35°C (American Public Health Association *et al.*, 1989). This group of bacteria is present in human and animal fecal matter and may be an indicator of fecal contamination and the presence of pathogenic agents. However, this group also contains bacteria that are not related to fecal matter (i.e., soil bacteria) and may only be an indicator of surface water runoff or surface water contamination of ground water. Total coliforms are most frequently monitored in water treatment as a way to evaluate overall disinfection performance, but have also been used to assess the safety of potable water supplies, shellfish harvesting beds, recreational swimming areas, and reclaimed wastewater.

Fecal coliforms are a subgroup within the total coliforms group that can ferment lactose at 44.5°C (APHA *et al.*, 1989). Recent refinements in testing permits direct detection for *E. coli* only. This subgroup contains bacteria, such as *E. coli* and *Klesiella pneumonae*, that are found in fecal matter of warm-blooded animals only. The fecal coliforms reflect contamination of surface and ground water with untreated or inadequately treated domestic wastewaters and nonpoint source agricultural runoff that contain fecal matter. This characteristic also makes fecal coliforms a good indicator for the presence of pathogenic bacteria. However, its usefulness in evaluating the presence of other pathogenic groups is limited because of differences in survival from exposure to environmental factors (e.g., disinfection).

To protect the public from potential pathogenic hazards the FDEP promulgated numeric criteria for both total and fecal coliforms for the various water classifications. Class I waters are not permitted to contain more than a monthly average (using log-normal statistics) of 200 fecal coliforms and 1,000 total coliforms in a 100-ml sample. Class II waters are not permitted to contain more than a median of 14 fecal coliforms and 70 total coliforms in a 100-ml sample. Class III waters are not permitted to contain more than a monthly average (using log-normal statistics) of 200 fecal coliforms and 1,000 total coliforms in a 100-ml sample.

H-A.2.2 Chlorophyll-*a*

Chlorophyll-*a* is a photosynthetic pigment in plants and algae. It is typically measured to estimate phytoplankton biomass in lakes and estuaries since planktonic algae contain a number of chlorophyll pigments including chlorophyll-*a*. Planktonic algae are comprised of between one and two per cent chlorophyll-*a* on a dry weight basis (APHA *et al.*, 1989). Biomass of algae in surface waters generally responds to nutrient loading (nitrogen and phosphorous) and as a result, chlorophyll-*a* can be used as an indicator of the trophic status of the water body and the severity of cultural eutrophication. Generally, the higher the chlorophyll-*a* concentration, the greater the productivity of the lake or other surface water. The National Academy of Science and National Academy of Engineering (1972), as reported in Thomann and Mueller (1987), have suggested lake trophic status for concentrations of chlorophyll-*a* that are less than 4 µg/L are oligotrophic, between 4 and 10 µg/L are mesotrophic, and greater than 10 µg/L are eutrophic.

Eutrophication is the natural aging process of lakes and estuaries. Cultural eutrophication is the acceleration of this aging process, or increased productivity, associated with increased loading of nutrients to the water body (Cole, 1979). Excess productivity associated with cultural eutrophication can result in deleterious consequences to lakes and estuaries. The large algal biomass can produce substantial organic material that when decomposed by bacteria in the waters, will consume dissolved oxygen and can potentially produce anoxia (i.e., DO less than 2 mg/L). This low DO is detrimental to aquatic life (e.g., fish and insect larvae), causing their avoidance of low DO areas and/or their mortality. Other water quality problems associated with excess productivity include floating algal mats, loss of submerged aquatic vegetation, fish kills, and odor problems from the anaerobic decay of organic matter. In addition, the excess productivity may impart taste and odor problems to the water if used as a drinking water supply.

H-A.3 NUTRIENTS

H-A.3.1 Nitrite/Nitrate

Nitrites (NO_3) and nitrates (NO_4), conveniently identified together as NO_X, because of the rapid biochemical transformation of the former into the latter in natural systems under aerobic conditions, are a significant form of nitrogen pollution in the aquatic environment. Nitrate is the final result of biological nitrification and in sufficient quantity can pose a significant health risk in drinking water. As an essential nutrient for photosynthesis, its presence in excessive amounts can create water quality problems through excessive plant growth. In undisturbed freshwater systems, nitrates and nitrites are usually undetectable or nearly so, with nitrate nitrogen taken up by plants very rapidly and measurable nitrogen existing almost completely in organic forms. While nitrates may be oxidized to nitrites under anaerobic conditions, this occurs primarily in the sediments and the results of these reactions are rarely seen in the water column of natural systems. Nitrite and nitrate are reported in milligrams per liter (mg/L) or micrograms per liter (µg/L) for convenience in reporting varying levels. The most significant sources of NO_X pollution include sewage effluents and agricultural runoff, although storm water runoff from development can also contain high levels of these compounds.

H-A.3.2 Ammonia/Unionized Ammonia

Ammonia is typically found in waters as ammonium (NH_4^+) which is formed as an intermediate bacterial decay product in the mineralization of organic nitrogen, principally proteins, to nitrate (NO_4). Ammonia may also be formed from the reduction of nitrate in organic sediments (e.g., wetlands) where anaerobic conditions prevail. In natural undisturbed aqueous environments, ammonia is typically found at very low concentrations (less than 1 mg/L) but may become temporarily elevated in surface waters during seasonal influx of detrital vegetative matter or from periodic turnover in freshwater lakes.

As a pollutant, ammonia can be released into waterbodies from agricultural runoff, fertilizers, animal waste, and treated municipal wastewater. Municipal wastewater treatment often incorporates nitrification, i.e., the process where ammonia is oxidized to nitrate, to minimize ammonia concentrations in the effluent to less than 2 mg/L (Metcalf and Eddy, Inc., 1979). As a nitrogen source, ammonia can act as a nutrient for primary productivity (i.e., algae and plants) and may be an agent in cultural eutrophication of surface waters. Nitrogen is frequently the limiting nutrient in surface waters, although the importance of nitrogen can be minimized in freshwater by blue-green algae (*Cyanobacter*) not found in saline environments, which are capable of fixing atmospheric nitrogen (N_2).

At elevated ammonia levels, the concentration of unionized ammonia (NH_3), a fraction of the total ammonia based on water temperature and pH, may increase to levels that may be toxic to aquatic life. The FDEP has propagated an ambient water quality standard of 0.02 mg/L, a concentration below which no toxic effects are likely for unionized ammonia, which equates to a total ammonia of approximately 3.5 mg/L for freshwater with a pH=7 and 1.3 mg/L for saltwater (salinity=35 ppt) with a pH=7.7, calculated at a temperature of 25°C and 1 atmosphere using information in Emerson *et al.*, 1975 and Stumm and Morgan, 1981. Elevated concentrations are typically only found in areas of high nonpoint source runoff or non-nitrified point source discharges.

Additional information on ammonia may be found in the USEPA Fact Sheet entitled *EPA Facts About Ammonia* (USEPA, 1992f).

H-A.4 PHYSICAL PARAMETERS

H-A.4.1 pH

The pH parameter reflects the intensity of the acidic or alkaline (basic) condition of water. By definition, pH is the negative logarithm of hydrogen ion concentration:

$$pH = -\log_{10} [H^+]$$

Typically, pH in natural waters ranges from about pH=6.0 to pH=8.5 expressed as (often assumed as) International Units (I.U.). However, there are many specific exceptions. Hypereutrophic lakes may range above a pH=9 as a result of intense photosynthetic activity which generates hydroxyl ions $[OH^-]$. Softwater systems, particularly those high in dissolved organic acids (so-called blackwater systems) may maintain pH levels well below pH=6. Organic sediments may exhibit very low pH due to the presence of humic acids and anaerobic bacterial oxidation of sulfur compounds as an energy pathway. The effects of pH changes to natural systems as a result of very acidic or basic pollution inputs are generally localized, and dramatic pH shifts of entire systems are most often the result of biological changes produced by other pollutants. Class III water quality standards for pH include 8.5> pH >= 6.0 in freshwater and 8.5> pH >= 6.5 in marine waters, with a variation of less than 1 unit from background value.

H-A.4.2 Dissolved Oxygen

Dissolved Oxygen (DO) is the amount of oxygen dissolved in the water column. Potential oxygen saturation levels are related to the water temperature and salinity (warmer water and higher salinity waters hold less oxygen). DO is a measure of the balance between theoretical oxygen concentration at saturation and the oxygen production and consumption of the water column. Photosynthetic activity produces oxygen during daylight hours, but also has a respiratory component (which is continuous, but is pronounced at night). Heterotrophic activity, from bacterial decay processes to vertebrate respiration, consume oxygen. Organic loading demands from sewage and other organic pollution sources (e.g., storm water runoff) likewise decrease DO. Physical re-aeration through the action of wind and turbulent mixing is an important oxygen pathway for DO increases in lakes and rivers, but much less important in emergent marshes. DO in marshes generally fluctuates widely and often approaches anoxia for short periods of time. Such conditions in lakes and rivers are unusual unless they are polluted. The water quality standard for DO is waterbody-dependent but often is set at a minimum of 5.0 mg/L.

H-A.4.3 Specific Conductance (Conductivity)

Specific Conductance or Conductivity (also known as electrical conductivity and abbreviated “cond.”) is a reflection of the total ionic strength of an aqueous solution, measured in µmhos/cm. It is the reciprocal of the resistance resulting between two platinum electrodes 1 cm^2 in area, placed 1 cm apart in solution. It is properly reported as adjusted to a temperature of 25°C, since temperature is a significant factor in the measured value. Conductivity is particularly useful as a convenient measure of salinity. However, it may be a relatively inaccurate description of hydrologic effects (rainfall, evapotranspiration, runoff) in wetlands because concentrations of dominant ionic salts there are altered by biological and physical conditions in the wetlands as well as by physical dilution and concentration. Conductivity of natural inland surface waters usually ranges from about 10µmhos/cm to 500 µmhos/cm . Conductivity in full seawater is about 3,500 µmhos/cm and conductance in salt pans can reach over 60,000 µmhos/cm. Changes in conductivity are particularly relevant to the effects of freshwater as a pollutant in estuarine and marine systems, when such inflows reduce salinity and affect natural and commercial animal populations such as shellfish. Class II criteria for specific conductance is less than or equal to the maximum of 50% above background or a value of 1,275 µmhos/cm.

H-A.4.4 Turbidity

Suspended and colloidal matter causes turbidity in water. It is generally measured as the amount of light scattered by a sample as compared to a reference sample of clear water, referred to as the nephelometric method. Values are reported in Nephelometric Turbidity Units (NTU). Freshwaters generally range between 0 NTU and 20 NTU. Nutrient-polluted waters tend to be more turbid as a result of increased algal biomass, resuspension and transport of sediments, and suspended bottom materials. Runoff from development and construction activities can significantly contribute to turbidity, particularly as a result of soil disturbance and erosion. Increased turbidity can result in the loss of submersed vegetation and reduced emergent vegetation growth and expansion. Turbidity standards for permitted activities adjacent water bodies are generally set to the ambient turbidity conditions. The turbidity Class III Water Quality Standard is <=29 units above background conditions.

H-A.4.5 Oil and Grease

Oil and grease is only rarely considered a component of natural ecosystems and never in Florida. These pollutants enter the environment from road and parking lot runoff, from industrial and commercial sources, and from leaking storage tanks both above and below ground. Oil and grease is processed slowly by living systems and after entry into a natural system, it tends to coat, smother, and poison the bottom communities, plants and animals with which they come into contact before they are degraded. Oil and grease is measured in mg/L and as one parameter (i.e., water chemistry analysis).

H-A.4.6 Temperature

Temperature, measured as degrees Celsius (°C) or degrees Fahrenheit (°F) is a physical characteristic of water that is influenced by the climate, the nature of the water body (e.g., ocean, estuary, river, lake or wetland), and ground-water inputs. Local air temperatures set the basic range for temperature, which is then modified by specific conditions. Water bodies with greater volumes and depth, tend to fluctuate less than shallow waterbodies such as wetlands. The water temperature in a marsh may reach the daily low in all except extreme cases and approach daily highs. Temperature is an important factor in DO and specific conductance measurements. Water temperature may be an important local effect around industries using water as a coolant (e.g., power plants) and where freshwater flows enter estuarine/marine systems.

H-A.4.7 Salinity

Salinity is a measurement of the mass of total dissolved ions in a water sample and is most often used as a descriptor of estuarine and marine ecosystems. It is reported as parts per thousand (ppt = $^0/_{00}$), which is the number of grams of salt dissolved in 1 kg of water. Salinity is inversely and non-linearly related to oxygen saturation, with saltwater DO saturation about 86% of the freshwater saturation value at 20°C. Seawater is considered to be about 35 ppt, and freshwater is often defined as having less than 0.05 ppt. Salinity is primarily of concern as an indicator of freshwater pollution by dilution of normal estuarine or marine salinities resulting from storm water management practices, or the saltwater intrusion of estuarine or marine waters into inland fresh waters due to increased inland freshwater usage or decreased rainfall. Salinity water quality standards are generally system specific.

H-A.5 OTHER PARAMETERS

H-A.5.1 Polycyclic Aromatic Hydrocarbons (PAHs)

Based on the USEPA Fact Sheet entitled *EPA Facts About Polycyclic Aromatic Hydrocarbon* (USEPA, 1992g), PAHs "are a group of chemicals formed during the incomplete burning of coal, oil, gas, refuse, or other organic substances." They are a class of chemicals that have a similar molecular structure, which is comprised solely of carbon and hydrogen atoms that form rings of various configurations. PAHs, as pure chemicals, are generally colorless, white, or pale-green solids that mostly occur as mixtures or compounds of two or more PAHs. Over 100 different PAH compounds have been identified. PAHs are not readily water soluble, can evaporate into the air, adhere to soil and dust particles, resist burning, and will persist for months to years in the environment (ATSDR, 1995).

PAHs are typically formed as combustion by-products from sources as common as car engines, wood burning stoves, cigarettes, industrial soot, and charbroiled foods. Creosote-treated wood also contains PAHs. Other sources include wood-preserving facilities and former gas-manufacturing sites. Natural sources of PAHs include volcanos, forest fires, and shale oil. Typical PAHs include the following compounds:

- acenapthene
- acenaphthylene
- anthracene
- benzo(a)anthracene
- benzo(a)pyrene
- benzo(b)fluoranthene
- benzo(g,h,i)perylene
- benzo(k)fluoranthene
- chrysene
- dibenz(a,h)anthracene
- fluoranthene
- fluorene
- indeno(1,2,3-cd)pyrene
- phenanthrene
- pyrene

PAHs can enter the human body through several routes of exposure, including inhalation, ingestion, and contact with skin. The rate at which PAHs are able to be absorbed by the body is increased when the compounds are found in oily mixtures. Once absorbed into the body, PAHs tend to be stored in fatty tissues. Most PAHs are eliminated from the body within a few days, primarily through bodily wastes (Andrews and Snyder, 1991; ATSDR, 1995).

Although most PAHs do not readily dissolve in water, PAHs have been identified in some U.S. drinking water supplies. As such, PAHs can become a water quality concern. In response to toxicological data for benzo(a)pyrene, federal guidelines have been developed to protect the public from potential health effects of PAHs in drinking water.

Various PAH treatment methods exist. PAHs in solution that bind to particles (some one-third of the PAHs) can be removed by sedimentation, flocculation and filtration processes. The rest of the dissolved PAHs can be partially removed or transformed by oxidation. Also, specific PAHs can be destroyed by rotary kiln incineration (1,500^{B} F to 3,000^{B} F), while others can be oxidated with concentrated sulfuric acid. Anthracene, a PAH form that may be a water contaminant, can be destroyed by sorption (activated charcoal), filtration (activated charcoal bed) and oxidation (chemical) (USEPA, 1992g).

H-A.5.2 Sulfate

Sulfate (SO_4^{-2}) is an anion found in fresh and saltwater. In freshwater, sulfate is usually the second most common anion after carbonate with concentrations typically ranging from 0 to 500 mg/L. In seawater, sulfate is the second most common anion after chloride with mean seawater sulfate concentrations averaging 2,600 mg/L (Thurmann, 1981). Sources of sulfate in waters can be attributed to natural and anthropogenic sources. In Florida, natural sources of sulfate in freshwater include geologic formations (i.e., connate water or gypsum-bearing strata), atmospheric entrained aerosols from sea spray, and volcanic activity. Anthropogenic inputs of sulfate to freshwater include fossil fuel combustion, agricultural fertilizers, industrial wastewater and treated municipal wastewater (sulfate surfactants in detergents).

Sulfate is the most oxidized form of sulfur but can be changed (reduced) to other oxidation states via a number of chemical and biologically-mediated reactions. Assimilatory sulfate reduction is a metabolic process performed by various biota to reduce sulfate to incorporate the reduced sulfur, as a sulfhydryl group (SH), into amino acids (cysteine, cystine, and methionine) which are important building blocks in many proteins (Atlas, 1984). Dissimilatory sulfate reduction is a bacterially-mediated process that occurs in anaerobic environments (e.g., wetland and lake sediments) in which sulfate is used as an electron acceptor producing sulfide during the decomposition of organic substances. The bacteria, known collectively as sulfate-reducing bacteria (SRB), and the sulfide end-product have been implicated in the biogeochemical cycling of various trace and toxic metals (e.g., iron, copper, lead and mercury) in the environment. Typically, metals have a very low solubility in the presence of sulfide but may be mobilized in a bacterially-mediated process known as methylation (Stumm and Morgan, 1981).

Sulfate is generally an indicator of ground-water pollution from saltwater intrusion along coastal waters or from influx of deep confined brackish aquifers into overlying fresh ground water. In coastal surface water tidal estuaries, sulfate may also be an indicator of salinity and seawater intrusion into predominately freshwater areas resulting from inadequate freshwater flow into the estuary. This estuary intrusion can have deleterious consequences on freshwater biota if salinity is increased above tolerances levels. Slight increases in sulfate concentrations are frequently associated with human activities but the increases tend not to have any direct deleterious consequences.

H-A.5.3 Chloride

Chlorine is a halide that is most commonly found as the chloride (Cl^-) ion in water. In freshwater, chloride is usually the third most common anion after carbonate and sulfate with concentrations typically below 250 mg/L. In seawater, sulfate is the most common anion with the mean seawater chloride concentration averaging 19 g/L (Thurmann, 1981). Sources of chloride in waters can be attributed to natural and anthropogenic sources. In Florida, natural sources of chloride in freshwater include geologic formations (i.e., connate water and evaporite minerals) and atmospheric entrained aerosols from sea spray. Anthropogenic inputs of chloride to freshwater include industrial and process wastewater, agricultural runoff, and treated municipal wastewater; human and animal excretions contain about 5 g/L of chloride (Cole, 1979).

Similar to sulfate, chloride is generally an indicator of saltwater intrusion into ground water along coastal waters or from influx of deep confined brackish aquifers into overlying fresh ground water. In coastal surface water tidal estuaries, chloride may also be an indicator of salinity and seawater intrusion into predominately freshwater areas resulting from inadequate freshwater flow into the estuary. This estuary intrusion can have deleterious consequences on freshwater biota if salinity is increased above tolerances of freshwater biota. In public drinking waters, chloride levels may be of human health concern because of its relationship with sodium concentrations.

H-A.5.4 Dioxins and Furans

Dioxins and furans are closely related chlorinated organic compounds that cause cancer in animals, are toxic to aquatic life at very low levels, and may affect immune, reproductive, and hormonal systems in humans. There are 75 different dioxin compounds (7 are toxic) and 135 different furan compounds (10 are toxic). The specific dioxin compound 2,3,7,8-tetrachloro-dibenzo-p-dioxin (TCDD) is the most potent of all the dioxins/furans and is classified as a probable human carcinogen by the USEPA. Sources to the environment are incinerators, cement kilns, smelters, and by-products from various manufacturing processes such as paper mills**.** In the environment, dioxins and furans can enter aquatic areas, are highly persistent, and have a strong affinity to attach to sediments, soils, and fatty tissue. The main routes of human exposure are thought to be via atmospheric deposition on plants and soil and subsequent ingestion through animals and fish.

The USEPA has developed water quality criteria for TCDD to protect against bioaccumulation in fish to levels that could cause cancer in humans. The USEPA believes that if water column values for TCDD do not exceed 0.014 parts per quadrillion (ppq), then there is less than one chance in a million that a person will develop cancer based on a lifetime of consuming fish from a given waterbody. To date, the USEPA has not developed aquatic life or sediment criteria for dioxin (USEPA, 1984). In December 1992, the USEPA promulgated 0.014 ppq as the water quality criterion for the State of Florida for all surface waters. However, based on the best available analytical methods, TCDD can be only detected in water down to levels of 1-5 ppq. To ensure that bioaccumulation is not occurring, the USEPA recommends that fish/shellfish tissue dioxin levels also be assessed. Since 1992, the USEPA has been reassessing the sources and health implications of dioxin in the environment and is expected to finalize its results by the end of 1998.

Additional general information on dioxin may be found in the USEPA Fact Sheet entitled *EPA Facts About Dioxin* (USEPA, 1992h).

H-A.5.5 Polychlorinated Biphenyls (PCBs)

PCBs are another class of chlorinated organic compounds that bioaccumulate in and are toxic to fish. They are classified by the USEPA as probable human carcinogens. Production of PCBs has been banned in the U.S. since the mid-1970's. Due to their long half-life and extensive use as heat transfer fluids and lubricants in capacitors and transformers, environmental contamination is ongoing. There are 10 classes or mixtures of PCBs, comprising 209 separate compounds. In the environment, PCBs can enter aquatic areas, are highly persistent and have a strong affinity to attach to sediments, soils, and fatty tissue.

The USEPA initially developed PCB water quality criteria in October 1980, but revised them in May 1989: for freshwater aquatic life - 0.014 ppb; for saltwater aquatic life - 0.03 ppb; and for human health from consumption of contaminated water and organisms - 0.000044 ppb. Florida has adopted the above criteria values. However, based on the best available analytical methods, PCBs can be only detected in water down to levels of 0.0065 ppb. To ensure that bioaccumulation is not occurring, the USEPA recommends that fish/shellfish tissue dioxin levels also be assessed. The USEPA is currently reassessing the PCB human health criteria and may be revising them in the near future.

Additional general information on PCBs may be found in the EPA Fact Sheet entitled *EPA Facts About Polychlorinated Biphenyl* (USEPA, 1992i).

H-A.5.6 Volatile Organic Compounds (VOCs)

According to the USEPA Fact Sheet entitled *EPA Facts About Air Stripping* (USEPA, 1992j), VOCs are "chemicals which tend to vaporize rapidly when heated or disturbed." A common example is gasoline fumes, which can be easily smelled during car fueling. Other VOCs include 1,1,1-trichloroethane, trichloroethylene, dichlorothylene, chlorobenzene, and vinyl chloride. VOCs can be associated with hazardous waste sites and the combustion of various fuels and materials relative to cars, incinerators, refineries, fossil fuel power plants, etc. VOCs can also be found in industrial products, such as pesticides, solvents, degreasers, and fumigants.

VOCs may also be released into the environment from vehicle exhaust, incinerators, and manufacturing processes. They can be found in soil, air, and water as a result of human activity. VOCs can enter the body through ingestion of drinking water, inhalation of airborne particulates, and dermal contact with contaminated soil containing these contaminants. Water supplies from nearly every region in the United States contain concentrations of VOCs. Generally, they are found in greater concentrations in groundwater than surface water. This is due to the exposure of surface water to air, which results in volatilization of these chemicals. VOCs enter the water supply from agricultural runoff, industrial processes, accidental chemical spills, and improper disposal of chemical substances. VOCs may also be introduced into the water supply as a byproduct of chlorine disinfection treatment (Domenico and Schwartz, 1990).

There is a wide range of health effects associated with exposure to VOCs due to the different chemical properties of each of these substances. VOCs have been associated with adverse health effects on the nervous, reproductive, and immune systems. Short-term exposure to VOCs may cause headaches, dizziness, and nausea. Long-term effects associated with exposure include kidney and liver dysfunction. In addition, some VOCs, such as benzene, have been categorized as human carcinogens (Andrews and Snyder, 1991).

Water sources containing high concentrations of VOCs may require water treatment to meet the established Federal Drinking Water Standards for these chemicals. An effective technology for the removal of VOCs from water is granular activated carbon (GAC). During this treatment process, the treated activated carbon material binds with these chemicals and removes them from the water supply. Another treatment method that is utilized for VOC removal is air stripping. This process involves the use of large quantities of air to eliminate the chemicals by evaporation. VOC contamination of water can be remediated (cleaned up) via the "air stripping" process, which essentially revaporizes and collects the VOCs out of a disturbed water stream and into an air stream (USEPA, 1992j). This process may or may not need to be supplemented by another process to completely remove the VOC contaminants. VOCs in soils can be removed by a soil vapor extraction (SVE) system (Domenico and Schwartz, 1990).

According to the USEPA Fact Sheet entitled *EPA Facts About Air Stripping* (USEPA, 1992j), air stripping has been successfully used at the Sydney Mine site in Valrico, FL and a municipal well site in Tacoma, WA. The air stripping method has been commonly used in association with pump-and-treat methods for treating ground water contaminated with VOCs.

In addition to air, VOCs can also eventually enter the water medium, both into surface water and ground water. VOC concentrations in water are typically measured in parts per million (ppm) or parts per billion (ppb). VOC contamination of water can be remediated (cleaned up) via the “air stripping” process, which essentially revaporizes and collects the VOCs out of a disturbed water stream and into an air stream. This process may or may not need to be supplemented by another process to completely remove the VOC contaminants. VOCs in soils can be removed by a soil vapor extraction (SVE) system.

H-A.5.7 Bioaccumulation and Biomagnification

Bioaccumulation is the process where the level of pollutants (e.g., metals, toxins, pesticides) in aquatic organisms increase through uptake from the water column and via food. Biomagnification is the process where the pollutant levels in aquatic organisms increase up the food chain. Both bioaccumulation and biomagnification are measured in parts ppm or ppb through analysis of flesh tissue or wholebody samples.

Chemicals that are absorbed by the body through inhalation, ingestion, or dermal contact are either removed from the body through elimination, are bound to bodily tissues, or a combination of the two. Some compounds, once absorbed by the body, may remain stored within bodily tissues for a period of several years or longer. Because the process of removal for these compounds is very slow, any new ingestion of the chemical adds to the overall “body burden,” or amount stored in bodily tissues. This process is known as bioaccumulation (USEPA, 1998: internet).

There are two factors that favor the bioaccumulation of certain chemicals. The first involves the persistence of chemicals in the environment, such as heavy metals and halogenated hydrocarbons. These chemicals are nonbiodegradable and many organisms lack the appropriate enzymes necessary to break them down. Another factor that affects the bioaccumulation of substances is their ability to be absorbed by the organism. Some substances readily enter the body, but are very slowly excreted. For example, heavy metals become tightly bound with proteins and cannot be easily removed. This is also true of halogenated hydrocarbons that are fat-soluble and unable to be removed from biological processes in the body and excreted. The strength of the bonds formed and the body's regulation of the chemical determines the length of time that the stored compound will remain within the body. Over time, the concentration of a contaminant stored within the body of an organism may exceed the concentration found in the environment (USEPA, 1998: internet).

Bioaccumulation can be especially important to organisms that live within a contaminated medium. For example, fish will bioaccumulate concentrations of mercury that can be orders of magnitude higher than the concentrations found in the water in which they swim. As a concentration bioaccumulates within an organism, it may eventually reach concentrations that are toxic to the organism.

In some cases it is possible for bioaccumulation to be compounded in a food chain. The concentrating effect that occurs through a food chain is referred to as biomagnifaction. Organisms at the bottom of the food chain exposed to contamination absorb chemical substances from the environment and store them within tissues. Organisms at the second trophic level (next level in the food chain) accumulate higher concentrations of the chemical within their tissues from feeding on these organisms, in addition to the concentrations that they are exposed to in their habitat. In some cases, organisms at the top of the food chain may accumulate levels that are as much as 100,000 times higher than environmental concentrations (USEPA, 1998: internet; Laws 1991).

USEPA's human-health-based water quality criteria are intended to protect against bioaccumulation. However, 30 of USEPA's 110 criteria cannot be detected by the best analytical methods that are available. That fact does not decrease their scientific validity. In such instances, USEPA recommends that fish or other aquatic organism tissue levels be assessed to ensure that bioaccumulation is not occurring.

It should be noted that although concentrations of water quality pollutants in the water column may be short termed or at low levels, these pollutants can be bioaccumulated and biomagnified to important levels over time in animals and can accumulate in sediments. As such, animals (particularly sessile species) and sediments can help provide a history of water quality conditions of a given project area.

ATTACHMENT B
ADDITIONAL PARAMETER DATA

In addition to the water quality data discussed in **Appendix H** for those water quality parameters considered "key" to respective regions designated in this PEIS, additional "other" water quality data are presented below by region. References used for the data compilation of the key and other parameters are provided in **Appendix H**.

H-B.1 KISSIMMEE RIVER REGION

Other Region-Specific Water Quality Parameters

Data for other water quality parameters for the Kissimmee River Region are presented below. These water quality parameters are pH, conductivity, turbidity, and pesticides.

H-B.1.1 pH

The pH level in the main channel of C-38 averaged 6.93 (range: pH=6.40 to pH= 7.75), while at the outflow from Lake Kissimmee in the north, pH averaged slightly though not significantly lower (pH=6.73) with a range from pH=5.6 to pH=7.45. There was not an apparent trend from north to south in the basin, and the circumneutral values are not indicative of any water quality problem with pH.

H-B.1.2 Conductivity

Specific conductance was generally low within the basin, averaging between 127 and 149 µmhos/cm along C-38 without any clear trend from north to south. The data suggest that tributaries had little influence on the quality of water with respect to conductivity. There were distinct seasonal changes, however, with typically lower values during discharges, which has been attributed to the dilution effect of rainfall. Different flow regimes affect the distribution of conductivity values with depth. During periods of high discharge, the water column is well mixed; however, during low-flow periods, gradients of 0 µmhos/cm to 10 µmhos/cm per meter depth develop.

H-B.1.3 Turbidity

Long-term mean turbidity values tended to be low throughout C-38, ranging from 2.8 NTU to 3.5 NTU at five points along the channel for the period 1973-1978. Tributary data showed similar values, with the maximum of 5.2 NTU.

H-B.1.4 Pesticides

Specific pesticides data exist for the Kissimmee River Region (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). Three monitoring sites were sampled by SFWMD (R. Pfeuffer: SFWMD, 1998 personal communication). The S65A and S65E sites were only sampled from October 1995 through May 1997. For these sites, only three pesticides were detected. None of the pesticides exceeded any numeric or calculated F.A.C. 62-302 criteria.

H-B.2 LAKE OKEECHOBEE

Other Region-Specific Water Quality Parameters

Data for other water quality parameters for Lake Okeechobee are presented below. These water quality parameters are pH, dissolved oxygen, ammonia/ unionized ammonia, conductivity, temperature, and pesticides.

H-B.2.1 pH

The 1996 305(b) report (FDEP, 1996) shows in-lake pH values ranged from a high of pH=8.4 to a low of pH=7.4. There were no apparent trends in the lake related to pH. The pH of water in the lake basin were generally lower than those observed in the lake as shown below:

- S-135 (current) pH=7.6
- S-135 (historic) pH=7.0
- Lettuce Creek pH=6.7
- Myrtle Creek pH=6.1

The mean pH value reported in James *et al.* (1995) for the period from 1973 to 1992 was pH=8.2, with an associated standard deviation of pH=0.3. The median pH value for the lake was reported as pH=8.1, with minimum and maximum values of pH=7.2 and pH=9.0, respectively.

H-B.2.2 Dissolved Oxygen

The 1996 305(b) report shows in-lake DO levels ranged from a high of 8.7 mg/L to a low of 6.0 mg/L. All reported values appeared to comply with State of Florida water quality standards. The mean value of the reported DO levels was 7.8 mg/L, and there were no apparent trends in the lake related to DO. The DO level of water in S-135 during the current period of record (1990-1995) was 6.8 mg/L; however, the data collected at this station prior to the current period averaged 2.9 mg/L. DO levels of 4.1 mg/L and 0.5 mg/L were reported for Lettuce Creek and

Myrtle Slough, respectively. The 305(b) report indicated the poorest water quality was found in Myrtle Slough, which may be related to the DO levels.

The mean DO concentration for the period of 1973 to 1992 was 8.4 mg/L, with an associated standard deviation of 1.0 mg/L (James *et al.*, 1995). The median concentration for the lake was reported as 8.3 mg/L, with minimum and maximum values of 5.9 mg/L and 12.6 mg/L, respectively.

H-B.2.3 Ammonia/Unionized Ammonia

James *et al.* (1995) reported that the mean ammonium concentration for the period from 1973 to 1992 was 0.02 mg/L, with an associated standard deviation of 0.02 mg/L. The median concentration for the lake was reported as 0.01 mg/L, with minimum and maximum values of 0.01 mg/L and 0.2 mg/L, respectively.

H-B.2.4 Conductivity

James *et al.* (1995) reported the mean specific conductance for the period of 1973 to 1992 was 595.9 µmhos/cm, with an associated standard deviation of 82.7 µmhos/cm. The median conductivity for the lake was reported as 589.5 µmhos/cm, with minimum and maximum values of 427 µmhos/cm and 895 µmhos/cm, respectively.

H-B.2.5 Temperature

James *et al.* (1995) reported that the mean temperature for the period of 1973 to 1992 was 24.7°C, with an associated standard deviation of 4.6°C. The median temperature for the lake was reported as 25.6°C, with minimum and maximum values of 10.7°C and 31.7°C, respectively.

H-B.2.6 Pesticides

Six locations within Lake Okeechobee were sampled in 1987 (Pfeuffer, 1989). Neither the water nor sediment samples had any detectable residues of the 61 different pesticides and degradation products. In addition, specific SFWMD pesticides monitoring information also exists for the Lake Okeechobee Region (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). During this period (1992-1997), five pesticides were detected. None of the pesticides exceeded any numeric or calculated State of Florida F.A.C. 62-302 criteria (R. Pfeuffer: SFWMD, 1998 personal communication).

H-B.3 UPPER EAST COAST AND INDIAN RIVER REGION

Other Subregion-Specific Water Quality Parameters

H-B.3.1 St. Lucie River Subregion

Data for other water quality parameters for the St. Lucie River subregion are presented below. These water quality parameters are pH, conductivity, and turbidity.

H-B.3.1.1 pH

The mean pH value for the river was pH=7.2 in the south and north Fork, and pH=7.5 in the estuary.

H-B.3.1.2 Conductivity

The mean specific conductance of the river was 888 µmhos/cm in the south Fork, 9,194 µmhos/cm in the north, and 19,475 µmhos/cm in the estuary.

H-B.3.1.3 Turbidity

According to the 1996 305(b) report (FDEP, 1996), the mean turbidity level in the river was 4.5 mg/L in the south Fork, 6.2 mg/L in the north, and 4.9 mg/L in the estuary.

(Note: Units for turbidity data for the St. Lucie subregion were inadvertently reported by FDEP (1996) as “mg/L” as opposed to “NTU”.)

H-B.3.2 Indian River Lagoon Subregion

Data for other water quality parameters for the IRL subregion are presented below. These water quality parameters are dissolved oxygen and Polycyclic Aromatic Hydrocarbons (PAHs).

H-B.3.2.1 Dissolved Oxygen

The mean DO concentration in the south IRL was 7.33 mg/L (with a standard deviation of 1.57 mg/L) for the period of 1989 to 1991. The maximum and minimum concentrations for the same period were 14.7 mg/L and 2.8 mg/L, respectively.

H-B.3.2.2 Polycyclic Aromatic Hydrocarbons (PAHs)

Based on FDEP and SFWMD data from ongoing monitoring programs, C-25 is known to transport PAHs into the estuary and offshore.

H-B.4 EVERGLADES AGRICULTURAL AREA

Other Region-Specific Water Quality Parameters

Data for other water quality parameters for the EAA are presented below. These parameters are pH, temperature, ammonia/unionized ammonia, and turbidity.

H-B.4.1 pH

The mean pH value for all stations reported for the EAA was pH=7.22, while the recorded mean pH values for these same stations ranged from pH=6.61 to pH=7.75. The median pH value for all stations reported by Limno-Tech (1995) was pH=7.21, while the median values ranged from pH=6.2 to pH=7.63. The minimum and maximum pH values reported by Limno-Tech (1995) were pH=3.4 and pH=10.7, respectively.

H-B.4.2 Temperature

Long-term average water temperatures in EAA waters are typical of regional values, ranging from 23.7 to 24.7°C at four pump stations sampled between 1977 and 1989.

H-B.4.3 Ammonia/Unionized Ammonia

The mean unionized ammonia concentration reported by Limno-Tech (1995) was 0.0072 mg/L, while the mean concentrations ranged from 0.0001 mg/L to 0.0522 mg/L. The median concentration for all stations reported was 0.0012 mg/L, while the range of median concentrations were 0.0001 mg/L to 0.0266 mg/L. The minimum and maximum concentrations recorded were <0.0001 mg/L and 8.2193 mg/L, respectively.

H-B.4.4 Turbidity

Long-term average turbidity levels at four pump stations draining the EAA ranged from 3.8 NTU to 4.6 NTU. One of the pumps had a very high coefficient of variation (220) suggesting the potential for unusually high values at that site.

H-B.5 WATER CONSERVATION AREAS

Other Subregion-Specific Water Quality Parameters

H-B.5.1 Loxahatchee National Wildlife Refuge Subregion

Data for other water quality parameters for the LNWR are presented below. These water quality parameters are ammonia/unionized ammonia, pH, turbidity, temperature, and pesticides.

H-B.5.1.1 Ammonia/Unionized Ammonia

The mean ammonia (NH_3) concentration collected at thirty-three stations in the LNWR was 0.0041 mg/L for the period from 1979 to 1993. The lowest mean concentration observed at any station in the LNWR was 0.0000 mg/L, while the highest concentration was 0.0169 mg/L. The lowest concentration observed in the basin was <0.0001 mg/L and the highest observation was 0.2775 mg/L.

H-B.5.1.2 pH

The mean pH value collected at thirty-three stations in the LNWR was a pH=6.81 for the period from 1979 to 1993. The mean pH values observed in the LNWR ranged from a pH=5.75 to pH=7.78.

H-B.5.1.3 Turbidity

The mean turbidity value collected in the LNWR was 2.4 NTU for the period from 1979 to 1993. The mean specific conductance values observed in the LNWR ranged from 0.8 NTU to 8.3 NTU.

H-B.5.1.4 Temperature

The mean temperature reading collected in the LNWR was 23.1°C for the period from 1979 to 1993. The temperature readings observed in the LNWR ranged from 10°C to 34°C.

H-B.5.1.5 Pesticides

SFWMD pesticides monitoring data (1992-1997) exist for the WCAs in general (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). Eleven inflow and outflow sites are currently sampled by SFWMD. None of the pesticides detected exceeded any numeric or calculated F.A.C. 62-302 criteria (R. Pfeuffer: SFWMD, 1998 personal communication).

H-B.5.2 Water Conservation Area 2A/2B Subregion

Data for other water quality parameters for the WCA 2A/2B subregion are detailed below. These parameters are ammonia/unionized ammonia, pH, turbidity, temperature, and pesticides.

H-B.5.2.1 Ammonia/Unionized Ammonia

The mean ammonia concentration collected in the WCA 2A basin was 0.0097 mg/L, and in the WCA 2B basin was 0.0024 mg/L, for the period from 1979 to 1993. The lowest mean concentration observed at any station in the WCA 2A basin was 0.0002 mg/L and in the WCA 2B basin was 0.0009 mg/L, while the highest concentration was 0.1041 mg/L in WCA 2A and 0.0045 mg/L in W2B. The lowest concentration observed in the WCA 2A basin was <0.0001 mg/L and in the WCA 2B basin was <0.0001 mg/L, while the highest observation was 0.6284 mg/L in WCA 2A and 0.0449 mg/L in WCA 2B.

H-B.5.2.2 pH

The mean pH value collected from WCA 2A was pH=6.98, and in WCA 2B was pH=7.34 for the period from 1979 to 1993. The mean pH values observed in WCA 2A ranged from pH=6.07 to pH=7.46, while in WCA 2B the pH ranged from pH=7.13 to pH=7.53.

H-B.5.2.3 Turbidity

The mean turbidity value collected in WCA 2A was 2.3 NTU, and for WCA 2B was 3.3 NTU for the period from 1979 to 1993. The mean values observed in WCA 2A ranged from 0.8 NTU to 9.5 NTU, while in WCA 2B these values ranged from 1.4 to 7.6 NTU.

H-B.5.2.4 Temperature

The mean temperature reading collected in WCA 2A was 24.8°C, and in WCA 2B was 25.2°C for the period from 1979 to 1993. The temperature readings observed in WCA 2A ranged from 12°C to 35.3°C, while those in WCA 2B ranged from 13°C to 33.2°C.

H-B.5.2.5 Pesticides

SFWMD pesticides monitoring data (1992-1997) exist for the WCAs in general (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). Eleven inflow and outflow sites are currently sampled by SFWMD. None of the pesticides detected exceeded any numeric or calculated F.A.C. 62-302 criteria (R. Pfeuffer: SFWMD, 1998 personal communication).

H-B.5.3 Water Conservation Area 3A/3B Subregion

Data for other water quality parameters for the WCA 3A/3B subregion are presented below. These parameters are ammonia/unionized ammonia, pH, turbidity, temperature, and pesticides.

H-B.5.3.1 Ammonia/Unionized Ammonia

The mean ammonia concentration collected in the WCA 3A basin was 0.001 mg/L, and in the WCA 3B basin was 0.0013 mg/L, for the period from 1979 to 1993. The lowest mean concentration observed at any station in the WCA 3A basin was 0.0000 mg/L and in the WCA 3B basin was 0.0000 mg/L (Limno-Tech, 1995). The highest concentration was 0.0049 mg/L in WCA 3A and 0.0032 mg/L in WCA 3B. The lowest concentration observed in the WCA 3A basin was <0.0001 mg/L and in the WCA 3B basin was <0.0001 mg/L, while the highest observation was 0.1262 mg/L in WCA 3A and 0.0146 mg/L in WCA 3B.

H-B.5.3.2 pH

The mean pH value collected in WCA 3A was pH=7.12, and in WCA 3B was pH=7.20 for the period from 1979 to 1993. The mean pH values observed in WCA 3A ranged from pH=6.65 to pH=7.52, while in WCA 3B the pH ranged from pH=7.00 to pH=7.67.

H-B.5.3.3 Turbidity

The mean turbidity value collected in WCA 3A was 3.2 NTU, and for W3B was 2.8 NTU for the period from 1979 to 1993. The values observed in WCA 3A ranged from 0.7 NTU to 32.0 NTU, while in WCA 3B these values ranged from 2.0 NTU to 3.7 NTU.

H-B.5.3.4 Temperature

The mean temperature reading collected in WCA 3A was 24.4°C, and in WCA 3B was 25.8°C for the period from 1979 to 1993. The temperature readings observed in WCA 3A ranged from 12.3°C to 34°C, while those in WCA 3B ranged from 14.6°C to 34°C.

H-B.5.3.5 Pesticides

SFWMD pesticides monitoring data (1992-1997) exist for the WCAs in general (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). Eleven inflow and outflow sites are currently sampled by SFWMD. None of the pesticides detected exceeded any numeric or calculated F.A.C. 62-302 criteria (R. Pfeuffer: SFWMD, 1998 personal communication).

H-B.6 LOWER EAST COAST REGION

H-B.6.1 Loxahatchee River Aquatic Preserve Subregion

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the WCA 3A/3B subregion are presented below. These parameters are pH, conductivity, and turbidity.

H-B.6.1.1 pH

The mean pH value for the estuarine section of the river was pH=7.8.

H-B.6.1.2 Conductivity

The mean specific conductance for the estuarine section of the river was 45,555 µmhos/cm.

H-B.6.1.3 Turbidity

According to the 1996 305(b) report (FDEP, 1996), the mean turbidity level for the estuarine section of the river was 2.4 mg/L.

(Note: Units for turbidity data for the LRAP were inadvertently reported by FDEP(1996) as “mg/L” as opposed to “NTU”.)

H-B.6.2 Lake Worth Subregion

Data for other water quality parameters for the Lake Worth subregion are presented below. These parameters are pH and conductivity.

H-B.6.2.1 pH

The 1996 305(b) report (FDEP, 1996) shows the mean pH reading recorded for the West Palm Beach Canal was pH=7.4.

H-B.6.2.2 Conductivity

According to the 305(b) report (FDEP, 1996), the mean specific conductivity level recorded for the West Palm Beach Canal was 704 µmhos/cm.

H-B.6.3 Biscayne Bay Subregion

Data for other water quality parameters for the Biscayne Bay subregion are presented below. These parameters are ammonia/unionized ammonia and salinity.

H-B.6.3.1 Ammonia/Unionized Ammonia

The mean ammonia concentration observed for the Bay ranged from 0.05 to 1.22 mg/L. Dade County has established a maximum concentration of 0.5 mg/L for total ammonia nitrogen for surface waters. Three stations in the bay exceeded this standard. Ammonia concentrations changed significantly at eleven stations during the period of record. Three stations showed declining trends in the Miami River.

H-B.6.3.2 Salinity

The mean salinity levels in the bay ranged from 0.1 ppt to 38.3 ppt. The extreme range for this parameter can be attributed to twenty-five percent of the monitoring stations being located upstream of salinity control barriers.

H-B.7 EVERGLADES NATIONAL PARK / FLORIDA BAY

Other Subregion-Specific Water Quality Parameters

H-B.7.1 Shark River Slough/Taylor Slough Subregion

Data for other water quality parameters for the Shark River Slough/Taylor Slough subregion are presented below. These parameters are nitrite/nitrate, ammonia/ unionized ammonia, pH, dissolved oxygen, conductivity, turbidity, temperature, and pesticides.

H-B.7.1.1 Nitrite/Nitrate

The SFWMD (1998a) indicated that NO_X concentrations ranged from 0.004 mg/L to 6.901 mg/L for the Shark River Slough and (one station in) Taylor Slough sub-basins. The mean NO_X concentrations ranged from 0.0279 mg/L to 0.1984 mg/L for the same time period.

H-B.7.1.2 Ammonia/Unionized Ammonia

The Limno-Tech (1995) report indicates that unionized ammonia concentrations ranged from 0.0011 mg/L to 0.01 mg/L for the period of record. The median concentrations ranged from 0.0002 mg/L to 0.0009 mg/L, while the minimum value recorded was <0.0001 mg/L and the maximum value reported was 0.2036 mg/L.

H-B.7.1.3 pH

The 1996 305(b) report FDEP (1996) indicates that the average pH value was pH=7.2 (Shark River Slough) and pH=7.3 (Taylor Slough). Limno-Tech (1995) reports that the mean pH values for this basin ranged from pH=7.28 to pH=7.48 for their period of record. The median pH values for the same period ranged from pH=7.2 to pH=7.5.

H-B.7.1.4 Dissolved Oxygen

The Limno-Tech (1995) reports shows the mean DO concentrations for this basin ranged from 4.0 mg/L to 6.4 mg/L. The median concentrations ranged from 3.8 mg/L to 6.5 mg/L, while the minimum and maximum concentrations reported were 1.2 mg/L and 11.6 mg/L, respectively.

H-B.7.1.5 Conductivity

The Limno-Tech (1995) reports shows the mean specific conductivity values for this basin ranged from 361.3 µmhos/cm to 756.7 µmhos/cm. The median values ranged from 340.5 µmhos/cm to 600 µmhos/cm, while the minimum and maximum concentrations reported were 94 µmhos/cm and 3,400 µmhos/cm, respectively.

H-B.7.1.6 Turbidity

The Limno-Tech (1995) report shows the mean turbidity level for this basin ranged from 1.7 NTU to 5.6 NTU. The median turbidity level ranged from 1.1 NTU to 4.7 NTU, while the minimum and maximum concentrations reported were 0.2 NTU and 106 NTU, respectively.

H-B.7.1.7 Temperature

Recorded water temperatures in the slough ranged from 23.6°C to 26.3°C (Limno-Tech, 1995). The median water temperature reported by Limno-Tech (1995) for the slough ranged from 24.5°C to 26.7°C, while the minimum and maximum recorded temperatures were 12.5°C and 36.5°C.

H-B.7.1.8 Pesticides

SFWMD pesticides monitoring data exist for the ENP in general (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). Nine sites are currently monitored by the SFWMD (R. Pfeuffer: SFWMD, 1998 personal communication). During 1992-1997, only endosulfan (sum of endosulfan alpha and beta) was found to exceed its Class III criterion of 0.056 µg/L. Exceedances occurred at Monitoring Site S178 on six occasions between 3/18/93 and 1/25/96. The only detection of ethion at Site S178, (0.053 µg/L, 10/16/97) exceeded the acute toxicity level (0.02 µg/L) reported for *Daphnia magna*, a sensitive indicator species for aquatic macroinvertebrate, calculated according to promulgated procedure (F.A.C. 62-302.200). At this level, short-term exposure can cause impacts to the macroinvertebrate populations.

H-B.7.2 Florida Bay Subregion

Other Subregion-Specific Water Quality Parameters

Data for other water quality parameters for the Florida Bay subregion are presented below. These parameters are nitrite/nitrate, ammonia/unionized ammonia, dissolved oxygen, turbidity, temperature, and pesticides.

H-B.7.2.1 Nitrite/Nitrate

For the 1991-1997 period of record (SFWMD, 1998: unpublished), the mean NO_X concentrations were higher, and showed greater variability, in the east basin than the west basin. The mean concentration in the east basin was 0.0224 mg/L for the period of record (1991-1997), with a corresponding standard deviation of 0.0256 mg/L. The median NO_X concentration in the east basin was 0.012 mg/L, with minimum and maximum values of 0.001 mg/L and 0.163 mg/L, respectively.

The mean NO_X concentration in the west basin was 0.0064 mg/L for the period of record, with a corresponding standard deviation of 0.0079 mg/L. The median NO_X concentration in the west basin was 0.016 mg/L, with minimum and maximum values of 0.001 mg/L and 0.061 mg/L, respectively.

H-B.7.2.2 Ammonia/Unionized Ammonia

The mean ammonia concentrations were higher and showed greater variability in the west basin than the east basin. The mean concentration in the east basin was 0.0683 mg/L for the period of record (1991-1997), with a corresponding standard deviation of 0.075 mg/L. The median ammonia concentration in the east basin was 0.046 mg/L, with minimum and maximum values of 0.0026 mg/L and 0.69 mg/L, respectively.

The mean ammonia concentration in the west basin was 0.1077 mg/L for the period of record, with a corresponding standard deviation of 0.1685 mg/L. The median ammonia concentration in the west basin was 0.042 mg/L, with minimum and maximum values of 0.002 mg/L and 1.681 mg/L, respectively.

H-B.7.2.3 Dissolved Oxygen

The mean DO concentrations were comparable for the east and west basins. The mean concentration in the east basin was 6.73 mg/L for the period of record (1991-1997), with a corresponding standard deviation of 1.0179 mg/L. The median DO concentration in the east basin was 6.7 mg/L, with minimum and maximum values of 3.2 mg/L and 15.2 mg/L, respectively.

The mean DO concentration in the west basin was 6.37 mg/L for the period of record, with a corresponding standard deviation of 1.2 mg/L. The median DO concentration in the west basin was 6.3 mg/L, with minimum and maximum values of 2.8 mg/L and 12.3 mg/L, respectively.

H-B.7.2.4 Turbidity

The mean turbidity values were higher and showed greater variability in the west basin than the east basin. The mean value in the east basin was 4.49 NTU for the period of record (1991-1997), with a corresponding standard deviation of 6.99 NTU. The median turbidity level in the east basin was 2.16 NTU, with minimum and maximum values of 0.001 NTU and 85.59 NTU, respectively.

The mean turbidity value in the west basin was 7.3 NTU for the period of record, with a corresponding standard deviation of 12.2 NTU. The median turbidity value in the west basin was 3.3 NTU, with minimum and maximum values of 0.0 NTU and 125.6 NTU, respectively.

H-B.7.2.5 Temperature

The mean temperatures were comparable for the east and west basins. The mean temperature in the east basin was 26.1°C for the period of record, with a corresponding standard deviation of 3.6°C. The median temperature in the east basin was 26.5°C, with minimum and maximum values of 15.9°C and 32.9°C, respectively.

The mean temperature in the west basin was 26.5°C for the period of record (1991-1997), with a corresponding standard deviation of 3.8°C. The median temperature in the west basin was 26.6°C, with minimum and maximum values of 16.2°C and 35.3°C, respectively.

H-B.7.2.6 Pesticides

SFWMD pesticides monitoring data exist for the ENP in general (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). Nine sites are currently monitored by the SFWMD (R. Pfeuffer: SFWMD, 1998 personal communication).

During 1992-1997, only endosulfan (sum of endosulfan alpha and beta) was found to exceed its Class III criterion of 0.056 µg/L. Exceedances occurred at Monitoring Site S178 on six occasions between 3/18/93 and 1/25/96. The only detection of ethion at Site S178, (0.053 µg/L, 10/16/97) exceeded the acute toxicity level (0.02 µg/L) reported for *Daphnia magna*, a sensitive indicator species for aquatic macroinvertebrate, calculated according to promulgated procedure (F.A.C. 62-302.200). At this level, short-term exposure can cause impacts to the macroinvertebrate populations.

H-B.7.3 Whitewater Bay Subregion

Data for other water quality parameters for the Whitewater Bay subregion are presented below. These parameters are nitrite/nitrate, ammonia/unionized ammonia, dissolved oxygen, turbidity, temperature, and pesticides.

H-B.7.3.1 Nitrate/Nitrite

The mean concentration in the bay was 0.029 mg/L for the period of record (1991-1997), with a corresponding standard deviation of 0.026 mg/L. The median NO_X concentration in the bay was 0.022 mg/L, with minimum and maximum values of 0.001 mg/L and 0.15 mg/L, respectively.

H-B.7.3.2 Ammonia/Unionized Ammonia

The mean concentration in the bay was 0.034 mg/L for the period of record (1991-1997), with a corresponding standard deviation of 0.072 mg/L. The median ammonia concentration in the bay was 0.014 mg/L, with minimum and maximum values of 0.002 mg/L and 1.046 mg/L, respectively.

H-B.7.3.3 Dissolved Oxygen

The mean concentration in the bay was 6.6 mg/L for the period of record (1991-1997), with a corresponding standard deviation of 1.4 mg/L. The median DO concentration in the bay was 6.6 mg/L, with minimum and maximum values of 2.2 mg/L and 10.7 mg/L, respectively.

H-B.7.3.4 Turbidity

The mean value in the bay was 6.3 NTU for the period of record (1991-1997), with a corresponding standard deviation of 10.6 NTU. The median turbidity level in the bay was 3.8 NTU, with minimum and maximum values of 0.2 NTU and 107.8 NTU, respectively.

H-B.7.3.5 Temperature

The mean temperature in the bay was 26°C for the period of record (1991-1997), with a corresponding standard deviation of 4.1°C. The median temperature in the bay was 26.5°C, with minimum and maximum values of 11.8°C and 32.3°C, respectively.

H-B.7.3.6 Pesticides

SFWMD pesticides monitoring data exist for the ENP in general (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). Nine sites are currently monitored by the SFWMD (R. Pfeuffer: SFWMD, 1998 personal communication). During 1992-1997, only endosulfan (sum of endosulfan alpha and beta) was found to exceed its Class III criterion of 0.056 µg/L. Exceedances occurred at Monitoring Site S178 on six occasions between 3/18/93 and 1/25/96. The only detection of ethion at Site S178, (0.053 µg/L, 10/16/97) exceeded the acute toxicity level (0.02 µg/L) reported for *Daphnia magna*, a sensitive indicator species for aquatic macroinvertebrate, calculated according to promulgated procedure (F.A.C. 62-302.200). At this level, short-term exposure can cause impacts to the macroinvertebrate populations.

H-B.7.4 Ten Thousand Islands Subregion

Data for other water quality parameters for the Ten Thousand Islands subregion are presented below. These parameters are phosphorus, nitrite/nitrate, pH, dissolved oxygen, conductivity, turbidity, and pesticides.

H-B.7.4.1 Phosphorus

The mean TP concentration recorded for this station was 0.03 mg/L (FDEP, 1996).

H-B.7.4.2 Nitrite/Nitrate

The mean total nitrogen concentration recorded for this station was 0.64 mg/L.

H-B.7.4.3 pH

The mean pH reading recorded for this station was pH=7.8.

H-B.7.4.4 Dissolved Oxygen

The mean DO concentration measured at this station was 8.5 mg/L.

H-B.7.4.5 Conductivity

The mean specific conductivity level recorded at this station was 41,250 µmhos/cm.

H-B.7.4.6 Turbidity

According to the 1996 305(b) report (FDEP, 1996), the mean turbidity concentration measured for this station was 3.0 mg/L.

(Note: Units for the mean turbidity concentration at this station in the Ten Thousand Islands subregion were inadvertently reported in FDEP (1996) as “mg/L” as opposed to “NTU”.)

H-B.7.4.7 Pesticides

SFWMD pesticides monitoring data exist for the ENP in general (see Table H.1.5.2.1.3.2-1 in Section H.1.5.2.1.3.2 of Appendix H). Nine sites are currently monitored by the SFWMD (R. Pfeuffer: SFWMD, 1998 personal communication). During 1992-1997, only endosulfan (sum of endosulfan alpha and beta) was found to exceed its Class III criterion of 0.056 µg/L. Exceedances occurred at Monitoring Site S178 on six occasions between 3/18/93 and 1/25/96. The only detection of ethion at Site S178, (0.053 µg/L, 10/16/97) exceeded the acute toxicity level (0.02 µg/L) reported for *Daphnia magna*, a sensitive indicator species for aquatic macroinvertebrate, calculated according to promulgated procedure (F.A.C. 62-302.200). At this level, short-term exposure can cause impacts to the macroinvertebrate populations.

H-B.8 FLORIDA KEYS

Other Region-Specific Water Quality Parameters

Data for other water quality parameters for the Florida Keys are detailed presented below. These parameters are ammonia/unionized ammonia, pH, conductivity, temperature, and salinity.

H-B.8.1 Ammonia/Unionized Ammonia

The median NH_4 concentrations for surface segments 1, 2, 4, 5, 6, 7, and 9 ranged from 0.24 µM to 0.49 µM. The maximum NO_X concentrations for the same segments ranged from 0.63 µM to 2.44 µM, while the minimum concentrations ranged from 0.02 µM to 0.13 µM.

H-B.8.2 pH

The mean pH values for the Keys monitoring stations ranged from pH=7.3 in Saddlebunch Key to pH=8.2 in Plantation Key. The mean pH value for all stations was pH=7.7.

H-B.8.3 Conductivity

The mean specific conductance for the Keys basin ranged from 52,600 µmhos/cm at Marathon Key to 69,350 µmhos/cm at Saddlebunch Key. The mean specific conductance for all reported stations was 59,743 µmhos/cm.

H-B.8.4 Temperature

The median temperature recorded for the surface monitoring stations in the Keys ranged from 26.8°C to 29°C, and from 25.5°C to 28.7°C for the bottom stations. The maximum surface temperature observed at any station was 39.6°C, while the minimum temperature was 21.1°C.

H-B.8.5 Salinity

The median salinity concentrations for surface segments 1,2,4,5,6,7, and 9 ranged from 36.2 ppt to 36.8 ppt. The maximum salinity concentrations for the same segments ranged from 36.6 ppt to 40.3 ppt, while the minimum concentrations ranged from 30.5 ppt to 35.7 ppt.

H-B.9 BIG CYPRESS REGION

Other Region-Specific Water Quality Parameters

No other water quality parameters for the Big Cypress Region are presented.

H-B.10 CALOOSAHATCHEE RIVER REGION

Other Region-Specific Water Quality Parameters

Data for other water quality parameters for the Caloosahatchee River Region are presented below. These parameters are pH, turbidity, and temperature.

H-B.10.1 pH

The pH values along the river and within the basin remained relatively constant, ranging from a high of pH=8.0 to a low value of pH=6.9. The mean value of all data points in the basin was pH=7.4, while the mean pH value in the river its tributaries was pH=7.4 in each area. No trends were apparent in the data presented in the 1996 305(b) report (FDEP, 1996).

H-B.10.2 Turbidity

According to the 1996 305(b) report (FDEP, 1996), the turbidity concentrations along the river and within the basin remained relatively constant, ranging from a high of 6.3 mg/L to a low value of 0.7 mg/L. The mean turbidity concentration of all data points in the basin was 2.7 mg/L, while the mean turbidity concentration in the river and its tributaries were 2.4 mg/L and 2.8 mg/L, respectively. No trends were apparent in the data presented in the 1996 305(b) report.

(Note: Units for turbidity data for the Caloosahatchee River Region were inadvertently reported by FDEP(1996) as “mg/L” as opposed to “NTU”.)

H-B.10.3 Temperature

Waters in the basin show a typical pattern of seasonal variation, ranging from 15.0°C to 21.1°C with a mean temperature of 24.3°C. There was only a minimal amount of variation between the sampling stations.

ATTACHMENT C
ADDITIONAL REGULATIONS AND STANDARDS

H-C.1 FEDERAL REGULATIONS AND STANDARDS

H-C.1.1 Federal Safe Drinking Water Act

The Safe Drinking Water Act of 1974 was the result of a nationwide study of community water systems, which revealed water quality as a potential health risk. The primary objectives of the Safe Drinking Water Act (SDWA) are to protect the nation's sources of drinking water, and to protect public health to the maximum extent possible.

The USEPA is required to impose national primary and secondary drinking water regulations on persons who own or operate a system which has at least 15 service connections or regularly serves at least 25 individuals at least 60 days per year. Primary drinking water regulations identify potential toxic contaminants and then set a Maximum Contaminant Level (MCL) for each contaminant if the contaminant can be measured. If the contaminant cannot be measured, then a treatment technique must be specified. Secondary drinking water regulations set MCLs for nontoxic contaminants that affect other factors, such as color and odor. Maximum contaminant levels are to be set at levels at which "no known or anticipated adverse effects on the health of persons occur and which allows an adequate margin of safety." All water suppliers must periodically sample the water they deliver to consumers and record and report their findings to the USEPA or to the state, whichever is appropriate. If all MCLs are not met, or if a supplier fails to sample or report, the supplier must publicly notify his consumers. Variances or exemptions are available for systems meeting certain qualifications. MCLs have been established for certain chemicals, coliform bacteria, turbidity, and radioactivity.

In order to protect underground sources of drinking water, any person who owns or operates a facility, which injects fluids below the surface of the ground must meet certain requirements. The USEPA's Underground Injection Control (UIC) protects Underground Sources of Drinking Water (USDW) by prohibiting injection if it results in the movement of fluid containing a contaminant that could cause a violation of a primary drinking water standard and adversely affect human health. Regulations are imposed that set different requirements for the different classes of injection wells, and impose sampling, record keeping and reporting requirements on all operators. The regulations also control the plugging and abandonment of inactive and abandoned wells.

On August 6, 1996, the Safe Drinking Water Act Amendments of 1996 became law. The amendments contain several key features. One is the drinking water source protection program, which funds state and local governments to protect their drinking water sources from pollution. Another is drinking water standards for cryptosporidium and certain carcinogens. Additionally, the amendments contain important right-to-know language which requires community water systems to notify customers every year of the levels of federally regulated contaminants and the presence of other suspicious but unregulated material.

H-C.2 STATE OF FLORIDA REGULATIONS AND STANDARDS

H-C.2.1 Florida Statutes 373 (Water Resources) and 403 (Environmental Control)

Chapter 373, F.S. was created by the Florida legislature with nine policies regulating the waters of the State of Florida. These policies are set forth to:

(1) provide for the management of water and related land resources
(2) to promote the conservation, development, and proper utilization of surface and ground water
(3) to develop and regulate dams, impoundments, reservoirs, and other works and to provide water storage for beneficial purposes
(4) to prevent damage from floods, soil erosion, and excessive drainage
(5) to minimize degradation of water resources caused by the discharge of stormwater
(6) to preserve natural resources, fish and wildlife
(7) to promote the public policy set forth within 403.021 (the Florida Air and Water Pollution Control Act)
(8) to promote recreational development, protect public lands, and assist in maintaining the navigability of rivers and harbors
(9) otherwise promote the health, safety, and general welfare of the people of the State.

The Florida Department of Environmental Protection (FDEP=Department) is the responsible agency for the administration of Chapter 373 at the State level. In 1976 the legislature divided the State into five Water Management Districts:

- St. John's River Water Management District (SJRWMD)
- South Florida Water Management District (SFWMD)
- Southwest Florida Water Management District (SWFWMD)
- Northwest Florida Water Management District (NFWMD)
- Suwanee River Water Management District (SRWMD)

The FDEP has delegated the implementation and regulation of much of the authority within Chapter 373 to the five regional Water Management Districts (not all Districts have been delegated the same responsibilities). The three largest Districts (SJRWMD, SFWMD, SWFWMD) have since implemented rules which govern the construction of surface water management systems. These have been defined as any storm water management system, dam, impoundment, reservoir, appurtenant work, or combination thereof. The storm water management system has also been defined to include dredging and filling activities within wetlands or surface water bodies. The implementation of this rule is designed to regulate any impacts that the construction of the storm water management facility may have on surface water quality, quantity, flow, wetland habitat and associated listed wildlife species, and ground water resources.

Chapter 403 provides the basis for pollution control (Florida Air and Water Pollution Control Act), environmental regulation (Florida Environmental Reorganization Act of 1975), and drinking water standards (Florida Safe Drinking Water Act). In general, this chapter defines the powers and duties granted to FDEP to control and prohibit pollution of air and water. The Florida Air and Water Pollution Control Act defines water resources restoration and preservation (also known as the Water Resources Restoration and Preservation Act); pollution control for underground, surface and coastal waters; ground water quality monitoring; the reuse of reclaimed waters; pollution prevention (Pollution Control Act); and sewage disposal facilities.

The Florida Reorganization Act of 1975 provides the basis for the determination/establishment of District boundaries, the issuance of dredge and fill permits, the sites for disposal of spoil from maintenance dredging, and the determination of the natural landward extent of waters for regulatory purposes. The Florida Safe Drinking Water Act provides the basis for the establishment of the drinking water standards.

H-C.2.2 Surface Water Quality Standards

On March 1, 1979, the State adopted water quality standards (Rule 62-302 F.A.C.) designed to protect the public health or welfare and to enhance the quality of waters of the State. These standards take into consideration the use and value of waters of the State for public water supplies, propagation of fish and wildlife, recreational purposes, and agricultural, industrial, and other purposes; as well as their use and value for navigation. Rule 62-302 F.A.C. requires FDEP to assure that there shall be achieved the highest statutory and regulatory requirements for all new and existing point sources, and all cost-effective and reasonable BMPs for nonpoint source control. The highest statutory and regulatory requirements for new and existing point sources are those which can be achieved through imposition of effluent limits required under Sections 301(b) and 306 of the Federal CWA (as amended in 1987) and Chapter 403, F.S. Cost-effective and reasonable BMPs for nonpoint source control are those nonpoint source controls authorized under Chapters 373 and 403, F.S., and Department rules.

Rule 62-302.300 defines the State's Antidegradation Policy for surface water quality. This section of the rule states that excessive nutrients (total nitrogen and total phosphorus) constitute one of the most severe water quality problems facing the State, and consequently, requires FDEP policy to limit the introduction of man-induced nutrients into waters of the State—with particular consideration given to the protection from further nutrient enrichment of waters which are presently high in nutrient concentrations or sensitive to further nutrient concentrations and sensitive to further nutrient loadings. The rule also requires the FDEP to give special consideration to the protection from nutrient enrichment of those waters presently containing very low nutrient concentrations: less than 0.3 mg/L total nitrogen or less than 0.04 mg/L total phosphorus.

If the FDEP determines that the applicant has caused degradation of water quality over and above that allowed through previous permits issued to the applicant, then the applicant shall demonstrate that this lowering of water quality is necessary or desirable under federal standards and under circumstances which are clearly in the public interest. These circumstances are limited to cases where it has been demonstrated that degradation of water quality is occurring due to the discharge. If the new or expanded discharge was initially permitted by the FDEP on or after October 4, 1989, and the Department determines that an antidegradation analysis was not conducted, then the applicant seeking renewal of the existing permit shall demonstrate that degradation from the discharge is necessary or desirable under federal standards and under circumstances which are clearly in the public interest.

Rule 62-302.400 defines the classification system for surface waters, their usage, reclassification, and classifies waters.

Rule 62-302.500 defines the minimum and general criteria for surface waters as follows:

Minimum Criteria

All surface waters of the State shall at all places and at all times be free from:

(a) Domestic, industrial, agricultural, or other man-induced non-thermal components of discharges which, alone or in combination with other substances or in combination with other components of discharges (whether thermal or non-thermal):

1. Settle to form putrescent deposits or otherwise create a nuisance; or
2. Float as debris, scum, oil, or other matter in such amounts as to form nuisances; or
3. Produce color, odor, taste, turbidity, or other conditions in such degree as to create a nuisance; or
4. Are acutely toxic; or
5. Are present in concentrations which are carcinogenic, mutagenic, or teratogenic to human beings or to significant, locally occurring, wildlife or aquatic species; unless specific standards are established for such components in Rules 62-302.500(2) or 62-302.530; or
6. Pose a serious danger to the public health, safety, or welfare.

(b) Thermal components of discharges which, alone, or in combination with other discharges or components of discharges (whether thermal or non-thermal):

1. Produce conditions so as to create a nuisance; or
2. Do not comply with applicable provisions of Rule 62-302.500(3), F.A.C.

(c) Silver in concentrations above 2.3 μg/L in predominately marine waters.

Effluent limits may be established for pollutants for which analytical detection limits are higher than the established water quality criteria based upon computation of concentrations in the receiving waters. Effluent limits will be established on site-specific conditions in the context of a Department permit. Monitoring reports and permit applications shall specify the detection limits and indicate non-detectable results in such cases. Unless otherwise specified, such non-detectable results shall be accepted as demonstrating compliance for that pollutant as long as specified effluent limits are met.

Notwithstanding the specific numerical criteria applicable to individual classes of water, dissolved oxygen (DO) levels that are attributable to natural background conditions or man-induced conditions which cannot be controlled or abated may be established as alternative DO criteria for a water body or portion of a water body. Alternative DO criteria may be established by the Secretary or a Director of District Management in conjunction with the issuance of a permit or other Department action only after public notice and opportunity for public hearing. The determination of alternative criteria shall be based on consideration of the factors described in Rule 62-302.800(2)(a)-(d), F.A.C. Alternative criteria shall not result in a lowering of DO levels in the water body, water body segment or any adjacent waters, and shall not violate the minimum criteria specified in Rule 62-

302.500(1), F.A.C. Daily and seasonal fluctuations in DO levels shall be maintained.

The surface water quality criteria are presented in Rule 62-302.530, F.A.C. A table within this rule contains both numeric and narrative surface water quality criteria to be applied except within zones of mixing. The left-hand column of the table is a list of constituents for which a surface water criterion exists. The headings for the water quality classifications are found at the top of the table. Applicable criteria lie within the table. The individual criteria should be read in conjunction with other provisions in water quality standards, including Rules 62-302.500 and 62-302.510, F.A.C. The criteria contained in Rules 62-302.500, F.A.C. or 62-302.510, F.A.C. also apply to all waters unless alternative or more stringent criteria are specified in Rule 62-302.530, F.A.C.

Rule 62-302.700 defines special protection, Outstanding Florida Waters, and Outstanding National Resource Waters. This section states the FDEP shall afford the highest protection to Outstanding Florida Waters and Outstanding National Resource Waters. No degradation of water quality, other than that allowed in Rule 62-4.242(2) and (3), F.A.C., is to be permitted in Outstanding Florida Waters and Outstanding National Resource Waters, respectively, notwithstanding any other Department rules that allow water quality lowering.

H-C.2.3 Beneficial Use Classifications (Class I-V)

Chapter 62-302.400, F.A.C. defines or classifies surface waters and their usage as follows:

- Class I - Potable Water Supplies
- Class II - Shellfish Propagation or Harvesting
- Class III - Recreation, Propagation and Maintenance of a Healthy, Well-Balanced Population of Fish and Wildlife
- Class IV - Agricultural Water Supplies
- Class V - Navigation, Utility and Industrial Use

These water quality classifications are arranged in order of the degree of protection required, with Class I water having generally the most stringent water quality criteria and Class V the least. However, Class I, II, and III surface waters share water quality criteria established to protect recreation and the propagation and maintenance of a healthy, well-balanced population of fish and wildlife. The classification of a water body according to a particular designated use or uses does not preclude use of the water for other purposes. The criteria applicable to a classification are designed to maintain the minimum conditions necessary to assure the suitability of water for the designated use of the classification. In addition, applicable criteria are generally adequate to maintain minimum conditions required for the designated uses of less stringently regulated classifications. Therefore, unless clearly inconsistent with the criteria applicable, the designated uses of less stringently regulated classifications shall be deemed to be included within the designated uses of more stringently regulated classifications.

The surface waters of the State of Florida are classified as Class III - Recreation, Propagation and Maintenance of a Healthy, Well-Balanced Population of Fish and Wildlife, except for certain waters, which are described in Rule 62-302.400(12), F.A.C. A water body may be designated as an Outstanding Florida Water or an Outstanding National Resource Water in addition to being classified as Class I, Class II, or Class III. A water body may also have special standards applied to it. Outstanding Florida Waters and Outstanding National Resource Waters are listed in Rule 62-302.700, F.A.C. Classifications shall be interpreted to include associated water bodies such as tidal creeks, coves, bays and bayous.

Exceptions to Class III surface waters include all secondary and tertiary canals wholly within agricultural areas. These are classified as Class IV and are not individually listed as exceptions to Class III. "Secondary and tertiary canals" shall mean any wholly artificial canal or ditch which is behind a control structure and which is part of a water control system that is connected to the works (set forth in Section 373.086, F.S.) of a water management district created under Section 373.069, F.S., and that is permitted by such water management district pursuant to Section 373.103, Section 373.413, or Section 373.416, F.S. Agricultural areas shall generally include lands actively used solely for the production of food and fiber, which are zoned for agricultural use where county zoning is in effect. Agricultural areas exclude lands which are platted and subdivided or in a transition phase to residential use.

H-C.2.4 Ground Water Quality Standards

Ground waters within the State are classified according to designated uses as follows (Rule 62-520.410):

Class F-I Potable water use, ground water in a single source aquifer described in Rule 62-520.460, F.A.C. which has a total dissolved solids content of less than 3,000 mg/L and was specifically reclassified as Class F-I by the Commission.

Class G-I Potable water use, ground water in single source aquifers which has a total dissolved solids content of less than 3,000 mg/L.

Class G-II Potable water use, ground water in aquifers which has a total dissolved solids content of less than 10,000 mg/L, unless otherwise classified by the Commission.

Class G-III Non-potable water use, ground water in unconfined aquifers which has a total dissolved solids content of 10,000 mg/L or greater; or which has total dissolved solids of 3,000-10,000 mg/L and either has been reclassified by the Commission as having no reasonable potential as a future source of drinking water, or has been designated by the Department as an exempted aquifer pursuant to Rule 62-28.130(3), F.A.C.

Class G-IV Non-potable water use, ground water in confined aquifers which has a total dissolved solids content of 10,000 mg/L or greater.

The highest protection is afforded to single source aquifers. Ground water quality classifications are arranged in order of the degree of protection required, with Class G-I ground water having generally the most stringent water quality criteria and Class G-IV the least.

The minimum criteria for ground water are set forth in Rule 62-520.400. These criteria state that all ground water shall at all places and at all times be free from domestic, industrial, agricultural, or other man-induced non-thermal components of discharges in concentrations which, alone or in combination with other substances, or components of discharges (whether thermal or non-thermal):

(a) Are harmful to plants, animals, or organisms that are native to the soil and responsible for treatment or stabilization of the discharge relied upon by Department permits; or
(b) Are carcinogenic, mutagenic, teratogenic, or toxic to human beings, unless specific criteria are established for such components in Rule 62-520.420, F.A.C.; or
(c) Are acutely toxic within surface waters affected by the ground water; or
(d) Pose a serious danger to the public health, safety, or welfare; or
(e) Create or constitute a nuisance; or
(f) Impair the reasonable and beneficial use of adjacent waters.

These minimum criteria do not apply to Class G-IV ground water, unless the Department determines there is a danger to the environment, public health, safety or welfare.

Waters classified as Class G-I and Class G-II ground water shall meet the primary and secondary drinking water quality standards for public water systems established pursuant to the Florida Safe Drinking Water Act, in addition to the minimum criteria provided in Rule 62-520.400, F.A.C. (Rule 62-520.420), except as provided in Rule 62-520.520, F.A.C., and subsections (4) and (5) below, and except that the total coliform bacteria standard shall be 4 per 100 milliliters. In addition, the primary drinking water standard for public drinking water systems for asbestos shall not apply as a ground water standard. If the concentration for any constituent listed in subsection (l) above in the natural background quality of the ground water is greater than the stated maximum, or in the case of pH is also less than the minimum, the representative natural background quality shall be the prevailing standard for Class G-I and Class G-II ground water.

The minimum criteria (Rule 62-520.430) for Class G-III ground water established in Rule 62-520.400, F.A.C., shall apply to all Class G-III ground water except for an underground injection facility that has received an aquifer exemption pursuant to Rule 62-528.300(3), F.A.C., unless there is danger to the environment, public health, safety, or welfare. The minimum criteria shall apply to all other facilities discharging to an exempted aquifer.

Rule 62-520.440 states that for the standards for Class G-IV ground water FDEP shall specify applicable standards on a case-by-case basis. The minimum criteria in Rule 62-520.400, F.A.C., shall not apply unless the Department determines there is danger to the environment, public health, safety or welfare.

H-C.2.5 Drinking Water Quality Standards

The drinking water standards are designed to assure that public water systems supply drinking water, which meets minimum requirements. The Federal Government enacted PL 93-523, the "Safe Drinking Water Act." The intent of that law was to give primary responsibility for public water systems programs to states to implement a public water system program. Also, the legislature of Florida has enacted the "Florida Safe Drinking Water Act," sections 403.850-403.864, F.S. This chapter and chapters 62-555 and 62-560, F.A.C., are promulgated to implement the requirements of the Florida Safe Drinking Water Act and to acquire and maintain primacy for Florida under the Federal Act. This chapter and chapter 62-555 and 62-560, F.A.C., adopt national primary and secondary drinking water standards of the Federal Government where possible, and otherwise create additional rules to fulfill state and Federal requirements.

Rule 62-550.300, F.A.C. defines the application of quality standards to public water systems. The ultimate concern of a public drinking water program is the quality of piped water for human consumption when the water reaches the consumers. The following rules establish the maximum contaminant levels for the water within public water systems. Public water systems shall not exceed the maximum contaminant levels established herein unless granted a variance or exemption pursuant to Rules 62-560.510 or 62-560.520, F.A.C., or identified as excluded from the standards by this Chapter. Public water systems shall take necessary corrective action approved by the Department to meet all applicable standards. Treatment techniques in lieu of maximum contaminant levels for surface water systems or ground water systems under the direct influence of surface water are referenced in Rule 62-555.600, F.A.C., Scope of Additional Requirements for Surface Water Systems.

As referenced, it may be noted that the primary drinking water standards maximum contaminant levels, are defined in Rule 62-550.310, F.A.C. (These standards may also apply as ground water quality standards as referenced in Chapter 62-520, F.A.C). Also, the secondary drinking water standards, are defined in Rule 62-550.320, F.A.C. This section applies only to community water systems. (These standards may also apply as ground water quality standards as referenced in Chapter 62-520, F.A.C.).

OVERVIEW OF HISTORIC CONDITION

H-E.1 OVERVIEW

Prior to efforts to drain portions of the Kissimmee River-Lake Okeechobee-Everglades (KOE) system in the early 1880's, water quality conditions in this 10,890 square mile wilderness watershed were unimpacted. The KOE watershed extended 310 miles north to south from its headwaters north of Lake Tohopekaliga to the coastal waters of Florida Bay and 62 miles east to west from the Atlantic Coastal Ridge to the eastern edge of the Big Cypress rise. Over the past 120 years efforts to drain, dike and convert wetlands and watercourses for urban and agricultural uses throughout the KOE watershed, have resulted in substantial degradation to water quality conditions across the fresh water lakes and marshes, estuaries and coastal marine environments of the area.

Due to the extent of the alteration to the natural systems by these activities over the past century, it is very difficult to estimate what the original undisturbed water quality conditions of the 1880's might have been. By characterizing the water quality of those few relatively unimpacted freshwater ecosystems remaining today, we can attempt to estimate what the original water quality in the ecosystem was prior to alteration. Graves *et al.*, 1997 has characterized freshwater water quality in the relatively unaltered Savannas Preserve as typified by low conductivity, hardness, pH and nutrient concentrations. These conditions may have been predominating in many other waterbodies in south Florida before anthropogenic alteration. In the estuarine regions of South Florida, it is unlikely that there are any ecosystems that have not been hydrologically altered with the subsequent alterations to water quality conditions. Therefore, there may be no estuaries systems in the immediate area suitable for use as a model of an undisturbed system.

For this discussion of historic water quality conditions, the study area of the C&SF Project was divided into six aggregate regions symbolic of historic conditions. The following subsections discuss the presumed early water quality conditions of these major historic regions in the study area.

H-E.2 KISSIMMEE RIVER BASIN

The 3,054-square-mile area of the Kissimmee River basin originates in the Shingle/Boggy/Reedy Creek area south of Orlando and flows approximately 110 miles south through Lake Tohopekaliga (Lake Toho), and Lake Kissimmee onto the northern shoreline of Lake Okeechobee. The drainage basin is about 27 miles wide at its maximum. Prior to installation of the drainage works in the Upper Kissimmee Chain of Lakes and Tributaries region in the 1850's, the headwater region of the Kissimmee River basin was Lake Kissimmee according to U.S. Army Corps of Engineers (USACE, 1975) navigability studies. Additional drainage works constructed after 1850 extended the Kissimmee drainage basin northward to the Bay/Clear/Conway Lakes area south of Orlando.

The Kissimmee River basin Chain of Lakes headwaters area contained hundreds of lakes, each contributing wet season flows to a series of creeks flowing across swampy terrain, south to Lake Toho. The general land elevation in this region is about 100 feet above mean sea level. Water flows across this region of the upper Kissimmee River basin were likely slow and seasonal with surface sheet flows highest during the annual summer/fall wet season. Due to the long residence time of surface and ground waters in contact with the moist sandy and organic soils, water quality conditions were likely low in dissolved nutrients, high in color and having a strong diel dissolved oxygen pattern. Many of the lakes in the region had extensive marsh littoral zones, which purified the lake waters, keeping turbidity low and light transmission high through the lake water column. Water level oscillations between dry and wet season in many of the lakes were likely substantial. It is likely that many of the lakes and creeks had extensive growth of rooted submerged aquatic vegetation, which purified the lake/creek waters.

South of Lake Toho, the tributaries of Canoe Creek and Reedy Creek significantly increased flows south through the Cypress Lake and Lake Hatchineha area, to the north shore of Lake Kissimmee. The Kissimmee River flowed south from Lake Kissimmee to Lake Okeechobee prior to navigation improves to the river. It was a 98-mile long, shallow, sluggish meandering river with water depths of only 1-2 feet in many locations. An extensive 50,000-acre wetland floodplain adjacent to the river moderated high water and wet season flows, and improved water quality in the river system. The Kissimmee River was channelized for flood control and navigation improvement purposes in the 1960's to become the 56-mile long, 300-foot wide, C-38 canal. This effectively isolated the wetland floodplain from river flows.

H-E.3 LAKE OKEECHOBEE

With an area of 730 square miles, Lake Okeechobee is the second largest freshwater lake in the southeastern U.S. and the central component of the KOE watershed. This broad, shallow lake with average depths of 9 feet was much less eutrophic than current conditions. Lake Okeechobee's major freshwater inflows come from direct rainfall (47%) and the Kissimmee River (25%) (Jones, 1987). Numerous other creeks providing significant inflows to the lake include Fisheating Creek, Taylor Creek/Nubbin Slough, and the Harney Pond and Indian Prairie basins. Prior to the drainage works of Hamilton Disston in the 1880's, the lake water surface oscillated between 18 to 22 feet Mean Sea Level (MSL), depending of the extent of the wet and dry season inflows and outflows as well as evaporation off the Lake's surface. When Disston excavated a drainage channel between Lake Okeechobee and nearby Lake Hicpochee along the lake's southwest shoreline, the average depth of Lake Okeechobee dropped 4 feet, sending massive volumes of water down the Caloosahatchee River. Historically, the oscillation between Lake Okeechobee's average wet season and dry season elevation (about 4 feet typically) was much less then the more drastic current wet and dry season lake surface oscillations which approach 9 feet.

Historically, Lake Okeechobee had a larger, more extensive wetland littoral zone then what exists today along the shoreline. Extensive adjacent wetland areas extended from the lake's northwestern and southern shorelines. Historic in-lake total phosphorus (TP) levels are estimated in the 40 ppb TP range (Joyner, 1974) as opposed to the current 100 ppb TP range. Due to the extensive littoral and shoreline wetland systems existing in the pre-drainage Lake Okeechobee, it is likely that in-lake turbidity was much lower then current conditions, that water column light transmission was much higher than current conditions, and that water quality in the lake was much better than the eutrophic conditions of today. In addition, it is also likely that extensive areas of rooted submerged aquatic vegetation, in addition to the extensive macrophytic littoral zone, purified the lake's waters.

H-E.4 UPPER EAST COAST (ST. LUCIE RIVER BASIN AND INDIAN RIVER LAGOON)

Prior to drainage activities, the St. Lucie River basin and southern Indian River Lagoon area was a low, flat coastal region with poorly drained sandy soil uplands intermixed with numerous scattered isolated freshwater wetlands grading to a broad, shallow coastal lagoon. Although inlets were periodically open in the southern portion of the Indian River Lagoon (IRL), in present-day St. Lucie and Martin Counties, the only dependable, natural connection between the IRL and the Atlantic Ocean occurred at the Jupiter Inlet at the extreme southern end of the lagoon. Thus, tidal flushing throughout the southern IRL was much more limited then current conditions (three inlets connecting IRL to the ocean) and the lagoon waters would have exhibited a much lower salinity than current conditions. Historic IRL substrates were dominated by freshwater plants rather then the current day seagrasses. Water depths in the southern IRL averaged only 3-4 feet and light transmission to bottom sediments would have enabled luxuriant growth of rooted aquatic plants. This dense assemblage of rooted aquatic vegetation efficiently trapped dissolved and suspended particles and nutrients, and helped to maintain low turbidity in lagoon waters.

Prior to the extensive drainage activities conducted in this region in the early 1900's, the major freshwater inflows to the southern IRL were dominated by wet season flows from the St. Lucie River and the Loxahatchee River systems. The St. Lucie Canal (C-44) was completed in 1924, connecting Lake Okeechobee to the southern IRL via the St. Lucie River. Extensive local agricultural drainage canal systems were constructed in the 1920-1930's, including channelization and drainage of the entire North Fork of the St. Lucie River basin. During the 1950-1970's, additional drainage canals (C-23, C-24 and C-25) were constructed. The drainage basin of the southern IRL was greatly expanded, resulting in massive additional episodic freshwater canal flows to the Lagoon, resulting in wide swings in salinity in the estuary, and introduction of stormwater-borne pollutants, excessive sediments and turbidity. These actions, together with construction of barrier island access causeways and navigational channel dredging, have resulted in the highly altered and ecologically degraded southern IRL ecosystem of the 1990's**.**

H-E.5 CENTRAL EVERGLADES BASIN

Prior to the initiation in 1906 of major drainage works (South and North New River Canals) from the southern shoreline of Lake Okeechobee southward through the Everglades to the Atlantic Ocean, the central Everglades ecosystem was one of the largest unaltered semi-tropical wetland systems in the world. Over the course of the next 70 years, the physical extent of this massive herbaceous wetland was diminished by 50% and water quality conditions in various locations in the Everglades were significantly degraded. In the early 1900's, the Everglades organic soils were categorized into three groups based on the overlying vegetation (Baldwin and Hawker, 1915). Within 3-5 miles of the southern shoreline of the lake, soils were classified as custard apple muck, based upon the dominance of the custard apple tree (McCormick *et al*., 1998(in-prep)). Further south from the lake, the wetland was dominated by soils derived from willow and alder trees. However, the predominant organic soil in the Everglades was sawgrass peat, with sawgrass as the dominant vegetation.

The Everglades ecosystem developed under extremely low rates of TP supply. Increased rates of TP loading from agricultural and urban sources over the past several decades have been associated with several changes in ecological conditions that are indicative of cultural eutrophication (McCormick *et al*., 1998(in-prep)). Historically, nutrient inputs to Everglades marsh waters were derived primarily from atmospheric deposition (rainfall and dry fallout). Median TP concentrations in historic rainfall to the Everglades marsh ranged between 4-7 ppb. Water column TP concentrations in the historic Everglades averaged 5-10 ppb throughout the northern and central Everglades and were lowest in the southern Everglades region (Taylor Slough area) (McCormick *et al*., 1998(in-prep)).

Periodic water flows during wet periods from Lake Okeechobee to the historic custard apple swamps and willow areas just south of Lake Okeechobee likely were somewhat enriched compared to the large expanse of Everglades sawgrass marsh further south. Nutrient inputs from surface water sheetflow from the lake to the custard apple and willow tree areas near Lake Okeechobee may have been in the 20-40 ppb TP range. However, these TP levels would be reduced quickly as waters traveled southward.

Relative to other key water chemistry features, the interior Everglades marsh (WCA-2A and 3A area and ENP) were slightly basic (pH) and highly mineralized containing bicarbonate, calcium and sodium as compared to the historic northeastern Everglades region (Loxahatchee NWR area). The northern region was slightly acidic and contained extremely low concentrations of major ions, a condition which reflects the rainfall-driven hydrology of the LNWR area (McCormick *et al.*, 1998(in-prep)). Concentrations of nitrogen and other macronutrients in interior Everglades surface waters were relatively high compared to TP. Concentrations of micronutrients in Everglades waters varied, but would not generally be considered limiting compared with the extremely low TP concentrations in the Everglades marsh. Dissolved oxygen (DO) in the predrainage Everglades marsh exhibited characteristic diel fluctuations in water column DO, with high daytime DO levels in open-water habitats such as sloughs and wet prairies which was a result of periphyton photosynthesis. The open water, slough habitats served as oxygen sources for adjacent sawgrass stands, where water-column photosynthesis is low (Belanger *et al.*, 1989).

H-E.6 LOWER EAST COAST (LAKE WORTH, NEW, HILLSBORO & MIAMI RIVERS & BISCAYNE BAY)

Prior to man's earliest colonization of the southeast Florida rock ridge stretching from modern-day Palm Beach south to Homestead in the mid-1800's, this subtropical area was densely vegetated with tropical hardwood hammocks, rockland pine forests, freshwater transverse glades connecting the interior Everglades to the coastal waters, and isolated freshwater wetlands on the ridge and brackish water wetlands along the shoreline. Water quality conditions in the diverse types of wetlands and watercourses in the southeast Florida Lower East Coast (LEC) would have varied considerably depending on salinity, substrate and nutrient input conditions; however, it can be inferred that water quality conditions were unimpacted simply because pollutant sources were non-existent.

Coastal rivers were likely highly stained and low in nutrients since they received mainly rainfall and inland surface water runoff from the interior oligotrophic Everglades (Pierce and Curl, 1970). Water quality conditions in the shallow freshwater coastal Lake Worth were likely nutrient poor with high color and low turbidity prior to inlet dredging activities that significantly modified salinity conditions in Lake Worth.

Historical accounts of Biscayne Bay (Thorhaug *et al.*, 1976; Parker *et al.*, 1955; SFWMD, 1995b) indicate that prior to inlet dredging and navigational channel dredging that the northern and central portion of the bay had much lower salinity conditions than present conditions. Prior to the excavation of the Miami Canal in 1911, the Miami River contained rapids, surficial aquifer flows to the bay and a number of springs in the bay producing freshwater boils. Prior to the excavation of the Miami Canal, wet season high water levels in the Everglades overflowed to the bay via coastal rivers and creeks, such as Arch and Snake Creek and the Miami River as well as through numerous transverse glades across the coastal limestone ridge. Biscayne Bay water quality in the late 1800's likely was low in nutrients, with low turbidity and high light transmittance to luxuriant seagrass meadows on the bay bottom. Hydrological and water quality conditions in the pre-drainage Biscayne Bay shallows were likely driven by surficial groundwater flows and wet season surface water flows.

With the major initiation of Everglades canal excavation projects in the 1905-1913 period, massive adverse impacts occurred not just to the interior glades but also to the coastal receiving waterbodies. Pre-construction water quality conditions in the coastal rivers, (such as the New and Hillsboro Rivers and Cypress Creek in Broward County and the Miami River), Snake and Arch Creeks and the Miami River in Dade County were significantly altered by substantial sedimentation resulting from canal construction and erosion. Alteration of the timing, quantity, and duration of freshwater flows to the coastal waterbodies, as well as drainage resulting in lower coastal ridge ground water table levels, resulted in sudden and significant water quality degradation in the receiving coastal water courses.

H-E.7 FLORIDA BAY AND THE FLORIDA KEYS

The 850-square-mile area of Florida Bay is bounded by the southern tip of the Florida peninsula and bounded to the east and south by the 110-mile-long string of islands called the Florida Keys. The landmass of the Florida Keys totals approximately 100 square miles. Keys soils consist of Miami oolite and Key Largo limestone and dominant vegetative communities consist of tropical hardwood hammocks, pine rocklands, brackish wetland transitional zones and tidal wetlands. Florida Bay is a subtropical estuary, averaging only 3 feet in depth. Historically, the estuarine waters of Florida Bay could be characterized as warm and very clear with lush seagrass beds growing on the expansive bay bottoms.

Freshwater flows to Florida Bay and the adjacent Florida Keys came mainly from rainfall, overland sheetflows from the Taylor Slough drainage in the southeastern Everglades and surficial ground-water flows from the Biscayne aquifer to the coastal bays along the northern shoreline of Florida Bay. Inflows of marine waters entered Florida Bay across its western margins from the Gulf of Mexico and through the Florida Keys passes separating the bay from the Atlantic Ocean.

Historically, both Florida Bay and Florida Keys estuarine and marine habitats evolved under very low nutrient conditions and were sensitive to increased levels of nutrients. The extensive seagrass meadows, low lying mangrove fringed islands, and submerged mud banks throughout the bay strongly influenced water circulation, wind fetch, and water turbidity conditions. Water quality in Florida Bay was highly variable with substantial variability in turbidity and salinity conditions relating to climatological events such as hurricanes, windy conditions with passage of cold fronts and large freshwater inflows from the southern everglades during annual wet seasons. In the deeper marine waters offshore of the Florida Keys, water clarity was excellent with visibility through the water column routinely exceeding 100 feet. The largest living coral reef in North America flourished in the marine waters offshore of the Florida Keys.

Significant man-induced impacts on water quality conditions throughout Florida Bay and the Keys began with the 1912 completion of Henry Flagler's Overseas railroad connecting the South Florida mainland with Key West. Construction of the approximate 113-mile-long railroad connecting numerous keys resulted in extensive filling and dredging of bay bottoms through a series of fill causeways and bridges. Alteration of historic water flow and salinity patterns in Florida Bay can be attributed to the construction of the Overseas Railroad and the subsequent 1938 completion of the Overseas Highway by the State of Florida. Railroad and highway alteration of water flow patterns between Florida Bay and the Atlantic Ocean, combined with major disruption and reduction of freshwater flows to the bay from the mainland as a result of mainland canal/levee construction and operation beginning in the 1920's, resulted in increased salinity occurring throughout Florida Bay. Degradation of historic Florida Bay water quality conditions is directly related to alteration of bay salinity patterns.

H-E.8 BIG CYPRESS BASIN

The 2,657 square-mile area (1.7-million acres) of the Big Cypress drainage basin was one of the last large natural areas in south Florida where water quality conditions were impacted by man's activities. This large area is very flat with maximum elevations of 17 feet above MSL in the northern region gradually grading 35 miles south to sea level in the coastal mangrove region of the Ten Thousand

Islands area, on the Gulf of Mexico (Duever *et al.*,1979). Prior to alteration by drainage works, the Big Cypress drainage area consisted generally of two watersheds, a smaller eastern area where surface drainage flowed southeasterly to the western region of Shark River Slough and a much larger central region characterized by north-to-south-oriented sloughs and Cypress strands flowing south to the Ten Thousand Islands coastal area.

Historic water quality conditions in the Big Cypress region were tied to the predominant carbonate marl soils of the area. Organic peats were found in the low lying north-south sloughs and strands as well as in the coastal mangrove areas; however, the organic peat areas covered a relatively small portion of the entire basin. Extensive areas of the Big Cypress coastal region are less then 2 feet above MSL and the water quality in this region was highly influenced by tidal fluctuations and salinity effects of the estuarine waters. The single largest physiographic region in the Big Cypress was the slightly elevated interior Pineland region, characterized by cypress domes and small circular depressions indicative of a juvenile karst terrain (Duever *et al.*, 1979). These topographic features suggest substantial vertical movement of rainfall derived surface waters downward to the surficial aquifer.

Drainage works and the associated effects on Big Cypress water quality conditions began in 1926 with the completion of the north-to-south-oriented Barron Collier Canal and associated State Road 29. In 1928, the east-to-west-oriented Tamiami Canal and associated Tamiami Trail was completed through the Big Cypress region. Although both of these canals were relatively shallow compared to other South Florida canal systems, the drainage effects of these canals was widespread in the Big Cypress, especially during the annual dry season. In addition, water flows were also affected by the constructed roadways.

Prior to the initiation of canal/road construction in the Big Cypress in the 1920's, water quality conditions could be described as high and unpolluted. Due to the topography, soils and vegetation of the area, water quality conditions had relatively high levels of dissolved constituents, such as calcium, chloride, sodium, potassium, hardness, specific conductance, and dissolved solids (Duever *et al.*, 1979). Dissolved oxygen, alkalinity, and pH were typical of unimpacted South Florida waters and likely exhibited strong diel fluctuations. Due to the extensive swamps and surface water contact times with vegetation, watercolor was highly stained with tannins and turbidity would have been relatively low. Historic nutrient concentrations in Big Cypress were relatively oligotrophic in phosphorus and nitrogen compounds (Odum, 1953; Klein *et al.*, 1970; Carter *et al.*, 1973**);** however, TP and nitrogen compound levels in Big Cypress surface waters would have been substantially higher than TP and TN concentrations in the central Everglades marshes due to differing soil conditions.

H-E.9 CALOOSAHATCHIE RIVER BASIN

As a result of Hamilton Disston's early drainage work in 1883 connecting Lake Okeechobee to Lake Hicpochee, the historic headwaters of the Caloosahatchee River and the drainage basin and water quality conditions of the Caloosahatchee River were drastically modified. Prior to Disston's drainage work (Leach *et al.*, 1972), the Caloosahatchee River was a shallow, meandering river. Water quality in the river prior to the 1880's was likely dominated by high color and high organics, exhibiting the highly stained tannic nature of many South Florida coastal rivers. Before dredging and channelization, the Caloosahatchee River meandered slowly from the headwater marshes on thick peat deposits west of Lake Okeechobee, spilling over falls and moving slowly through a series of oxbows before emptying into the Gulf of Mexico (Florida Gov. Commission Interim Report, 1998). Dissolved oxygen levels in the river likely fluctuated widely with a diel pattern. In the lower Caloosahatchee River near it's convergence with San Carlos Bay, the Caloosahatchee estuary likely exhibited luxuriant seagrass beds with high light transmittance to the substrate and low nutrient and suspended solids conditions.

ENVIRONMENTAL EFFECTS

F.1 REGIONAL SYSTEM

F.1.1 Effects of the Recommended Plan

Viewed from a regional perspective, the recommended comprehensive plan is expected to greatly improve water quality conditions in the study area. The Recommended Plan creates approximately 181,250 acres of surface water storage area (WSA), totaling approximately 1.5 million-acre feet of additional storage volume compared to existing and future base conditions (***Table F.1***). This proposed increase in surface water storage volume is expected to result in a reduction in pollution loading into downstream receiving water bodies, through the attenuation of surface flows and settling of attendant sediment-bound pollution loads and through biological uptake processes in the WSAs prior to discharge. Aquifer Storage and Recovery (ASR) components in the Recommended Plan provide additional deep aquifer storage capacity totaling approximately 1,665 Million Gallons Per Day (MGD) (***Table F.2***). This additional storage capacity will also improve regional water quality conditions through aquifer storage of existing flood discharges.

Additionally, many components of the Recommended Plan include treatment features to assure that water quality conditions are improved or not degraded as a result of the operation of those components. Specifically, the Recommended Plan includes over 19 Stormwater Treatment Areas (STAs) totaling at least 35,550 acres, providing approximately 126,770 acre-feet of treatment volume (***Table F.3***). These STAs also represent additional storage volume beyond that provided by the designated water storage areas. Furthermore, those components of the Recommended Plan involving ASR and wastewater reuse include treatment facilities to meet applicable State of Florida water quality standards.

The ad hoc Restudy Water Quality Team (WQT), which was created to evaluate the effect of Restudy alternatives on water quality conditions in the study area and co-chaired by the USEPA and FDEP, determined that the Recommended Plan was preferred over other alternatives and the future (2050) base condition from a water quality perspective (see Section 7.3.2.4.3). The WQT consisted of staff from the following agencies: USEPA, FDEP, USACE, SFWMD, ENP, LNWR, USFWS, BCNP, NOAA/NMFS, FDACS, Seminole Tribe, Palm Beach County, Broward County and Miami-Dade County. The WQT's evaluation was conducted iteratively, using water quality models, hydrologic data, and performance indicators. The WQT provided recommendations to the Alternatives Evaluation Team (AET) for optimizing the performance of the alternative plans to achieve water quality objectives. Many of these suggested modifications were subsequently included in the design of the components. A summary of the WQT's conclusions and recommendations is included below in ***Table F.4***. A detailed description of the work done by the WQT is located in the Water Quality Analysis section of Appendix D, Attachment D.

TABLE F.4 Restudy Water Quality Team's Combined *Ranking* Matrix

The Base Conditions and alternative plans were ranked on a scale of 1-7, with higher scores indicating a more preferred condition from a water quality perspective.

Subregion	95B	50B	A	B	C	D	D13R
1. Lake Okeechobee (see footnote 1)	2.5	2.5	2.5	6.5	4.5	6.5	4.5
2. EAA/ECP	1	3.5	7	6	3.5	2	5
3. WCAs 2 & 3 (see footnote 2)	1	6	7	2	3	4.5	4.5

Restudy WQT Recommendations to Restudy Team

From a water quality perspective, Alternative D13R is preferred over Alternatives B, A, & C. The 95 Base and the 50 Base were not acceptable.

1. The WQT determined that the Base Conditions and alternative plans should not be ranked based upon the USEPA preliminary mercury model results (model needs further development). Atmospheric deposition is the dominant contributor of mercury in the Everglades Protection Area (EPA). Restudy alternative plans as evaluated by the USEPA preliminary mercury model are not expected to significantly affect mercury in the EPA.

2. Due to a lack of model results (particularly Everglades Landscape Model results), Restudy alternative plans could not be ranked based upon an empirical evaluation of water quality impacts or benefits in Big Cypress

National Preserve and the Holeyland and Rotenberger Wildlife Management Areas.

Footnotes

1. Ranking of alternatives for Lake Okeechobee is based on evaluation of selected performance indicators. Comparing alternatives, differences greater than one percent in relative performance calculated by the model were assigned different ranks. Although the differences between simulated conditions for the alternatives are within the uncertainty of the model, the WQT felt it was important to rank the plans for Lake Okeechobee from a water quality perspective.

2. WCAs 2 & 3 rankings were weighted to account for relative size (acreage).

3. Ranking of the alternatives based on an evaluation of potential water quality impacts/benefits in the LEC is primarily based upon salinity targets in Lake Worth and Biscayne Bay. The presumed water quality benefits resulting from an evaluation of the hydraulic performance of selected reservoirs were also evaluated. For those performance indicators, a score of zero was assigned to alternatives for which no hydraulic performance for the reservoirs was observed.

Implementation of the Comprehensive Plan consistent with the Implementation Plan (see ***Section 10***) will lead to improved water quality throughout the study area. However, achieving water quality objectives for ecological restoration in all water bodies within the study area depends on actions outside the scope of the Restudy. To fully achieve ecological restoration pollution loads must be identified and quantified within each of the study area regions, and load reduction and concentration targets for pollutants of concern must be established. Concurrent with or prior to the proposed operation of components of the Comprehensive Plan, water quality remediation programs for degraded and/or designated use-impaired water bodies must be implemented by the responsible agencies in order to fully achieve ecological restoration objectives.

The components of the Recommended Plan will be adaptively constructed and operated generally in accordance with the implementation plan. Adaptive implementation of the components may require incremental improvement of existing and projected future water quality conditions within the watersheds in which the components are implemented. Concurrent with or prior to the proposed operation of components of the Recommended Plan, water quality remediation programs for 303(d)-listed and other impaired water bodies must be implemented in order to fully achieve ecosystem restoration objectives.

Watershed water quality improvements are especially critical when the operation of a component or several components of the Recommended Plan would result in significant hydrologic changes within those watersheds. Many of the plan components will substantially affect the volume and timing of surface water deliveries in several of the Restudy area's watersheds. The SFWMD, FDEP, and other agencies have developed water quality improvement strategies for several of the impaired waterbodies within the Restudy area. The most notable example is the Everglades Forever Act (EFA), which focuses on achieving adequate water quality in the Everglades. The EFA provides an iterative process that is designed to insure that after implementation, compliance with all water quality standards will be achieved in the Everglades Protection Area (EPA).

However, the EFA is limited geographically to the defined Everglades Protection Area. Other examples include Surface Water Improvement and Management (SWIM) Act planning efforts for the Indian River Lagoon, Lake Okeechobee, and Biscayne Bay, and the Florida Keys National Marine Sanctuary Water Quality Protection Program.

There is not, presently, a comprehensive water quality strategy for the entire Restudy area, and the degree to which some of the existing water quality improvement plans have been implemented has been limited by lack of funding necessary to complete assessment and planning activities. Watershed assessments are necessary to develop pollutant source reduction programs and to design and construct water quality treatment facilities, if necessary. In some cases, future water quality certification in accordance with section 401 of the Federal Water Pollution Control Act (=Clean Water Act) for construction and operation of some of the components included in the Recommended Plan may be dependant upon the successful implementation of watershed water quality improvement projects or programs prior to or concurrent with construction of those Recommended Plan components. Accordingly, the implementation plan for the eventual Recommended Plan includes a framework for evaluating water quality conditions, data and monitoring needs, developing water quality criteria and pollution reduction targets, and watershed water quality improvement programs as part of the overall implementation of the Recommended Plan.

F.2 KISSIMMEE RIVER REGION

Water quality conditions in the Kissimmee River Region are expected to be improved compared to both the 1995 and 2050 base conditions through implementation of the Recommended Plan. Construction and operation of two water storage/treatment components in the Kissimmee River Region, Components A6 and W2, as well as two "Other Project Elements" (OPE), combined reservoir/STAs in the S-154 basin and the S65-D basin, will provide water quality benefits to both the lower Kissimmee River and Taylor Creek/Nubbin Slough (TCNS) basins as well as to downstream, Lake Okeechobee.

Construction and operation of Component A6 (north of Lake Okeechobee water storage reservoir and stormwater treatment area) would result in 17,500 acres of Water Storage Area (WSA) with a maximum depth of 11.5 feet and a 2,500-acre stormwater treatment area (STA). The conceptual design of Component A6 is described as either being operated as a:

1) WSA/STA near the Lake where Lake Okeechobee water will be backpumped to, or;
2) WSA/STA(s) located near the Kissimmee River in the S-65 E basin , north of the Lake, and used to attenuate high river flows and treat stormwater prior to passing into Lake Okeechobee.

From a water quality enhancement perspective, the second operation scenario would be preferred over the first, since the second operating scenario would maximize reduction in pollutant loading from the Kissimmee River to Lake Okeechobee. Total phosphorus (TP) loading data provided in the Lake Okeechobee SWIM Plan (SFWMD, 1997) indicates that average TP concentrations in the lower Kissimmee River, i.e., Pools S-65D and S-65E, during 1990-94, were 0.77mg/L and 0.36 mg/L respectively (see table 8.2.6-1 excerpted from SFWMD (1997)).

These average TP concentrations in the lower Kissimmee River are some of the highest TP average concentrations in the entire Kissimmee River drainage basin. The associated average TP loading from Pools S-65 D&E, during 1990-94, were 29.1 and 43.0 tons/year, respectively. These TP loading rates were some of the highest in the entire Kissimmee River basin with the exception of the TP loading to Lake Okeechobee coming from the TCNS area (90.4 tons/year).

The SFWMD 1997 Lake Okeechobee SWIM Plan (SFWMD, 1997) identifies four critical upstream drainage basins where TP loading to the Lake must be significantly reduced to enable long-term recovery and restoration of Lake Okeechobee water quality conditions and ecological health (Figure F.1, excerpted from SFWMD (1997))

Table F.5 Phosphorus Loading to Lake Okeechobee (excerpted from SFWMD, 1997a)

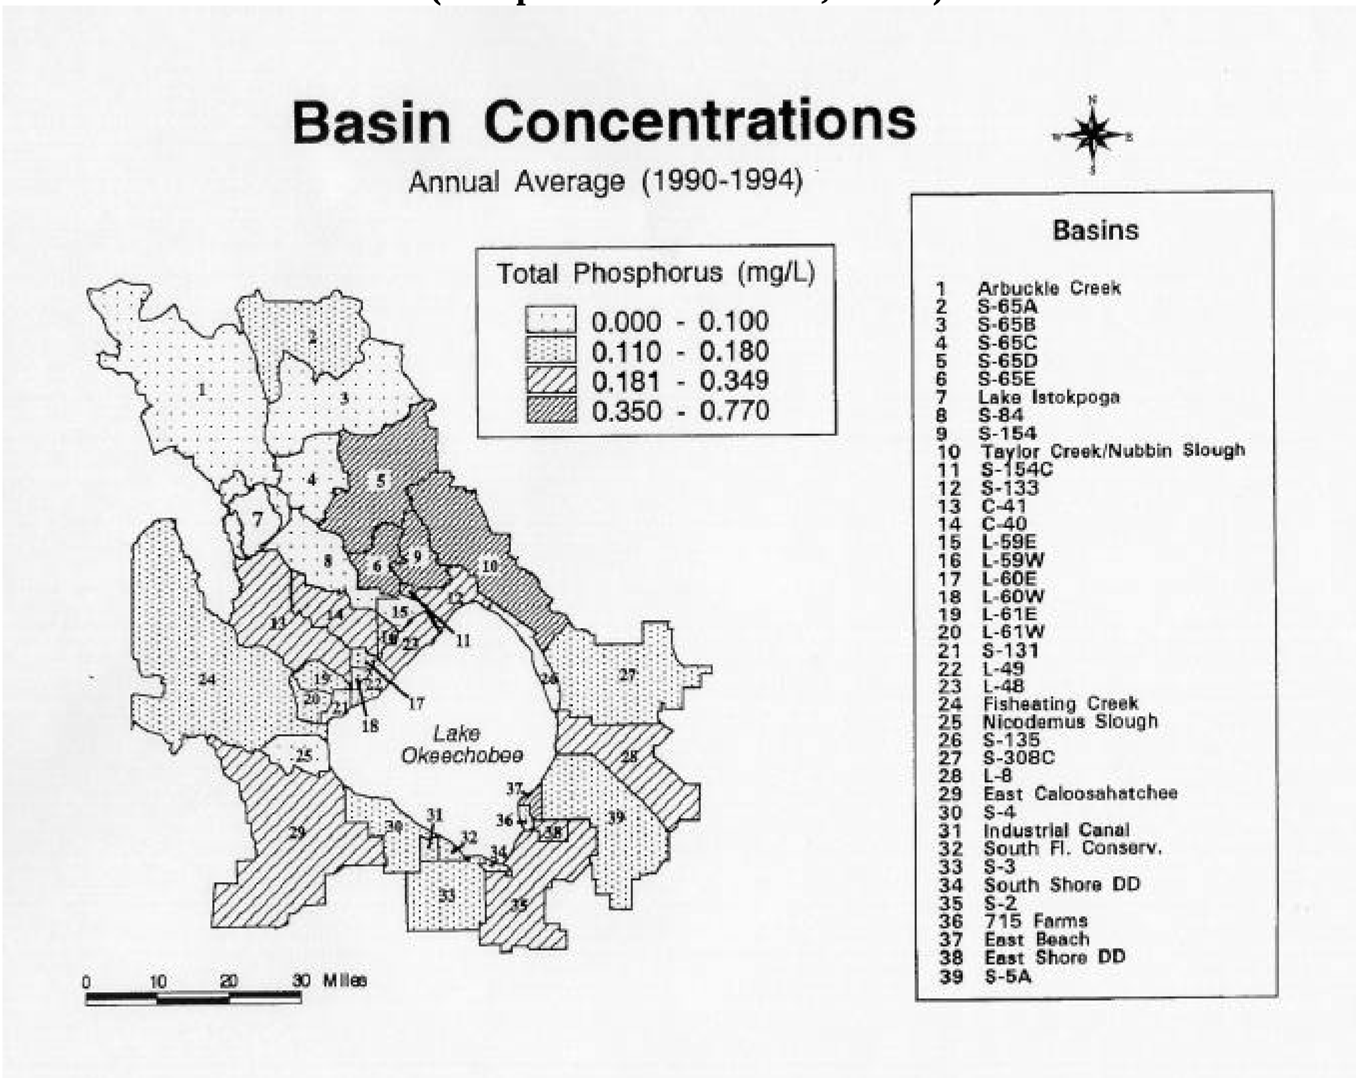
Figure F.1 Contributions of Phosphorus from Lake Okeechobee Basins (exerpted from SFWMD, 1997a)



Those four critical basins which produce high TP loads to the downstream Lake Okeechobee are: the S-65 D basin, the S-65-E basin, the TCNS basin, and the S-154 basin. Water quality degradation in the lower Kissimmee River region south of Lake Kissimmee is mainly attributable to agricultural nonpoint pollution consisting primarily of elevated nutrients and fecal bacteriological contamination and increased turbidity and sedimentation in watercourses of the region.

Construction of one or more WSA/STAs in the Kissimmee River region consistent with Component A6 would result in sequestration of particulate and dissolved nutrients and other pollutants in the WSA(s) through sedimentation and biological uptake processes. Maximizing the hydrologic retention time of surface runoff waters captured in the WSA(s) would increase the pollutant reduction benefits provided by the WSA/STA(s).

In addition to phosphorus loading, other key water quality parameters of concern in the Kissimmee River region are dissolved oxygen (DO) and nitrogen compounds (NOx). Construction of WSA/STAs north of Lake Okeechobee would also, based on similar water quality treatment processes, result in reduction on NOx loading to the surface waterbodies in the basin as well as to Lake Okeechobee.

In terms of maximizing future water quality benefits provided by WSA/STA construction and operation in the lower Kissimmee River area, it is likely that water quality benefits could be increased by siting multiple WSA/STAs totaling 20,000 acres at strategic locations, optimized for reducing nutrient loading to downstream surface waterbodies, as opposed to the construction of one large contiguous 20,000-acre WSA/STA in the basin. Existing and ongoing water quality monitoring in the Kissimmee river region being conducted by the SFWMD could be used to optimally site several WSA/STAs totaling 20,000 acres while realizing the primary hydrologic water storage purpose of the Kissimmee River basin WSA(s).

Construction and operation of Recommended Plan Component W2, a combined 5,000-acre WSA (maximum depth 10 feet) coupled with a 5,000-acre STA (maximum depth 4 feet) will result in substantial reduction of nutrient loads entering the Taylor Creek/Nubbin Slough watercourses and Lake Okeechobee. The purpose of this component is to provide flood protection, water quality treatment, water supply benefits and enhancement of the St. Lucie and Caloosahatchee River estuaries. This WSA combination is sized to capture and treat storm water runoff from the TCNS basin, which is the highest nutrient loading basin flowing to the eutrophic Lake Okeechobee. The design of the combination WSA/STA is intended to reduce TP concentrations in TCNS runoff to Lake Okeechobee by 80 percent from 0.528 mg/L down to 0.107 mg/L. This reduction in nutrient loading to the Lake would contribute toward the Lake Okeechobee SWIM Plan target for reducing TP loading to the Lake and ultimately restoring the ecological health of the Lake.

Two additional water-quality-related Recommended Plan components which will attenuate peak flows and improve water quality conditions in tributary basins flowing to Lake Okeechobee are described in the OPE entitled "Lake Okeechobee Watershed Water Quality Treatment Facilities". This OPE is a logical extension of the WRDA '96 Critical Project entitled "Lake Okeechobee Water Retention/Phosphorus Removal" which is not associated with the Recommended Plan. The Lake Okeechobee Watershed Water Quality Treatment Facilities OPE will result in construction and operation of a 1,775-acre combined reservoir/STA in the S-154 basin and a 2,600-acre reservoir/STA in the S65-D basin. Additionally this OPE project would entail re-isolation of approximately 3,500 acres of previously drained wetlands (ditch plugging) in the previously identified critical phosphorus loading basins north of Lake Okeechobee. The main purpose of this OPE would be nutrient load reduction within the basins and to the downstream Lake. There are potentially additional combined reservoir/STA stormwater treatment facilities needed in the Lake Okeechobee watershed that are not included in the Recommended Plan. The recommended Restudy Comprehensive Water Quality Plan will further evaluate the potential need for other water quality treatment facilities in the Region.

F.3 LAKE OKEECHOBEE

Water quality conditions in Lake Okeechobee are expected to be slightly improved relative to the 1995 base and the 2050 base conditions as a result of implementation of several components of the Recommended Plan. Water quality improvements in water inflows to the Lake will be more marked than immediate in-lake water quality improvements. The above discussed Recommended Plan-related water quality improvements in watersheds north of the Lake will result in reduction of agricultural nonpoint source pollutants (nutrients, bacteriological contamination, turbidity/sedimentation) entering Lake Okeechobee relative to the 1995 and 2050 base conditions.

The key water quality parameters of concern in Lake Okeechobee waters are TP, NOx, chlorophyll-a and turbidity. Currently, water quality can be characterized as eutrophic, with in-lake TP concentrations averaging 90-100 ppb TP. Pollutant loading, primarily nutrients, over the past several decades has significantly degraded Lake Okeechobee water quality and resulted in massive loading of nutrients to Lake sediments. Average in-lake TP concentrations have increased from 40 ppb in the early 1970's to current conditions in the 100 ppb range. Resuspension of nutrient laden lake sediments during strong wind events dominate pollutant loading within the lake (Reddy et. al., 1995).

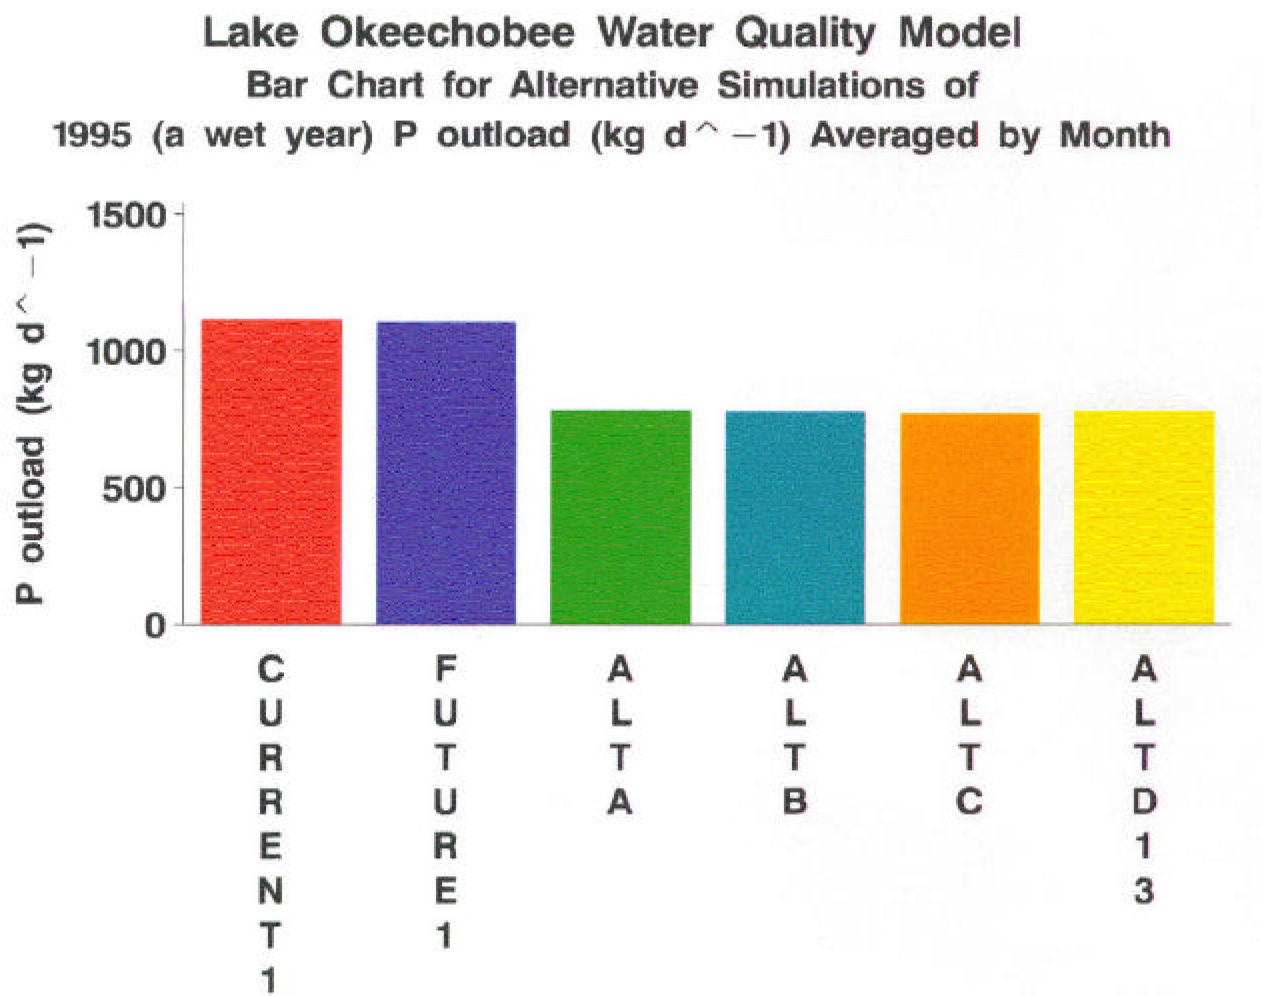
Recommended Plan components GG4 and DDD5 are expected to result in incremental improvement for in-lake water quality conditions. Component GG4 is the Recommended Plan Lake Okeechobee Aquifer Storage and Recovery (ASR) project. This component would result in the construction and operation of 200 ASR wells located on the Lake's peripheral levee (Hoover Dike) with each ASR pump having a maximum capacity of 5 million gallons per day (MGD), for a total Lake ASR maximum capacity of 1 billion gallons per day. The multiple purposes of Lake ASR include: 1) providing additional regional water storage while reducing evapotranspiration losses and minimizing the acreage of regional above-ground storage reservoirs; 2) improving the Lake's water supply capacity for downstream environmental/urban/ agricultural users; and 3) reducing harmful regulatory discharges to the St. Lucie and Caloosahatchee estuaries and maintaining existing flood protection.

Although implementation of ASR facilities on the scale proposed by Component GG4 is unprecedented, preliminary data (David Pyne, CH2M Hill, personal communication) indicates that nutrient levels in ASR waters stored and recovered from the upper Floridan aquifer may be significantly decreased from concentrations in well injectate. If future pilot project associated with Component GG4 prove this nutrient reduction feature of ASR to be present in large scale ASR projects, then some water quality benefits may be realized in Lake Okeechobee waters (at least localized) as a result of large scale ASR implementation. As required in the Clean Water Act, the COE and SFWMD will have to commit to the ASR regulating agencies (FDEP and USEPA) that all recovered ASR waters will be fully treated to met the Class I Water Quality Standards applicable to Lake Okeechobee waters. Regulatory issues involved with operating the raw water ASR facilities proposed in the Recommended Plan will need to be successfully resolved by the involved agencies. Operational data from several large ASR pilot projects will be needed to successfully resolve the regulatory issues involved with Restudy ASR components.

Recommended Plan Component DDD5 calls for the construction and operation of a 5,000-acre STA (maximum depth 4 feet) in the vicinity of structure S-77, where the Caloosahatchee River flows from Lake Okeechobee. The STA would be coupled with a backpumping facility to backpump excess Caloosahatchee basin water to the Lake. Backpumping would only occur when Lake water levels and storage capacity was appropriate. Based on the design of the 5,000-acre STA and the performance of the Everglades Nutrient Removal (ENR) Project, it is anticipated that backpumped water from the STA to the lake would be below 50 ppb TP. Since average TP concentrations in the Lake are 100 ppb, it is anticipated that the backpumped Component DDD5 waters would have a localized beneficial effect.

Although implementation of Lake Okeechobee watershed Recommended Plan components along with Components GG4 and DDD5 are anticipated to reduce nutrient and pollutant loading to Lake Okeechobee, the Restudy Water Quality Team's analysis of the overall effect of the Recommended Plan on Lake waters concluded that only minor improvements would result to Lake Okeechobee water quality. This conclusion was based on several analyses, including extensive water quality modeling of the 1995 and 2050 base conditions and all evaluated Restudy alternatives (A, B, C, and D13R) using the Lake Okeechobee Water Quality Model (LOWQM) (James et. al., 1997). The LOWQM analysis concluded that when comparing the Recommended Plan to the 1995 and 2050 base conditions using six Lake Okeeechobee water quality performance indicators (TP Inload; TP Outload; Median Lake TP; Median Lake chlorophyll; Maximum Lake TP and Maximum Lake chlorophyll-a, that the Recommended Plan would result in slightly better cumulative water quality conditions in Lake Okeechobee waters than either the 1995 or the 2050 base conditions (see Table F.2 excerpted from LOWQM web site, 1998: internet). However, the slight water quality benefits of Recommended Plan components GG4 and DDD5 on in-lake water quality conditions are overwhelmed by the effects of lake resuspension of nutrient rich sediments as well as by nutrient enriched inflows from the watersheds flowing into the Lake.

Figure F.2 Lake Okeechobee Water Quality Model. 1995 (a wet year) Phosphorus Outload (exerpted from Lake Okeechobee Water Quality Model web site, James



1998)

This general conclusion is supported by recent work (Havens, 1997). This recent work indicates that due to the dominant effect of Lake Okeechobee sediment resuspension with the associated release of nutrients into the lake water column, it would be several decades before lake-wide TP concentrations and other associated lake water column parameters would show significant improvement, even if all nutrient inflows to the lake were eliminated. Therefore, water quality improvements to Lake Okeechobee waters resulting from Recommended Plan implementation will be gradual and it will take several decades for these benefits to be fully realized.

F.4 UPPER EAST COAST AND INDIAN RIVER LAGOON

The Recommended Plan includes several components specifically addressing ecological conditions in the Upper East Coast and Indian River Lagoon region, including the St. Lucie River estuary. Furthermore, other regional storage features (e.g., Components A6, D5, G6, W2, and GG4: see below) are expected to improve water quality conditions in the region by contributing to the attenuation of flood discharges via the C & SF Project. Additionally, an OPE outside of the Restudy Recommended Plan involves attenuation of C-25 Canal flows to improve water quality in the Indian River Lagoon.

Water quality conditions in the St. Lucie River and Indian River Lagoon estuaries are expected to be significantly improved as a result of the implementation of the following components:

Component A6 – North Storage 17,500-acre reservoir (maximum depth 11.5 feet) with 2,500-acre stormwater treatment area, Kissimmee River watershed; regional system storage reduces flood discharges from Lake Okeechobee into St. Lucie (C-44) Canal;

Component B2 – C-44 (St. Lucie) Canal 10,000-acre reservoir (maximum depth 4 feet); attenuates C-44 basin runoff, reduces flood discharges into C-44 Canal;

Component C7 – Environmental water supplies to St. Lucie River estuary to achieve optimal salinity;

Component D5 – Caloosahatchee (C-43) Canal 20,000-acre regional system storage (maximum depth 8 feet) reduces flood discharges into St. Lucie and Caloosahatchee Canals;

Component F3 – modified regulation schedule for Lake Okeechobee to provide increased environmental deliveries to the WCAs/Everglades national Park (ENP) and reduce flood discharges to St. Lucie and Caloosahatchee estuaries;

Component G6 – Everglades Agricultural Area (EAA) 60,000-acre reservoir (maximum depth 6 feet); regional system storage reduces Lake Okeechobee flood discharges into C-44 Canal;

Component W2 – TCNS storage and treatment; regional system storage reduces flood discharges from Lake Okeechobee into C-44 Canal; long-term net improvement of Lake Okeechobee water quality discharged into C-44 Canal;

Component GG4 – Regional-scale aquifer storage of Lake Okeechobee water reduces flood discharges into C-44 Canal; water supply to St. Lucie River estuary upon recovery;

Component UU7 – Surface water storage reservoirs totaling 27,200 acres in C-23 and C-24 Canal basins and 21,150 acres of storage in North Fork and South Fork basins of the St. Lucie River. The reservoirs provide regional storage volume totaling 349,400 acre-feet and are designed to prevent undesirable flood discharges to the St. Lucie River estuary.

Key water quality parameters of concern in this region include nutrients, mercury and other heavy metals, dissolved oxygen, pesticides, salinity, turbidity, and coliform bacteria. A substantial amount of the surface water storage area in the Recommended Plan (Components B2 and UU7, see Table F.6) was developed specifically to prevent freshwater inundation of the St. Lucie River estuary consistent with salinity targets. It is expected that these surface water storage areas can be optimized to reduce nutrient and heavy metal concentrations and turbidity levels in inflows to the estuary. Nutrient reductions may also improve dissolved oxygen conditions by reducing Biochemical Oxygen Demand (BOD). Attenuation of runoff should also reduce coliform bacteria concentrations in the estuary. Certain pesticide concentrations may also be reduced, depending upon pesticide forms (dissolved or particulate) and pesticide application practices in the watershed. It is not expected that increased surface water storage will affect mercury concentrations.

F.5 EVERGLADES AGRICULTURAL AREA

F.5.1 Water Quality in the EAA

The Recommended Plan is expected to improve water quality conditions in the Everglades Agricultural Area (EAA). Phosphorus is the primary pollutant of concern in the EAA, particularly as it affects ecological conditions in the downstream WCAs.

The principle water quality benefit to the EAA resulting from the Recommended Plan is the conversion of approximately 60,000 acres (Component G6) of farmland and concomitant elimination of attendant nonpoint source pollution loads to surface water storage.

The phosphorus load reduction estimate for the EFA BMP regulatory program in the EAA is 25 percent. The three-year average (for the period ending April 30, 1997) in total phosphorus loads originating from EAA farms indicates a 51 percent reduction compared to the 1979–1988 baseline period (SFWMD, 1997). Other pollutants of concern in the EAA include mercury, NOx, dissolved oxygen, and pesticides. Water column mercury concentrations in the EAA are not expected to be affected by construction and operation of G6.

Combined, the existing EAA regulatory program and the increase in storage volume on former farmland in the EAA will result in a net reduction of phosphorus and other non-point source pollutants in surface waters of the EAA compared to existing and future base conditions.

F.5.2 Effects of Recommended Plan on the Everglades Construction Project

The water quality performance of the ECP is expected to be somewhat improved over the 2050 base condition. Increasing hydraulic and phosphorus loads are predicted to affect the performance efficacy of the Everglades Construction project (ECP). The ECP and BMPs in the EAA comprise the primary water quality improvement strategy for the downstream WCAs.

For purposes of evaluating the future (2050) base condition and alternative plans, the so-called “Phase 2” treatment technologies necessary to meet water quality criteria adopted pursuant to the EFA were assumed to be implemented. The EFA requires that, by December 31, 2006, the ECP treat EAA stormwater runoff delivered to the EPA to either the adopted criterion or to the default numeric water quality criteria of 10 parts per billion (ppb) total water column phosphorus concentration (TP).

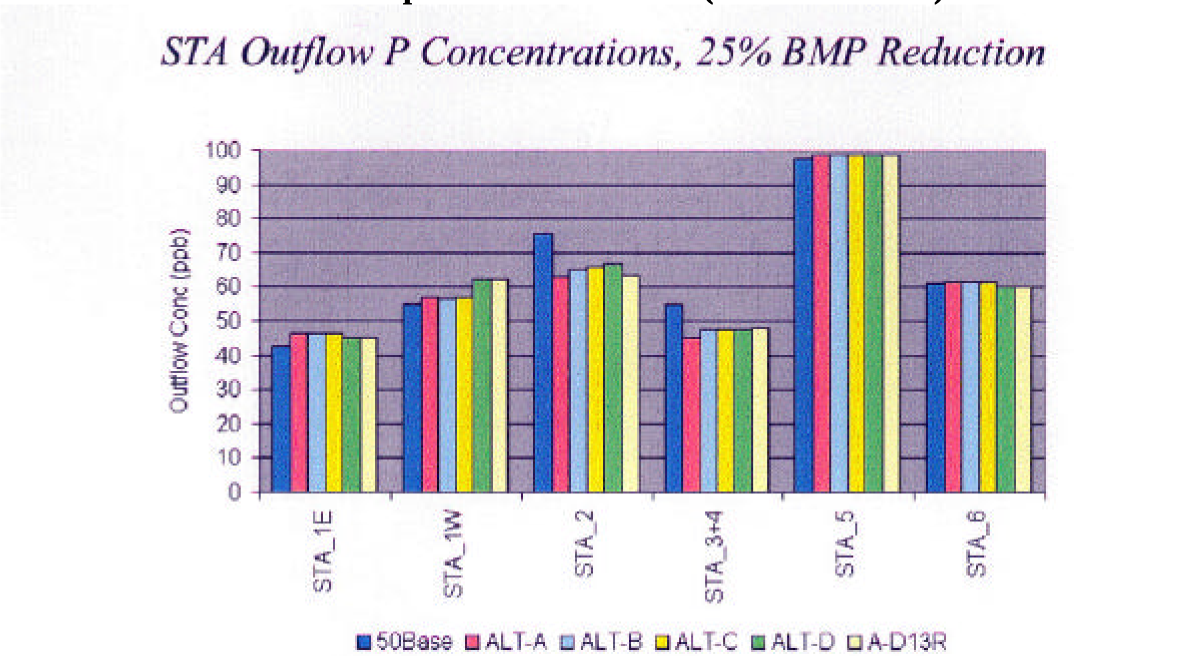
However, since the numeric treatment targets are not yet known, nor has the most appropriate supplemental treatment technology been selected, the Restudy Water Quality team (WQT) determined that the potential impact of the future base and Restudy alternatives on the design and operation of the ECP could best be evaluated in the context of the interim treatment targets defined in the conceptual plan for the ECP (Burns & McDonnell, 1994) and current design criteria for the ECP.

An evaluation of the effect of the future base condition and Restudy alternatives on the interim operation of the ECP was conducted by William W. Walker, Jr. (Walker, 1998). Walker's evaluation indicates that, utilizing existing water quality data and the phosphorus settling rate constant and EAA BMP phosphorus load reduction assumptions used in the conceptual design for the ECP (Burns & McDonnell, 1994), the 31-year average hydraulic and phosphorus loads in the Recommended Plan would cause the interim phosphorus concentration target (50 ppb) to not be met at STAs 1W, 2, 5, and 6. This potential problem also exists for all of the STAs except STA 1E in the 2050 base condition.

On the other hand, using the 51% observed average phosphorus reduction rate from 1995 to 1997 for the EAA BMP significantly changes the outcome. Walker observes that all STAs with the exception of STA 5, meet or exceed the interim phosphorus concentration target. STA 5 is the sole exception due to the hydrologic model not including the nearly 2,000 acre treatment area of STA 6 Section 2. Changing other criteria such as the settling rate constant to that observed in the Everglades Nutrient Removal project over the 1995 to 1997 period would also significantly improve the STA performance models.

It is important to note that when compared to projected 2050 base conditions, the Recommended Plan is not predicted to exacerbate performance deficiencies predicted for the ECP. Significantly, the Recommended Plan improves the predicted performance at STA 3\4. STA 3\4 benefits from the proposed 60,000-acre EAA reservoir (Component G6), acting as a net sink for phosphorus. STA 1E is not predicted to be adversely affected by the future base or Recommended Plan flows, as shown in Figure F.3 (excerpted from Walker, (1998: Internet)).

Figure F.3 STA Outflow Phosphorus Concentrations, 25% BMP Reduction Excerpted from Walker (1998:internet)



This chart shows the flow-weighted-mean concentration in the combined discharge from each STA for 1965-1995. Results assume a BMP load reduction of 25% (ECP Design Basis). The combined discharge consists of the treatment area outflow plus bypasses (excluding urban water-supply deliveries).

As noted above, the predicted performance deficiency at STA 5 is caused by not including STA 6 Section 2 as a future base condition or in any of the Restudy alternatives. For modeling purposes, STA 6 Section 2 was not included in the SFWMM simulations because this element was not included in the conceptual design. The construction schedule for the ECP indicates that construction of STA 6 Section 2 is to be completed by October, 2004. Elimination of STA 6 Section 2 from the SFWMM simulations requires all of the C-139 basin runoff to be routed through STA 5, thereby increasing the average hydraulic and phosphorus loads above the amounts for which it was designed.

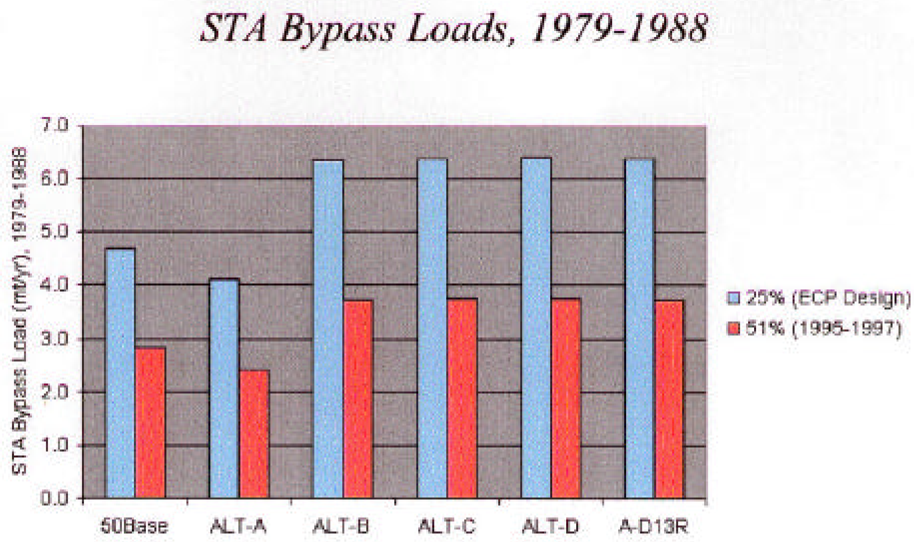
The ECP is designed to treat one hundred percent of the runoff originating within the EAA for the 1979-1988 baseline period to an interim phosphorus concentration target of 50 ppb. The conceptual design for the ECP does not provide for any bypasses of 1979-1988 flows. It is important to note that the period of record utilized for evaluating alternatives during the Restudy was 1965-1995, a much longer and, on average, wetter period than the baseline period utilized to design the ECP. In addition, different operational rules (Rain-Driven Operational Rules, Component H7) were used to evaluate the effects of Restudy alternatives, including the Recommended Plan, on the ECP.

Nevertheless, using 1979-1988 hydrologic conditions, Walker's evaluation indicates that bypasses of the STAs are predicted to occur in the 2050 base condition. Furthermore, the amount of bypassing is predicted to increase over the 2050 base with implementation of the IDP. Bypass phosphorus loads to the WCAs are further increased when considering 1965-1995 average hydrologic conditions. (See Figures F.4 and F.5 from Walker (1998: internet)). Bypasses of the STAs induced by high-flow events may cause water quality criteria to not be met in the WCAs and create an ecological impact through increased phosphorus loading.

Since the ECP is designed to treat all of the EAA runoff volume for the 1979-1988 baseline years, it is assumed that the ECP will be modified to handle bypass volumes which are inherent in the 2050 base operations. Bypass volumes created by the IDP which are greater than those in 2050 base conditions may necessitate further design or operational changes to assure that downstream water quality criteria continue to be achieved.

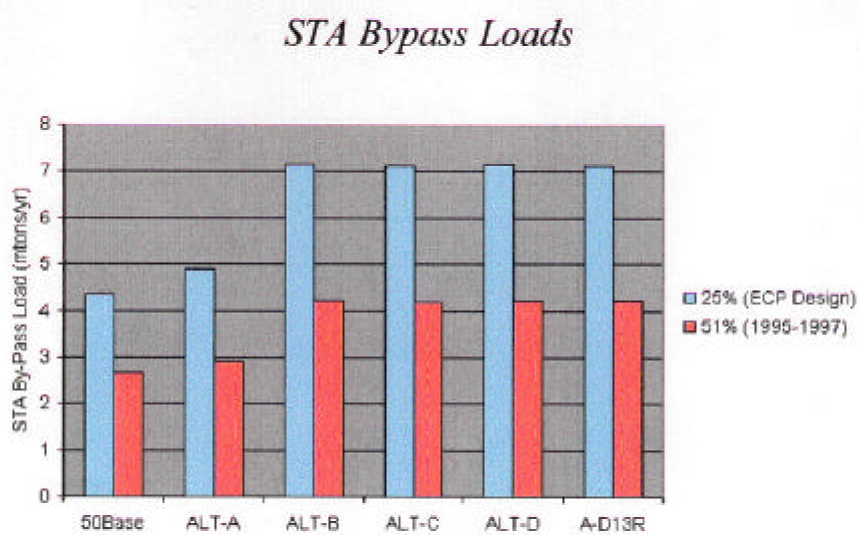
One of the main objectives of the Restudy is to create additional regional water storage to increase the volume and optimize the timing of water delivered to the EPA. This objective is consistent with the 28 percent average increase to the WCAs requirement contained in Section 373.4592(4)(b)2 of the EFA. According to Walker, the IDP resulted in a 19 percent increase in flow from the ECP to the WCAs compared to the baseline period (1979-1988). This was an improvement over the projected 12 percent increase predicted for the 2050 base condition. It should be noted that the 19 percent increase predicted for the IDP is to be achieved concurrent with other measures to be undertaken to achieve optimal hydrologic conditions in the Everglades. Therefore, increasing average volumes delivered from the ECP to the WCAs beyond that predicted for the IDP may create, under certain conditions, adverse ecological effects (e.g. prolonged hydroperiods, inundation of tree islands) in the WCAs. No alternative plan delivered more than 23 percent (Alternative B) greater flows via the ECP to the WCAs.

Figure F.4 STA Bypass Loads, 1979-1988
Excerpted from Walker (1998:internet)



This chart shows average annual STA bypass loads for Water Years 1979-1988 and for two BMP performance assumptions (25% & 51%). Bypass occurs when basin outflow (required for flood control) exceeds STA hydraulic capacity. This 10-year period was used as a hydrologic basis for designing the Stormwater Treatment Areas. Both the Everglades Forever Act and Settlement Agreement require that treatment facilities be sized to treat all flows during this period(excluding urban water-supply deliveries) without hydraulic bypass.

Figure F.5 STA Bypass Loads, 1965-1995
Excerpted from Walker (1998: internet)



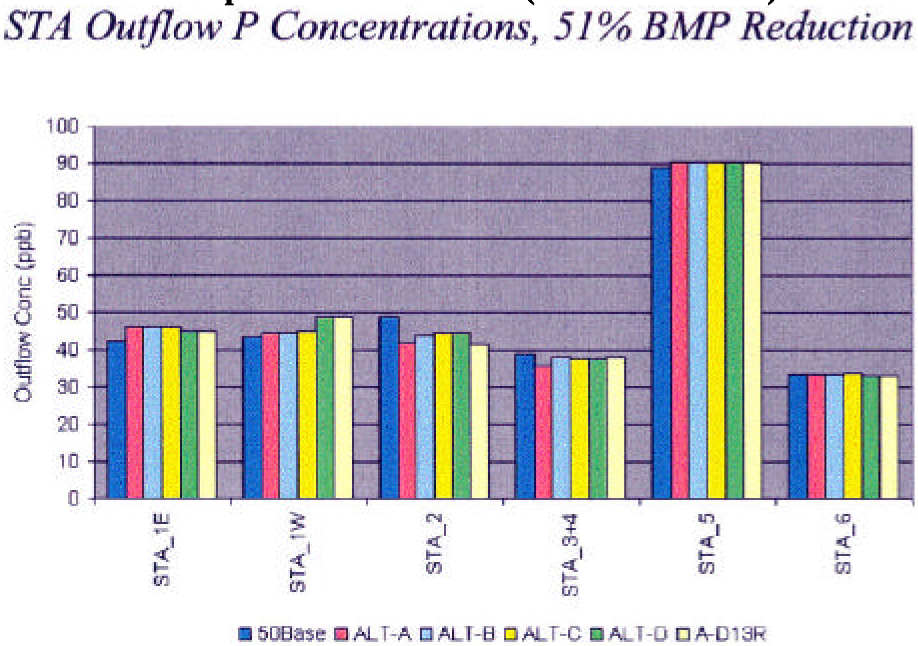
This chart shows average annual STA bypass loads for 1965-1995 and for two BMP performance assumptions (25% & 51%). Bypass occurs when basin outflow (required for flood control) exceeds STA hydraulic capacity. Click here to view bypass volumes & loads for each STA & 25% BMP performance assumption.

One preliminary conclusion which can be drawn from this evaluation is that if the EAA reservoir (Component G5) is constructed and operated as modeled in the Recommended Plan, the size of STA 3\4 could either be reduced and still achieve the interim phosphorus concentration target or the water quality benefits of the 60,000 acres of EAA storage could be expanded to benefit other ECP STAs. The beneficial effect of Component G5 on STA function illustrated by Walker's evaluation suggests that splitting the 60,000 acres of storage area into other basins or delivering water from other basins would similarly benefit other STAs.

Supplemental treatment technologies designed to achieve low phosphorus concentrations (Phase 2) in discharges from the STAs consistent with the requirements of the EFA should be designed consistent with the average hydraulic and phosphorus loads inherent in the Recommended Plan. It should be noted that this conclusion is based on Walker's modeling results utilizing existing water quality data, operational rules (lake regulation schedule, etc.) for the 2050 base condition and the Recommended Plan, and the phosphorus settling rate (10.2 m/yr.) and the BMP load reduction (25 percent) assumptions used to develop the conceptual plan for the ECP (Burns & McDonnell, 1994).

The observed three-year average in actual phosphorus load reduction resulting from implementation of BMPs in the EAA is 51 percent (SFWMD, 1997b), not the 25 percent assumed for the conceptual design of the ECP. Walker's evaluation further indicates that a 51 percent load reduction resulting from BMPs enhances the performance of the STAs (see Figure F.6, excerpted from Walker (1998: Internet)). Furthermore, observed performance at the ENR STA demonstration project indicates the cumulative three average settling rate constant and outflow concentrations of phosphorus were significantly better than the 10.2 meters per year settling rate constant used for ECP design and interim concentration target of 50 ppb (SFWMD, 1998). Increased phosphorus load reduction and an increased settling rate consistent with that observed at the ENR Project may negate the need to modify the size and/or operation of the STAs if attained over the long-term. The underlying assumption remains that Phase 2 water quality treatment technologies will achieve EFA required default numeric TP criterion of 10 PPB or an alternative approved numeric TP criterion.

Figure F.6 STA Outflow P Concentrations, 51% BMP Reduction
Excerpted from Walker (1998: Internet)



This chart shows the flow-weighted-mean concentration in the combined discharge from each STA for 1965-1995. Results assume a BMP load reduction of 51% (1995-1997 average). The combined discharge consists of the treatment area outflow plus bypasses (excluding urban water-supply deliveries).

F.6 WATER CONSERVATION AREAS (INCLUDING ROTENBERGER AND HOLEY LAND WMAS)

The primary pollutant of concern in the WCAs and Rotenberger and Holeyland WMAs is phosphorus. A principle assumption for purposes of evaluating the effect of the Recommended Plan on water quality in the WCAs is that the EFA is fully implemented, and that all discharges into the EPA comply with all water quality criteria, including the yet-to-be-established phosphorus criterion. Accordingly, the evaluation focused upon projected increases and decreases of structural flows into the WCAs.

Other parameters/pollutants of concern in the WCAs and Rotenberger and Holeyland WMAs include NOx, dissolved oxygen, conductivity, and mercury.

Many of the components of the Recommended Plan are designed to achieve hydrologic targets in Loxahatchee National Wildlife Refuge (WCA 1) and WCAs 2 and 3 and downstream in ENP and Florida Bay. Generally, these components are to be operated to increase the volume of water delivered into and retained in the WCAs and to optimize the timing of those deliveries. The following components are expected to affect hydrologic and water quality conditions in the WCAs and downstream in Everglades National Park and Florida Bay:

Component F3 - modified regulation schedule for Lake Okeechobee to provide increased environmental deliveries to the WCAs and ENP;

Component H6 - Rain-driven operations in WCAs 2 and 3 to improve hydropatterns and hydroperiods in the WCAs and ENP;

Component 04 - WCA 3A/3B levee seepage management;

Component Q5 - Western C-11 basin diversion (eliminates discharges of urban runoff to eastern WCA-3A via S-9 pump station);

Component S6 - Central Lake Belt Storage Area, operated to improve hydropatterns and hydroperiods in WCA 3B;

Component AA3 - Additional water control structures between WCA3A & 3B;

Component GG4 - Lake Okeechobee ASR to increase storage of lake water for environmental and water supply deliveries;

Component II3 - Increased capacity of ECP pump station G-404 to improve hydropatterns and hydroperiods in WCA 3A;

Component KK4 - Internal L-7 and L-40 canal structures to improve hydropatterns and hydroperiods in WCA1 (Loxahatchee National Wildlife Refuge: LNWR);

Component QQ6 - Partial decompartmentalization of WCA 3 to reestablish ecological and hydrologic connection between WCA 3A and 3B and Northeast Shark River Slough;

Component RR4 - Relocation and increase in capacity of pump station S-140 to improve hydropatterns and hydroperiods in central WCA 3A;

Component SS4 - Increasing capacity of S-150 to discharge LEC water supply deliveries to US 27 borrow canal (potential adverse impact in WCA 3A associated with Component SS4);

Component ZZ5 - Storage of excess flows in WCA 3A and 3B in Central Lake Belt storage area, to be returned to WCA 3A to achieve preferred hydropatterns and hydroperiods;

Component AAA6 - Conservation of water use in LEC; expected to benefit WCAs through reducing water supply demand from WCAs/regional system;

Component CCC6 - L-28I levee modifications;

Component EEE5 - Storage of excess flows from WCA 2A & 2B in Central Lake Belt storage area, to be returned to WCA 3B to achieve preferred hydropatterns and hydroperiods.

Seminole Tribe Water Conservation Plan OPE - Detention and treatment of stormwater runoff from Tribal Big Cypress reservation lands.

Miccosukee Tribe Water Conservation Plan OPE - Detention and treatment of stormwater runoff from Miccosukee Tribal lands.

Collectively, these components will result in an increase in the average annual volume of water (and phosphorus and nitrogen loads) delivered to the WCAs compared to current (1995) and future (2050) base conditions. Utilizing the water budget data generated from the SFWMM simulations of the base conditions and the alternatives, 31-year average structural flows into the EPA are projected to increase from approximately 2,092.0 thousand acre-feet (k ac. ft.) per year (2050 base condition) to 2,181.9 k ac. ft. per year in Alternative D13R (SFWMD, 1998).

The projected increase in average annual volume is not, however, simply an accumulated incremental increase for all of the existing and proposed water control structures discharging into the EPA. For example, the volume of water delivered by some of the structures contained in the Recommended Plan discharging water into the WCAs is predicted to increase greatly (e.g., S-140 pump station, 31-year average increase in volume is approximately 285.0 k ac. ft.; S-150 pump station, 31-year average increase in volume is approximately 32.2 k ac. ft), whereas other structures will be significantly decreased (e.g., S-9 pump station, 31-year average decrease in volume is 185.8 k ac. ft.; S-190 water control structure, 31-year average decrease in volume is 89.3 k ac. ft., 2050 flows from S-190 eliminated;(see Table F.6).

Decreases in average annual structural flows containing significant pollution loads (e.g., S-9, S-190) would be expected to improve water quality conditions in those areas within the water conservation areas impacted by those discharges. Conversely, increases in structural discharges (e.g., S-140, S-150) could create potential water quality problems except where treatment facilities are provided. Treatment facilities are provided in nearly every instance where increases occur. For modified pump station S-140 (Component RR4), the majority of the projected increase in volume is flow out of STA 3\4 directed west along the L-5 and L-4 borrow canals via modified pump station G-404 (Component II3). However, a portion of the water discharged via S-140 would include runoff from cattle pastures on the Seminole (see Seminole Tribe Big Cypress OPE) and Miccosukee tribal reservation lands (see Miccosukee Tribe WCP OPE) adjacent to northwest WCA 3A. The Seminole Tribe and Miccosukee Tribe have identified stormwater runoff treatment facilities for discharges from their respective reservations.

The affect of flows and attendant pollution loads into the WCAs resulting from the implementation of Recommended Plan components will be evaluated in future detailed design studies and may affect the final design of treatment facilities. Implementation of the Recommended Plan is not expected to alter mercury concentrations (which is primarily atmospheric in origin), or conductivity within the canals and marsh areas. Similarly, dissolved oxygen levels are not expected to be affected by Recommended Plan components.

It is also important to note that even with such modifications in place, the net phosphorus load delivered into the EPA is projected to increase (compared to projected 2050 base conditions) as a result of increasing the quantity of water provided by the Recommended Plan to the EPA; however, any increase in the net phosphorus load delivered to the WCAs and ENP would be delivered at a concentration which would not cause the numeric phosphorus criterion to be exceeded.

The Seminole Tribe Big Cypress OPE project would result in construction and operation of approximately 5,270 acres of Wetland Resource Areas WRA), that would be operated much like STAs, treating agricultural stormwater runoff in wetland cells impounded to no deeper then one foot in depth. Additionally, approximately 1,860 acres of Irrigation Storage Areas (maximum depth of 4 feet) would be constructed to attenuate peak flows and be operate in conjunction with the WRAs. These OPE project features would sequester particulate and dissolved nutrients and others pollutants, reducing pollutant loads to the downstream S-140 pump, adjacent to WCA 3A. The Seminole Tribe Big Cypress OPE is consistent with the Non-ECP permit provisions of the EFA.

The Miccosukee Tribe Water Conservation Plan would result in the construction and operation of approximately 900 acres of wetland stormwater treatment areas, treating agricultural stormwater runoff in wetland cells impounded to no deeper then four feet in depth. This OPE project feature would sequester particulate and dissolved nutrients and others pollutants, reducing pollutant loads to the downstream S-140 pump, adjacent to WCA 3A. The Miccosukee Tribe Water Conservation Plan OPE is consistent with the Non-ECP permit provisions of the EFA.

The IDP results in increased average annual flows to the Rotenberger and Holey Land WMAs consistent with preferred regulation schedules for those areas. The average annual volume of water discharged from STA 5 to the Rotenberger WMA is projected to increase from 128.5 k ac. ft. (2050 base condition, 31-year average) to 156.0 k ac. ft. as a result of IDP implementation. Most of this increase in volume comes from STA 5. For the Holey Land WMA, the average annual volume increases from 11.0 k ac. ft. to 42.8 k ac. ft. (SFWMD, 1998).

Prior to implementing the canals and water control structures necessary to implement the proposed regulation schedules (Components DD5 and EE5), water budget data indicate that if will be necessary to construct STA 6 Section 2 or modify STA 5 to assure that water quality criteria (including Florida's antidegradation requirement for OFWs) for the Rotenberger and Holey Land WMAs are achieved. Further evaluation of the IDP water budget and routing mechanisms for those areas will also be necessary to ascertain whether additional design or operational modifications are necessary to meet EFA requirements for discharges into the Rotenberger and Holey Land WMAs created by the IDP.

F.7 LOWER EAST COAST AND BISCAYNE BAY

Water quality conditions in portions of the Lower East Coast (LEC) and Biscayne Bay are currently degraded. FDEP listed approximately 90 water bodies or segments of water bodies within the LEC sub-region as not presently meeting water quality standards (FDEP, 1998:draft). Parameters and pollutants of concern include phosphorus, NOx, dissolved oxygen, mercury, coliform bacteria, volatile organic compounds, heavy metals, pesticides, tri-butyl tin (TBT), and salinity.

There are several components in the Recommended Plan designed to achieve public water supply, salinity control and water quality objectives in the LEC region (Palm Beach, Broward, and Miami-Dade Counties), and to meet environmental targets in Lake Worth Lagoon and Biscayne Bay. The following components are expected to affect hydrologic conditions in the LEC:

Component K6 – Southern L-8 basin improvements to enhance water supply function in Palm Beach County Water Catchment Area;

Component L3 – Relocate coastal wellfield operations to minimize threat of saltwater intrusion;

Component M6 – Site 1 reservoir adjacent to Hillsboro Canal; supplemental storage for LEC water supply;

Component R4 – C-9 Canal impoundment/diversion canal for treatment of water supply deliveries from North Lake Belt Storage Area (Component XX6);

Component S6 – Central Lakebelt storage area; provides regional storage for public and environmental water supply, and salinity control, includes 640-acre STA;

Component T6 – C-4 Canal divide structures for seepage control and coastal wellfield recharge;

Component U6 – Bird Drive basin reservoir; seepage control, flood attenuation, and water supply deliveries to South Dade Conveyance System;

Components X6 & Y6 – Backpumping of urban runoff from C-17 Canal and C-51 Canal watersheds to supplement water storage/supply in West Palm Beach Water Catchment Area;

Component BB5 – Improvements to Dade-Broward Levee to reduce seepage losses, enhancing Miami-Dade County Northwest Wellfield;

Component CC6 – Improve Broward County secondary canal system to enhance wellfield recharge and salinity control functions;

Component LL6 – C-51 Canal aquifer storage and recovery water supply and salinity control;

Component VV6 – Palm Beach County Agricultural Reserve reservoir to increase water supply storage in central and southern Palm Beach County;

Component WW5 – C-111N Spreader Canal, improve flows to Model Lands/southern Biscayne Bay, 3,200-acre STA:

Component XX6 – North Lake Belt storage area to provide public water supply, canal stage (salinity) control, and to achieve salinity targets in Biscayne Bay, STA of undetermined acreage;

Component ZZ5 – Diversion of excess flows out of WCA 3A & 3B to enhance function of Central Lakebelt storage area (Component S6);

Component AAA6 – Increased conservation of regional system water delivered to LEC public water supply/distribution systems;

Component BBB6 – Reuse of treated wastewater to meet salinity targets in Biscayne Bay;

Component FFF5 – Higher stages in C-102 and C-103 Canals for urban and environmental (Biscayne Bay) water supply;

Component GGG6 – C-51 Canal/Southern L-8 basin reservoir to achieve salinity targets in Lake Worth Lagoon, control flooding, and provide additional water supply to Lake Worth Drainage District, 1,100 acre STA;

Component HHH6 – West Miami-Dade County wastewater reuse to enhance ground water recharge and provide additional water supply for salinity control and to meet environmental targets in the ENP;

Acme Basin B OPE - Combination reservoir/STA adjacent to the Loxahatchee National Wildlife Refuge in Palm Beach County to provide water quality treatment and stormwater attenuation;

Biscayne Bay Coastal Wetlands OPE - rehydrate coastal wetlands and reduce point source discharges to southern Biscayne Bay, STA of undetermined acreage.

Construction and operation of these components is expected to result in a net improvement in water quality conditions in the LEC. Water quality improvements are expected simply through the attenuation function (and attendant pollutant load reduction, particularly nutrients and heavy metals) of the storage components for those surface waters presently discharged to coastal canals and estuaries. Storage and attenuation facilities may also improve bacteriological quality through attenuation of surface waters containing coliform bacteria and will improve dissolved oxygen conditions where existing conditions have been adversely affected by increases in BOD loading. Salinity regimes are also expected to be improved consistent with ecological targets.

Additionally, water quality conditions are expected to be improved as a result of the incorporation of treatment features into the design and operation of several components. Where the design and operation of a component could increase pollution loads in ground water or downstream receiving waters through aquifer injection or diversion of surface waters, treatment facilities necessary to meet water quality standards have been included in the design and cost estimates for those components (e.g., chlorination treatment prior to aquifer injection, STAs associated with diverting runoff into reservoirs/storage areas, treatment works at wastewater reuse facilities to produce effluent meeting water quality standards). These facilities, depending upon location and further detailed design (volumes, attenuation times, discharge points), could result in a net reduction of pollutants in receiving water bodies compared to existing and future base conditions.

The beneficial effect of such facilities is not quantifiable at the feasibility investigation stage, for several reasons. First, exact locations of the components and volumes of water added to downstream receiving waters have not been determined. This information will be determined at the detailed design stage of project implementation.

Second, and most importantly, existing and projected pollution loads and TMDLs in receiving waters affected by the operation of the components of the Recommended Plan necessary to achieve ecologically sustainable conditions have not been determined, particularly for nutrients. According to FDEP's draft 1998 303(d) list (FDEP, 1998:draft), 90 of the 169 listed water bodies and/or segments of water bodies designated by FDEP as not meeting water quality standards criteria in the Restudy area are within the LEC (FDEP, 1998). TMDLs have not been established for any of these waterbodies.

While it is expected that components of the Initial Draft Plan would improve water quality for Lake Worth Lagoon and Biscayne Bay compared to existing and projected future conditions additional analysis is needed to fully quantify the water quality objectives for these areas. Construction and operation of those components of the Recommended Plan affecting hydrologic conditions in the LEC are not expected to affect total mercury concentrations and loads, the primary source of which is atmospheric deposition.

F.8 EVERGLADES NATIONAL PARK AND FLORIDA BAY

Water quality conditions in freshwater regions of Everglades National Park (ENP) are not expected to be significantly changed by implementation of the Recommended Plan compared to the 1995 and 2050 base conditions as the water quality meets the default phosphorus criterion now. Water quality conditions in the estuarine portion of ENP and in Florida Bay are expected to be improved by the Recommended Plan relative to the 1995 and 2050 base conditions. The key water quality parameters of concern in the ENP and Florida Bay are TP, mercury and salinity.

Currently ENP freshwater marshes are oligotrophic (low nutrient levels) with TP concentrations in the ENP marsh routinely below 10 ppb TP (McCormick et. al., 1998). A primary evaluation tool used by the Restudy Water Quality Team (WQT) to evaluate the relative water quality effects of the various Restudy alternatives reviewed during the Restudy Plan Formulation and Evaluation Phase (October 1997 - June 1998: also see Section 7) was the Everglades Water Quality Model (EWQM) (SFWMD, 1998). The EWQM simulates phosphorus transport in the EPA (ENP and WCAs) and links to hydrologic output from the South Florida Water Management Model (SFWMM). Relative ranking of the various Restudy Alternatives as well as the 1995 and 2050 base cases are shown in Table F.4. The EWQM evaluation of the Restudy alternatives and the 1995 and 2050 base conditions indicated that Alternatives B and D-13R were the preferred alternatives from a water quality perspective. This conclusion is tied closely to the decompartmentalization aspects of the Recommended Plan and Alternative B, which reduce structural flows into ENP and increase surface water sheetflow of waters entering ENP. The EWQM results suggest and the Restudy WQT concluded that maximizing surface water sheetflow of hydrologic flows entering ENP would reduce the net nutrient load within ENP.

The following Recommended Plan components are of particular interest relative to potential effects they may have on water quality conditions in ENP:

Component Q5 - Western C-11 basin diversion (eliminates discharges of urban runoff to eastern WCA 3A and ENP via S-9 pump station);

Component FF4 - Relocation of a portion of L-31 North canal with new water control structures (S-356 A&B) to increase flows to NE Shark River Slough (ENP);

Component OO4 - Modify operation of S332- A/B/D structures in ENP Taylor Slough area to increase flows delivered to ENP and Florida Bay;

Component RR4 - Relocation and increase in capacity of pump station S-140 to improve hydropatterns and hydroperiods in WCA 3A, ENP and Florida Bay;

Component CCC6 - L-28I Canal modifications and STAs: convert existing canal flow discharge into western WCA 3A to surface water sheetflows through Everglades marsh and add two STAs to clean water prior to sheetflow;

Recommended Plan Components Q5 and CCC6 will have beneficial effects on water quality conditions in ENP. Table F.6 provided water flow information from the SFWMM showing increases and reductions of flows resulting from implementation of the Recommended Plan compared to 2050 base conditions. Component Q5 will relocate the discharge of C-11 west basin stormwater runoff at the S-9 pump structure which discharges to WCA 3A south to the North Lake Belt storage area with eventual routing of these flows to Biscayne Bay. Table F.6 shows that the Recommended Plan will result in 185,800 acre-feet/year (SFWMM 31-year average) less water being discharged from S-9 into WCA 3A than the 2050 base condition. Component Q5 will therefore result in a significant reduction of pollutant loading into WCA 3A and downstream ENP. Component CCC6 will result in a reduction of pollutant loading to the western portion of WCA 3A and the downstream ENP. This is demonstrated in Table F.6 under structure L28WQ, that shows that average flows (SFWMM 31 year average) from the L-28 I canal will be reduced from 89,300 acre-feet/year in the 2050 base condition to zero. Component CCC6 will replace L-28 I canal flow with overland sheetflow, resulting in significant reduction of pollutant loading to the downstream waterbodies (WCA 3A and ENP).

Recommended Plan Components FF4, OO4 and RR4 will result in increased flows entering ENP as a result of Recommended Plan hydrological restoration actions (Table F.6). This table shows that Components FF4, OO4 and RR4 will result in 263,600 acre-feet/year, 106,000 acre- feet/year and 285,000 acre-feet/year (SFWMM 31 year average) greater water discharges into WCA 3A and ENP than the 2050 base condition. Although these increased flows are important to future restoration of the WCAs, ENP and Florida Bay, it is important to note that the implementation of the Recommended Plan will have to ensure that all additional flows greater than 2050 base condition flows will have to be adequately treated in order to meet all State/Tribal water quality standards in the receiving waterbodies. If not adequately treated these additional flows to WCA 3A and ENP could have negative water quality effects. For Recommended Plan components FF4, OO4 and RR4, it is assumed that additional waters delivered to the EPA by these structures will be adequately treated consistent with the water quality requirements of the EFA.

The focus of the Restudy water quality evaluation for Florida Bay relates to restoring ecologically desirable freshwater flows to the Bay, thereby restoring seasonal salinity conditions across the Bay to as close to historic conditions as possible.

The following Recommended Plan components are expected to operate synergistically in a manner which will improve estuarine water quality conditions in the ENP/Florida Bay region:

Component F3 - Modified regulation schedule for Lake Okeechobee to provide increased environmental water delivers to the WCAs, ENP and Florida Bay;

Component G6 - EAA reservoir - 60,000 acres at a maximum of 6 feet depth; regional storage that results in increased environmental water delivers to the WCAs, ENP and Florida Bay;

Component H7 - Everglades rain-driven operations in WCAs 2 and 3 to improve hydropatterns and hydroperiods in the WCAs and ENP;

Component S6 - Central Lake Belt Storage Area, operated to improve hydropatterns and hydroperiods in WCA 3B and ENP;

Component U6 - Bird Drive Basin reservoir; seepage control, flood attenuation, and water supply deliveries to the South Dade Conveyance System;

Component V4 - L 31 North seepage management, reducing seepage to the east from NE Shark River Slough and maintain higher water stages and longer water duration in NE Shark River Slough;

Component AA7 - Additional water control structures between WCA 3A and 3B to increase flows to ENP;

Component FF4 - Relocate a portion of L-31 North canal with new water control structures (S-356 A&B) to increase flows to NE Shark River Slough (ENP);

Component GG4 - Regional-scale Lake Okeechobee ASR (1,000 MGD); improve water flows to WCAs and ENP;

Component OO4 - Modify operation of S332- A/B/D structures in ENP Taylor Slough area to increase flows delivered to ENP and Florida Bay;

Component QQ7 - Partial decompartmentalization of WCA 3A, backfill Miami Canal, reestablish historic hydrologic sheetflows between WCA 3 and ENP;

Component RR4 - Relocation and increase in capacity of pump station S-140 to improve hydropatterns and hydroperiods in WCA 3A, ENP and Florida Bay;

Component WW5 - C-111N Spreader Canal; backfill C-110/lower C-111 canal systems, remove S-197/S-18C structures, extend C111N east to create a water spreader: improved water management for ENP panhandle area and NE FL Bay;

Component YY4 - Diversion of excess WCA 2B water to NE Shark River Slough or Central Lake Belt storage area, enhance hydropatterns/hydroperiods in NE Shark River Slough (ENP) and Florida Bay;

Component EEE5 - Storage of excess flows from WCA 2A/B & WCA 3A in Central Lake Belt storage area, to be returned to WCA 3B, and ENP to acheive preferred hydropatterns and hydroperiods, benefits to downstream FL Bay also;

Component HHH6 - West Miami-Dade Reuse; enhance groundwater recharge in bird Drive basin and provide additional water supplies to the South Dade Conveyance System to enhance seepage control in eastern ENP.

From a cumulative water quality benefits to Florida Bay perspective, several Hydrological Performance Measures (HPM) developed by the Restudy Project, relating to improved freshwater flows to Florida Bay and improved salinity conditions in Florida Bay, demonstrate the positive synergistic effect of the above listed 16 Recommended Plan components. The HPM entitled "Average Annual Flows toward FL Bay across Taylor Slough for the 31 yr. simulation" period indicates that Recommended Plan freshwater flows from Taylor Slough to Florida Bay are closer to the Natural System Model (NSM) target than either the 1995 or 2050 base condition flows. Another relevant HPM in the Florida Bay area entitled "Average Annual Overland Flows toward Whitewater Bay and Florida Bay for the 31 year simulation period" indicates that: 1) Recommended Plan flows from the

Shark River Slough (SRS) are closer to the NSM target than either the 1995 or the 2050 base condition SRS flows (SRS freshwater flows enter the western portion of Florida Bay) and 2) total southward flows to the northeastern portion of Florida Bay from three ENP basins indicate that the Recommended Plan freshwater flows are much closer to the NSM target then the 1995 base condition flows and are generally equal to 2050 base condition freshwater flows.

Relative to HPM that relate to restoration of ecologically beneficial salinity conditions in eastern Florida Bay, which receives flows from the Taylor Slough/River, the HPM entitled "Number of Months high/low Salinity Criteria Exceeded for Little Madeira Bay" is especially important. Little Madeira Bay receives freshwater from Taylor Slough/River in a portion of northeastern Florida Bay where ecologically damaging hypersaline conditions have been documented in the past decade. This HPM clearly indicated that the Recommended Plan salinity characteristics in Little Madeira Bay are much closer to the NSM salinity targets than either the 1995 or 2050 base conditions.

In summary, the above discussed HPM indicate that improved hydroperiods and hydropatterns of Recommended Plan (synergistic effect of above referenced 16 Recommended Plan components) freshwater flows to Florida Bay, relative to both the 1995 and 2050 base conditions, will result in improved water quality conditions in Florida Bay.

F.9 FLORIDA KEYS

Water quality conditions in the Florida Keys are not expected to be significantly affected by the Recommended Plan relative to the 1995 and 2050 base conditions. Major water quality parameters of concern in waters of the Florida Keys are: DO; TP; NOx; turbidity; chlorophyll-a and coliforms. For the purposes of this study, the waters of the Florida Keys are evaluated as those waters within the boundaries of the Florida Keys National Marine Sanctuary (FKNMS). The waters of Florida Bay are contiguous with Florida Keys waters on the northern side of the Keys. Salinity conditions in Florida Keys waters are dominated by marine influences, although in the area of northeast Florida Bay, freshwater runoff from the southern Everglades to the north seasonally influences Florida Keys water quality conditions.

Although Recommended Plan Components OO4 and WW5 will alter freshwater flows to coastal waters near Key Largo, no evidence exists that these Restudy water management effects will significantly modify Florida Keys water quality relative to the 2050 base condition. Component OO4 will increase freshwaters flows to the Taylor Slough/Florida Bay coastal region. Component WW5 will eliminate C-111 canal flows and increase surface water sheet flows from the southern Everglades to coastal portions of northeast Florida Bay and, Blackwater Sound.

Further development of the Florida Bay hydrodynamic and water quality models currently under development should provide more information relative to the potential effects of Restudy components on water quality conditions in the Florida Keys. Also, if a Florida Bay Feasibility Study is initiated, it is likely that future evaluations of potential removal/culverting of portions of Florida Keys highway causeways, currently restricting upper Florida Keys hydrological flushing, would be conducted. Future potential removal/culverting of highway causeways in the upper Florida Keys could have significant beneficial effects on water quality conditions in Florida Keys waters.

F.10 BIG CYPRESS REGION

Water quality conditions in the Big Cypress Region are expected to be improved compared to both the 1995 and 2050 base conditions through implementation of the Recommended Plan. The key water quality parameters of concern in the Big Cypress region are: TP, NOx and DO. The largest beneficial effect of the Recommended Plan on Big Cypress water quality conditions will result from implementation of Recommended Plan component CCC6 (modifications to the L-28 Interceptor Canal). Improvement to Big Cypress water quality conditions is expected to result from implementation of Recommended Plan component QQ7 - partial decompartmentalization of WCA 3A, although to a lesser extent than from CCC6 implementation.

Implementation of Recommended Plan component CCC6 would result in the backfilling of the southern portion of the L-28 Interceptor canal south of existing Structure S-190 (approximately 12 miles) and degrading the existing levee on the southwest side of the L-28 I canal. Current canal water flows in the west feeder and north feeder canals upstream from structure S-190 will be modified to be surface water sheetflows south across the Big Cypress National Preserve (BCNP), downstream from the Seminole Tribe's Big Cypress Reservation, using several pump stations and a spreader canal system. Additionally, S-190 would be converted from a gated structure to a pump station to maintain upstream flood protection. Two new STAs would be constructed adjacent to the west and north feeder canals to treat storm water runoff from upstream basins prior to entering the Seminole Tribe's Big Cypress Reservation. The two STAs, a 1,100-acre STA adjacent to the north feeder canal and a 800-acre STA adjacent to the west feeder canal are sized to reduce TP and other pollutant loads entering the downstream waters of the Seminole Tribe, the BCNP, the Miccosukee Tribe Reservation and ultimately WCA 3A, so as to assure compliance with Tribal and State water quality standards in the receiving waterbodies. Modification of the existing west and north feeder canal flows and L-28 I canal flows to Recommended Plan surface water sheetflows across the BCNP is also anticipated to provide beneficial water quality treatment for the downstream nutrient-sensitive waterbodies.

Recommended Plan component QQ7 would result in the partial decompartmentalization of WCA 3A. Of particular relevance to Big Cypress region water quality conditions is the degradation of the L-28 and L-28 Tieback levees with backfilling of the adjacent borrow canals and removal of the S-343A and S-344 structures in the L-28 levee. Removal of the L-28 and L-28 Tieback levees/canals and S-343A/344 will enable wet season surface water sheetflows in the western region of WCA 3A to flow in a southwesterly direction across the eastern region of BCNP. Therefore, existing pollutant loading being delivered to the southeastern region of BCNP and the westernmost region of ENP through the S-343A/S-344 structures will be spread out across an approximate 15-mile long front in the eastern area of BCNP. Replacing the existing structural point source wet season flows from WCA 3A with broad dispersed surface water sheetflows will result in pollutant uptake and sequestration by the native vegetation in the area and generally improve water quality conditions in the eastern BCNP.

F.11 CALOOSAHATCHEE RIVER REGION

Water quality conditions in the Caloosahatchee River Region are expected to be improved compared to both the 1995 and 2050 base conditions through implementation of the Recommended Plan. The key water quality parameters of concern in the Caloosahatchee River region are: TP, NOx, DO, conductivity, coliforms and pesticides. The following Recommended Plan components are expected to operate synergistically in a manner which will improve freshwater and estuarine water quality conditions in the Caloosahatchee River basin:

Component A6 - North of Lake Okeechobee storage - 20,000 acres at a maximum of 10 feet depth, Kissimmee River watershed; regional storage reduces flood discharges from Lake Okeechobee to the Caloosahatchee River;

Component B2 - C-44 (St. Lucie) Canal reservoir - 10,000 acres at a maximum of 4 feet depth, increases C-44 basin and regional storage capacity and reduces need to release Lake Okeechobee flood discharges to the Caloosahatchee River basin;

Component D5 - Caloosahatchee (C-43) Canal reservoir with aquifer storage and recovery (ASR) wells - 20,000 acres of reservoir at a maximum of 8 feet depth, 44 five MGD ASR wells (220 MGD maximum capacity) increases Caloosahatchee River basin storage and reduces Lake Okeechobee flood releases to the Caloosahatchee estuary;

Component E5 - Environmental water supply deliveries to the Caloosahatchee estuary to achieve optimal salinity;

Component F3 - Modified regulation schedule for Lake Okeechobee to provide increased environmental deliveries to the WCAs/ENP and reduce flood discharges to the Caloosahatchee estuary;

Component G6 - EAA reservoir - 60,000 acres at a maximum of 6 feet depth; regional system storage that reduces Lake Okeechobee flood releases to the Caloosahatchee estuary;

Component GG4 - Regional-scale aquifer storage (ASR) of Lake Okeechobee water - 1000 MGD maximum capacity, reduces Lake Okeechobee flood discharges to the Calooashatchee estuary and improves low flow augmentation from Lake Okeechobee to the Caloosahatchee River/estuary during dry periods;

Component DDD5 - Caloosahatchee River (C-43) backpumping to Lake Okeechobee with STA - increases regional water storage by capturing C-43 excess storm water runoff, and after water quality treatment via a 5,000-acre STA, diverts storm water flows to Lake Okeechobee when Lake Okeechobee is at appropriate water level.

Major benefits of the Recommended Plan components to Caloosahatchee River and estuary water quality conditions result from substantially reducing the levels of non-point source pollutant loading to basin waters during the annual wet season rain events and Lake Okeechobee flood control discharges by capturing these runoff waters in the regional water storage facilities. Of particular importance to water quality improvement in the C-43 basin are the 20,000-acre reservoir in the basin (Component D5) and the 60,000 acre reservoir in the EAA (Component G6). By retaining wet season stormwater runoff in the regional water storage facilities, sedimentation processes will sequester sediment-bound pollutants and biological uptake processes in the water storage facilities will sequester dissolved pollutants. Operation of the water storage facilities will reduce loading of TP, NOx, coliforms and pesticides to C-43 basin waters. Additionally, operation of the ASR facilities in the C-43 basin and around Lake Okeechobee (Components D5 and GG4), implementation of the modified Lake regulation schedule (Component F3) and operation of the C-43 backpump with STA facility (Component DDD5) will reduce wet season peak flows to the Caloosahatchee River and estuary and thereby reduce nonpoint source pollutant loading to the river and estuary.

Conversely, during the dry season when maintenance of adequate low flows to the river and estuary dominants water quality concerns in the region, implementation of the Recommended Plan components that increase flows to the river/estuary are important. The Recommended Plan components that improve dry season river/estuary water quality conditions are: the C-43 and Lake Okeechobee ASR facilities (Components D5 and GG4) and improved environmental flows from Lake Okeechobee (Component E5). These components are expected to specifically improve DO and conductivity conditions in the river/estuary identified as key water quality parameters in the basin.

APPENDIX I
AIR QUALITY

To supplement Section 3.1.3, the existing air quality in the region covered by this C&SF Restudy PEIS is discussed in detail in this Appendix I and its Attachments A-C. Overall, the air quality for the region is considered good, or to be in attainment with all National Ambient Air Quality Standards (NAAQS), as established by the Clean Air Act (CAA). Within south Florida however, a concern exists regarding the deposition of mercury into the Everglades through the atmosphere. This issue, along with the status of attainment of the NAAQS, location of ambient air monitoring stations, identification of emission sources, emission restrictions, and other special concerns are discussed.

I.1 ATTAINMENT STATUS OF CRITERIA POLLUTANTS

This region, along with the entire State of Florida, is currently in attainment for the six criteria pollutants. These six pollutants have limits on the amount that may be present in the atmosphere, as established by the CAA. ***Table I.1-1*** identifies the six criteria pollutants and their associated NAAQS, based upon the mechanism of measurement.

The 8-hour ozone and $PM_{2.5}$ standards were promulgated by the U.S. Environmental Protection Agency (USEPA) in July of 1997. The attainment determinations for these new standards will not be made until the years 2000 and 2003-2004, respectively. A concern exists as to the ability of the PEIS study area, particularly the southeast portion, to maintain NAAQS compliance in the future, considering the expected growth rate. Below is a brief discussion of each criteria pollutant, and concerns related to that pollutant that may affect future activities within the PEIS study area.

I.1.1 Carbon Monoxide (CO)

CO is a colorless, odorless, gas formed when carbon in fuels is not completely burned. Emissions of this pollutant are primarily attributed to motor vehicles, which account for about 60% of the CO nationwide. In urban areas, motor vehicles are responsible for as much as 95% of the CO in the atmosphere. While motor vehicle emissions are a concern in the southeastern region of Florida as the population in this area is expected to continue to grow, sub-tropical climates such as those found in the PEIS study area, generally do not have problems in maintaining the CO NAAQS. Currently, the entire PEIS study area is in attainment for this criteria pollutant.

Table I.1-1. The Six Criteria Pollutants and Their Associated NAAQS.

Criteria Pollutant	Common Abbreviation	Measurement Period	Standard
Carbon Monoxide	CO	8-hour average	9ppm[1] 10 mg/m^3
		1-hour average	35ppm 40 mg/m^3
Lead	Pb	quarterly average	1.5$\mu g/m^3$
Sulfur Dioxide	SO_2	annual arithmetic mean	0.03ppm 80 $\mu g/m^3$
		24-hour average	0.14ppm 365$\mu g/m^3$
		3-hour average	0.50ppm 1300$\mu g/m^3$
Nitrogen Dioxide	NO_2	annual arithmetic mean	0.053ppm 100$\mu g/m^3$
Ozone	O_3	1-hour average[2] 8-hour average	0.12ppm 235$\mu g/m^3$ 0.08ppm 157$\mu g/m^3$
Particulate Matter < 10 microns Particulate Matter <2.5 microns	PM_{10} $PM_{2.5}$	annual average 24-hour average	50$\mu g/m^3$ 150$\mu g/m^3$
		annual arithmetic mean 24-hour average	15 $\mu g/m^3$ 65$\mu g/m^3$

[1] ppm = parts per million

[2] the 1-hour standard for areas demonstrating attainment has been revoked. As such, the PEIS study area is now only subject to the 8-hour ozone standard.

Attainment for this pollutant is defined as no more than one exceedence of the NAAQS in a calendar year. Carbon monoxide data for 1996-97 are presented in Table A-1 (see Attachment A), and demonstrate this region's compliance with the CO Standard.

I.1.2 Lead (Pb)

Since the ban on leaded gasoline, dramatic decreases in atmospheric lead concentrations have occurred, and industrial processes are now responsible for most violations of the Pb standard. The PEIS study area is no exception to this trend. Lead levels in this area are typically attributed to waste incineration. Currently, the study area is in attainment for the lead NAAQS, even though lead emission sources exist within the region. Concentrations of lead in the study area are well below the Pb NAAQS. Pb monitoring data for 1995-97 are presented in Table A-2 (see Attachment A), along with Pb emission values within the region.

I.1.3 Sulfur Dioxide (SO_2)

SO_2 forms when fuels such as coal and oil are burned, and during certain industrial processes such as smelting. Like many of the other criteria pollutants, SO_2 can bring about respiratory illnesses in humans and can also damage foliage on trees and agricultural crops. SO_2 and nitrogen oxides are the major precursors of acid rain. SO_2 emissions in Florida are primarily attributed to electric power generation. While the State is currently in attainment for this pollutant, occasional excursions above the standard have been reported. Air monitoring results from monitors within the study area are presented in Table A-3 (see Attachment A), for the years 1995-97. Title IV of the CAA requires that total annual SO_2 emissions be reduced by 40% from 1980 levels by the year 2010.

I.1.4 Nitrogen Dioxide (NO_2)

NO_2 is one of a category of compounds entitled nitrogen oxides (NO_x). NO_x is formed when fuel is burned at high temperatures. The NAAQS focuses on NO_2, the primary source of which is exhaust from motor vehicles and emissions from stationary sources, such as electrical utilities and industrial boilers. In addition to its effects on the respiratory system, this pollutant is a concern because it reacts in the atmosphere to form nitric acid, a component of acid rain. Nitrogen oxides also play a role in the formation of ozone, particulate matter, and regional haze and can contribute to eutrophication of water bodies through deposition and global warming (when in the form of nitrous oxide). At this time, the entire study area is in attainment for this criteria pollutant. Because NO_x emissions in the region are primarily generated by motor vehicles, the projected growth in Florida could impact the levels of this pollutant in the atmosphere within the PEIS region. Title IV of the CAA requires that by the year 2010, emissions of this pollutant will have been reduced by 10% from 1980 levels. Currently available data on levels of this pollutant throughout the study area for the years 1995-97 are presented in Table A-4 (see Attachment A).

I.1.5 Ozone (O_3)

Ground-level ozone is considered the most pervasive of the six criteria pollutants, and the hardest of the pollutants to control. Unlike the other criteria pollutants, ozone is not directly emitted to the atmosphere. Ozone forms through a series of photochemical reactions between NO_x and Volatile Organic Compounds (VOCs). Some of the more common sources of VOCs and NO_x are gasoline vapor, chemical solvents, and combustion of fuels. Often these precursors of ozone are emitted in one area, but travel to another before the ozone forming reactions take place. Ozone formation is influenced by prevailing meteorological conditions, population growth, and VOC to NO_x ratios in the atmosphere. While ozone in the upper atmosphere is beneficial, at ground level it can damage lung tissue, reduce lung function, and sensitize the lungs to other irritants. Ground level ozone also damages the foliage on trees and interferes with the ability of plants to produce and store food. Although the southeastern Florida and Tampa Bay areas (located just outside the northwestern edge of the PEIS study area) were originally listed as nonattainment areas for the 1-hour ozone NAAQS, they have recently been redesignated as "maintenance" areas, indicating their attainment status. The southeastern region of Florida, originally designated as a "moderate" nonattainment area for this pollutant, includes the counties of Dade, Broward, and Palm Beach. Currently covered by a maintenance plan for ozone, the southeastern region is expected to also meet the 8-hour ozone standard recently promulgated by the USEPA. Ozone monitoring data are presented in Table A-5 (Attachment A).

I.1.6 Particulate Matter (< 10 Microns (PM_{10}) and < 2.5 Microns ($PM_{2.5}$)

Particulate matter (PM) is the general term for solid, liquid or gaseous particles found in the atmosphere. This criteria pollutant is both emitted to (primary PM), and formed in (secondary PM) the atmosphere. Primary PM is typically emitted from industrial facilities, power plants, and open burning, and as fugitive dust from road work, construction projects, phosphate mining, and agricultural activities (e.g., plowing of fields). The recently promulgated $PM_{2.5}$ standard was imposed because smaller particles have been determined to cause adverse health effects, due to their ability to reach the lower regions of the respiratory tract. The ambient monitoring network for $PM_{2.5}$ will not be fully established and operational until 2000. At present, no violation of the PM_{10} standard has been recorded in Florida. Air monitoring results for PM_{10} for 1995-97 are presented in Table A-6 (Attachment A).

I.2 HAZARDOUS AIR POLLUTANTS

In addition to criteria pollutants, the CAA also regulates 188 Hazardous Air Pollutants (HAPs). These pollutants may present significant ecological threats and cancer and non-cancer health risks to urban populations. Many HAPs can be transported through the atmosphere over long distances and are persistent in the environment.

The Urban Air Toxics Monitoring Program (UATMP) was initiated in 1987 and provided an opportunity for State and local air agencies to obtain air toxic monitoring data. Normally, only one monitoring location is located in each city; however, some larger urban areas have two monitors. Under the UATMP, monitoring data were obtained for Fort Lauderdale (1989), Miami (1988, 1989), and Orlando (1990). Data from the UATMP indicate there is an increased probability for persons residing in these areas to contract cancer due to inhalation of the HAPs monitored. The respective increases in probability are 2.7 in 10,000 (primarily due to butadiene), 4.3

in 10,000 (primarily due to chloroform) and 3.3 in 10,000 (primarily due to butadiene), for the carcinogenic HAPs that were monitored. These numbers indicate the number of persons, in excess of what would be expected for that area, that are likely to develop cancer based upon typical exposures in the area. Additionally, all three areas demonstrated increased levels of concern for certain non-carcinogenic HAPs. Xylene was a concern in all three cities. Acrolein concentrations also presented a concern in Miami.

I.3 AMBIENT AIR MONITORING SITES

Ambient air monitoring sites for criteria pollutants throughout the United States are typically located in urban and suburban areas, and to a lesser extent in rural areas. The majority of monitoring sites are operated by state and local government agencies, with a few being operated by federal agencies and tribes. Data from monitoring stations are typically reported by the operating entity through a computer database operated and maintained by the USEPA. While most of the monitoring sites are located in urban and suburban areas, not all monitoring locations are selected based upon the same criteria. For instance, CO monitoring sites are located primarily to measure mobile source emissions, lead monitoring sites are placed to measure point source emissions, and SO_2 monitoring sites are almost always placed in populous locations. Generally, the selective placement, or the strategy behind how the monitoring sites are located, is based upon the premise of measuring ambient concentrations where the suspected sources are expected to have the greatest impact.

Within the counties of the study area, there are 57 criteria air pollutant monitoring sites spanning 10 of the 16 counties within the study area. These monitoring sites measure the concentrations of a variety of the six criteria pollutants in the atmosphere at a given time. Figure I.3-1 depicts the general locations of these 57 monitors. The list of analytes for each monitoring site is included in Attachment B. Of the 57 monitoring sites currently operational, 16 are located in Broward County, the largest number in any single county, and 12 are located in Dade County. Polk, which ties with Dade County for the largest number of criteria pollutant emitting sources, has only four monitoring sites. The 16 counties and the number of monitoring sites in each county are provided in ***Table I.3-1***.

While there have been special UATMP studies to measure ambient levels of hazardous air pollutants, there are no permanent HAP monitors in the PEIS area at this time, nor are any planned.

Table I.3-1. The Number of Air Quality Monitors in the 16 Counties of the Study Area.

County	Number of Monitors
Broward	16
Collier	1
Dade	12
Glades	0
Hendry	0
Highlands	0
Lee	3
Martin	1
Monroe	0
Okeechobee	0
Orange	7
Osceola	1
Palm Beach	10
Polk	4
St Lucie	2
Charlotte	0

I.3.1 Emission Sources

Approximately 73 "large" (see Attachment C) criteria air pollutant or pollutant precursor emission sources are present within the counties of the PEIS study area. Specifically**,** these sources are located within a majority of the 16 counties comprising the study area, and emit between one and four of the criteria pollutants per facility. The distribution of the large air emission sources within the study area is presented in ***Figure I.3.1-1***. As is depicted in this figure, almost one-half (40%) of the large sources are located in just two counties, Dade and Polk. Of the 73 large sources reporting criteria pollutant emissions, a approximately 65% are required to report NO_2 releases, approximately 45% of the reporting facilities emit SO_2, and approximately 35% are required to report VOC emissions.

Hazardous air pollutant sources in the study area are less well identified. Within Dade, Broward, and Palm Beach Counties, sources currently regulated by any of the twenty-two (22) existing Maximum Achievable Control Technology (MACT) standards have been identified. Dade County reports 329 HAP sources, Broward County reports 95 HAP sources and Palm Beach reports 400 HAP sources.

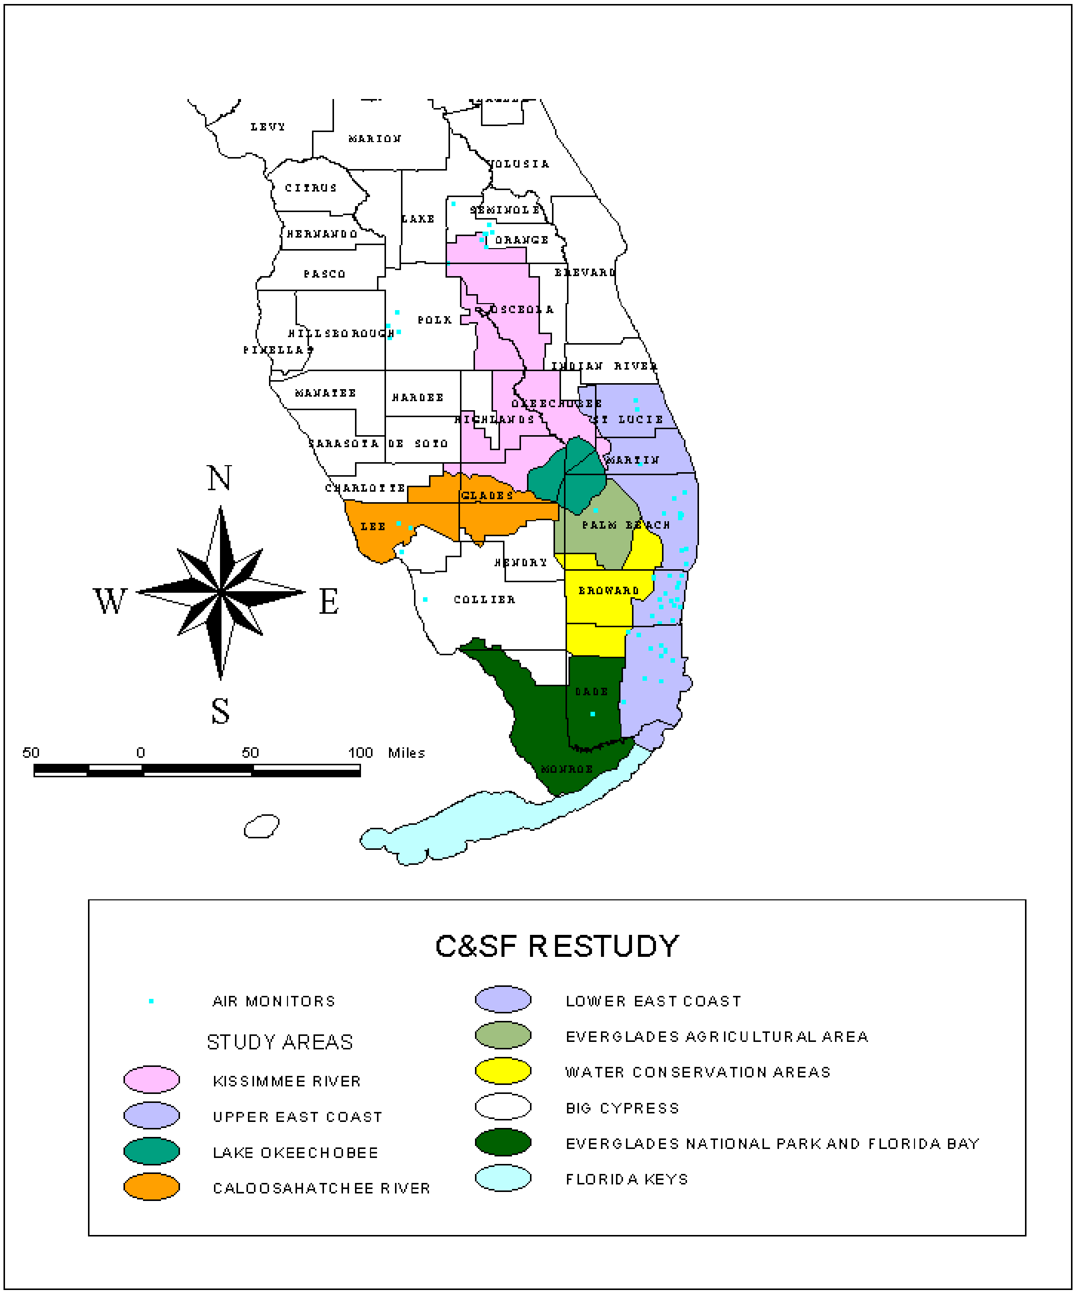

Figure I.3-1. General locations of the 57 criteria air pollutant monitoring sites within 10 of the 16 counties of the study area.

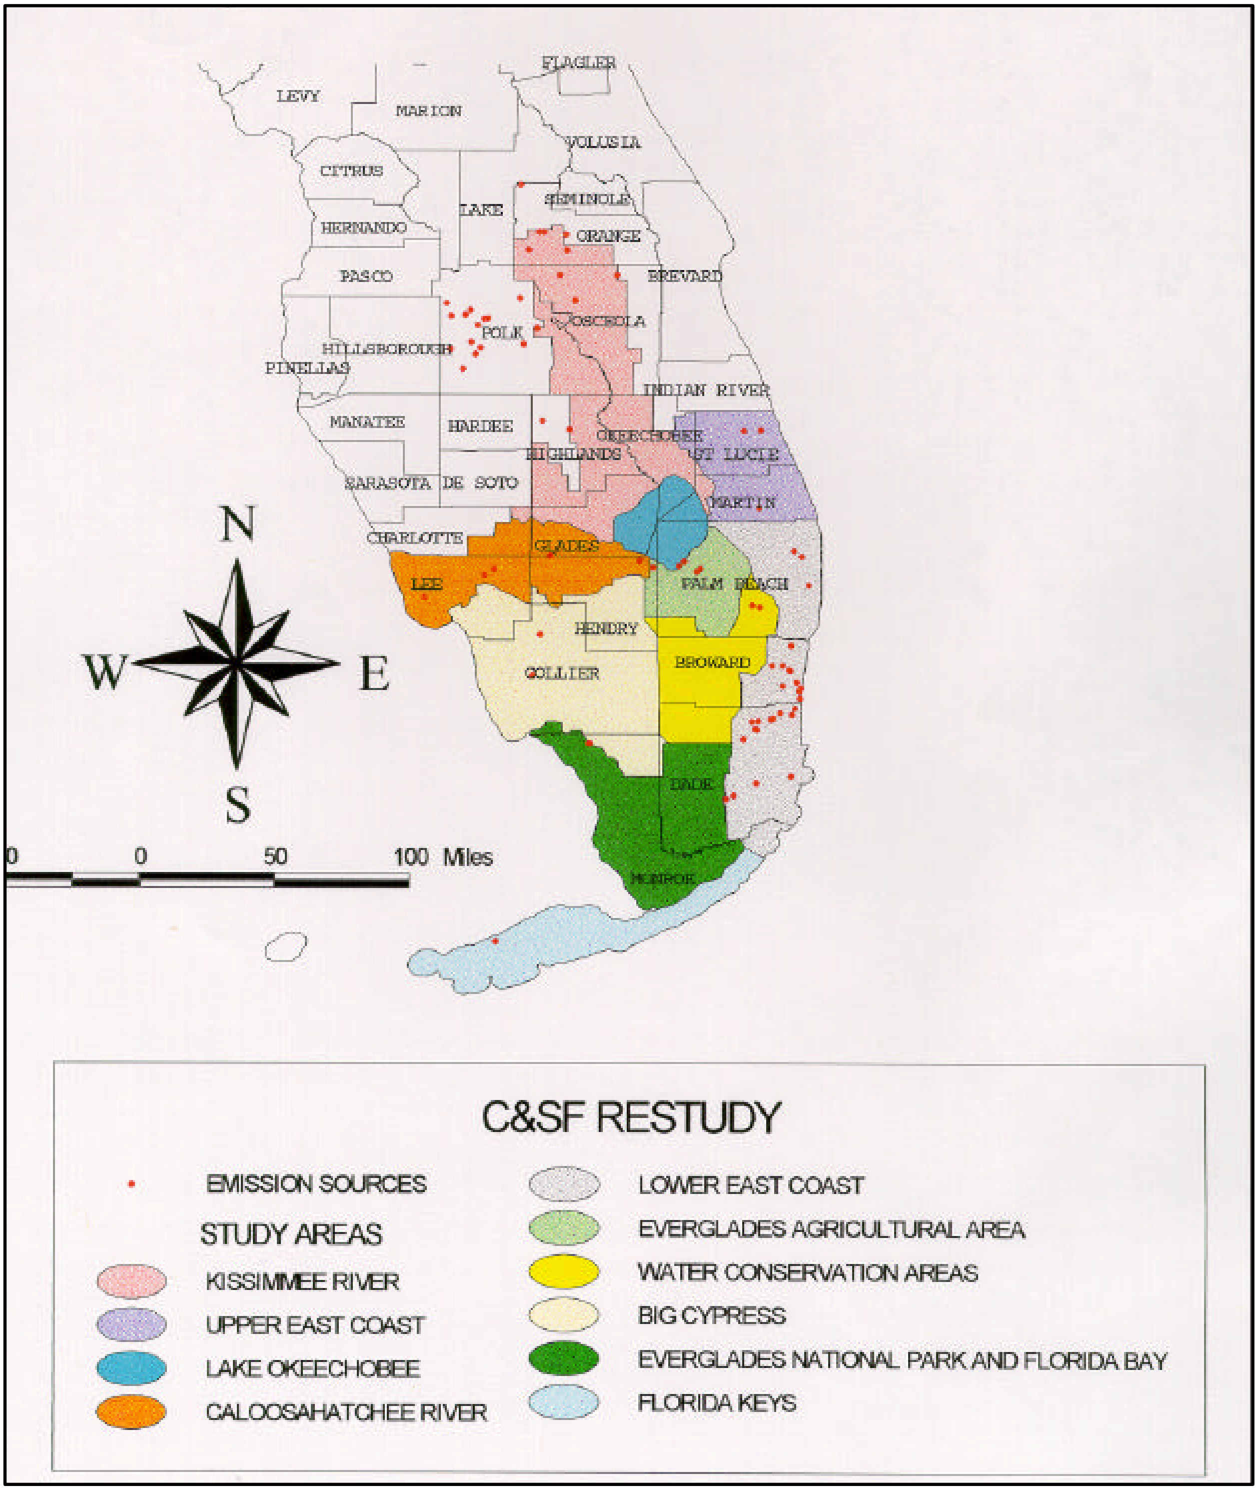

Figure I.3.1-1. The distribution of large air emission sources within the 16 counties of the study area.

I.3.2 Emission Restrictions

Because the southeastern portion of the study area is classified as an "Ozone Maintenance Area" under the CAA, it is required to have a Maintenance Plan to maintain attainment of the 1-hour ozone standard. The maintenance plan is an addendum to the State Implementation Plan (SIP) that requires the affected area to continue implementing the emission reduction measures that brought the area into attainment. This SIP also contains a contingency plan that will require additional emission reduction measures, should emission increases above target levels occur. As mentioned above, the existing Maintenance Plan was developed to comply with the 1-hour ozone standard which has now been revoked for this area, and only the 8-hour standard now applies. As a result, the State of Florida will be allowed to remove any contingency measures from the maintenance plan that are linked to the 1-hour ozone air quality standard; however, contingency measures related to controlling increases in emissions will remain.

Emission restrictions, or limits, exist for specified categories of industrial sources emitting hazardous air pollutants. These limits are outlined within the promulgated MACT standards. The specific HAP emissions controlled by any given MACT are dependent upon the industry subcategory and the HAP(s) that subcategory is expected to emit. MACT standards have been promulgated in three phases, with all but the final phase having been completed.

I.4 SPECIAL CONCERNS

Within the study area, work has been ongoing to address the issue of elevated levels of mercury in the Everglades. Mercury is a concern because it can be transformed in the environment to methylmercury, a persistent, bioaccumulative, toxic compound. Mercury, a HAP, can cause nerve damage in humans and wildlife that consume aquatic organisms, such as plankton and fish. Effects on Everglades wildlife resulting from mercury ingestion may include irregularities in the wading bird population and the death of at least one Florida Panther. The elevated mercury level in the Everglades, and its effects throughout the food chain, has resulted in fish consumption advisories and bans within the PEIS study area

Two of the major studies being conducted to determine the extent and nature of the atmospheric deposition of mercury into the Florida Everglades, the Florida Atmospheric Mercury Study (FAMS) and the South Florida Mercury Monitoring Study (SOFAMMS) have been completed. EPA funded part of each of these studies through grants to the State of Florida. The FAMS monitoring network has been dismantled, with the exception of three sites that are going to be maintained for the National Mercury Deposition Network (MDN), under the National Atmospheric Deposition Program. Although all field work is completed for SOFAMMS, data analysis still needs to be performed for some samples. Preliminary results of the FAMS indicate that the current primary source of mercury to the Everglades system is atmospheric; however, it is not known whether the mercury deposition to the Everglades is from local sources such as incinerators, or if it results from enhanced deposition of the global pool of mercury due to the unique climate of the area. Preliminary results of the SOFAMMS suggest that the form of mercury emitted by several incinerators may have a very short atmospheric half life. Annual average mercury emissions from South Florida are three times higher than the State average. MACT regulations for medical and municipal waste incinerators will reduce mercury emissions; however, it is unknown whether these emission reductions will adequately protect the South Florida ecosystem from the impacts of mercury deposition.

The estimation of mercury evasion from natural and anthropogenic sources, an assessment of trends in sediment mercury accumulation in South Florida, and the development of a method to measure reactive gaseous mercury in source gasses and at ambient levels are all underway by the State of Florida and the USEPA. USEPA Region 4 is currently surveying policies and regulations that are being used nationally and internationally to limit or ban mercury emissions. The Region is also working with the Office of Air and Radiation to insure that the South Florida research is integrated into national efforts on mercury under Section 112 of the CAA. The Office of Research and Development has been approached regarding additional South Florida mercury research needs. These needs include a determination of the acceptable mercury loading to the system, the relative contribution of local versus global sources of atmospheric mercury deposition, models and data required to establish mercury emission limits based on the protection of water quality and additional technologies to reduce mercury emissions. Specifically, future research is needed to identify and characterize emissions from key mercury emitting sources within the study area from Hillsborough, Dade, Broward, and Palm Beach Counties, including inputs from non-traditional sources such as sewage sludge aeration and landfill off-gassing. The vertical profile of mercury and reactive gaseous mercury within the atmosphere and the amount of dry deposition of mercury to the ecosystem must also be determined. Ultimately, modeling will be used to determine the atmospheric background and how mercury gets into the rainfall in South Florida.

Another issue of interest is the atmospheric deposition of NO_x . The deposition of nitrogen compounds through the atmosphere is a growing concern in South Florida. This concern has been drawing increased attention with the plans to lower anthropogenic phosphorous levels in the Everglades. These lower phosphorous levels may result in nitrogen becoming the driving factor in eutrophication.

I.5 REFERENCES

Several publications and internet web sites were consulted in order to develop Appendix I. These references were the Code of Federal Register (40 CFR 53); the State of Florida Administrative Code (F.A.C. 62-296) and statutes (Chapter 403); the website for the Broward County Department of Natural Resources Protection (1998: internet) Air Division; the website for the Florida Department of Environmental Protection (FDEP, 1998: internet) Division of Air Resources; the FDEP 1997 Earth Day Report (FDEP, 1997); and various USEPA publications, websites, and databases (USEPA, 1994a; 1994b; 1998: internet-a; 1998:internet-b; 1998: draft). The latter includes the USEPA AIRS database which incorporates AIRS-AFS (facilities emissions data) and AIRS-AQS (ambient air quality data). It also includes the USEPA web page (internet address: http://www.epa.gov/oar/aqtrnd96/) and the USEPA website known as "AIRSWeb" (USEPA, 1998: internet-a; internet address: http://www.epa.gov/airsweb) which provides portions of the AIRS database (see Attachment C).

CRITERIA USED IN SELECTING EMISSION SOURCES AND MONITORING DATA USED IN APPENDIX I

ATTACHMENT C
CRITERIA USED IN SELECTING EMISSION SOURCES AND MONITORING DATA USED IN APPENDIX I

The USEPA's web site AIRSWeb (http://www.epa.gov/airsweb) was used in gathering the data used in this report. Monitor Reports were used to gather information on all currently active ambient air criteria pollutant monitoring sites within the study area. The tables in Attachments A and B were developed using these reports. Source Reports were used to find information on the facilities within the study area. Source Reports include facilities that emit criteria pollutants in amounts sufficient to be designated "large" sources. Criteria pollutants are those for which the USEPA has set health-based standards. Based on AIRSWeb, ***Table C-1*** below lists criteria pollutants and the threshold amounts for designation as large sources (excerpted):

TABLE C-1. Criteria Pollutant Emission Thresholds (Tons/Year)

CO	Carbon Monoxide gas	1000
NO_2	Nitrogen Dioxide gas	100
SO_2	Sulfur Dioxide gas	100
VOC	Volatile Organic Compounds *	100
PT	Particulate Matter (total)	100
PM_{10}	Particulate Matter (<10 µm)	100
Pb	Lead particles	5

** VOCs are not criteria pollutants, but they are precursors of criteria pollutant ozone (smog).*

Disclaimer (excerpted from AIRSWeb):

AIRSWeb reports are produced from a monthly extract of the USEPA's air pollution database, AIRS. The Source Report data for this report were extracted on July 31, 1998. They represent the best information available to the USEPA from state agencies on that date. However, some values may be absent due to incomplete reporting, and some values subsequently may be changed due to quality assurance activities. The AIRS database is updated daily by state and local organizations who own and submit the data. Please contact the pertinent state agency to report errors.

Readers are cautioned not to infer a qualitative ranking order of geographic areas based on AIRSWeb reports. Air pollution levels measured in the vicinity of a particular monitoring site may not be *representative of the prevailing air quality of a county or urban area. Pollutants emitted from a particular source may have little impact on the immediate geographic area, and the amount of pollutants emitted does not indicate whether the source is complying with applicable regulations.*

ENVIRONMENTAL EFFECTS

ATTACHMENT D

ENVIRONMENTAL EFFECTS

EXECUTIVE SUMMARY

Air Quality: In general, the Recommended Plan (Alt. D13R) and the other action alternatives (Alt. A, B, C) are not expected to significantly impact the air quality of the South Florida project area of the C&SF Restudy. While some short-term impacts are predicted, the overall long-term direct air quality impacts due to the project would either be negligible (no effects) in southern regions or be slightly positive (beneficial effects) in northern regions. No regions are expected to experience negative long-term air quality impacts due directly to the project.

Air Quality

This section discusses the air quality impacts of the four alternatives considered in the C&SF Restudy PEIS. These four alternatives consist of three action alternatives, Alternatives A, B, and C, and the Initial Draft Plan (IDP), Alternative D13R. The IDP (= PEIS Preferred Alternative or Preferred Plan) will eventually evolve into the Recommended Plan through further study design. In addition to air quality impacts, mitigative measures that can be used to lessen impacts will be identified and explored where short-term impacts have the potential to be detectable. Overall, it is expected that none of the proposed alternatives will have a long-term detrimental impact on air quality in the study region. In fact, some activities may have a slight, net positive impact on air quality. These positive impacts would mostly be associated with changes in land use. Negative impacts resulting from the implementation of the IDP or any of the other alternatives will be of limited duration, and solely related to dredging, excavation, and/or construction activities.

Table D-1 provides a summary of the activities expected to have an impact on air quality. The regions identified within the “Locations” column correspond to the regions identified within the Component Summaries on the South Florida Water Management District’s [SFWMD] Central and Southern Florida Restudy Web Page. This web page is located at the following address: http://www.sfwmd.gov/org/pld/restudy (SFWMD, 1998: internet).

Impacts on Attainment Status of Criteria Pollutants

It is not expected that implementation of the IDP or any of the action alternatives will negatively impact the long-term attainment status of the PEIS study area. Some short-term impacts are expected, however. Of the pollutants for which National Ambient Air Quality Standards (NAAQS) exist, the standard for particulate matter less than ten microns in diameter (PM_{10}) is the most likely to be measurably impacted on a short-term basis. Particulate matter levels in the Lake Okeechobee, Everglades Agricultural Area, Water Conservation Areas/Everglades National Park, and the Water Preserve Areas are likely to increase over the short-term as a result of any of the four alternatives being selected. This short-term increase will be associated with earth-moving activities required to accomplish the proposed construction activities. Alternatives C and D13R will result in a short-term increase in particulate matter in the Lower East Coast region. No measurable negative impact on the NAAQS attainment status or existing air quality is expected as a result of these activities.

Slight long-term improvements in air quality are likely. These improvements will occur due to changes in land use from agricultural to uses such as water storage and impoundments. This change in land use may result in slight improvements in carbon monoxide, nitrogen dioxide, ozone, particulate matter, and hazardous air pollutant levels. Table D-2 below provides a summary of impacts over the long and short term for each pollutant evaluated for the C&SF Restudy**.**

Table D-1. Comparison of Action Alternative

LOCATION	ALTERNATIVE A	ALTERNATIVE B	ALTERNATIVE C	ALTERNATIVE D13R
Lake Okeechobee	- construct storage reservoirs N, E, and W of the Lake	No Change From A	No Change From A	No Change From A
Everglades Agricultural Area	- construct storage reservoirs	No Change From A	in addition to A: - operate second reservoir as "dry storage" and subdivide it into 2 - 20,000 acre compartments	No Change From C
Water Conservation Areas / Everglades National Park	- relocate S-345 structures	-relocate and increase capacities of S-356 pumps -decompartmentalize the WCA-3 - eliminate additional S-345 structures in L-67A - relocate S-140 pump station -relocate L-31N levee	in addition to A & B: - dredge L-29 south of WCA-3B - maintain L-28 & L-29 levees - replace S-345 structures	in addition to A, B, & C: - remove L-28 tie back levee - increase S-140 pump station capacity - remove S-344, S-343 A & B, and S-12 structures -backfill L-67A canal south of S-345 structures - backfill Miami canal
Other Natural Areas	NO ACTIVITY	NO ACTIVITY	-modify west feeder canal structure S-190 of the L-28 interceptor canal	No Change From C
Water Preserve Areas	- construct water preserve areas for site 1, C-9, and C-11 STAs/impoundments, Central Lake Belt im-ground storage area, and Bird Drive recharge area	- add water preserve areas for North Lake Belt Storage area and Palm beach County Agricultural Reserve Reservoir	in addition to A & B: - modify North Lake Belt storage area - modify Palm Beach County Agricultural Reserve reservoir	in addition to A, B, & C: - increase size of Site 1 impoundment -increase storage in southern L-8 basin by 1,200 acres
Lower East Coast	- construction of canal improvements to Broward County secondary canals - construct pump facilities	NO ACTIVITY	- extend C-111N spreader canal east of Card Sound Road	in addition to C: - construct storage reservoir as part of L-8 project - increase pump capacities of Broward secondary canals - improve Dade/Broward levee - add 2 control structures to C-4 canal

Table D-2. Anticipated Direct Short- and Long-Term Impacts on Levels of Each Criteria Air Pollutant.

POLLUTANT		**CO**	**Pb**	**SO_2**	**NO_2**	**O_3**	**PM_{10}**	**$PM_{2.5}$**	**HAP**	**Overall**
IMPACTS	Short-term	0	-	0	0	0	-	0	0	slight -
	Long-term	+	0	0	+	+	+	+	+	+

NOTE: "+" indicates a positive impact (i.e. lower levels), "0" indicates no impact and "-" indicates a negative impact (i.e. increasing levels) on emissions of that pollutant or its precursors.

Carbon Monoxide (CO)

Evaluation of the IDP and the other action alternatives reveals that there may be only a negligible impact on CO emissions within the study area. CO emissions are typically associated with motor vehicle use, and the proposed alternatives primarily alter water flow and storage within the Everglades. Any short-term impacts will be associated with the operation of heavy equipment used to excavate and create reservoirs, impoundments, water preserve areas, etc. These impacts will not only be short term, but will also be intermittent in nature and likely offset by the cessation in use of agricultural equipment. Thus, CO levels in the study area will not be measurably impacted by any of the proposed alternatives in the short term. Over the long term, a slight positive impact on air quality may be attained. This positive impact can be attributed to the removal of land from agricultural use, resulting in a decrease in emissions from farm equipment.

Lead (Pb)

Existing lead emission levels and atmospheric concentrations will not likely be significantly affected by the IDP or the other action alternatives on a long-term basis. Recent lead emissions in the study area are associated with waste incineration. However, there is the possibility that historic lead deposits attributable to atmospheric deposition could be re-suspended by excavation and earthmoving activity. This lead would have been atmospherically deposited as a result of leaded gasoline usage prior to the 1980's. Because activities being undertaken as part of the C&SF Restudy are construction/excavation related activities, and do not involve burning or incineration, it is likely there will only be a negligible short-term negative impact on air quality in the study region. Regardless of this short-term impact, there is a high probability there will be no detectable long-term impact on lead levels in the atmosphere.

Sulfur Dioxide (SO_2)

None of the four proposed alternatives will affect existing sulfur dioxide emission levels. Within the study area, emissions of sulfur dioxides are normally associated with the burning of coal and oil by electric utilities. Because none of the four alternatives are likely to cause an appreciable increase in electric power consumption in the region, no impacts on existing SO_2 levels in the atmosphere are expected.

Nitrogen Dioxide (NO_2)

Emissions of nitrogen dioxide within the study area are typically associated with exhaust emissions from motor vehicles and emissions from stationary sources such as industrial boilers and electric utilities. All four of the proposed alternatives involve some construction activity. Normally, construction activities involve the use of heavy equipment which emit similar pollutants to motor vehicles. Considering the planned construction activities of all four alternatives, it can be deduced that some NO_2 emissions will occur as a result of implementing any of the proposed alternatives. However, such emissions will be negligible when considered in conjunction with emission levels expected from routine motor vehicle and stationary source operation within the region. In fact, no net change in NO_2 emissions will likely occur over the region as a whole due to a deceased level of agricultural equipment use in some portions of the study area. Thus, implementation of any of the proposed alternatives will not appreciably affect short term attainment of the air quality standard for NO_2 within the region, and may even reduce NO_2 levels slightly in the long term.

Ozone (O_3)

Although the study area is currently designated as a “maintenance” area for this air quality standard, it is not expected that implementation of any of the four proposed alternatives will have a significant impact on ozone levels in the short term. Ozone levels in the atmosphere are influenced by the levels of volatile organic compounds (VOCs) and nitrogen oxides (NO_x), as well as by meteorological conditions. Negligible amounts of additional NO_x emissions are expected to be generated over the short-term, regardless of which alternative is implemented, due to emissions from construction equipment, as mentioned previously (Section 8.1.3.1.4: *Nitrogen Dioxide*). Nevertheless, these will be offset by a reduction in use of agricultural equipment within the region. Therefore, it is unlikely there will be any increase in ozone levels within the study area as a result of the IDP or any of the other action alternatives being implemented. Over the long term, a slight positive impact on air quality may be attained. This positive impact can be attributed to the removal of land from agricultural use, resulting in a decrease in ozone precursor emissions from farm equipment.

Particulate Matter Less Than 10 Microns in Diameter (PM_{10})

As stated earlier in the Existing Conditions Section (3.1.3: *Air Quality*), particulate matter is the general term for solid, liquid, or gaseous particles found in the atmosphere. PM_{10} refers to coarse particles associated with open burning and fugative dust emissions from road work, construction projects, mining, and plowing of agricultural fields. As noted earlier in this section, all four alternatives proposed involve either construction activities, excavation, or earth moving. Additionally, it is conceivable that some open burning of vegetated land may be performed as part of the clearing process to prepare for construction, excavation, or earth moving activities. Although a significant increase in coarse particulate matter is expected during implementation of the IDP or any of the other action alternatives, it is unlikely that the air quality standard for particulate matter will be exceeded.

On a long-term basis, the Everglades Agricultural Area (EAA) dry storage reservoir planned under Alternatives C and D13R, will increase particulate matter levels in the air if dust suppression techniques are not employed while the area is dry. However, the removal of lands from agricultural use through the construction of storage reservoirs will provide a net positive impact on particulate matter levels. This positive impact will be achieved through the reduction of particulate matter associated with plowing and sugar cane harvesting. If either action Alternative A or B is implemented, a net overall improvement in particulate matter levels will be realized.

Some mitigative measures that can be undertaken to reduce particulate emissions include wetting down of un-vegetated areas with water for dust control, and completely covering excavated materials with tarps or other impervious materials. These actions will prevent particulates from becoming airborne prior to the materials being spread or transported off site. By timing activities according to favorable meteorological conditions, emissions of coarse particulate from open burning can also be minimized. These activities will keep the suspension of particulate matter to a minimum during associated Restudy operations.

Considering the goal of the C&SF Restudy is to hydrologically restore South Florida and increase the acreage of wetted areas (e.g., additional surface water storage reservoirs and increased hydroperiods for existing wetlands), the chance of natural (lightning) peat and other fires in South Florida may decrease. As such, the Restudy could reduce the amount of PM_{10} emissions associated with natural open burning as well.

Particulate Matter Less Than 2.5 Microns in Diameter ($PM_{2.5}$)

Particulate matter less than 2.5 microns in diameter, also called fine particulates, is associated with emissions from industrial facilities, power plants, and combustion processes. As noted earlier, all four proposed alternatives will result in short-term emissions from construction equipment involved in excavation and earth moving. Any increase in $PM_{2.5}$ emissions associated with the IDP or the other action alternatives may be offset in the short-term by an associated reduction in agricultural equipment emissions and associated agricultural activities. The long-term reduction in agricultural activity associated emissions will lead to a net decrease in $PM_{2.5}$ levels.

Hazardous Air Pollutants

Hazardous Air Pollutants (HAPs) are typically released by identifiable air pollution sources, such as chemical plants, industrial operations, dry cleaners, printing plants, and motor vehicles. The Clean Air Act lists 188 HAPs for regulation based upon their potential for adverse health and/or environmental impact. Regulation of these 188 HAPs occurs through Maximum Achievable Control Technology (MACT) regulations directed at controlling HAP emission sources. The activities proposed under the IDP and the other action alternatives involve redirecting water flow and construction of levees, pump stations, and water impoundment areas. Because the associated activities do not involve any of the regulated industries under the MACT standards, no additional industrial-related emissions of hazardous air pollutants are expected regardless of which alternative is implemented. However, it must be noted that HAP emissions are also attributed to emissions from motor vehicles such as cars, buses, and trucks. Consequently, it is expected that some additional emissions of HAPS, such as formaldehyde and benzene, will be generated on a short-term basis as a result of construction equipment operation. Nevertheless, these emissions will be negligible when compared to routine emissions from automobiles and other mobile sources in the study area. Therefore, no significant short-term or long-term increases in HAP emissions are expected. In fact, a slight long-term decrease in HAP emissions associated with reduced agricultural activities may occur as a result of implementing any of the proposed alternatives.

Emission Sources and Restrictions

No permanent new emission sources will be created as a result of implementation of the IDP or any of the other action alternatives. Although a short-term increase in mobile source emissions may occur through the introduction of construction vehicles, it is expected that on a net basis, no increase will be realized. The no net increase in mobile source assumption is based upon the presumption that local contractors will be used to perform construction related activities, thus simply repositioning the sources from one location within the project area to another. In the long term, no change in the number or type of regulated emission sources is expected as a result of this project.

No new emission restrictions beyond those identified within the Ozone Maintenance Plan for this area. However, should any criteria pollutant standard be violated, provisions exists within the Clean Air Act and the Florida State Implementation Plan (SIP) to impose additional restrictions.

Special Concerns

Special concerns previously mentioned in the Existing Conditions Section (3.1.3: *Air Quality)* relate to mercury. Regarding mercury emissions, although no new emission sources will be created, nor will the emissions of existing sources be affected, activities are planned within areas of the Everglades where mercury in fish, soil and sediments is a concern. Mitigative measures to prevent volatilization of mercury from dredged/excavated sediments and soils should be implemented in these areas. Areas with a potential for the presence of mercury in dredged sediment or excavated soil are Water Conservation Areas 1, 2 and 3, and the Everglades National Park.

Indirect Air Quality Impacts

In addition to the discussed direct air quality impacts of the Restudy, consideration should also be given to indirect impacts. From an indirect impact perspective, the levels of several air quality pollutants associated with development (e.g., ozone) may increase over the project horizon (2050). Given that the Restudy proposes new water supplies and water reuse projects for public drinking water consumption, the potential for continued development and population growth in South Florida is enhanced beyond what is currently projected. If so, additional infrastructure development attendant with increasing populations (e.g., power plants with associated emissions) can also be expected. Although continued development in South Florida is projected even without implementation of the Restudy, the construction of water supplies at relatively inexpensive consumer cost and the increased availability of power, increases this likelihood of development and the associated air quality emissions as well as other sources of pollution, beyond what is currently projected for the region. Therefore, based upon the preceding scenario, air pollution in the study area could measurably increase over what is currently projected for this region. This increase could ultimately be offset by further promulgation of MACT and implementation of projected Clean Air Act air pollution controls, such as the Residual Risk provisions of Section 112(k).

Summary

Table D-3 provides a summary of expected direct air quality impacts by the action alternatives, including the IDP. Impacts are presented for several geographic areas within the study region. The “Locations” within the table correlate with the components identified in the Component Summaries found on the South Florida Water Management District Central and Southern Florida Restudy Web page (SFWMD, 1998: internet).

Table D-3. Summary of Direct Air Quality Environmental Effects.

Location	Alternative A		Alternative B		Alternative C		Alternative D13R	
	short-term	long-term	short-term	long-term	short-term	long-term	Short-Term	long-term
Lake Okeechobee	-	+	-	+	-	+	-	+
Everglades Agricultural Area	-	+	-	+	-	+	-	+
Water Conservation Areas/ Everglades National Park	-	0	-	0	-	0	-	0
Other Natural Area	0	0	0	0	-	0	-	0
Water Preserve Areas	-	0	-	0	-	0	-	0
Lower East Coast	-	0	0	0	-	0	-	0

NOTE: "+" means beneficial effects, "0" means no effects, and "-" indicates negative effects. Further explanation of each alternatives affect on air quality is provided within this section.

APPENDIX J

EXISTING CONDITIONS

The area covered by this study involves a significant portion of the State of Florida. This appendix describes the existing physical, ecological, and socio-economic conditions within this large study area. The study area has been arranged, purely for organization purposes for the NEPA document, into ten physiographic regions as depicted in ***Figure J.1-1***. Within ***Appendices J and K***, a regional overview of the study area is discussed first, followed by each of the ten physiographic regions, individually and in greater detail. The physiographic regions are: Kissimmee River, Lake Okeechobee, Upper East Coast (Martin and St. Lucie Counties), Caloosahatchee River, Everglades Agriculture Area, Lower East Coast (Palm Beach, Broward, and Miami-Dade Counties, including Biscayne Bay), Water Conservation Area (including the WCAs and Holey Land and Rotenberger Wildlife Management Areas), Everglades National Park (including Florida Bay, Whitewater Bay, and the Ten Thousand Islands), Big Cypress (the entire Big Cypress Basin, including the southwest coast from Estero Bay to Everglades City, and the Big Cypress National Preserve), and the Florida Keys.

J.1 REGIONAL OVERVIEW

The following section provides a comprehensive regional overview of the existing physical, ecological, and socio-economic conditions within the study area described above.

J.1.1 Geology and Soils

The following section is a discussion of the geology and soils of central and south Florida, resources that determine, in conjunction with rainfall, evapotranspiration and other factors, the hydrologic framework and ultimately the ecological framework for this study. This section does not strictly adhere to the regional organization described above due to geologic formations which extend beyond hydrologic and other boundaries used to define the physiographic regions.

J.1.1.1 Geology of Project Area

Geologic units exposed at land surface in southern Florida have been mapped by Puri and Vernon (1964) and Brooks (1981), and have been presented in detailed county maps by the Florida Geological Survey. The surficial geology is extremely important to environmental issues such as land use, waste disposal, surface- and

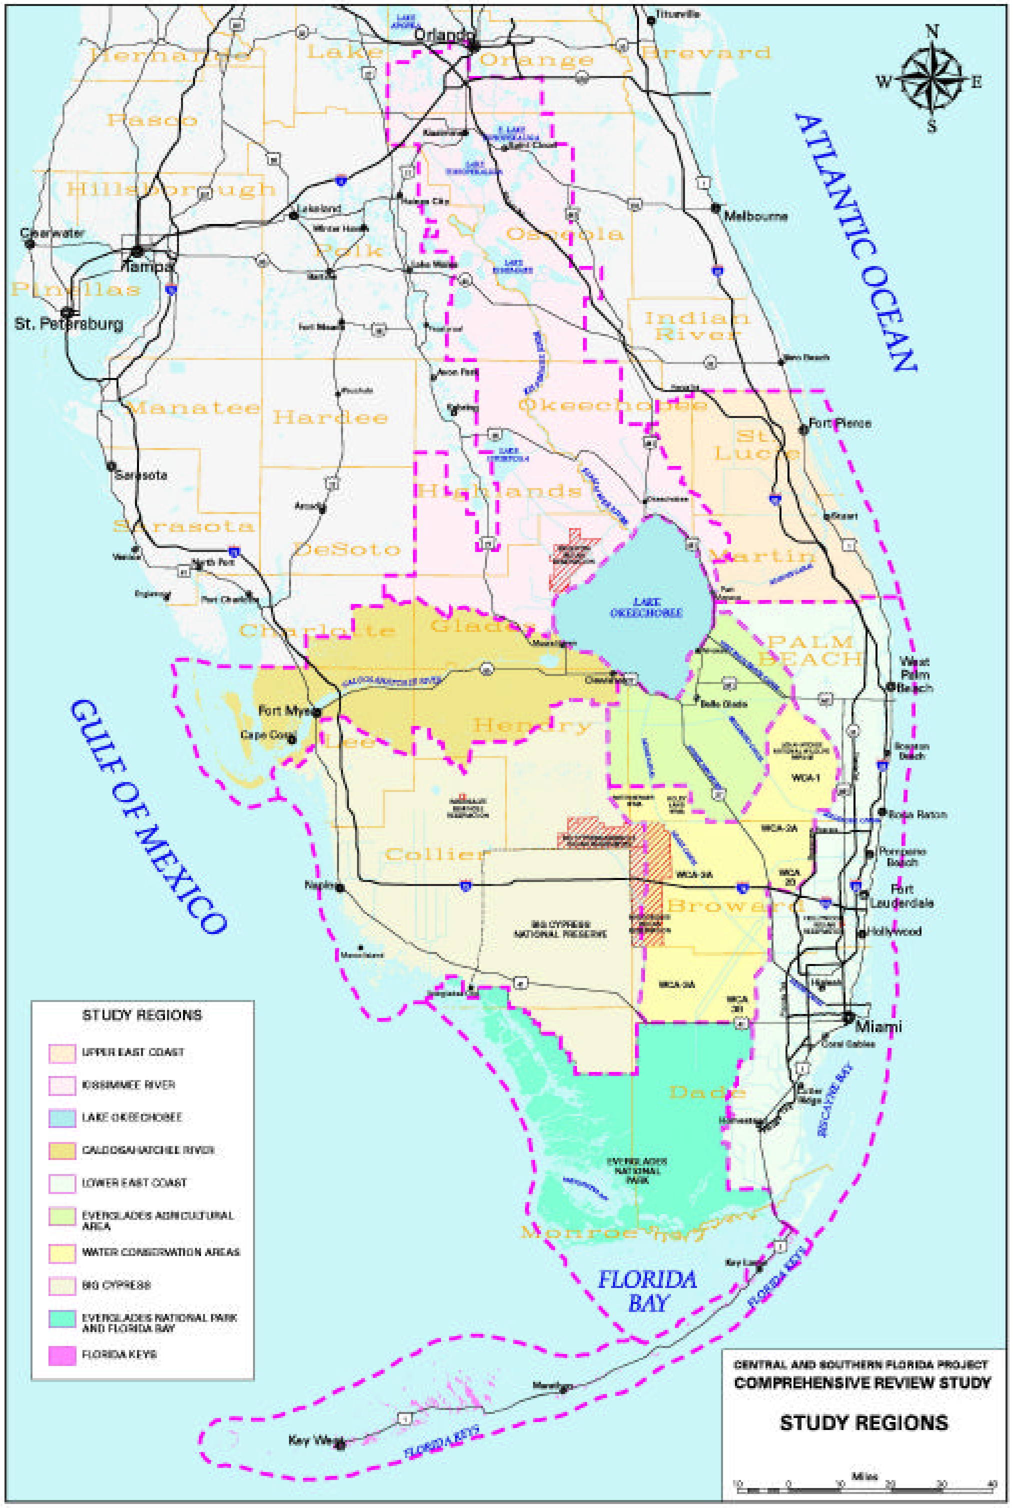

Figure J.1-1 Study Regions

groundwater quality, drainage, ground water recharge, physiographic characteristics, and ecological zonation.

The surficial geology described by Puri and Vernon (1964) generally corresponds to the distinct regions that have been identified for discussion within the draft PEIS. The lithology of geologic units that are at or near land surface plays a major role in determining the physiography by controlling drainage, elevation, soil development, recharge and runoff, and the dominant ecological environment.

The Kissimmee River region is underlain by marine and estuarine terrace deposits of Pleistocene to Holocene age, including fine- to medium-grained Pamlico sands. The Kissimmee River basin is poorly drained due to the low permeability of these siliciclastic sediments. To the south these insoluble sediments thin and become more carbonate. The higher elevations at the southern end of the Lake Wales Ridge and the Eastern and Southwestern Flatwoods provinces are underlain by the Hawthorn Group and a thin fine-grained sand veneer. The Caloosahatchee Formation, a highly variable lithologic unit, underlies the northern perimeter of Lake Okeechobee and extends to the southwest, north, and east of the Big Cypress Swamp basin.

Upper East Coast and Caloosahatchee River regions - Drainage within the Upper East Coast and the Caloosahatchee River basin formed on top of the Anastasia Formation, a variably shelly, sandy limestone. In the southwestern region, the higher elevation associated with the Immokalee Rise is an accumulation of sands overlying the Caloosahatchee Formation.

Lake Okeechobee, Everglades Agriculture Area, the Water Conservation Area regions - These areas developed primarily on top of the Fort Thompson Formation (Pleistocene age), a formation comprised of interbedded sand, shell and limestone and to the south, the Tamiami Formation of Pliocene age. The quartz sand content within the Fort Thompson Formation and the Miami Limestone decreases southward and the ridges change from quartz dominated coastal ridges to wider oolite shoals.

Lower East Coast - Thin sand and the Miami Limestone underlie most of the Lower East Coast and form the highest elevations in the area corresponding to the Atlantic Coastal Ridge. These units are highly permeable and higher elevations are well drained. The oolitic facies of the Miami Limestone is breached by numerous shallow sloughs, further enhancing drainage. Coastal marshes form at lower elevations and within the breaches created by the sloughs. The higher elevations of the Lower East Coast and Atlantic Coastal Ridge are due to the cemented deposits of the Anastasia Formation to the north and the Miami Limestone to the south.

Florida Keys - The shape, size, and hydrologic characteristics of these islands are based on geologic differences (White, 1970). The Upper Florida Keys are narrow islands oriented northeast/southwest and are made up of exposed Pleistocene age coral reefs known as the Key Largo Limestone (Perkins, 1977). The Key Largo Limestone is highly permeable and has non-uniform porosity development due to the highly variable texture of the reef deposits. The Lower Florida Keys are underlain by the Miami Oolite which was originally formed as oolitic shoals like those to the north in the southern part of the Atlantic Coastal Ridge. The permeability of the Miami Limestone (oolite facies) is an order of magnitude less than that of the Key Largo Limestone. These islands are generally larger than those in the Upper Keys and are oriented in a northwest/southeast direction. The areal expanse of these islands and the homogenous texture and lower permeability of the limestones cause freshwater lenses (up to 20 feet thick) and ponds to accumulate more readily (Vacher and others, 1992).

The Big Cypress region - This area developed on top of the sandy, marly, fossiliferous limestone and sand of the Tamiami Formation of Pliocene age.

Lower West Coast, Ten Thousand Islands, Whitewater Bay - The variation observed in these 3 regions is related to the change from a sand covered limestone to an exposed limestone surface. In the Lower West Coast, from the Caloosahatchee River basin to Naples, there is significant sand cover that has been modified by coastal processes, with oyster bars scattered throughout. Ten Thousand Islands is a transitional region where some sand is available to create barrier islands, but is underlain primarily by the Tamiami Formation. Because of the low relief, numerous marshy backbays or lagoons, such as Whitewater Bay, occupy exposed limestone surfaces behind the slightly higher sand buildup of Cape Sable. Drainage east of Whitewater Bay, along the sloughs of the Everglades, is primarily across exposed Tamiami Formation and the bryozoan facies of the Miami Limestone between Cape Sable and the Lower East Coast (Hoffmeister and others, 1967).

Florida Bay - Florida Bay consists of open water and isolated islands. It is underlain by the burrowed bryozoan facies of the Miami Limestone. Sediment cover is highly variable consisting of open sand, exposed bedrock, and mudbanks (Prager, 1997).

J.1.1.2 Hydrostratigraphy

Much of the work in identifying, mapping and describing the geologic units within southern Florida has been done in an effort to understand the hydrologic resources of the area. The relation between the carbonate units and the interfingering siliciclastic sediments (quartz rich sand) controls numerous environmental aspects of the south Florida ecosystem mainly due to the profound influence these units have on the movement of water. Along with stratigraphic names, these units also are delineated as hydrologic units based on their hydraulic properties.

In general, the southern part of the Florida carbonate contains three major aquifer systems: the surficial aquifer system, the intermediate aquifer system/ intermediate confining unit, and the Floridan aquifer system (Klein, et al. 1975; Causarus, 1985; Fernald and Patton, 1986; Southeastern Geological Society, 1986; Miller, 1986; Causarus, 1987; Johnston and Miller, 1988; Fish and Stewart, 1991; McPherson and Halley, 1997; Miller 1997).

J.1.1.3 Surficial Aquifer System

In southern Florida, because the Floridan and intermediate aquifer systems are saline or have low yield, practically all municipal and irrigation water is obtained from the surficial aquifer system. The surficial aquifer system comprises all the rocks and sediments from land surface to the top of the intermediate confining unit. The discontinuous and locally productive nature of the shallow water bearing units reflect the complex interfingering of lithologic units throughout southern Florida (Causarus, 1985, 1987; Fish and Stewart, 1991; Weedman and others, 1997). Surficial aquifers of southern Florida include: the Biscayne aquifer, the undifferentiated surficial aquifer, the coastal aquifer of Palm Beach and Martin Counties and the shallow aquifer of southwest Florida. As more mapping and hydrologic investigations are completed, it is likely that additional surficial aquifers will be delineated within this system.

The Biscayne aquifer is a highly productive unconfined aquifer that underlies parts of Miami-Dade, Broward, and southern Palm Beach Counties. It is wedge shaped, highly permeable, and is more than 200 feet thick in the Atlantic Coastal Ridge and thins to a feather edge about 35 to 40 miles west in the Everglades.

Several unconfined surficial aquifers have been identified within the surficial deposits of quartz sand, shelly beds of the Anastasia Formation, shelly limestone of the Tamiami Formation, and limestone units of the upper Hawthorn Group. Although these local, discontinuous, unconfined, shallow aquifers are not as productive as the Biscayne aquifer, they are an important source of water for Martin, Palm Beach, Hendry, Lee, Collier, St. Lucie, Glades and Charlotte Counties (Hyde, 1975).

The coastal aquifer of Palm Beach and Martin Counties occurs within the Anastasia Formation, which is composed of discontinuous permeable limestone interbedded with thick sand sections. This aquifer is about 250 feet thick near the coast and thins inland, becoming more mineralized. Maximum yield has been determined to be 1,000 gallons per minute.

The shallow aquifer of southwest Florida provides an important source of potable water to the municipal communities of southwestern Florida. This aquifer is wedge shaped; ranging from 130 feet thick near Naples to between 60 and 80 feet in the central part of Collier County, thinning to a feather edge near the east edge of the county. The permeability decreases to the west and the aquifer is thickest and most productive in the solution-riddled limestone of the Tamiami Formation in central and west-central Collier County. Maximum yield is 2,500 gallons per minute.

In the Florida Keys, the lack of freshwater resources requires that potable water supplies are piped in from wellfields near Homestead. The Miami Limestone (oolite and Key Largo facies) is highly permeable. In some areas, particularly in the larger islands of the lower oolite Keys, freshwater or brackish water lenses may occur. Although ground waters generally have salinities equal to or greater than sea water, sewage effluent and waste disposal within these units may contribute to a decrease in salinity and an influx of nutrients (Shinn and et al. 1994).

J.1.1.4 The Intermediate Aquifer System / Intermediate Confining Unit

The intermediate aquifer system consists of beds of sand, sandy limestone, limestone, and dolostone of Oligocene to Pliocene age that dip and thicken to the south and southwest. It includes the Tampa Member, the undifferentiated Arcadia Formation, and the Peace River Formation, all of the Hawthorn Group, and the Tamiami Formation. In southwestern Florida (Lee and Collier Counties), the intermediate aquifer system is under confined conditions and is used as a source of potable water. The transmissivity values reported for the aquifer system are 10,000 ft^2/d or less and yields are highly variable (Miller, 1997). To the south and east the clay content increases and the aquifer system becomes predominantly a low permeability clay forming the intermediate confining unit (SEGS, 1986). In much of southern Florida, the intermediate confining unit effectively separates the surficial aquifer system from the Floridan aquifer system. Although the extent of the intermediate aquifer system is limited to southwestern Florida, local water-yielding zones in the Hawthorn Group exist along the east coast of Florida, but are not considered part of the intermediate aquifer system (Miller, 1997).

J.1.1.5 The Floridan Aquifer System

The Floridan aquifer system is a thick sequence of carbonate units, including the Avon Park Formation of Eocene age, the Ocala Limestone of Eocene age, the Suwannee Limestone of Oligocene age, and the Arcadia Formation of the Hawthorn Group of Oligocene to Miocene age (Miller, 1986, 1997). Less permeable carbonate units, referred to as the middle confining unit, separate the system into two major aquifers called the Upper and Lower Floridan aquifers. North of Lake Okeechobee, the Floridan aquifer system yields freshwater although it is more mineralized (total dissolved solids are greater than 1,000 mg/L) along coastal areas and in southern

Florida (Sprinkle 1989). In southern Florida, more than 600 feet of low permeability siliciclastic sediments confine this aquifer and create artesian conditions. Although the head gradient is upward, the low permeability units prevent significant upward migration of saline waters into the shallower aquifers. Depth to the Floridan aquifer is approximately 400 feet near Naples and 900 feet in coastal Miami-Dade County (Klein and others, 1975). The transmissivity is generally less that 250,000 ft^2/d, generally decreasing to the south due to the presence of low permeability limestones. In the Upper East Coast, the Upper Floridan aquifer is used for drinking water supply. In the Lower East Coast, from Jupiter to south Miami, the Upper Floridan aquifer is being considered for storage of potable water within an aquifer storage and retrieval program. In the Lower Floridan aquifer, there are zones of cavernous limestones and dolostones with transmissivities in excess of 3,000,000 ft^2/d. However, because these zones produce saline water, they are not used for drinking water supply. Because of their depth and salinity, these deeper zones of the Lower Floridan aquifer are used primarily for injection of treated effluent wastewater.

J.1.1.6 Soils

Soils of the south Florida ecosystem range from excessively drained on the ridges to very poorly drained in wet depressions. Many of the soils of the Everglades are underlain by limestone. Most soil differences are related to organic matter, geologic substrate and hydrology. Soil classification is controlled by three major factors: 1) the sand and clay content of the substrate which influence the chemical and hydrologic properties of the soil; 2) the depth from the soil surface to the water table which controls the wetness of the soil; and 3) the available water capacity, or the amount of water retained by a soil after a thorough wetting and subsequent drainage, which is highly important in sustaining plant life.

Soils are highly variable across the landscape and often are mapped at varying scales based on the need for detailed information. Detailed soil mapping for each county of Florida has been done by the Soil Conservation Service (now called the National Resources Conservation Service) of the U.S. Department of Agriculture, and is available for detailed site investigations. There are approximately 31 general soil associations in the south Florida ecosystem generally corresponding to major physiographic regions (Caldwell and Johnson, 1982; Brown, Stone and Carlisle, 1990). Soil associations consist of soil series and soil map units. Identifying and describing soil associations, series and map units is beyond the scope of this report. The general soil map prepared by Caldwell and Johnson (1982) was used to describe the general soil orders found in the south Florida ecosystem.

Soil orders are related to the physiographic provinces and substrate origin. Four major soil orders found within the south Florida ecosystem are: Histosols, Spodosols, Entisols, and Alfisols. In areas where rock outcrops occur, weathering of the limestone forms caliche or calcrete. Caliche is not a soil but can influence physiography, drainage and vegetation.

Histosols are soils that are dominantly organic, consisting of peat and muck deposits of varying thickness over sand, marl, or limestone. These soils usually are found in swamps, mangroves, and fresh and saltwater marsh environments. They are less frequently found in rockland areas.

Spodosols are soils characterized by a spodic horizon, a zone where organic matter combined with aluminum and/or iron has accumulated due to downward leaching. These soils usually are associated with flatwoods and dry prairies, sandhill and sand pine scrub, mixed hardwood forests, swamps, marshes, and infrequently in salt marsh and mangrove ecosystems.

Entisols are soils that have a minor or undeveloped soil profile. Entisols are found in nearly all of the physiographic provinces in the south Florida ecosystem.

Alfisols are soils that have light colored surface horizons, low organic matter content and loamy subsoil horizons with moderate to high base saturation. They occur throughout the physiographic provinces in the south Florida ecosystem.

Caliche is not a soil, but a weathering surface formed by the intensive dissolution of original limestone and rapid reprecipitation of calcite. The reprecipitation of calcite results in significantly reduced porosity and creates a relatively impervious, hard surface or calcrete on exposed limestone rocks or beneath thin organic soils. The hard, protective surfaces, also known as cap rock, are often red-brown in appearance and range from less than an inch to more than a foot in thickness. Where successive caliche weathering surfaces occur in limestone deposits, their impervious nature can create vertical divisions of porous zones (Hoffmeister and others, 1967; Moore, 1989).

The general characteristics of soils within the south Florida ecosystem are discussed below:

The Kissimmee River region is underlain by poorly drained sandy and sandy-over-loamy soils or muck (spodosols, alfisols, and some histosols). To the west in the Lake Wales Ridge soils are excessively drained thick sands (entisols).

The Upper East Coast is characterized by sandy and sandy-over-loamy soils with moderate natural drainage (spodosols and alfisols). In coastal areas, soils are predominantly sandy although some organic soils may be scattered throughout (entisols, histosols, and some alfisols).

Lake Okeechobee is underlain by peat and muck (histosols of organic origin and entisols) although much of the peat has been altered to muck by oxidation processes. In surrounding drainage areas, soils range from fine sand and loamy material having poor natural drainage (predominantly alfisols and entisols with some histosols) to sandy and sandy-over-loamy soils with moderate natural drainage (spodosols and alfisols).

The Everglades Agriculture Area is primarily underlain by peat and muck (histosols of organic origin and entisols) although much of the peat has been altered to muck by oxidation processes.

The Water Conservation Areas are primarily underlain by peat and muck (histosols of organic origin and entisols) although much of the peat has been altered to muck by oxidation processes. Other soils in these areas include fine sand and loamy material that have poor natural drainage (predominantly alfisols and entisols with histosols).

The Lower East Coast has several predominant soil characteristics, including sandy and sandy-over-loamy soils with moderate natural drainage (spodosols and alfisols). To the west of the Atlantic Coastal Ridge, soils contain fine sand and loamy material and have poor natural drainage (predominantly alfisols and entisols with some histosols). In coastal areas the soils are predominantly sandy although some organic soils are scattered throughout (entisols, histosols, and some alfisols). There are also areas where rock outcrops sometimes referred to as 'rockland' or a weathered rock surface (caliche and entisols of recent limestone origin) occurs. Rock outcrops are characterized by karst features such as solution pits, caves and sinkholes. Commonly the rock surface is extremely rugged and pitted. Pits in the rock surface range from several inches to several feet in diameter and depth. Where soils occur on these rock surfaces, they are primarily entisols, but may also include alfisols and histosols.

The Everglades National Park is underlain by peat and muck (histosols of organic origin and entisols) although much of the peat has been altered to muck by oxidation processes. There are also areas where rock outcrops or a weathered rock surface (caliche and entisols of recent limestone origin) occurs. Rock outcrops are characterized by karst features such as solution pits, caves and sinkholes. Commonly the rock surface is extremely rugged and pitted. Pits in the rock surface range from several inches to several feet in diameter and depth. Where soil development has occurred on these surfaces, soils are primarily entisols but may also include alfisols and histosols.

Florida Bay, Whitewater Bay, and the Ten Thousand Islands are underlain by exposed rock surfaces and modern sediment. On islands and in coastal areas, soils are predominantly sandy although some organic soils are scattered throughout (entisols, histosols, and some alfisols). Exposed rock surfaces also occur and are characterized by karst features such as solution pits, caves and sinkholes. Commonly the rock surface is extremely rugged and pitted. Pits in the rock surface range from several inches to several feet in diameter and depth. Where soil development has occurred, soils are primarily entisols but may also include alfisols and histosols.

The Florida Keys are underlain primarily by exposed rock outcrops with caliche crusts. Rock outcrops are characterized by karst features such as solution pits, caves and sinkholes. Commonly the rock surface is extremely rugged and pitted. Pits in the rock surface range from several inches to several feet in diameter and depth. Where soil development has occurred in the rock surface, soils are primarily entisols but may also include alfisols and histosols.

Big Cypress Swamp basin is underlain by soils containing fine sand and loamy material that have poor natural drainage and scattered areas of rock outcrop. Rock outcrops are characterized by karst features such as solution pits, caves and sinkholes.

Caloosahatchee River basin and Lower West Coast soils are characterized by sandy and sandy-over-loamy soils with moderate natural drainage (spodosols and alfisols). In coastal areas, the soils are predominantly sandy although some organic soils are scattered throughout (entisols, histosols, and some alfisols).

J.1.2 Climate

The south Florida ecosystem has a generally subtropical climate, characterized by long, hot, humid and wet summers followed by mild, dry winters. The wet season extends from May to October, while the dry season occurs from November to April (Thomas, 1974). The wet season is characterized by high humidity, intense solar radiation, and unstable atmospheric conditions that result in frequent local thunderstorms, often accompanied by intense rainfall of short duration. Severe tropical storms can also occur during the wet season. Large amounts of rain can fall over localized areas in a short period of time and can result in extended periods of flooding.

The fall-winter dry season is characterized by mild, dry weather. Frontal storms dominate the weather during the dry season often bringing cool, sometimes freezing temperatures, and rainfall of moderate amount and low intensity. Severe weather can accompany some fronts, bringing thunderstorms, tornadoes, and large amounts of rainfall. Thunderstorms that are not associated with fronts are possible in the dry season, but are relatively infrequent compared to the wet season.

Mean annual temperature for the south Florida ecosystem ranges from 72°F (22°C) in the northern Everglades to 76°F (24°C) in the south (Thomas, 1974). Mean monthly air temperatures range from a low of 63°F (17°C) in January to a high of 85°F (29°C) (Thomas, 1974). Infrequently, freezing temperatures and frost occur when arctic air masses follow winter cold fronts into the area.

J.1.2.1 Rainfall

On the average, south Florida receives about 53 inches (135 cm) of rain annually, 75 percent of which falls in the wet season (Shih, 1983). During the dry season, precipitation is governed by large-scale (synoptic) winter weather fronts which pass through the region roughly every seven days (Bradley, 1972). Rainfall from these fronts exhibits a more uniform distribution across the south Florida ecosystem as compared to rainfall derived from the highly variable convection-type thundershowers that occur during the wet season.

Rainfall distributions over the south Florida ecosystem follows a bimodal pattern with one peak occurring in May or June and the other in September or October (Thomas, 1974). Annual rainfall for the entire period of record throughout the south Florida ecosystem has ranged from a low of 37 inches (94 cm) in 1961 to a high of 106 inches (269 cm) in 1947. Typically annual values vary from 40 to 65 inches (102 to 165 cm) with a mean annual rainfall over the Everglades of 51 inches (130 cm) (MacVicar and Lin, 1984). Within the Everglades the greatest average annual rainfalls occurs in the Everglades Agriculture Area and in Everglades National Park. The lowest average annual rainfall occurs in WCA-3A (MacVicar, 1983; Sculley, 1986).

During the wet season, convective showers (thunderstorms) occur almost daily, and their distribution across the study area is largely dependent on sea breeze circulation. Short-duration, high intensity thundershowers are related to cyclic land-breeze convection patterns resulting in midday to late afternoon shower activity. Convective storms exhibit larger differences in precipitation from station to station as compared to winter frontal (synoptic) storms (Bradley, 1972; Woodley *et al*, 1974). Woodley (1970) estimates that, due to natural variability, rainfall generated from a single cumulonimbus cloud in south Florida can range from 200 to 2,000 acre-ft (244,000 to 2,440,000 m^3).

J.1.2.2 Wind

Wind direction and patterns are determined by the easterly tradewinds and land-sea convection patterns during the wet season and by synoptic weather fronts during the dry season (Schomer and Drew, 1982). Southern Florida shows a dominant easterly influence, which varies from east southeast in the spring-summer to due east in the fall (Schomer and Drew, 1982). During the winter dry season, cold fronts pass over the basin approximately once a week (Schomer and Drew, 1982). Prevailing wind patterns are affected during the summer wet season by convective heating and during the dry season by regional scale weather systems (Schomer and Drew, 1982).

J.1.2.3 Tropical Cyclones

Strong winds associated with hurricanes and other storm events are an important physical process shaping the Everglades and Florida Bay (Craighead and Gilbert, 1962). The natural communities of the south Florida ecosystem are, to a large extent, hurricane adapted and respond quickly with few long-term effects (Deuver et al., 1994). High winds and associated wave action can redistribute such physical features as barrier islands, inlets, channels and sand shoals, and change established plant and animal communities. South Florida has been struck by more hurricanes and tropical storms than any other equally sized area in the United States (Gentry, 1974). This area was close enough to the paths of 138 tropical storms between the period 1871-1981 to have been potentially affected by them (Duever et al., 1994). The south Florida ecosystemis exposed to Atlantic, Gulf, and Caribbean generated hurricanes. Hurricanes strike most frequently during August, September and October with a return frequency of about every three years (Gentry, 1984). Destruction occurs from storm surges, wind, tornadoes, and rainfall (flooding). The hurricanes of 1926, 1928, 1935, 1947, 1960, 1962, and 1965 caused loss of life and/or major damage to the region that led to additional water management and drainage efforts in the Everglades.

J.1.2.4 Evapotranspiration

Evapotranspiration is the combined process of evaporation from land and water surfaces and transpiration from plants. It is the method by which the bulk of the rainfall in the area is returned to the atmosphere and plays a major role in the climate of the south Florida ecosystem. This process is estimated to remove between 70-90 percent of the rainfall in undisturbed south Florida wetlands (Duever et al., 1994). Evaporation from open water surfaces peaks annually in the late spring when temperatures and wind speeds are high and relative humidities are low. Evaporation is lowest during the winter when the temperatures and wind speeds are low (Duever et al., 1994). The depth to the water table and type of vegetative cover are also important in determining the amount of evapotranspiration losses. Where the water table is close to the land surface, evaporation from the soil is increased by capillary rise of moisture, and is about the same as evaporation from an open body of water. Lake evaporation in south Florida ranges from about 50 to 54 inches per year (in/yr).

Jackson and Maurrasse (1976) made water budget studies of selected quarry lakes. In one lake in northern Miami-Dade County, 49 feet deep, with a surface area of 6,741,000 square feet, they determined a storage volume of approximately 2.5

billion gallons of water, compared with about 0.5 billion gallons in the original rocks. This represented a gain in storage of about 2.0 billion gallons for the lake. For an assumed annual lake evaporation of 51 inches, total evaporation losses were only about 210 million gallons. The authors also indicated that over the long term, average rainfall should largely compensate for lake evaporation losses. Even for short term annual rainfall deficits (periods of drought) of 5 to 6 inches, the gain in net storage would still be approximately 1.8 billion gallons or more than 5 times the original storage in the rock.

The 1994 landcover map (***Figure J-1.1.2.5-1***) of the Lakebelt area shows that this portion of the Lower East Coast study area consists of large patches of the invasive non-native melaleuca (*Melaleuca quinquenervia*) and limestone quarry lakes. Unfortunately, there is presently very little information available regarding the evapotranspiration rates of melaleuca. The recent report on evapotranspiration rates of melaleuca (Chin,1996) was used to select appropriate parameters for modeling melaleuca evapotranspiration in both the regional model and the MODFLOW model. The method includes two factors for determining melaleuca losses in the lakebelt region. First, Chin (1996) calculated the actual evapotranspiration rates for melaleuca utilizing the Penman-Monteith method. In addition to the Penman-Monteith evapotranspiration rates calculated for melaleuca, Chin (1996) suggests that a second component be added which accounts for evaporative losses due to interception of rainfall within the melaleuca canopy. It is assumed that these interception losses are removed from the system during heavy rainfall events and not available as recharge to the aquifer or for utilization by the vegetation. In order to determine the interception losses, Chin (1996) utilized Woodall’s (1984) empirical equation for estimating interception losses. The result is that Chin (1996) determined that the maximum evapotranspiration rate for melaleuca is approximately 51 in/yr plus an interception loss of approximately 12 in/yr resulting in a total loss of 63 in/yr.

J.1.3 Air Quality

The existing air quality within the region is currently considered good and the region is in attainment for all National Ambient Air Quality Standards (NAAQS). In 1995, southeastern Florida was redesignated to "attainment" for the one-hour ozone standard and is now a “maintenance” area for ozone. Ozone is the primary regulated pollutant of concern in this region. Another air quality concern within the region is the atmospheric deposition of mercury, although no NAAQS for this pollutant currently exists. For additional specific and detailed information on air quality within the project area, refer to ***Appendix I.***

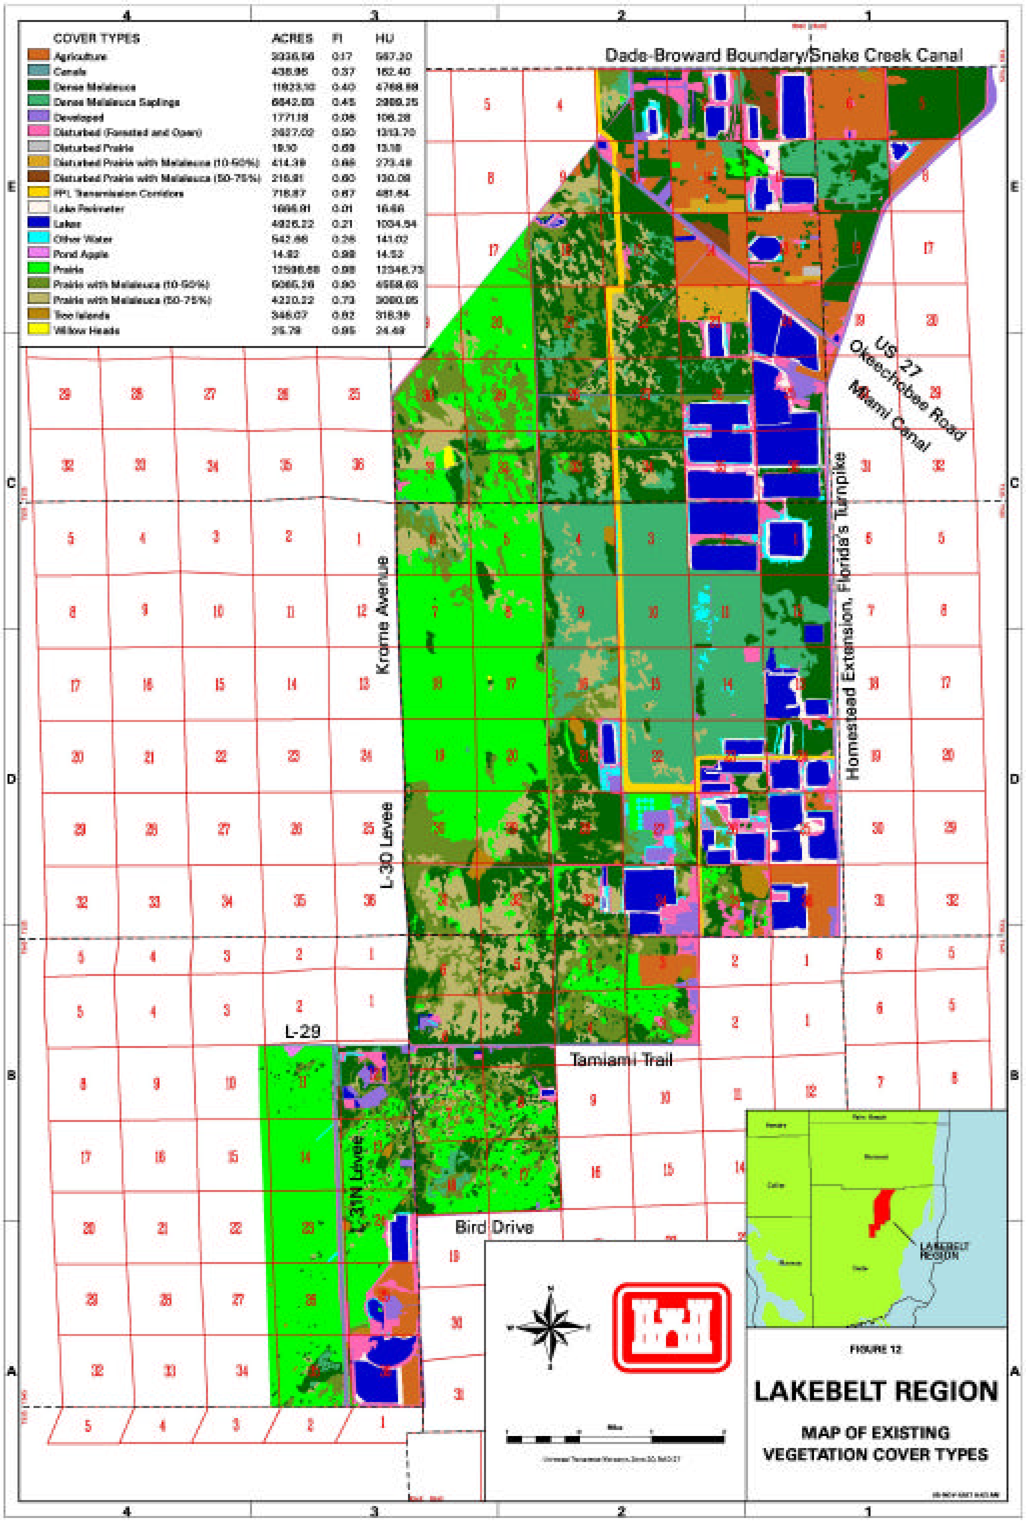

Figure J-1.1.2.5-1 Lakebelt Vegetation Map

J.1.4 Noise

Within the natural areas of the proposed project, including the Everglades Protection Area, Everglades National Park, Big Cypress National Preserve, Florida Bay, Lake Okeechobee and other peripheral natural areas, the wilderness character of the area is such that external sources of noise are limited and of low occurrence. Existing sources of noise are limited to vehicles that travel on transportation arteries that are often miles distant, and airplanes. Other sources of noise, more voluminous, but less frequent, and which may occur within these natural areas, are that of air boats, off road vehicles, swamp buggies, motor boats, and airplanes.

Rural, undeveloped sites have typical noise levels in the range of 35-55 dB. Levels along transportation arteries are typically about 70 decibels (dB). Additional sources of noise, in rural, agricultural areas such as within the Kissimmee region, the Everglades Agricultural Area, Caloosahatchee and St. Lucie basins, and in south Miami-Dade County, include noise associated with agricultural production, processing and transportation of agricultural produce. Specifically, the use of farm equipment, transport trucks, heavy equipment, tractors, plows, irrigation equipment, agricultural processing facilities, railroad and other transportation facilities, would be expected to provide dominant background noise to the otherwise relative quiet natural soundscape.

Within the rural municipalities, and urban areas along the Upper and Lower East Coast, as well as the West Coast, sound levels would be expected to be of greater intensity, frequency, and duration. Noise associated with transportation arteries, such as highways, railroads, primary and secondary roads, airports etc., inherent in areas of higher population would be significant and probably override those sounds associated with natural emissions. Other sources of noise might be expected to include noise from everyday social and human communication and activity, operation of construction and landscaping equipment, and operations at commercial and industrial facilities. In general, urban emissions would not be expected to exceed about 60 dB, but may attain 90 dB or greater in busier urban areas or near to frequently used, high volume transportation arteries.

J.1.5 Vegetation

The C&SF region consists of a complex system of hydrologically interrelated landscapes. Because the Everglades is located on a peninsula that extends from a temperate to a subtropical climate, the associated flora consists of tropical, temperate, and endemic species (Gunderson 1994). Descriptions of historical communities for the south Florida ecosystem are provided by Davis (1943). Gunderson (1994) grouped Everglades communities into upland and wetland vegetative components based on hydro-edaphic conditions, water chemistry, and vegetative growth form. Everglades uplands are composed of rockland communities, which include rockland pine forests and tropical hardwood hammocks.

Everglades freshwater wetland communities are categorized as forested wetlands, marshes, prairies, and ponds and sloughs. The periphyton community, composed of many taxa of microalgae, occurs in many of the freshwater communities in the Everglades, and is an important element of the base of the food chain.

J.1.5.1 Uplands/Pine Rocklands

South Florida upland forest types can be classed as either pine forests or hardwood hammocks. They occur on the Atlantic Coastal Ridge, which extends south a distance of 65 miles from north Miami, along the east coast, and then turns inland in a long curve, terminating at the end of Long Pine Key in Everglades National Park. This outcropping was formed from mid-pleistocene marine limestone (Snyder et al. 1990) and decreases in elevation from north to south, starting at 20 feet near Miami, decreasing to 5 feet at the entrance to Everglades National Park, and terminating at 1.5 feet on Long Pine Key (Craighead 1974; Gunderson 1994). The distribution of pine forests and hardwood hammocks on the ridge is largely affected by fire frequency and substrate (Gunderson 1994). The soils of pine forests and hammocks are very different from soils found elsewhere in Florida. They are largely organic in matter and have good drainage; they remain saturated only when flooded by high water levels. Due to the high proportion of organic matter, the soils burn easily during drought conditions (Snyder et al. 1990). The relative cover of pine forests and hardwood hammock on rockland is the direct result of the fire history; pine forests burn more frequently. The hydroperiod for the pine forest is 0 to 60 days (Duever et al., 1986; USACE, 1990).

J.1.5.2 Pine Flatwoods

Pine flatwoods, unlike rockland pine communities, usually develop in flat areas where the soil is sandy and fairly deep, often mineral-poor and poorly drained, and showing a spodic (organic matter) horizon (spodosols). Some flatwoods soils also have a clay hardpan. Pines up to 60 feet tall, with a shrubby or grassy understory dominate the forest canopy. In the central and south Florida landscape, pine flatwoods are important in the Kissimmee, Upper East Coast, Lake Okeechobee and Caloosahatchee regions. They cover a much smaller percentage of the landscape in the northern Lower East Coast and Big Cypress regions, and are nearly absent south of a line extending roughly between Marco Island, on the west coast, to Fort Lauderdale in the east. Flatwoods are open, pine dominated woodlands with an understory and scattered shrub layer of hardwoods, and often a grassy or herbaceous ground cover layer. Fire is a natural controlling factor in flatwoods communities. By periodically setting back invading hardwood plant species, lightning-set fire maintains a mosaic of plant communities in flatwoods areas, and generally the density and height of the hardwood understory in pine stands is an indicator of fire history. All of the tree, shrub and grass species in flatwoods are drought tolerant, and many are fire-resistant. Flatwoods soils characteristically suffer strong seasonal fluctuations in the amount of water available for plant growth. During the rainy season, they drain slowly, and water may pond at or over the surface. In contrast, during the annual dry season, tree evapotranspiration may exhaust all available soil water, limiting conditions for many herbaceous and shrubby plants. Plants adapted to this association must tolerate soil saturation or flooding as well as drought. Although four species of pine can be found in Florida flatwoods, in the south Florida region only one, south Florida slash pine (*Pinus elliottii* var. *densa*), is widespread. Typical understory tree species include live oak (*Quercus viriginiana*), wax myrtle (*Myrica cerifera*), gallberry (*Ilex glabra*), saw palmetto (*Serenoa repens*), and others. Pine flatwoods provide important habitat for large resident mammals, including white-tailed deer, bobcat, grey fox, opossum, Florida panther and black bear. They also support many species of reptiles, including the gopher tortoise and the eastern indigo snake. They are nesting habitat for the endangered red-cockaded woodpecker.

J.1.5.3 Rockland Pine Forests

The dominant species in rockland pine forests is the Florida slash pine *(Pinus elliotti var. densa*) (Gunderson 1994; Lodge 1994; Snyder et al. 1990). They occur in areas that have slightly higher elevations of bedrock limestone than the surrounding wet prairies or mangroves (Snyder et al. 1990). A sub-canopy of rockland pine forests rarely occurs but may consist of wild tamarind (*Lysiloma latisiliqua*) and live oak (*Quercus virginiana*) (Snyder et al. 1990). Pine forests have been categorized based on their understories; some pine forests have a low stature understory and some have a well-developed hardwood understory (Gunderson 1994). Those rockland pine forests with a low-stature understory burn more regularly. The understories in pine forests are species rich (Gunderson 1994); Loope et al. (1979) reported 186 species in the understory of the pine forests on Long Pine Key in Everglades National Park. This made it the most species rich community in Everglades National Park.

The dominant understory hardwoods that occur in pine rocklands include rough velvetseed (*Guettarda scabra*), indigo berry (*Randra aculeata*), varnish leaf (*Dodonea viscosa*), myrsine (*Myrsine floridana*), and willow bustic (*Bumelia salicifolia*). The palm species that most often occur in rockland pine forests are cabbage palm (*Sabal palmetto*) and saw palmetto (*Serenoa repens*) (Gunderson 1994). The herbaceous layer of rockland pine forests is species diverse and contains a mixture of tropical and temparate species, many which are endemic. The temparate species are more common in the Big Cypress and northern Miami (Biscayne pinelands) rockridge regions. Snyder et al. (1990) listed herbaceous species restricted to rockland pine forest; they include *Angadenia sagrae*, *Melanthera parvifolia*, *Jacquemontia curtissii*, *Crossopetalum ilicifolium*, *Acalypha charmaedrifolia*, *Cassia deeringiana*, *Crotalaria pumila*, *Andropogon cabanisii*, and *Anemia adiantifolia*.

Rockland pine forests are fire "climax" communities (Lodge 1994). Slash pine communities are highly resistant to fire and are actually maintained by fire. Fire affects rockland pine forests by controlling the dominant upland species. Rockland pine forests that have experienced recent fire (3-4 years) have an open understory. Those forests that have not experienced fire for over five years begin to support dense hardwood species in their understory. If the understory succeeds to support a dense understory and fire occurs, the results can be devastating; the dense understory provides a large fuel load and causes the fire to become so hot that it burns and kills the pine overstory (Lodge 1994).

J.1.5.4 Tropical Hardwood Hammocks

Tropical hardwood hammocks are composed of broad-leafed evergreen species of Antillean-West Indian origin (Gunderson 1994; Snyder et al. 1990). Similar to the rockland pine forests, many of the taxa are endemic. Inundation may occur only during extremely high water periods (Duever et al., 1986; Gunderson et al., 1982; Olmstead et al., 1980), although forests have been observed with hydroperiods of 10 to 45 days (Duever et al., 1986). Tropical hardwood hammocks occur on regions of higher elevation and, unlike pine forests, rarely experience fire. Although influenced by fire, there are many other environmental components that influence the structure and composition of tropical hardwood hammocks; these include rainfall, temperature, hurricanes, type of adjacent vegetation, elevation, and substrate. The primary overstory species include live oak, mastic (*Mastichodendron foetidissimun*), willow bustic (*Bumelia salicifolia*), strangler fig (*Ficus aurea*), wild tamarind (*Lysiloma latisiliqum*), cabbage palm (*Sabal palmetto*), and gumbo limbo (*Bursera simaruba*) (Gunderson 1994, Snyder et al. 1990). Other species include sugarberry (*Celtis laevigata*) and mahogany (*Swietenia mahogani*). Smaller trees include lancewood *(Nectandra coriacea),* stoppers *(Eugenia spp.),* pigeon plum *(Cocoloba diversifolia*) and marlberry (*Ardisia escalloniordes*). They tend to be depauparate in terrestrial herbaceous species as a result of the lack of light that penetrates the canopy. Most of the herbaceous species found in hammocks are epiphytes, including vines, orchids and ferns.

The largest number (59 taxa) of rare and threatened plants are supported by hardwood hammocks. Gunderson (1994) lists the rarest of these taxa as follows: hand fern (*Ophioglossum palmatum*), Floridian royal palm (*Roystonea elata*), bromeliads (*Catopsis floribunda, Gusmania monostachia, Encyclia, Brassia cuadata, Oncidium floridanum, Macradenia lutescens*), and myrtle-of-the-river (*Calyptranthes zuzygium*).

J.1.5.5 Forested Wetlands (Swamp)

The woody wetland communities in south Florida consist of bay heads, willow heads, and cypress heads (Gunderson 1994; Lodge 1994; SFWMD 1992); they are found dispersed throughout the freshwater marshes at sites with the highest elevation (SFWMD 1992). Depending on the type of vegetation they support, they are sometimes called tree islands (Lodge 1994). Tree islands that support tropical hardwood hammock species have higher elevations and are more correctly referred to as hammocks (Lodge 1994). Tree islands add functional diversity to the surrounding freshwater marsh by adding habitat with variable structure that can be utilized by numerous species during portions of their life cycles. Wading birds often use tree islands for nesting and many rookeries are found on tree islands.

The dominant type of tree composing the overstory distinguishes the type of tree island (Lodge 1992). The understories of tree islands are often composed of a dense shrub layer composed primarily of cocoplum (*Chrysobalanus icaco*), buttonbush (*Cephalanthus danaeifolium*), leatherleaf fern (*Acrostichum danaeifolium*), cinnamon fern (*Osmunda cinnamonea*), royal fern (*O. regalis*), chain fern (*Anchistea virginica*), bracken fern (*pteridium aguilinum*) and lizards tail (*Saururus cenvus*) (SFWMD 1992).

Tree island communities are maintained by a combination of fire and hydrology. When fire is either too frequent or too infrequent and/or the natural hydroperiod is altered, the vegetative components of tree islands become stressed. Alligators may also have an influential role on the health of tree islands; alligator holes are usually associated with some type of tree island.

Bay heads

Bay heads are dominated by bay trees (Davis 1943; Craighead 1971) and are the most common type of tree island (Lodge 1992). They are found in the sloughs of the Loxahatchee National Wildlife Refuge and all of Shark River Slough. In the northeast portion of the Everglades, two types of bay heads have been described (Gleason and Stone 1994) and are distinguished by their shape, size, topography and vegetation; tree islands dominated by red bay (*Persea borbonia*) are usually round in shape and tree islands that are larger and elongated in shape are often dominated by dahoon holly (*Ilex cassine*). Some tree islands are dominated by swamp bay *(Magnolia virginiana*). Species present in addition to the dominant canopy species include dahoon holly, pond apple (*Annona glabra*), and wax myrtle (*Myrica cerigera*). On tree islands with higher elevations, tropical hardwoods, such as strangler fig (*Ficus aurea*), may be present. Age dating of peat forests suggests that tree islands formed only 1200 years ago and therefore, are a relatively new component of the landscape (Gleason and Stone 1994).

Willow heads

Willow heads are composed of generally monotypic stands of willow *(Salix caroliniana*) and often grow on sites with disturbed soils. Disturbance may include physical alteration by man through forestry practices, agricultural activities, or by natural disturbance, such as alligators creating alligator holes (Gunderson 1994).

Other species common to willow heads include phragmites (*Phragmites australis*), sawgrass (*Cladium jamaicense*), alligator flag (*Thalia geniculata*), whitevine (*Sarcostemma clausum*), climbing hempweed (*Mikania scandens*), and Everglades morning glory (*Ipomoea sagittata*). Willows are important community components in that they serve as roosting and nesting sites for many wading birds.

Cypress Forests

Cypress forests are found in south Florida in depressions, when the hydroperiod is longer than the surrounding marsh (Lodge 1994). Two types of cypress communities exist in the south Florida ecosystem, cypress domes and cypress prairies. Cypress domes are distinguished from cypress prairies by their structure and support tall, dense pond cypress (*Taxodium ascendens*) (Gunderson 1994). The understories of cypress domes are dependant on soil elevations; those cypress domes with higher elevations may consist of species also found in bay heads (woody species) and those with lower elevations, aquatic species. The centers of cypress domes tend to favor more optimal growth conditions and the result is taller trees towards the centers or the “dome-like” appearance. Cypress "strands", differ from domes only in their general physical shape, strands being more elongate and tending to orient in the direction of predominant overland flow. Cypress strands are common in the Big Cypress region and elsewhere. Cypress trees in the south Florida ecosystem rarely reach heights greater than 50 feet.

Cypress prairies, also called dwarf or hatrack cypress (Gunderson 1994; Lodge 1994), support stunted cypress trees that are widely distributed with understories that consist of wet prairie species (Gunderson 1994) and are more marsh-like in their appearance than swamps (Lodge 1994).

Cypress trees, similar to pine trees, have a high resistance to fire, except during times of drought. If drought conditions prevail and the surrounding wetlands soils are dry, fire will burn the upper peat layer and cause root damage that often kills the trees (Lodge 1994).

J.1.5.6 Pond Apple Forests

Pond apple stands occur throughout south Florida. These trees exist at localities that have long hydroperiods. Pond apple trees have large trunks and buttresses roots and grow to heights of 35 feet or less (Lodge 1994). Many epiphytes use pond apples as sites of attachment; during the dry season, pond apple trees drop their leaves, creating an environment suitable for epiphyte attachment. Wading birds use pond apple trees for nesting; the configuration of the branches and usual location near open water make them a good nesting substrate (Lodge 1994).

Historically, a dense forest of pond apple trees existed at the southern end of Lake Okeechobee. Some believe that this forest used to help to “regulate” flows that occurred out of Lake Okeechobee during periods of high water. Today, no forest exists, having been replaced years ago by agricultural crops (Gunderson 1994; Lodge 1994).

J.1.5.7 Freshwater Marsh

Freshwater marsh communities include sawgrass marshes, which grow in peat soils; wet prairies, which grow in either peat or marl soils, and ponds and sloughs. Wet prairies growing in marl soils have shorter hydroperiods and are restricted to the southern part of the Everglades system. The composition of freshwater marshes is affected by prevailing water conditions (Loveless 1959). The abundance and density of the vegetative components of wetlands is partly determined by the water depth, duration of inundation, and the rate of a rise or decline in water levels.

Sawgrass Marsh

Sawgrass (*Cladium jamaicense*) is one of several dominant vegetative community types found throughout the freshwater Everglades marsh. Sawgrass can survive in low-nutrient environments; this is one characteristic that made it suitable for the oligotrophic conditions of the historic Everglades. It typically occurs on land elevations slightly higher than aquatic sloughs but lower than bayhead tree islands (SFWMD 1992). Estimates of the extent of sawgrass range from 65 to 70 percent of the remaining Everglades marsh (Dineen 1972; Kushlan 1987; Loveless 1959; Schomer and Drew 1982). In the northern Everglades, sawgrass that grows where peat soils are deep is tall and dense, reaching heights of up to 3 m (Gunderson 1994; Kushlan 1990). Dense sawgrass communities limit the growth of other species and few species co-exist, with the exception of some woody plants which establish in openings in or on the border of dense marshes. In the southern portion of the Everglades, where soil depths are less, sawgrass is less dense and attains heights of 80-150 cm. Sawgrass is most often the dominant plant but occurs with a number of other sedges, grasses, herbs, and attached emergent or floating-leafed aquatic plants (Loveless 1959).

Sawgrass tolerates a wide range of hydroperiods, from 6 months to nearly continuous flooding, but the average hydroperiod is around 10 months (Lodge 1994); extended periods of high water will kill sawgrass (Davis 1990). Water depth works in concert with hydroperiod to create optimal conditions for sawgrass. Sawgrass regrowth is rapid after a burn (SFWMD 1992). However, if following a burn, sawgrass in inundated with water for an extended period of time, it will die.

Wet Prairie

Wet prairies are seasonally inundated wetland communities with intermediate hydroperiod and depth requirements; they require shorter hydroperiods (6-10 months) and depths than do sawgrass marsh. Seasonal drying of these communities is required for seed germination and the establishment of new seedlings. Common aquatic emergent plants in wet prairies include spikerush (*Eleocharis cellulosa*), beak rush *(Rhynchospora tracyi*), maidencane (*Panicum hemitomon*), arrowhead (*Sagittaria latifolia*), and pickerel weed (*Pontederia lanceolata*) (SFWMD 1992).

An important distinction must be made between wet prairies supported by peat soils and those supported by marl soils; each soil type supports vegetation distinct from the other (SFWMD 1992). Wet prairies growing over peat soils have longer hydroperiods than do marl prairies, support vegetation distinct to peat soils, and are often a transition between sawgrass marsh and the deeper sloughs in the Everglades. These peat-based prairies occur in the northern and central Everglades. Marl prairies are restricted to the southern end of the Everglades system and occur on the east and west margins of Shark River Slough and Taylor Slough (Gunderson 1994). Marl prairies require the shortest hydroperiod of all the marsh communities in the Everglades, averaging between three and seven months (Lodge 1994). The majority of the marl prairies in Everglades National Park are dominated by muhly grass (*Muhlenbergia filipes*) and sawgrass (Gunderson 1994). Plant diversity is high with over 100 species occurring; other species that co-occur include blackrush (*Schoenus nigricans*), arrowfeather (*Aristida purpurascens*), Florida bluestem (*Schizachyrium rhizomatum*), and Elliot's lovegrass (*Eragrostis elliotti*).

Many wading birds use marl prairies as important short-hydroperiod feeding grounds. Early in the dry season, when the sawgrass marshes are inundated with higher water levels, these transitional areas become accessible for foraging (Lodge 1994). The endangered Cape Sable seaside sparrow is dependant on the short-hydroperiod marl prairies to successfully breed.

Sloughs

Sloughs occur in the northern Everglades in what is now known as the Loxahatchee National Wildlife Refuge and the Hillsborough Lake area, as well as in the central and southern Everglades. They are typically the deepest wetland community, with hydroperiods of about 11 months (Lodge 1994). Sloughs, such as Shark River Slough, may obtain a depth of 3 feet or greater and may be inundated for several years continuously. Therefore they provide valuable habitat for a variety of fishes and aquatic invertebrates, and provide refugia for other animals during drought. Sloughs occur over peat soils and are often characterized by a vast number of tree islands, which provide a type of upland habitat within the deeper aquatic ecosystem. The dominant vegetation occurring within the sloughs include submerged and floating aquatic plants such as water lily, pond lily, spatterdock, bladerwort, and maidencane. Normally sawgrass is absent or comprises a modest amount of the total biomass.

J.1.5.8 Mangrove Swamps

Historically, mangrove swamps occurred along much of the coastal areas of the periphery of central and south Florida (Davis 1943). Today, while reduced in abundance through development and naturally occurring events such as hurricanes and freeze events, mangrove swamps still occupy over 500 square miles along the perimeter of Florida Bay, within the Florida Keys, and particularly in the coastal areas of Whitewater Bay northward into the Ten Thousand Islands. Acting as a buffer between the saline, marine environment and the freshwater marsh, wet prairie, and slough environment, mangroves can be one of the most productive ecosystems of all within the study area.

Mangrove forests are the most extensive habitat type in the Lower Everglades and Florida Keys areas (Schomer and Drew, 1982; Minerals Management Service, 1990). Mangrove communities are composed of an association of unrelated tropical hardwood tree species adapted to grow in saline soils under conditions of intermittent flooding. Mangrove species are not generally frost hardy, and are found throughout the tropical world along low energy coasts. In the Keys and coastal Florida, the red mangrove (*Rhizophora mangle)* dominates the intertidal zone of outer fringes and mangrove cays, while black mangrove (*Avicennia germinans)* occupies the inner side of fringing stands, as well as lower-energy hypersaline flats and deeply flooding basins. White mangrove (*Laguncularia racemosa)* is found in lower salinity areas, as well as forming extensive “dwarfed” stands over rocky flat areas of the lower Keys. Mangrove stands and cays are important wildlife habitat. Most mangrove stands export particulate and dissolved organic matter to surrounding waters, supporting a diverse food web (Odum, 1982). Red mangrove prop roots provide vital nursery and grow-out habitat for many species of commercial fish and such invertebrates as lobsters and crabs, and many species of wading birds utilize mangrove canopies and islets for roosting and nesting.

J.1.5.9 Periphyton

The periphyton community is an assemblage of many different species of green, and blue-green algae and diatoms. They are key components of the Everglades ecosystem in that they act as primary producers, producing O_2 through photosynthesis, serve as a food source to many invertebrates, and herbivorous fish, and through their decay, build a calcitic mud sediment. Periphyton are generally attached to floating or emergent vegetation or grow along the substrate where they are referred to as an algal mat. Periphyton act as important indicator organisms, as they are very sensitive to changes in water chemistry, nutrients, and other ions such as calcium. There are generally two kinds of periphyton. In areas with high concentrations of calcium, periphyton species are dominated by blue-green algae, and often are encrusted calcium carbonate crystals, which give a spongy texture. These periphyton communities often occur over marl soil, in wet prairie communities with relatively short hydroperiods. In areas of relatively low calcium concentration, in sloughs and deeper wet prairie communities, the periphyton is dominated by green algal species which are more nutritious for primary consumers.

J.1.5.10 Marine and Coastal Resources

The following are not so much vegetation types as habitats that are important in the overall system, in terms of their productivity and fragility. These key habitats, or ecosystems, are threatened by current water management practices and merit recognition and mention here as they may be affected by the Restudy Initial Draft Plan.

Estuaries

Estuaries are critically important as nursery, breeding, staging, and resting areas for fish, shellfish, reptiles, birds, and mammals. The south Florida ecosystem contains numerous coastal resources, some of which are found nowhere else in North America. The south Florida ecosystem includes several major estuarine ecosystems: southern Indian River Lagoon, Lake Worth Lagoon and Biscayne Bay on the east coast; Florida Bay on the southern coast; and the Ten Thousand Islands region, Rookery Bay, Estero Bay, Caloosahatchee River, Charlotte Harbor, and Sarasota Bay on the Gulf Coast.

Seagrasses

Of the 3,860 square miles of seagrasses in the United States portion of the Gulf of Mexico, more than 85 percent occur in Florida waters (Iverson and Bittaker 1986). More than 2,124 square miles of seagrass beds occur in the shallow waters of Florida Bay and the adjacent reef tract alone; seagrasses cover 80 percent of the submerged lands between Cape Sable, north Biscayne Bay, and the Dry Tortugas (Jaap and Hallock 1990). Seagrass meadows improve water quality by removing nutrients, by dissipating the effects of waves and currents, and by stabilizing bottom habitats thereby reducing suspended solids. Seagrass beds support some of the most abundant fish populations in the Indian River Lagoon, with a large species diversity. Pinfish and several species of mojarra are very abundant in the seagrass habitat. These species are known to feed on seagrasses and on the epiphytes and epifauna of the seagrasses, providing a critical link in the food chain between the primary producers and the higher level consumers such as the common snook and spotted seatrout.

The seagrass habitat is also a critical resource for the Florida manatee *(Trichechus manatus latirastris).* This marine mammal depends on seagrasses for a major part of its food supply (Lain, 1978; Van Meter, 1989; Provancha and Hall, 1992). It has been reported that manatee grazing may result in up to a 68 percent decrease in seagrass biomass (Virnstein, 1987; Provancha and Hall, 1991a), illustrating the importance of seagrasses as manatee forage. Juvenile sea turtles have also been documented as foraging on turtle grass (*Thalassia testudinum*) and other seagrasses in the Indian River Lagoon (Mendonca, 1981; Mendonca and Ehrhart, 1982). Turtlegrass is the predominant species in waters deeper than 1-2 feet. Associated with the turtlegrass is manatee grass (*Cymodocea manatorum*). Shallower areas may have a thin cover of shoal grass (*Halodule wrightii*). Seagrass beds are essential habitat for juvenile fish and invertebrates. Calcareous algae often occur interspersed with seagrasses in mixed assemblages.

The seagrass communities of south Florida have experienced substantial declines in acreage and quality in recent years. An estimated 30 percent of the seagrass communities have been destroyed in Florida’s estuaries since the 1940's. Indian River Lagoon and Charlotte Harbor have each lost about 30 percent of their seagrass beds. Since 1987, more than 59,306 acres of seagrasses have been affected by several factors including degraded water quality, dredging from boat propellers, freshwater management of the Everglades flow, severe temperature variability, and others; resulting in a massive die-off (Haddad and Sargent 1994). Seagrass beds in Monroe, Lee, Miami-Dade, and Charlotte Counties have experienced the heaviest damages from propellers.

Coral Reefs

Coral reefs are a prominent coastal resource in the south Florida ecosystem, which contain several different kinds of coastal reef assemblages: ivory tree coral reefs, worm reefs, vermetid reefs, and the coral reef of the Florida Keys. The Keys coral reef complex consists of a tract of semi-continuous offshore bank reefs that make up the third largest barrier reef in the world and more than 6,000 inshore patch reefs. As such, the Keys’ reef constitutes the only coral assemblages of any significance in the continental United States. In addition, coral reefs hold unparalleled marine diversity and are likened to the tropical rainforests of the sea. The Florida Keys coral reef is the most visited and heavily used reef in the world, hosting millions of users annually. Coral reefs also exist in the nearshore and offshore waters of the Lower East Coast, which may be affected by freshwater discharges from C&SF canals and inland rivers and streams.

J.1.6 Fish and Wildlife

The following discussion is an overview of common, keystone, and/or indicator fish and wildlife species that inhabit the central and south Florida study area.

J.1.6.1 Invertebrates

Macroinvertebrates represent an important component of the Everglades food web. Kolpinsky and Higer (1969), working in the marshes of Everglades National Park, first reported the importance of crustaceans to the Everglades food web. Such species as crayfish (*Procambarus alleni*), and the freshwater shrimp (*Palaemonetes paludosus*) as well as small forage fish represent a major component of the Everglades food web providing prey for larger fish, amphibians, reptiles and wading birds. Most freshwater invertebrates are temperate species. The Everglades do not have a great diversity of freshwater invertebrates due to its limited type of habitat and nearly tropical climate, which many temperate species cannot tolerate (Lodge 1994). Important invertebrates include: the Florida apple snail (*Pomacea paludosa*), Seminole rams-horn (*Planorbella duryi*), riverine grass shrimp (*Palaemonetes paludosus*), Florida spiny lobster (*Panulirus argus*), blue crab (*Callinectes sapidus*), pink shrimp (*Penaeus duorarum*), crayfish (*Procambarus alleni*). The importance of the Florida apple snail to the diet of the snail kite *(Rostrhamus sociabilis)* is widely documented in the literature. There are also dozens of species of aquatic and terrestrial insects and spiders, many that are important in the food chain in the juvenile or adult phase of their life cycle.

J.1.6.2 Fishery Resources

Within the study area there are a large number of fish species, residing in the inland freshwater lakes, canals, sloughs, and borrow pits. Some of the important commercial and freshwater sport fish found in south Florida include: largemouth bass (*Micropterus salmoides*), redear sunfish (*Lepomis microlophus*), bluegill (*Lepomis macrochirus*), black crappie (*Pomoxis nigromaculatus*), Florida gar (*Lepisosteus platyrhincus*), threadfin shad (*Dorosoma petenense*), gizzard shad (*Dorosoma cepedianum*), white catfish (*Ameirus catus*), yellow bullhead (*Ameiurus natalis*), and Tilapia (*Tilapia* spp.). These fish are not only sought after by fisherman, but are critically important in the diets of predators including wading birds, alligators, otters, racoons, mink, and other animals.

Numerous forage species, including the Cyprinodontids such as the golden topminnow (*Fundulus chrysotus*), the least killifish (*Heterandria formosa*), and the Florida flagfish (*Jordanella floridae*) are commonly found and are known to be important food resources for wading birds, amphibians, and reptiles. Other important forage fish include: golden shiners (*Notemigonus crysoleucas*), marsh killifish (*Fundulus chrysotus*), sailfin molly (*Poecilia latipinna*), bluefin killifish (*Lucania goodei*), oscars (*Astronotus ocellatus*), and eastern mosquitofish (*Gambusia holbrooki*). These fish are important in the processing of food in the form of plankton, macroinvertebrates, and algae and plant material, which is then available to first order predators.

Within the study area, fish inhabit the open water aquatic sloughs and wet prairie communities, as well as the deep-water canal environments. While canals and many sloughs contain water throughout the year and from year to year, many areas of the interior marsh experience seasonal drydowns. As a result, fish populations within the marsh fluctuate widely, moving from shallower areas into the sloughs, alligator holes, and canals during dry periods. The gradual recession in water levels, during the dry season, concentrates fish in shallow water and renders them more susceptible to predators such as wading birds. This is a key component in the ecology of the south Florida ecosystem. ***Table J-1.6.2-1*** lists some of the common species found in the study area.

The extensive canal system supports fish species that normally would not be common inhabitants of the Everglades marshes, but are typically found in lakes. These fish include black crappie *(Pomoxis nigromaculatus)*, catfish (*Ictalurus* spp.), and shad (*Dorosoma* spp.). Oscars *(Astronotus* spp,), spotted tilapia (*Tilapia mariae*), walking catfish (*Clarias batrachus*), and the black acara (*Cichlasoma bimaculatum*) are examples of exotic fish species that have become established within south Florida. The origin of these exotics is assumed to be from tropical fish farms in Florida. The extensive canal system offers refuge for fish during drought conditions allowing for rapid repopulation of the marsh when water levels rise. Generally, sport fish are harvested from the borrow canals that surround Everglades marsh. As water levels in the canal and marsh rise, fish populations disperse into the interior marsh and reproduce with minimum competition and predation. As water levels recede, fish concentrate into the deeper waters of the surrounding canals where they become available as prey for wildlife and fishermen. In some instances, the canal fishery has experienced major fish kills due to overcrowding and oxygen depletion.

Estuarine and Marine Fisheries

Anglers spend millions of dollars annually in Florida, fishing for such species as red drum, spotted seatrout, tarpon, snook, jacks, snappers, groupers, sharks, spiny lobsters, and stone crabs. In 1991, anglers landed more than 23.3 million pounds of fish and 9.9 million pounds of shellfish. Some 217 fish species have been collected from various marine and estuarine mangrove communities of south Florida, including sport and commercial fish and invertebrates such as the spiny lobster, pink shrimp, mullet, tarpon, and mangrove snapper (Lewis et al. 1985). Over 600 species of fish have been noted from the Indian River Lagoon region (IRLNEP 1996). A total of 246 fish species have been reported from the estuarine ecosystem of Charlotte Harbor, including 18 commercially important species and 5 species that are important for recreational fisheries (Taylor 1974). Also, Charlotte Harbor is the southern range of the threatened Gulf sturgeon.

Table J-1.6.2-1
Common Everglades Fresh Water Fish Species
(After Gunderson And Loftus, 1993)

Common Name	Scientific Name
Florida Gar	*Lepisosteus platyrhincus*
Bowfin	*Amia calva*
Golden shiner	*Notemigonus crysoleucas*
Tailight shiner	*Notropis maculatus*
Coastal shiner	*Notropis petersoni*
Lake chubsucker	*Erionyzon sucetta*
Yellow bullhead	*Ictalurus natalis*
Brown bullhead	*Ictalurus nebulosus*
Tadpole madtom	*Noturus gyrinus*
Diamond killifish	*Adinia xenica*
Sheepshead minnow	*Cyprinodon variegatus*
Golden topminnow	*Fundulus chrysotus*
Marsh killifish	*Fundulus confluentus*
Seminole killifish	*Fundulus seminolis*
Flagfish	*Jordanella floridae*
Bluefin killifish	*Lucania goodei*
Rainwater killifish	*Lucania parva*
Mosquitofish	*Gambusia affinis*
Least killifish	*Heterandria formosa*
Sailfin molly	*Poecilia latipinna*
Brook silverside	*Labidesthes sicculus*
Everglades pygmy sunfish	*Elassoma evergladei*
Bluespotted sunfish	*Enneacanthus gloriosus*
Warmouth	*Lepomis gulosus*
Bluegill	*Lepomis macrochirus*
Dollar sunfish	*Lepomis marginatus*
Redear sunfish	*Lepomis microlophus*
Spotted sunfish	*Lepomis punctatus*
Largemouth bass	*Micropterus salmoides*
Swampdarter	*Etheostoma fusiforme*

An estimated 96 percent (98 percent Gulf of Mexico and 94 percent southeast Atlantic) by weight of commercially and recreationally important marine fish species in south Florida are dependent upon estuarine habitats for critical life processes (Chambers 1991). The coastal, estuarine, and nearshore ecosystems of south Florida provide a nursery for a wide variety of fish and shellfish species supporting offshore fisheries in the south Atlantic and Gulf of Mexico. However, the habitats that historically supported south Florida fish populations have declined significantly in area and quality over the past 50 years. The alteration of freshwater flows to the estuaries along the southern and southwestern coasts of Florida has reduced water quality of the estuarine habitats of the region. Florida Bay is a key nursery area for various marine species including spotted seatrout, bonefish, red drum, tarpon, pink shrimp, and spiny lobster. However, a 90 percent reduction in freshwater inflow and increased levels of nutrient and pesticides have contributed to an increase of algal blooms, lost seagrass beds, sponge mortality, and salinity increases. These changes have caused increased incidences of fish kills and serious losses of mangroves, all of which are directly linked to land use or land misuse in areas surrounding the Everglades, as well as to south Florida's water management regime.

J.1.6.3 Reptiles and Amphibians

Important reptile species commonly encountered within the study area include the American alligator (*Alligator mississippiensis*), American crocodile (*Crocodylus acutus*), turtles, lizards, and snakes. The American alligator, more than any other species, is most often identified with the Everglades and it's unique wetland ecosystem. Turtles include the five species of sea turtles, including the loggerhead (*Caretta caretta*), hawksbill (*Eretmochelys imbricata*), Kemp's ridley (*Lepidochelys kempii*), and the green turtle (*Chelonia mydas*). Freshwater species include snapping turtle (*Chelydra serpentina*), striped mud turtle (*Kinosternon bauri*), mud turtle (*K. subruburm*), cooter (*Chrysemys floridana*), Florida chicken turtle (*Deirochelys reticularia*), and Florida softshell turtle (*Trionys ferox*). Lizards such as the green anole (*Anolis carolinensis*), are found in the central Everglades, and several species of skinks occur more commonly in terrestrial habitats. Numerous snakes inhabit the wetland and terrestrial environment of the south Florida ecosystem. Drier habitats support such species as the Florida brown snake (*Storeria dekayi*), southern ringneck snake (*Diadophis punctatus*), southern black racer (*Coluber constrictor*), scarlet snake (*Cemophora coccinea*), and two rattlesnakes (*Sistrurus miliarius* and *Crotalus adamanteus*). The eastern indigo snake (*Drymarchon corais*), a Federally listed endangered species, and the Florida pine *snake (Pituophis melanoleucus mugitus*), a state species of special concern, may also exist in drier areas of the study area. Wetter habitats support more aquatic species such as the water snake (*Natrix sipedon*), the green water snake (*N. cyclopion*), mud snake (*Francia abacura*), eastern garter snake (*Thamnophis sirtalis*), ribbon snake (*T. sauritus*), rat snake (*Elaphe obsoleta*), and the Florida cottonmouth (*Agkistrodon piscivorus*) (McDiarmid and Pritchard, 1978).

Important amphibians, known to occur in south Florida, include the Everglades bullfrog, or pig frog (*Rana grylio*), which occurs primarily within wet prairie and aquatic slough habitats throughout the Everglades (Ligas, 1960). This amphibian is considered an important economic species and provides recreation for sportsmen and some supplemental income for a few commercial froggers who market these animals through wholesalers, hotels and restaurants. Other important frog species, including the Florida cricket frog (*Acris gryllus*) and southern leopard frog (*Rana sphenocephala*), are common in marshes and wet prairies, while such species as the southern chorus frog (*Pseudacris nigrita*) and various tree frogs (squirrel tree frog, *Hyla squirela*; green tree frog, *H. cinerea*) are common to tree islands and cypress forests. Salamanders inhabit the densely vegetated, still or slow-moving waters of the sawgrass marshes and wet prairies. They include the greater siren (*Siren lancertina*) and the Everglades dwarf siren (*Pseudobranchus striatus*). Toads such the eastern narrow-mouth toad (*Gastrophryne carolinensis*) also occur within the study area.

J.1.6.4 Avifauna

Robertson and Kushlan (1984) indicate that even though nearly 400 species of birds have been recorded in southern Florida, the regional avifauna is characterized by about 300 taxa. Of these species listed, approximately 60 percent are wintering and migrant birds, while about 116 species comprise the native breeding avifauna. South Florida's wetland habitats have historically supported a great diversity and abundance of wading birds (Kushlan and White, 1977). Despite the 95 percent reduction in wading bird population in the state reported since the 1800s, all fourteen species of wading birds found in the eastern United States were reported nesting in Florida in 1977 (Custer and Osborn, 1977).

Colonial wading birds (Order Ciconiformes) commonly observed within the the study area include eleven species of herons and egrets, two species of ibis, the wood stork, and the roseate spoonbill (Robertson and Kushlan, 1984). Important species include white ibis (*Eudocimus albus*), glossy ibis (*Plegadis falcinellus*), the great egret (*Casmerodius albus*), great blue heron (*Ardea herodias*), little blue heron (*Egretta caerulea*), tricolored heron (*E. tricolor*), green-backed heron (*Butorides striatus*), snowy egret (*E. thula*), cattle egret (*Bubulcus ibis*), black-crowned night heron (*Nycticorax nycticorax*), and yellow-crowned night heron (*N. violacea*). The roseate spoonbill (*Ajaia ajaja*), a state species of special concern, and the wood stork (*Mycteria americana*), a Federally listed endangered species, both occur within the study area. Most wading bird species exhibit a seasonal pattern of abundance, being more abundant during the dry season than during the wet season. The majority of species nest in late winter or early spring, although a few, such as the great egret, are reported to nest at different times throughout the year (Kushlan and White, 1977a).

The reproductive cycle of most wading birds is tightly linked with seasonal water level fluctuations within the marsh. During the rainy season, when water levels are high, fish and invertebrate prey species repopulate the newly flooded marsh and begin to increase in abundance. As water levels recede during the dry season, the density of these prey species (topminnows, mosquitofish, killifish, crayfish, freshwater prawns and insect larvae) increase as they concentrate in remnant pools and along the edge of the drying marsh.

Diving birds commonly found in the south Florida ecosystem include the pied-billed grebe (*Podilymbus podiceps*), anhinga (*Anhinga anhinga*), double-crested cormorant (*Phalacrocorax auritus*), common merganser (*Mergus merganser*), and red-breasted merganser (*Mergus serrator*).

Just over 70 species of land birds breed in southern Florida, half of which are songbirds, or passerine types (Lodge 1994). Birds of prey include: the Federally listed (threatened) bald eagle (*Haliaeetus leucocephalus*), Federally listed (endangered) snail kite (*Rostrhamus sociabilis*), and osprey (*Pandion haliaetus*).

Migratory Birds

The south Florida ecosystem is located along one of the primary migratory routes for bird species that breed in temperate North America and winter in the tropics of the Caribbean and South America. More than 116 species of neotropical migrants have been recorded in the south Florida ecosystem. Large numbers of species like the bobolink migrate through the south Florida ecosystem, as they fly from their breeding grounds in southern Canada and the northern Great Plains to the marshes of Argentina and Brazil. Virtually the entire North American population of blackpoll warblers migrates to South America along a route that passes through Florida to the West Indies. Other migratory species like the tanagers, chimney swifts, tree swallows, nighthawks, royal terns, and blue-winged teal also have major migratory pathways through the south Florida ecosystem.

More than 129 bird species migrate to the south Florida ecosystem to overwinter. Another 132 bird species breed in the south Florida ecosystem. Because the south Florida ecosystem lies near Cuba and the West Indies, it draws Caribbean species that rarely appear elsewhere in North America. Examples of these species include the smooth-billed ani, mangrove cuckoo, bananaquit, white-crowned pigeon, and black-whiskered vireo. The south Florida ecosystem has an endemic race of the yellow warbler and contains the majority of the nesting locations for the great white heron, reddish egret, roseate spoonbill, swallow-tailed kite, and short-tailed hawk in the United States.

The coastal area of the south Florida ecosystem like the rest of Florida provides important breeding and wintering areas for shorebirds. The beaches provide nesting habitat for 13 species of shorebirds and support one of the two largest concentrations of wintering shorebirds in Florida. A list of resident and migrant species observed during a recent avian survey on Lake Okeechobee (USACE 1998), and indicative of species found throughout the study area are presented in ***Table J-1.6.4-1.*** For a more complete listing of Florida bird life reference USFWS Draft Multi-Species Recovery Plan.

Table J-1.6.4-1
List Of Common Resident And Migratory Avifauna Of South Florida (After USACE Wildlife Survey Of Lake Okeechobee 1998).

Common/Scientific Name	**Status**
Arboreal Birds [a]	
Blue-gray gnatcatcher (*Polioptila caerulea)*	Resident
Boat-tailed grackle (*Quiscalus major*)	Resident
Common yellowthroat (*Geothlypis trichas*)	Resident
Downey woodpecker (*Picoides pubescens*)	Resident
Eastern meadowlark (*Sturnella magna*)	Resident
Fish crow (*Corvus ossifragus*)	Resident
Killdeer (*Charadrius vociferus*)	Resident
Northern cardinal (*Cardinalis cardinalis*)	Resident
Red-bellied woodpecker (*Melanerpes carolinus*)	Resident
Red-winged blackbird (*Agelaius phoeniceus*)	Resident
Eastern phoebe (*Sayornis phoebe*)	Migrant
Marsh wren (*Cistothorus palustris*)	Migrant
Northern rough-winged swallow (*Stelgidopteryx serripennis*)	Migrant
Palm warbler (*Dendroica palmarum*)	Migrant
Savannah sparrow (*Passerculus sandwichensis*)	Migrant
Sedge wren (*Cistothorus platensis*)	Migrant
Swamp sparrow (*Melospiza georgiana*)	Migrant
Yellow-rumped warbler (*Dendroica coronata*)	Migrant
Aerial Feeding Birds [b]	
Barn swallow (*Hirundo rustica*)	Migrant
Chimney swift (*Chaetura pelagica*)	Migrant
Tree swallow (*Tachycineta bicolor*)	Migrant
Aerial Searching Birds [a]	
Belted kingfisher (*Ceryle alcyon*)	Resident
Caspian tern (*Sterna caspia*)	Resident
Laughing gull (*Larus atricilla*)	Resident
Ringed-billed gull (*Larus delawarensis*)	Resident
Ruddy duck (*Oxyura jamaicensis*)	Resident

b Supplemental Avifaunal Groups

J.1.6.5 Mammals

North America is the origin of all of Florida's native mammalian species, none of the native species had their origin in the tropics (Lodge 1994). Layne (1984) lists up to 30 species, which have been seen or collected in Everglades National Park. The most diverse group of mammals is the carnivores, while the most abundant group is the rodents. A noted feature of the mammal fauna is the near absence of bats (Layne, 1984). ***Table J-1.6.5-1***, below lists the most common mammals of the Everglades region.

South Florida is also home to three species of exotic mammal, which are widespread in natural habitats. In sandy upland areas of the Big Cypress, but less common in other wetland areas of the system, is found the nine-banded armadillo (*Dasypus novemcinctus*). Feral populations of domestic hogs (*Sus scrofa*) are distributed around fringe wetlands in the Big Cypress and elsewhere. Finally, the black rat (*Rattus rattus*) is found around garbage dumps, and buildings, but also in coastal areas including mangrove swamps (Davis and Ogden 1994).

Table J-1.6.5-1 Common Mammals Of The Everglades Region (After Lodge 1994)	
Common name	**Scientific name**
terrestrial and terrestrial/aquatic species	
opossum	*Didelphis virginiana*
marsh rabbit	*Sylvilagus palustris*

Atlantic bottlenose dolphin	*Tursiops truncatus*
West Indian manatee	*Trichechus* manatus

J.1.7 Threatened and Endangered Species

The U.S. Fish and Wildlife Service (USFWS) identified the following eighteen Federally listed plant and animal species that would likely be affected by Restudy alternatives within the study area. For a complete species description, taxonomy, distribution, habitat requirements, management objectives, and current recovery status, reference the Draft Multi-Species Recovery Plan for the Threatened and Endangered Species of south Florida, Volume I (USFWS 1998) or the USFWS endangered species web site at *http://www.fws.gov/~r9endspp.* For a complete listing of all the Federally listed threatened and endangered plant and animal species occurring or thought to occur within the study area, reference the above web site. The Florida Game and Fresh Water Fish Commission (GFC) in a letter dated February 23, 1998, provided information on state listed species. This information is incorporated below. These species and their designation are listed in ***Table J-1.7-1***.

Table J-1.7-1 Threatened, Endangered & SSC Plant And Animal Species Likely To Be Affected By The C&Sf Restudy			
Scientific Name	**Common Name**	**USFWS**	**GFC**

T Threatened
SSC State listed Species of Special Concern

J.1.7.1 Animal Species

The following is an overview of the listed animal species identified by the USFWS as likely to be affected by Restudy alternatives, including two mammals, eight birds, and one reptile.

West Indian manatee

The West Indian manatee (*Trichechus manatus*) has been recognized as an endangered species since 1967. Both the USFWS and GFC list it as an endangered species. Manatees are also protected under the provisions of the Marine Mammal Protection Act of 1972, as well as by Florida law. Manatees occur in both fresh and salt water habitats, and are believed to show preference to waters with salinity levels < 25ppt. Waters colder than 20^0C increase the manatee's susceptibility to cold-stress and cold-induced mortality. Manatees therefore generally seek out warm water refuges in quiet areas in canals, creeks, lagoons or rivers. Manatees are also found throughout the waterways in south Florida, Lake Okeechobee and occasionally in the Florida Keys. In south Florida, manatees are most prominent year round in the Indian River, Biscayne Bay, Everglades and Ten Thousand Islands area, Estero Bay and Caloosahatchee River area and Charlotte Harbor area. Manatees feed on a variety of submergent, emergent and floating vegetation and usually forage in shallow grass beds adjacent to deeper channels. The primary threats to manatees today are due to collisions with watercraft, degradation of seagrasses and accidents occurring at water control structures.

Florida panther

The Florida panther (*Felis concolor*), Florida's state animal, is one of the most endangered large mammals in the world. Although it is listed as endangered by the USFWS and GFC, no critical habitat has been designated. Population estimates in south Florida range between 30 to 80 total animals. The only known, remaining panther population is centered in and around the Big Cypress Swamp/Everglades physiographic region of south Florida. About half of the known panther range is situated on private lands north of Interstate 75, the remainder being located on key public lands. In general, panthers prefer lands of higher elevation, better drained, with a high percentage of hardwood hammocks and pine flatwoods. These lands are most productive for important prey species, white-tailed deer, feral hogs, raccoon and 9-banded armadillo. Environmental factors affecting the Florida panther include habitat loss and fragmentation, environmental contaminants, prey availability, human-related disturbance and mortality, disease, and genetic erosion (Dunbar 1994).

Snail kite

The snail kite (*Rostrhamus sociabilis plumbeus*) is wide ranging raptor, listed as endangered by the USFWS and GFC. Within the study area, critical habitat includes portions of the Water Conservation Areas (WCAs), portions of Everglades National Park and western portions of Lake Okeechobee. Lake Okeechobee and surrounding wetlands are major nesting and foraging habitats, particularly the large marsh in the southwestern portion of the lake. The snail kite has a highly specific diet composed almost exclusively of apple snails (*Pomacea paludosa*), which makes the kite directly dependent on hydrology and water quality within these watersheds. Preferred habitat for the snail kite includes long hydroperiod wetlands, flooded for $\geq$ 1 year, with marsh vegetation dominated by spike rush, beak rush, maidencane, sawgrass and/or cattails, and relatively clear and open areas in order to visually search for apple snails. Nesting almost always occurs over water, near suitable foraging habitat, but may occur in herbaceous vegetation during periods of low water when dry conditions prevail beneath willow stands. The principal threats to snail kites are related directly to the water management of the C&SF Project, which may contribute to the loss or degradation of wetlands, as well as degradation of water quality from agricultural and urban sources.

Wood stork

The wood stork (*Mycteria americana*) is listed as an endangered species by the USFWS and the GFC. In a USFWS coordinated survey of wood stork colonies, conducted from 1991-1995, between 1,339 (1991) and 2,639 (1995) wood stork nests were surveyed in south Florida, approximately 35 percent of the total nesting effort in the southeast United States. In south Florida, breeding colonies of the wood stork occur throughout the study area, with particularly important colonies occurring at Corkscrew Wildlife Sanctuary, Cuthbert Lake, East River and Sadie Cypress. Wood storks forage in freshwater marshes, seasonally flooded roadside or agricultural ditches, narrow tidal creeks, shallow tidal pools, managed impoundments, and depressions in cypress heads and swamp sloughs. Wood storks feed almost entirely on fish between 2 and 25 cm in length (Kahl 1964, Ogden *et al.* 1976, Coulter 1987), and depend on prey species being concentrated in receding waters as they use a tactile feeding technique, using their stout beak as a probe. A key environmental concern is that of nesting failure due to water management practices currently in place. During wet years, fish are not sufficiently concentrated in shallow pools for the storks to forage effectively. In dry years, freshwater sloughs are overdrained, and thus unable to produce the fish on which storks feed.

Cape Sable seaside sparrow

Cape Sable seaside sparrows (*Ammodramus maritimus mirabilis*) are listed as endangered by the USFWS and the GFC. Critical habitat for the Cape Sable seaside sparrow was designated in 1977. They have the most restricted range of any of the seaside sparrows, and occur only in the Everglades region of Miami-Dade and Monroe Counties in south Florida. Presently, the known distribution of the sparrow is restricted to two areas on the east and west sides of Shark River Slough and Taylor Slough in Everglades National Park. The preferred habitat of the sparrow are short-hydroperiod marl prairies, dominated by muhly grass (*Muhlenbergia filipes)* with open space for ground movement. Nesting occurs from late February through early August, with the majority of nesting occurring in the spring when the marl prairies are usually dry. Sparrows build nests of grassy materials about 14 cm above the ground (Werner 1975, Lockwood *et al*. 1997). Currently the greatest threat to the Cape Sable seaside sparrow appears to be loss of its nesting habitat due to changes in historical hydropatterns within the sparrow range as a result of the C&SF Project, its associated operational schedules, and flood control regulatory releases.

American crocodile

The American crocodile (*Crocodylus acutus*) is designated as endangered by the USFWS and the GFC. Critical habitat was designated in 1979, and is described in the Multi-Species Recovery Plan for south Florida (USFWS 1998). The American crocodile inhabits coastal habitats of extreme south Florida, including coastal areas of Miami-Dade, Monroe, Collier, and Lee counties. Crocodiles are regularly observed in Florida and Biscayne Bays, found primarily in mangrove swamps, along low energy mangrove lined bays, creeks, and inland swamps (Kushlan and Mazzotti 1989). The crocodile population in Florida, although small, appears stable. Recent changes in nesting effort, from survey data collected from the late 1970's, indicate population levels be on the rise. Crocodiles are susceptible to poaching for their hides and for meat. Habitat loss and fragmentation due to increases in urbanization and agricultural land uses, natural catastrophes e.g. hurricanes, changes in the distribution, timing, quantity, and quality of freshwater flows, and direct human disturbance to animals and their nests, also affect crocodiles.

Florida grasshopper sparrow

The USFWS listed the Florida grasshopper sparrow (*Ammodramus savannarum floridanus*) as endangered in 1986 because of habitat loss and degradation resulting from conversion of native vegetation to improved pasture (USFWS 1998). It is also listed as endangered by the GFC. No critical habitat has been designated for this sub-species. The Florida grasshopper sparrow is non-migratory, and is limited to the prairie region of south-central Florida. Within the study area, it is known to inhabit Glades, Highlands, Okeechobee, Osceola, and Polk Counties, in habitat consisting primarily of tree-less, relatively poorly drained grasslands that have a history of frequent fires (USFWS 1988, Delany 1996a). Less than 600 Florida grasshopper sparrows are thought to exist as of the 1997 breeding season. The Florida grasshopper sparrow is currently protected on three large tracts of land, including Avon Park Air Force Reserve (Highlands and Polk Counties), Three Lakes Wildlife Management Area (Osceola County), and the National Audubon Society's Ordway-Whittell Kissimmee Prairie Sanctuary. Threats to the Florida grasshopper sparrows include habitat loss, overgrazing, unfavorable hydrologic conditions which prevent nesting. If unfavorable conditions continue for extended periods, they alter the vegetation composition, predation and nest parasitism.

Red-cockaded woodpecker

The USFWS has listed the Red-cockaded woodpecker (*Picoides borealis*) as endangered, due largely to destruction of its habitat, and fragmentation of its historic home range. It is listed as threatened by the GFC. The estimated Florida breeding population of the red-cockaded woodpecker is about 1,500 pairs, with about 75 percent of that total occurring in the panhandle (Cox *et al.* 1995). Active colonies of red-cockaded woodpeckers are interspersed throughout the study area, most notably in Osceola, Highlands, St. Lucie, Palm Beach, Glades, Charlotte, Lee, and Monroe Counties. Pine stands, or pine-dominated hardwood stands, with a low or sparse understory and ample old-growth pines, constitute primary red-cockaded woodpecker nesting and roosting habitat (USFWS 1998). Longleaf pine provide important nesting habitat where available, however cavities are also constructed in other pines, and in southwest Florida, the hydric slash pine is preferred. Throughout its range, the red-cockaded woodpecker is threatened by habitat loss and fragmentation, lack of fire or infrequent fire which maintains habitat quality, and invasion by exotic vegetation.

Bald eagle

The bald eagle (*Haliaeetus leucocephalus*) is listed as threatened by both the USFWS and the GFC. Bald eagles are known throughout the study area, where they typically are found near estuaries, large lakes, reservoirs, major rivers and particularly along the southwest coast and in the Kissimmee River region. Eagle numbers have responded positively to the banning of DDT and other organochlorines and the listing of the bald eagle as an endangered species (since re-classified to threatened). Eagles feed primarily on fish, water dependent birds, and mammals. Eagles are opportunistic feeders and will also eat carrion. Current threats to the bald eagle include habitat loss and fragmentation, collisions with cars and powerlines, and shooting (USFWS 1998).

Audubon's crested caracara

The Florida population of this resident, non-migratory raptor is listed as threatened by the USFWS and GFC. The caracara (*Polyborus plancus)* commonly occurs in dry or wet prairie areas, as well as improved or semi-improved pasture. The region of greatest abundance is a five county area north and west of Lake Okeechobee, including Glades, DeSoto, Highlands, Okeechobee, and Osceola counties (Kissimmee River and Caloosahatchee River regions). Caracara have also been observed nesting in the Big Cypress region, west of the Big Cypress Seminole Indian Reservation. Caracaras are highly opportunistic feeders, eating carrion and a large variety of live prey. Their numbers continue to decline throughout their range due largely to loss of habitat. In particular, the caracara has suffered because its preferred dry prairie habitat has been destroyed or modified for agriculture or residential development. Direct human mortality, e.g. vehicular accidents and illegal trapping, also pose a significant threat to caracara.

Eastern indigo snake

The eastern indigo snake (*Drymarchon corais couperi*) is a large, black, non-venomous snake and occurs within every major physiographic region within the study area. The USFWS and GFC list it as a threatened species. The eastern indigo snake, generally an upland species, occupies a wide variety of habit, including pine flatwoods, scrubby flatwoods, dry prairie, tropical hardwood hammocks, along the margins of freshwater marshes, agricultural fields, coastal dunes, and human altered habitats. They are usually not found in abundance in the wetland complexes of the central Everglades region. In wetter habitats, eastern indigo snakes may take shelter in hollowed root channels, hollow logs, or the burrows of rodents, armadillo, or crabs (Lawler, 1977, Moler 1985b, Layne and Steiner 1996). Currently the greatest impact to the eastern indigo snake has been by the loss, degradation, and fragmentation of their habitat due to residential and commercial construction, agriculture and timbering. Pesticides, mortality from vehicles, and illegal trapping also pose a threat to recovery efforts of this species.

Florida scrub-jay

The Florida scrub-jay (*Aphelocoma coerulescens*) is a medium sized song bird, which occurs in relict oak dominated scrub or xeric oak scrub, on well drained, sandy soils. Optimal habitat for scrub-jays is one in which oaks are one to three meters high, interspersed with 10 to 50 percent of unvegetated, sandy openings, and with a sand pine (*Pinus clausa*) cover of less than 20 percent (Woolfenden and Fitzpatrick 1990). One of three, "core populations", which comprises a significant portion of the remaining scrub-jay population, is found in the Lake Wales Ridge region (Fitzpatrick et al. 1994). This region encompasses parts of Polk, Osceola, Highlands, and Glades Counties. Scrub-jays are extremely territorial, habitat-specific, and sedentary and the species has declined by an estimated 25 to 50 percent in the past ten to twelve years (USFWS 1998). Currently the greatest impact to this state (threatened) and Federally (threatened) listed species is from habitat fragmentation, degradation and loss of scrub habitat. This is thought to be due to widespread fire suppression, conversion of rural lands to citrus production and residential development (Fernald 1989, Fitzpatrick et al. 1991).

J.1.7.2 Plant Species

The following is an overview of the listed plant species identified by the USFWS as likely to be affected by Restudy alternatives. The Okeechobee gourd resides within the Herbert Hoover Dike along Lake Okeechobee, while the other plant species identified mostly inhabit the pine rocklands, along the Atlantic Coastal Ridge.

Okeechobee gourd

The Okeechobee gourd (*Cucurbita okeechobeensis*) is listed as endangered by the USFWS. There are several localized sites along the southeastern shore of Lake Okeechobee, where this vine is found within the study area, including: Torry Island, Ritta Island, Kreamer Island, Bay Bottom Dynamite Hole Island, South Shore Dynamite Hole Island, and the southern shore of the Lake Okeechobee Rim Canal (Walters et al. 1992; Walters and Deckers-Walters 1993). Fluctuating lake levels are necessary for the continued survival and recovery of the gourd within and around Lake Okeechobee. High lake levels facilitate seed dispersal and inhibit proliferation of aggressive weeds and exotic plants in local habitats. As lake levels decrease, the cleared open habitats allow gourds to germinate and quickly climb onto adjacent trees. Prolonged high or low lake stages are detrimental to the gourd as well, affecting seed germination, plant survival, and encroachment by woody vegetation, eg. Melaleuca.

Crenulate Lead-plant

The crenulate lead-plant (*Amorpha crenulata*) is an endangered shrub endemic to Miami-Dade County. It occurs on marl prairies and wet pinelands. It was Federally listed as endangered species by the USFWS in 1985. The crenulate lead-plant has a restricted range, and is known from only nine sites from Coral Gables to Kendall. Vegetative communities within the historic range of the crenulate lead-plant have been almost entirely destroyed, and its habitat remains threatened by expanding development and agriculture. Fire suppression, invasion by exotic vegetation, and drainage further threatens its habitat.

Deltoid Spurge

Designated by USFWS as endangered in 1985, the deltoid spurge (*Euphorbia deltoidea*) is endemic to Miami-Dade County and occurs from south Miami to the Homestead area. It occurs in the pine rocklands, in areas with an open shrub canopy, on exposed limestone, or along the edges of sand pockets. Ninety-eight percent of its historic range has been destroyed as a result of urban expansion. Periodic fires, necessary to maintain spurge habitat, are routinely suppressed, and exotic plant invasions of spurge habitat threaten the recovery of this plant.

Small's Milkpea

Small's milkpea (*Galactia smallii*) is endemic to the pine rocklands of Miami-Dade County. As with the deltoid spurge, it has been designated by USFWS as endangered since 1985. Due to the nearly total destruction of pine rocklands in Miami-Dade County, habitat is limited and fragmented and difficult to manage. Periodic fires, necessary to maintain appropriate habitat, are routinely suppressed, and exotic plants, most notably *Schinus* and *Neyraudia*, further degrade milkpea habitat.

Tiny Polygala

Tiny polygala (*Polygala smallii*) is listed as an endangered plant species by the USFWS. This short-lived herb occurs along the Atlantic coast, within the Lower East Coast and Martin and St. Lucie Counties. The tiny polygala inhabits the remaining pine rocklands, open sand pine scrub, sandhill, and well drained coastal spoil habitats (Bradley and Gann 1995). The USFWS (1998) Multi-Species Recovery Plan for south Florida, may be referenced for a complete description of tiny polygala habitat occurring in counties within the study area. Tiny polygala populations are estimated to contain roughly 2,000-2,500 individual plants, although tiny polygala is known to exhibit annual fluctuations as much as several hundred percent, season to season (Bradley and Gann 1995, DERM 1993). Environmental factors affecting tiny polygala are similar to those for the deltoid spurge and Small's milkpea.

Garber's Spurge

Garber's spurge (*Euphorbia garberi*) is a short-lived perennial herb known to inhabit pine rocklands, coastal flats, coastal grasslands, and beach ridges in Miami-Dade and Monroe counties, including the Florida Keys. Garber's spurge was listed by the USFWS as an endangered species in 1985 because of habitat loss from residential and commercial development (50 CFR 29349). Cape Sable, Long Pine Key and Big Pine Key all contain populations of Garber's spurge, which typically grow at low elevations, on thin sandy soils, or directly on limestone. As with the other pine rockland herb species above, development, fire suppression and invasive exotics continue to contribute to the overall decline in spurge populations and habitat quality.

Presently twenty-three species of animals occur within the study area that are designated as threatened or endangered by the USFWS. An additional twenty-two species are under review to determine their status. The GFC has identified thirty-two species designated as threatened or endangered which occur within the Everglades. An additional eighteen species are classified as species of special concern. These species and their designation are listed in ***Tables J-1.7-2*** and ***J-1.7-3***.

J.1.7.3 Critical Habitat

Critical Habitat is a Federal term used to formally designate a specific area of habitat to the survival of that species. Of the listed species, Critical Habitat has been designated for the West Indian manatee, snail kite, Cape Sable seaside sparrow and American crocodile. For specific descriptions of these critical habitat geographic designations, refer to the draft Multi-Species Recovery Plan for the Threatened and Endangered Species of south Florida, Volume I (USFWS 1998).

J.1.8 Water Management

The Central and Southern Florida (C&SF) Project has been broken down into four hydrologically related geographical areas consisting of: 1) the Kissimmee River – Istokpoga Basin; 2) the Lake Okeechobee and Everglades Agricultural Area; 3) the Water Conservation Areas, Everglades National Park, and Everglades National Park - South Miami-Dade Conveyance Canals; and 4) the East Coast Canals.

J.1.8.1 Kissimmee River – Istokpoga Basin

The Kissimmee River – Lake Istokpoga Basin portion of the project includes most of Osceola and Okeechobee and parts of Orange, Polk, Highlands, and Glades Counties. It is bounded on the north by the lakes of the Orlando area, on the west by the Peace River watershed, on the south by Lake Okeechobee and on the east by the Upper St. Johns River Basin and the Taylor Creek-Nubbin Slough Basin. The project purposes include flood control, water supply, navigation, and the preservation of fish and wildlife. The project protects the lands adjacent to the lakes and along the Kissimmee River from frequent and prolonged flooding. It provides water supply for agricultural uses in the area in and around the lakes and the Kissimmee River. It also provides for navigation on the Kissimmee River and all lakes in the middle and upper Kissimmee River Basin. Locks are provided at control structures on the main watercourse between East Lake Tohopekaliga and Lake Okeechobee. Boatlifts are provided at all other structures. Maintaining lake stages at a desirable level for fish and wildlife and for recreational purposes is also important.

The Kissimmee Basin is an integrated system of lake storage capabilities and structure outlet capacities. The Upper Kissimmee Basin structures are operated according to regulation schedules. The regulation schedule essentially represents the seasonal and monthly limits of storage that guide the regulation of the project for the planned purposes. The regulation schedules vary from high stages in the late fall and winter to low stages at the beginning of the wet season. The lakes are drawn down in the spring to provide flood control storage and for fish and wildlife enhancement. The minimum levels are set to provide for sufficient flood control storage and navigation depths. The amount of seasonal fluctuation was derived by determining the effect of various water levels on the flood control, low water regulation, groundwater, fish and wildlife, and recreation. Runoff during the wet season is stored for use in the dry season. The regulation schedules take into account these varying, and often, conflicting purposes.

The Lake Istokpoga Project works were primarily designed to protect lands adjacent to the lake from flooding by lake waters and provide water supply for agricultural use in areas around the lake and in the Indian Prairie area. At the same time, project works maintain the lake at a desirable level for fish and wildlife, navigation, and for recreational purposes.

The project has resulted in the reduction of areas inundated by major floods with floodwaters being passed for storage in Lake Okeechobee, and prevention of longer duration of low to no-flow water conditions during prolonged periods of drought in the lower basin. This is accomplished by conserving or storing waters within both the controlled pools behind the existing structures and in the channelways for drought protection. Other effects include year-round small boat navigation of the system from Lake Tohopekaliga to Lake Okeechobee with boat access to the Kissimmee River for fishing and recreation. The C-38 pools add to the total volume of water available for aquatic species support.

J.1.8.2 Lake Okeechobee and Everglades Agricultural Area

Lake water levels in Lake Okeechobee are regulated by a complex system of pumps and locks. The regulation schedule attempts to achieve the multiple-use purposes as well as provide seasonal lake level fluctuations. The schedule maintains a low lake stage to provide both storage capacity and flood protection for surrounding areas during the wet season. During the winter, lake levels may be increased to store water for the upcoming dry season. The general plan of operation for Lake Okeechobee is based on the following: 1) flood protection from lake waters and hurricane-driven wind tides for lands adjacent to the lake; 2) maintenance of an 8-foot navigation channel across Lake Okeechobee, as part of the Okeechobee Waterway and; 3) storage of water to meet the requirements of the agricultural area south and east of the lake.

Flood control works on Lake Okeechobee consist of a system of about 1,000 miles of encircling levees, designed to withstand a severe combination of flood stage and hurricane occurrence, plus the regulatory outlets of St. Lucie Canal and the Caloosahatchee River. The design discharge of Moore Haven Spillway is 9,300 cfs; that of St. Lucie spillway is about 16,000 cfs. Following removal of local runoff from the agricultural areas south of the lake, an additional regulatory capability of several thousand cfs is available through the Miami, North New River, Hillsboro, and West Palm Beach canals by pumping into the three Water Conservation Areas (WCAs). The crest elevation of the levee system surrounding the lake ranges from 32 to 45 ft., NGVD. The likelihood of overtopping the levees from having excess storage is almost non-existent. Possible flooding due to overtopping of levees within the Herbert Hoover Dike system is limited to short duration events involving wave runup in addition to hurricane-induced storm surge. The likelihood of such events is remote and the expected extent of flooding is minimal.

J.1.8.3 Water Conservation Areas (WCAs)

The primary purposes for the WCAs and their appurtenant levees, canals, structures, and pump stations include flood control, water conservation, prevention of salt-water intrusion, recreation, preservation of fish and wildlife, and water supply for Everglades National Park. The WCAs are completely contained by levees, except for about 7 miles on the west side of WCA-3A, which has a tieback levee. There are also levees on the east side of the East Everglades, which protect the agricultural and industrial areas, which otherwise would have been short hydroperiod wetlands, from inundation. This whole region is managed with a system of canals, multiple pump stations, and control structures. The main canals are West Palm Beach Canal, Miami Canal, Bolles and Cross Canals, North New River Canal, South New River Canal, Hillsboro Canal, and Tamiami Canal.

The WCAs provide a detention reservoir for excess water from the agricultural area and parts of the east coast region, and for flood discharge from Lake Okeechobee to the sea. The WCAs provide levees to prevent Everglades floodwaters from inundating the east coast urban areas; provide a water supply for east coast areas and Everglades National Park; improve the water supply for east coast communities by recharging underground freshwater reservoirs; reduce seepage; ameliorate salt-water intrusion in coastal wellfields; and benefit fish and wildlife in the Everglades. The South Miami-Dade Conveyance System provides a way to deliver water to areas of south Miami-Dade County. This canal system was overlaid on top of the existing flood control system. Many of these canals are used to remove water from interior areas to tidewater.

The regulation schedules contain instructions and guidance on how project spillways are to be operated to maintain water levels in the WCAs. The regulation schedule essentially represents the seasonal and monthly limits of storage which guides project regulation for the planned purposes. The schedules vary from high stages in the late fall and winter to low stages at the beginning of the wet season. This seasonal range permits the storage of runoff during the wet season for use during the dry season. In addition, it serves to maintain and preserve the vegetative regimen in the WCAs, which is essential to fish and wildlife and the prevention of wind tides. Regulation schedules must take into account various, and often conflicting, purposes. Conceptually, reservoir storage is commonly divided into the inactive zone, the water supply (conservation) zone, and the flood control zone. The distribution of water between the flood control and water supply zones varies seasonally in the WCAs. The regulation schedules for WCA-1, WCA-2A, and WCA-3A include a minimum water level, as measured in the borrow canals, below which water releases are not permitted unless water is supplied from another source. Note that this does not mean that a minimum stage is maintained in the WCAs. When water levels fall below the minimum levels, transfers from Lake Okeechobee or the WCAs are made to meet water supply demands.

J.1.8.4 East Coast Canals

The East Coast Canals (ECC) are the flood control and outlet works that extend from St. Lucie County southward through Martin, Palm Beach and Broward

Counties to Miami-Dade County, a distance along the Atlantic Coast of about 170 miles. The ECC encompasses the majority of the canals and water control structures located along the lower east coast of Florida. The main design functions of the project canals and structures in the ECC area are to protect the adjacent coastal areas of the east coast of Florida against floods; store water in conservation areas west of the general alignment of the levees; control water elevations in adjacent areas; and provide water for conservation and utilization purposes. There are 40 operating canals, one levee, and 50 operating structures, consisting of 35 spillways, 14 culverts, and 1 pump station. The project works prevent major flood damages. However, due to urbanization, the existing surface water management system now has to handle greater peak flows than in the past.

Areas become flooded during heavy rainfall events due to antecedent conditions that cause saturation and high runoff from both developed and undeveloped areas. The automatic controls installed on some of the water control structures allow them to be placed on low range, which provides limited extra storage in the lakes and canals, increasing the gradient and capacity of the secondary systems. The automatic controls also allow for frequent gate changes that keep the water levels in the safe range. Saltwater intrusion has declined considerably at coastal structures since the installation of salinity dams downstream and the placement of salinity monitoring sensors near the structures. Damage to agriculture, citrus, and pasturelands has been reduced due to the effective drainage capabilities of the canals.

The project works maintain optimum stages for the purposes of flood control, water supply, groundwater recharge, and prevention of salt water intrusion. The coastal canals and control structures between St. Lucie and Miami-Dade Counties are designed to permit rapid removal of floodwaters from their immediately adjacent drainage area. The degree of flood protection provided by outlet capacity is dependent on whether the protected area is urban or agricultural. Maximum rates of removal vary from 40 percent to 100 percent SPF. Many of these coastal area structures have gates that open and close automatically to maintain optimum water levels upstream, with the exception of hurricane or tropical storm regulation. The canals and structures will be regulated automatically or manually, as designed, in accordance with the optimum water control and design elevations.

The network of canals and control structures provides for water and salinity control in the area. Wellfields, which are the source of municipal water supplies, are significantly recharged by conservation area water. Water stored in the WCAs can be used to maintain groundwater levels in the coastal area for public water supply, to irrigate the vast agricultural areas interspersed within the project area, and to maintain a freshwater head along the lower east for salinity control.

J.1.9 Water Quality

This baseline water quality section, together with ***Appendix H***, provides an overview of the existing conditions of the ten regions of the C&SF Restudy study area. Specifically, it identifies water quality parameters potentially affected by the current conditions in the region, selects “key” and additional “other” water quality parameters by region, highlights and discusses three major parameters of regional concern, provides water quality references used for baseline data compilations, and presents narrative on the overall water quality of the region. Surface water conditions are emphasized with some ground water information also being provided.

Because there currently are water quality concerns for several of these parameters, the U.S. Environmental Protection Agency (USEPA) and Florida Department Environmental Protection join the U.S. Army Corps of Engineer’s concerns about the water quality of south Florida. As National Environmental Policy Act Cooperating Agencies to the U.S. Army Corps of Engineers (USACE) for this PEIS, the U.S. Environmental Protection Agency and Florida Department of Environmental Protection encourage the U.S. Army Corps of Engineers to fully consider both water quantity and water quality actions in their hydrologic restoration of south Florida via the Restudy PEIS.

Study Area Regions - As previously indicated in this PEIS, the project area of the C&SF Restudy project area is divided into ten designated regions. These regions are as follows: Kissimmee River Region, Lake Okeechobee, Upper East Coast and Indian River Lagoon (including the St. Lucie River and the Indian River Lagoon), Everglades Agricultural Area, Water Conservation Areas, (including the Loxahatchee National Wildlife Refuge, WCA 2A/2B, WCA 3A/3B, and Holey Land and Rotenberger Wildlife Management Areas), Lower East Coast and Biscayne Bay (including the Loxahatchee River Aquatic Preserve, Lake Worth, and Biscayne Bay), Everglades National Park and Florida Bay (including the Shark River Slough/Taylor Slough, Florida Bay, Whitewater Bay, and Ten Thousand Islands), the Florida Keys, Big Cypress Region, and Caloosahatchee River Region.

Water Quality Parameters and Data - Numerous water quality parameters are potentially affected by the current conditions in the C&SF Restudy project area. This suite of water quality parameters of potential concern consists of metals, pesticides, nutrients, biologicals, physical parameters, and other parameters. These are listed below in ***Table J-1.9-1*** and are further addressed in ***Appendix H*** and its Attachment A. Of these parameters, several “key” parameters of concern were selected for each region. These key parameters were selected (see Table J-1.9.5-1) based on the perceived relevance to the regions and study area and the reasonable availability and accessibility of published data.

Table J-1.9-1
Suite Of Water Quality Parameters Potentially Affected By The Current Conditions Of The C&SF Restudy Project Area

Category	Water Quality Parameter
METALS:	Mercury, Copper, Cadmium, Lead, Zinc, Arsenic, and Tributyltin (TBT)
PESTICIDES:	DDT and Derivatives, Atrazine, Simazine, Ametryn, Endosulfan Compounds, Ethion, Bromacil, 2,4-D, Aldecarb, and Fenamiphos
NUTRIENTS:	Phosphorus, Nitrite/Nitrate, and Ammonia/Unionized Ammonia
BIOLOGICALS:	Fecal Coliforms and Pathogens, and Chlorophyll-a
PHYSICAL:	pH, Dissolved Oxygen, Conductivity, Turbidity, Oil & Grease, Temperature, and Salinity
OTHER	Polycyclic Aromatic Hydrocarbons (PAHs), Dioxins and Furans, Sulfate, Chloride, Polychlorinated Biphenyls (PCBs), and Volatile Organic Carbons (VOCs)

Water Quality Data - Data are compiled by region for those parameters considered "key" for individual regions (see ***Appendix H***), and by region for additional "other" parameters (see Attachment B of ***Appendix H***).

General Regional Conditions - The following overview description of the baseline water quality conditions of the C&SF Restudy project area is primarily based on the Florida Department of Environmental Protection (FDEP) Water Quality Assessment for the State of Florida also known as the 1996 Florida Department of Environmental Protection 305(b) report (FDEP, 1996), the 1997 Everglades Annual Report (Boyer and Jones, 1998), and the U.S. Geological Survey (USGS) Water Quality Assessment of south Florida (USGS, 1996).

The existing water quality conditions in the C&SF Restudy study area are significantly influenced by development related activities throughout the region. Hydrologic alterations have led to significant changes in the landscape by opening large land tracts for urban development and agricultural practices, and by the construction of extensive drainage networks. Natural drainage patterns in the region have been disrupted by the extensive array of levees and canals such that nonpoint runoff (agricultural and urban) is now part of the normal hydrological regime in many areas. Lake Okeechobee is at the center of the south Florida drainage system, receiving flow from the Kissimmee River basin, and to a lesser extent from Everglades Agriculture Area pumps back, and discharges water south and east through five major canals, and to the west through the Caloosahatchee River.

Lake Okeechobee may be considered a naturally eutrophic water body that is tending to become hypereutrophic, due primarily to nutrient inputs from the Kissimmee River and the Taylor Creek basins. Water quality conditions in the upper Kissimmee River appear to be improving, primarily due to rerouting of wastewater flows from the river to reuse and ground-water discharge sites. However, large quantities of nutrients are still discharged from Lake Toho to Lake Kissimmee and other downstream areas. Water quality improves from Lake Kissimmee to near Lake Okeechobee, where the channel flows mostly through unimproved rangeland; however, pollutant loadings increase as cattle and dairies grow more numerous near the lake. The lake's Total Phosphorous levels have doubled in the last decade, due in large part to agricultural runoff. This same runoff also has contributed to frequent and widespread algal blooms and at least one major fish kill. Because the lake's phosphorus is internally recycled and a vast reservoir of the nutrient is stored in ground water as well as wetland and canal sediments, phosphorus may not reach acceptable levels for many decades or even a century.

The Caloosahatchee River forms the major basin to the west of the lake, and exemplifies the water quality patterns throughout the remainder of the C&SF region. Water quality conditions are degraded in the upper and lower areas of the basin, due to agricultural and urban runoff, respectively. The channelized section of the river also shows degraded water quality conditions, due to agricultural inputs, as compared to tributaries lying in less developed areas of the basin. Problems associated with the degraded areas of the basin are typified by low dissolved oxygen levels, elevated conductivity, and decreased biodiversity. Conditions in the urbanized sections of the basin are influenced by nonpoint storm water flows, and are manifested in the river by elevated chlorophyll levels, algal blooms, periodic fish kills, and low dissolved oxygen levels.

Agricultural Best Management Practices (BMPs) have been implemented in the Everglades Agriculture Area however, this area remains a primary source of pollutants for the WCAs. The WCAs form the remnant wetland communities for the northern section of the Everglades system. These areas have been isolated from contiguous lands by a series of levees and pump stations. Water moving south from the lake and Everglades Agriculture Area is pumped through the WCAs, thereby making these areas nutrient filters for downstream basins. The highly altered hydroperiod, resulting from the levees and pump schedules, may exacerbate water quality conditions in the WCAs, as evidence by a general degradation of quality in the areas along the canals and pump stations, as compared to conditions in the central portions of the basins. Construction of the Stormwater Treatment Areas upstream of the WCAs will serve to improve water quality conditions in the latter through time; however, other problems may persist. No consumption advisories for largemouth bass have been issued for portions of the WCAs due to mercury contamination.

Water quality conditions along the Upper East Coast are rated as good in less developed areas of the basin. However, conditions are degraded in urbanized areas and along the extensive network of canals that drain this area. The worst water quality conditions in the Upper East Coast basin are reported in the St. Lucie River and the canals leading from the Everglades Agriculture Area. Other major problem areas are found in Five Mile and Ten Mile creeks (in the areas near Port St. Lucie), the main channel of North Fork in Port St. Lucie, and Manatee Pocket, a small port on the St. Lucie Estuary. Although the Savannas State Preserve, a 15 mile long freshwater marsh between Ft. Pierce and Stuart, has fairly good water quality, mercury concentrations in fish tissue were high enough to warrant a no consumption advisory for Largemouth bass. As described above, the major sources of pollution in this basin are urban runoff, agriculture, rangeland runoff, boat discharge, and sewage overflows.

Water bodies in the Lower East Coast basin are seriously degraded in the heavily urbanized areas, included the numerous man-made canals associated with the coast and drainage canals. This trend becomes obvious in Lake Worth, which has good water quality near the inlet and fair to good water quality north of the inlet, but poorer water quality to the south, especially in the area around the inlet to the West Palm Beach Canal. Water quality improves again at the South Lake Worth Inlet and near Boca Raton Inlet. A small section of the North Fork of the Loxahatchee River has low dissolved oxygen levels, and waters in Jonathan Dickinson State Park have high coliform bacteria counts. In the last decade, seagrass beds in the estuarine portion of the Loxahatchee River have declined dramatically. Canals and water bodies in and around Ft. Lauderdale are particularly degraded by urban runoff and historical wastewater treatment discharges, and in the westernmost areas on the canals by agricultural runoff. Problems associated with these pollutants are manifested in the canals dense growth of weeds, low biological diversity, and the occurrence of exotic plants and animals. The New and Miami Rivers run through highly urbanized areas of Ft. Lauderdale and Miami, respectively. Both are polluted by improperly functioning septic tanks, illegal discharges from vessels, industrial activities, illegal sewer connections, and storm water runoff. These discharges result in high nutrient pollution, high coliform bacteria counts, and heavy metals such as tin, copper, zinc, and chromium in sediments at all marina sites. Biscayne Bay has good water quality in the open water areas of the bay, and degraded conditions associated with the canals and their discharge points.

The phosphorus concentrations entering the Everglades National Park were lower in 1997 than the interim and long term limits established by the 1992 Settlement Agreement. While no significant trends in annual average mercury concentrations in water, sediment, or fish have been observed for the past five years, mercury concentrations in fish tissue were high enough to warrant a no-consumption advisory for Largemouth bass throughout most of the eastern two thirds of the Everglades National Park, and a recommendation of limited consumption for the southeast east corner of Everglades National Park. The best water quality conditions in the Everglades National Park were found along the coastal regions of the basin. Some parts of Florida Bay have experienced a massive seagrass and mangrove die-off, that likely stems from a lack of flushing from hurricanes, high water temperatures, and high levels of salinity. Water diverted into canals has reduced freshwater flows, and the salinity of bay water has been recorded as high as 70 ppt. The 1997 Everglades Annual Report states that for 1997, the highest observed salinity levels occurred in Whipray Bay, and ranged from 40.6 ppt to 42.3 ppt (water conditions in the bay are considered hypersaline when salinity exceeds 35 ppt). Hypersaline conditions were observed throughout most of the western portion of the bay during the dry season; however, they decreased below hypersaline levels once freshwater inputs increased in June 1997.

Water quality conditions in the Keys are generally good in areas open to the Atlantic or Gulf of Mexico. However, many manmade canals and marinas have water quality problems that are exacerbated by decreased flushing. Most of these problems are localized and generally can be attributed to wastewater plants and small "package plants" discharging to poorly flushed canals, septic tanks and cesspools, marinas lacking facilities to pump out waste from boats, fish processors, and storm water runoff, especially into the canals.

J.1.9.1 Water Quality Regulations and Standards Applicable to Region

Several Federal, State and Tribal regulations and standards are relevant to water quality maintenance in the C&SF Restudy region. These include the Federal Clean Water Act (CWA) and the Federal Safe Drinking Water Act; the State of Florida Everglades Forever Act, State Water Quality Regulations (i.e., Florida Statutes section 373 (Water Resources) and Florida statutes section 403 (Environmental Control), Surface Water Standards, Beneficial Use Classifications (Classes I-V), Ground Water Quality Standards, and Drinking Water Standards; and the Tribal Codes (Seminole Tribe of Florida Water Code and the Miccosukee Tribe of Indians of Florida Environmental Protection Code). Summaries of these regulations and standards are provided in ***Appendix H*** and its Attachment C. A related litigative action, the 1992 Settlement Agreement, is also relevant to the region and is summarized in ***Appendix H.***

In addition, U.S. Environmental Protection Agency or State of Florida aquatic life criteria (if established) and U.S. Environmental Protection Agency human health criteria (if established) are presented in (see Table H.1.4.1-1 in ***Appendix H***) for the suite of water quality parameters introduced previously in Section 1.9.1. In the absence of U.S. Environmental Protection Agency aquatic criterion or if the State of Florida criterion was more stringent than the U.S. Environmental Protection Agency criterion, the State of Florida criterion is listed. The table was developed from updates of U.S. Environmental Protection Agency (1986) and also references the State of Florida F.A.C. 62-302 for State pesticide criteria.

J.1.9.2 Regional Water Quality Monitoring

The following discussion summarizes current State and Federal Water Quality monitoring efforts within the existing study area.

Federal Monitoring

The U.S. Geological Survey, U.S. Environmental Protection Agency, and U.S. Army Corps of Engineers are conducting Federal water quality monitoring in south Florida.

The U.S. Geological Survey has conducted extensive long-term monitoring of surface water and groundwater quality at hundreds of locations throughout the south Florida ecosystem. This monitoring has included water physical parameters, nutrients, ions, metals, pesticides and other organic compounds. The U.S. Geological Survey (1996) has provided an overview of available information on surface water and ground water quality for waterbodies throughout the ecosystem. In 1993, the U.S. Environmental Protection Agency initiated the Regional Environmental Monitoring and Assessment Program (REMAP), which is the only system wide monitoring of the freshwater Everglades ecosystem (USEPA, 1996). This program monitors nutrient, phosphorus, mercury, water management, and habitat indicators. Such information is important for assessing ecosystem health and tracking the effectiveness of the Project Restudy and other efforts directed at ecosystem protection or restoration. The U.S. Army Corps of Engineers has also conducted water quality monitoring at key locations throughout south Florida.

The U.S. Army Corps of Engineers has historically conducted water quality monitoring at key locations throughout south Florida. Monitoring efforts have been undertaken around Lake Okeechoobee, the Loxahatchee NWR, Water Conservation Areas 1-3, and the Upper St. Johns portion of the C&SF project. Water quality data including field parameters, nutrients, metals, pesticides, and inorganic constituents are available from those programs. Funding and manpower considerations have changed the scope of this program several times in the last several years from long-term operation and maintenance efforts to more short-term synoptic studies associated with specific events or projects. As part of a long term effort the U.S. Army Corps of Engineers continues to maintain several water quality monitoring stations at 1) inflows to Everglades National Park, 2) stations required for operation of some of the features of the Modified Water Deliveries to Everglades National Park project, and 3) in the Upper St. Johns Project.

Because of the historical impacts and the difficulty in finding a concise, yet comprehensive, water quality data set addressing the entire system, phosphorus has been the Restudy's primary focus. Understanding is incomplete about the types, concentrations and loads of pollutants that are causing ecological problems and likely to create future ecological problems at critical locations. This lack of understanding exists in spite of a significant collective monitoring effort. A number of different agencies routinely collect large quantities of water quality data in the region, yet this data is seldom collected in conjunction with important events such as agricultural pesticide and fertilizer applications, major stormwater discharges or pumping activities. Many monitoring programs are localized efforts collecting data at fixed locations at scheduled times, which are then stored in databases and seldom used. When pollution impacts do become evident, existing monitoring efforts are often unable to identify the source or cause of the impacts. A detailed water quality monitoring program that is well coordinated among the collecting agencies is necessary to adequately ensure that water quality considerations are included in the stages of the design process for project features."

State of Florida Monitoring

The Florida Department of Environmental Protection and the South Florida Water Management District (SFWMD) conduct State of Florida water quality monitoring. Monitoring includes surface water, ground water and atmospheric deposition. Key references for these monitoring programs are South Florida Water Management District (1998a) and the Florida Department of Environmental Protection website (FDEP, 1998: internet). Florida counties also have various monitoring programs.

The Florida Department of Environmental Protection has developed an integrated ambient monitoring network to address point and nonpoint sources of pollution, BMPs, pesticides, habitat area, atmospheric deposition, land use/land cover, and the interactions of surface and ground waters. The South Florida Water Management District has grouped its 40 individual monitoring programs together under 24 main networks, where 22 are geographic areas and the other two (pesticide and atmospheric deposition) monitoring programs are District wide (SFWMD, 1998a).

J.1.9.3 Regional Water Quality Parameters and Pollutants of Concern

The suite of water quality parameters potentially affected by the existing conditions of the C&SF Restudy region were introduced in Section H.1.1. These water quality parameters were grouped as metals, nutrients, biologicals, physical parameters, and other parameters. Of this list, mercury, phosphorus and pesticides are considered three of the most important water quality parameters of the region. These three are described below.

Mercury

Mercury is a toxic heavy metal. Levels of mercury in south Florida water, animal tissue, sediment, periphyton, air, and soil have been shown by U.S. Environmental Protection Agency (1998) and other State and Federal agencies and other entities such as universities to be elevated in certain areas of south Florida. However, the sources, distribution, magnitude, transport, transformations and pathways of mercury through the south Florida ecosystem are poorly understood. Among the possible mercury sources in south Florida are natural mineral and peat deposits (Rood et al., 1995), and atmospheric deposition from global, regional and local (e.g., fossil fuel fired electrical generating plants, municipal waste incinerators, medical waste incinerators, paint operations, and agricultural operations) sources. Sources of mercury are now believed to primarily be from atmospheric deposition. Once elemental mercury is methylated by microbial action, it becomes biologically available for bioaccumulation at various levels of the food chain and for biomagnification up the food chain to top carnivores such as the Florida panther. Mercury is generally analyzed as total mercury (HgT) or methylmercury (HgMe) and measured in parts per trillion (ppt) or parts per billion (ppb).

Phosphorus

Phosphorus is a nutrient that often controls primary productivity in aquatic systems. Excess phosphorus entering natural systems is a result of many human activities, with urban runoff, agriculture, construction, development, sewage, and sewage treatment effluents, chief among them. The ecological significance of phosphorus loading in water bodies is increased primary productivity, loss of water column dissolved oxygen, algal blooms and changes in biodiversity. These may ultimately result in the loss of a waterbody's usefulness for recreation or as habitat for wildlife. In south Florida, agricultural practices in the Everglades Agriculture Area and other agricultural areas surrounding Lake Okeechobee have been a major source of phosphorus due to fertilizer applications and field runoff and southward migration through the Everglades. Phosphorus is considered a key water quality parameter of concern in this section for all ten regions considered in this PEIS for the study area (see Table J-1.9.4-1). Water concentrations of phosphorus are often analyzed as Total Phosphorus (TP) and measured in milligrams per liter (mg/L) or micrograms per liter (µg/L).

Pesticides

An extensive array of pesticides is applied to (or persists in) south Florida waters, sediments and/or soils. The south Florida region is unique in that a very large and sensitive ecosystem exists in the midst of an evergrowing urban population and an extensive and intensive agricultural production area. A variety of pesticides are used in this area for a number of different reasons. Major uses are ground and/or aerial applications related to agricultural production, mosquito control, and aquatic plant growth in local waterways, golf course maintenace, and homeowner lawn and vegetation maintenance. Pesticides used in these ways are effective in controlling the pest of concern; however, the use of pesticides may also pose possible threats to the sensitive ecosystems in Florida due to the intense year round agriculture, coupled with the shallow water tables and the ever increasing urban sprawl that demands an increasing supply of quality water.

J.1.9.4 General Overview of Current Regional Water Quality Conditions

Presented below is an overview of regional water quality concerns for ground water and surface water within the study area.

Groundwater Conditions

Groundwater in south Florida consists of the surficial Biscayne aquifer and the Floridan aquifer. Both are critical to south Florida inhabitants and industry. The Biscayne aquifer has been classified as a Sole Source Aquifer under the Safe Drinking Water Act based on the aquifer's susceptibility to contamination and the fact that it is a principal source of drinking water. The Floridan aquifer system is one of the most productive aquifers in the world and is a multiple use aquifer system. Where it contains freshwater, it is the principal source of water supply. In several places where the aquifer contains saltwater, such as along the southeastern coast of Florida, treated sewage and industrial wastes are injected into it.

Because the Biscayne aquifer is highly permeable and is at or near the land surface practically everywhere, it is readily susceptible to groundwater contamination. Major sources of contamination are saltwater encroachment and infiltration of contaminants carried in canal water. Additional sources include direct infiltration of contaminants, such as chemicals or pesticides applied to or spilled on the land, or fertilizer carried in surface runoff, landfills, septic tanks, sewage plant treatment ponds, and wells used to dispose of storm water runoff or industrial waste. Numerous hazardous waste sites (e.g., Superfund and Resource Conservation and Recovery Act (RCRA) sites) have been identified in the area underlain by the Biscayne aquifer. Remedial action to cleanup existing contamination is underway at many of these sites, and waste management practices are generally monitored to prevent further contamination. Additional information on groundwater conditions and contamination in south Florida is presented in ***Appendix H***, including specific Superfund (National Priority List: NPL) and RCRA hazardous waste sites in south Florida. Trichloroethylene (TCE) and vinyl chloride are examples of groundwater contaminants of concern.

Surface Water Conditions

As previously suggested, perhaps the three most important water quality parameters of concern in the C&SF Restudy region are mercury, phosphorus, and pesticides. These are discussed below from a regional perspective. A more detailed discussion can be found in ***Appendix H*** and its Attachment E (mercury).

Mercury

Prior to the turn of the century, most of the mercury in the Everglades peat probably came from natural sources. Mercury deposition rates have increased about five fold since then. Some of this historically accumulated mercury is being recycled by the south Florida ecosystem; however, a mercury cycling model developed by Ambrose et al. (1998) indicates that this historical mercury can be buried beneath the recycling zone by accumulating peat if new sources are shut off, and that this process occurs in a timeframe of a decade, not a century. Potential sources of new mercury to the south Florida ecosystem include Lake Okeechobee releases, Everglades Agriculture Area runoff, and atmospheric deposition. It is now believed that atmospheric deposition may contribute more than 95 percent of the new mercury load to south Florida annually. Further study is required to quantify the relative contributions of local and global sources to the new mercury entering the study area. If local mercury sources, like municipal and medical waste incinerators, are making a significant contribution, rules limiting mercury in feed stocks and air emissions should result in a substantial benefit to the system.

The central Everglades is a wide, shallow, slow moving river. It has a large surface area for atmospheric deposition and methylation of mercury ions with little dilution other than rain. In order to further synthesize and integrate the interactions of the water quality and biota, the central Everglades flowway was parsed by latitude into seven units averaging approximately 27 km in length (north-south) over a total distance of 189 km (USEPA, 1998). Latitudinal parsing of the data aggregated the subtle patterns in plant and floating periphyton responses relative to TP concentrations in the system. These data indicated that TP affects the spatial distributions of emergent plant communities, floating periphyton presence, aquatic habitat and food web complexity, which in turn affect mosquitofish growth, biodilution and bioaccumulation of methylmercury (HgMe) in the system.

The canal data indicated that mercury interactions with Total Organic Carbon (TOC) and Sulfate (SO4), and biodilution of mercury in mosquitofish where TP concentrations were high, resulted in lower mosquitofish mercury concentrations north of Alligator Alley. However, South of Alligator Alley where TP, TOC, and SO4 concentrations declined, there was increased bioaccumulation of mercury in mosquitofish and periphyton, until TP declined to a median of 13.9 ug/L, when both biodilution and bioaccumulation of mercury declined. These data suggest that high methylmercury concentrations in water in the northern Everglades did not lead to high Total Mercury (HgT) in mosquitofish (HgT in mosquitofish = 95 percent HgMe) due to interactions with other constituents, biodilution, and associated changes in the food chain (USEPA, 1998).

The marsh data were more definitive, indicating mercury biodilution north of Alligator Alley and mercury interactions with TOC and SO4. As median TP declined from 16 to 12 µg/L, however, the median mercury concentration in mosquitofish nearly doubled to 208 µg/L and remained high south through the northern portion of the Everglades National Park. However, the mercury concentration in mosquitofish declined to 156 µg/kg in the southern portion of the Everglades National Park where median TP in water declined to 8.6 µg/L, indicating the absence of an inverse relationship between TP in water and mercury in mosquitofish in the southern Everglades. Median methylmercury concentrations in water declined north-to-south in both canal (i.e., 0.3 to 0.06 ng/L) and marsh (i.e., 0.54 to 0.15 ng/L) habitats indicating higher methylation occurred in the marsh. The marsh median mosquitofish Bioaccumulation Factor (BAF) for mercury increased from 0.6 x 105 in the north to 8.5 x 105 in southern Everglades National Park, indicating an increasing bioaccumulation efficiency in the food chain from northern-to-southern areas. Total mercury in periphyton, great egrets, and mosquitofish was spatially correlated with a mercury "hot spot' between Alligator Alley and Tamiami Trail. The stimulatory effects of TP on the plant communities and the methylating microbes appears to be a key component in mercury contamination.

Nearly all of the methylmercury in the south Florida ecosystem is produced internally. Only a fraction of the new and old mercury cycling is in a form that can be readily transformed into methylmercury. Numerous hypotheses have evolved over the last several years to explain the role of water quality in mercury methylation and bioaccumulation. While there is no single hypothesis that will explain the governance of methylmercury in this system, the effects of anthropogenic phosphorus exerts the most pervasive impact on this ultra-oligotrophic system. Even slight increases of phosphorus can act directly to increase the activity of both producers and decomposers in this system which can result in both increased biological production of green plant matter, diluting the bioconcentration of mercury, as well as an increased activity of the decomposing bacteria which can indirectly result in increased areas devoid of oxygen, further favoring the activities of methylating bacteria. Extreme increases in phosphorus, which occur in the northern Everglades, can maximize the production of methylmercury in the water while simultaneously altering the plant communities to pollution tolerant types (e.g., filamentous and bluegreen algae; cattails) and changing the food web sufficiently to severely reduce the bioaccumulation efficiency of methylmercury in fish. The complexity increases with the introduction of large amounts of sulfate into WCA-2 north of Alligator Alley which is rapidly reduced to sulfides providing an additional stimulatory effect on the methylating sulfur reducing bacteria in the marsh. The declining north-south gradients of TP, TOC, and HgMe in water are similar, while large amounts of sulfate only impact WCA-2. In contrast, total mercury in mosquitofish is lowest where phosphorus and sulfate are highest, and mercury is highest in mosquitofish where phosphorus moderates and sulfate is near background.

The lowest mercury in fish occurs in the southern Everglades National Park where phosphorus is lowest and the least methylmercury occurs in water. The rapid increase in the bioaccumulation factor from north-to south indicates a recovery in the structure and efficiency of the food web, where phosphorus concentrations decline to near background. These complex interactions cannot be explained by a single hypothesis but by several interacting together. Simultaneous controls of local atmospheric mercury emissions in concert with the phosphorus control strategies underway and the associated control of carbon, oxygen and sulfur, should result in the reduction of available inorganic and organic mercury in this system during the next several decades.

Based on the system-wide spatial data collected to date, it is apparent that the problems facing the south Florida ecosystem are highly interdependent. Approaches to restoring the ecosystem should follow a system wide methodology to address the interactive nature of the system. Additional technical findings are presented in a draft U.S. Environmental Protection Agency technical report (USEPA, 1998).

Phosphorus

Historically, south Florida waters were low nutrient waters (i.e., an oligotrophic system). Due to anthropogenic activities including the ditching and draining of wetlands and the expansion of agricultural practices applying fertilizers, waterbodies from the Kissimmee River southward have become nutrient ladened to various degrees. This is due to water body receipt of agricultural runoff from such land uses as pastures truck farming, and sugar cane fields. The Everglades Agriculture Area is one such area of farming, although the farming areas surrounding Lake Okeechobee in general have contributed to elevated nutrients in the Kissimmee River, Lake Okeechobee, the Caloosahatchee River, and the

Everglades. In addition, urban storm water runoff is another potential source of phosphorus to the natural areas and coastal systems of south Florida. Elevated phosphorus loading of waterbodies and the resulting increased water phosphorus concentrations (eutrophication) may have various ecological effects. These effects may include increased primary productivity, loss of water column dissolved oxygen, algal blooms, and changes in vegetation and biodiversity. The significance of such phosphorus loading may be the reduction or loss of a waterbody's habitat and/or recreational value.

The most significantly elevated nutrient in south Florida is phosphorus. In general, the trend for phosphorus concentrations is a decrease from north (Kissimmee River and Everglades Agriculture Area) to south (Everglades National Park) since the major anthropogenic sources are in the agricultural areas. Nutrient removal from marsh water is due to the natural water quality treatment processes associated with south Florida wetlands, notably the Everglades. Phosphorus levels in water bodies throughout south Florida have been summarized by the U.S. Geological Survey (1996). The highest concentrations (about 100 to 200 ppb) are in water discharged from the Kissimmee River, Lake Okeechobee, the Everglades Agriculture Area, the Caloosahatchee River, and the St. Lucie Canal. The lowest concentrations (about 10 ppb) are reported for marsh stations within the Everglades National Park. The Florida Everglades Forever Act (EFA) specifies that a yet to be established numeric phosphorus criterion is to be established for the Everglades by the State of Florida and then approved by the U.S. Environmental Protection Agency, or a default level of 10 ppb will be implemented. Currently, stormwater treatment areas (STAs) established by the EFA and being implemented by the approved U.S. Army Corps of Engineers, Everglades Construction Project would reduce phosphorus levels in agricultural runoff (in addition to the agricultural BMPs being implemented). A pilot STA, i.e., the Everglades Nutrient Removal (ENR) Project, is currently functioning and reducing phosphorus levels to less than 30 ppb. Additional STA treatment (Phase II) would be needed to reduce concentrations to levels in the range of the 10 ppb default level.

Pesticides

Three major areas of agricultural production are present in south Florida: 1) Miami-Dade County (which, relevant to agriculture, is located in the region designated in this PEIS as the Lower East Coast and Biscayne Bay); 2) the agricultural areas surrounding Lake Okeechobee (consisting of Palm Beach, Hendry, Glades and Martin Counties, which, relevant to agriculture, are located in the regions designated in this PEIS as the Kissimmee River Region, Upper East Coast and Indian River Lagoon, Lower East Coast and Biscayne Bay, Everglades Agricultural Area, Big Cypress Region, and Caloosahatchee River Region); and 3) Collier County (which is located in the regions designated in this PEIS as the Big Cypress Region and the Caloosahatchee River Region). Miami-Dade County ranks among the top counties in winter vegetable production in the U.S. and is number one in tropical fruit production. Agriculture in the four Everglades Agriculture Area counties includes sugar cane and truck farming. Collier County has approximately one third of its land utilized for agricultural purposes. Pesticide transport to the Everglades National Park from these three major agricultural areas can occur through hydrological connection to Everglades National Park from all three areas. Field studies have detected the presence of endosulfan and other pesticides in Florida Bay, especially near the C-111 basin (Scott et al. 1994; Scott et al. 1995). NOAA is continuing work on an ecotoxicological assessment of endosulfin and other potential endocrine-disrupting chemicals on living marine resources in Florida Bay.

The only long term pesticide monitoring in the C&SF Restudy project area is being conducted by the South Florida Water Management District (R. Pfeuffer: SFWMD, 1998 personal communication). The District has maintained a pesticide monitoring program in south Florida since 1984. The pesticide monitoring network includes sites designated in the Everglades National Park Memorandum of Agreement, the Miccosukee Tribe Memorandum of Agreement, the Lake Okeechobee Operating Permit and the Non-Everglades Construction Project Structure Permit. The monitoring provides data to determine the condition or changes in the quality of water being delivered to Lake Okeechobee, Everglades National Park, and the WCAs and Florida Bay. Additional pesticide residue data are collected to determine water quality conditions at the major water control structures throughout the District. The data collected for each sampling event provide information on potential short term, acute environmental effects for any of the compounds detected. An indication of possible fish toxicity, bioaccumulation for wildlife, or human health impacts can also be inferred from the data. The program has been dynamic over time, as concerns arise about pesticide use within the District, to accommodate sampling for new pesticides and the addition of sampling sites to the network. The current monitoring program consists of analyses for 66 pesticides at 37 sites within District boundaries. This set of compounds includes chemicals currently utilized in the associated agricultural areas, chemicals regulated by Florida's Surface Water Quality Standards (F.A.C. 62-302), and restricted use pesticides.

Regional 303(d) Impaired Waterways

Section 303(d) of the Federal Clean Water Act and the U.S. Environmental Protection Agency, Water Quality Planning and Management Regulations (40 CFR Part 130) require States to develop Total Maximum Daily Loads (TMDLs) for their water bodies that are not meeting designated uses under technology-based controls for pollution. The TMDL process establishes the allowable loadings of pollutants or other quantifiable parameters for a water body based on the relationship between pollution sources and instream water quality conditions, so that States can establish water quality based controls to reduce pollution from both point and nonpoint sources and restore and maintain the quality of their water resources. The Section 303(d) list, which is prepared every two years, is based on priority water bodies identified as part of the Florida Surface Water Improvement and Management (SWIM) Act and data from the 1996 Florida Department of Environmental Protection 305(b) report (FDEP, 1996).

Several water bodies/segments in the C&SF Restudy region are listed on the 1998 303(d) list. The number of 1998 priority water bodies/segments in each of the basins listed in the 1996 305 (b) report relevant to the C&SF Restudy study area are as follows: Kissimmee River Basin (29), Lake Okeechobee (12), Caloosahatchee River Basin (11), Everglades-West Coast or Big Cypress Basin (14), Southeast Florida Basin (95), and the Florida Keys (0). These basins are further discussed (and are related to the corresponding region(s) designated in this PEIS) in ***Appendix H***, including Table H.1.5.1.2.2-1.

Approach to Baseline Water Quality Data Compilation

A suite of baseline water quality parameters potentially affected by the existing conditions of the C&SF Restudy region were introduced in Section 1.9.1 and described in ***Appendix H*** and its Attachment A. Subsets of these parameters of potential concern were considered "key" degraded parameters for the study area. Those considered key for each of the ten regions designated in this PEIS and is presented below by region in ***Table J-1.9.4-1***. These key parameters were selected based on the perceived relevance to the regions and study area and the reasonable availability and accessibility of published data.

Baseline water quality conditions described in this section were primarily taken from South Florida Water Management District, Florida Department of Environmental Protection, and U.S. Environmental Protection Agency references. Data in published references were chiefly relied upon, as opposed to more recent but raw sampling data. The notable exception to this approach was the use of South Florida Water Management District raw database (SFWMD, 1998: unpublished) used to compile water quality data for the Florida Bay and Whitewater Bay (areas of the Everglades National Park and Florida Bay region designated in this PEIS) for which published data were limited. This database (1991-1997) was made available by the South Florida Water Management District through personal communication (M. Slayton, SFWMD) in 1998 and was reduced to means and medians by U.S. Environmental Protection Agency contractor. In addition, summarized pesticide monitoring data (1992-1997) were obtained through 1998 personal communication with the South Florida Water Management District (R. Pfeuffer).

Table J-1.9.4-1
Listing Of Key Water Quality Parameters
Considered Degraded Within The C&SF Restudy Project Area

Physiographic Region	Water Quality Parameter
Kissimmee River	TP, NOx, DO
Lake Okeechobee	TP, NOx, Chlorophyll-a, turbidity, chlorine
Upper East Coast & Indian River Lagoon	TP, pesticides, DO, mercury and other heavy metals, NOx, salinity, coliformes
Everglades Agricultural Area	TP, pesticides, mercury, NOx, DO, conductivity
Water Conservation Areas	TP, DO, conductivity, mercury, NOx
Lower East Coast & Biscayne Bay	TP, DO, mercury, NOx, coliforms, salinity, heavy metals, turbidity, VOCs, TBT
Everglades Natl Park & Florida Bay	TP, mercury, salinity, chlorophyll-a
Florida Keys	TP, NOx, DO, turbidity, chlorophyll-a, coliforms
Big Cypress	TP, NOx, DO
Caloosahatchee River	TP, pesticides, NOx, DO, conductivity

DO = Dissolved Oxygen
NOx = Nitrite/Nitrate Nitrogen
TP = Total Phosphorus
TBT = Tributyltin
VOCs = Volatile Organic Compounds

Reliance on published data resulted in the typical period of record for the data being from the late 1980's to the early 1990's. However, the specific period of record ranged from 1973 to 1997 and included some very recent (1996-1998) published data such as the U.S. Environmental Protection Agency mercury data (USEPA, 1998), the South Florida Water Management District, Everglades data (SFWMD, 1998b), and the Florida International University Florida Keys data (Boyer and Jones, 1998). The established baseline year for this PEIS is 1995.

J.1.10 Water Supply

There is no evidence that the climate in south Florida has changed sufficiently to alter the dry and wet season rainfall patterns since the first attempts to drain the Everglades. Many people believe, therefore, that restoration is possible, even with the water supply requirements of the urban and agricultural community, given that the sharply-reduced size of the Everglades will reduce its demand for water.

One of the primary functions of the C&SF Project is to provide a highly-efficient flood control system designed to keep urban and agricultural areas dry in the wet season by discharging excess water to tide or into the WCAs and Everglades National Park. Rapid wet season flood releases, coupled with the lack of retention in Lake Okeechobee, the northern historical sawgrass plains, and the eastern peripheral wetlands and sloughs, have severely reduced storage within the system causing excessive dry season demands on the regional system. The sawgrass plains, for example, once stored and slowly passed on much of the water that overflowed from the Lake. Today, a large portion of the sawgrass plains habitat that was converted to agriculture within the Everglades Agricultural Area, quickly passes excess runoff to the WCAs and the coast during the wet season. Releases of Lake Okeechobee water are then necessary to meet dry season demands. The lack of storage, not the lack of water, is the problem.

Minimum levels for Lower East Coast canals are set by Florida Legislation principally to provide the volume of water needed to protect the Biscayne aquifer from saltwater intrusion, a major threat to this water resource. The head created in the canals raises groundwater levels, recharging the aquifer and the urban wellfields. During the wet season, wellfields are recharged by local rainfall and by the regional system that provides ongoing seepage from the WCAs and the canals. During the dry season, they are more dependent on the regional system. Unfortunately, during the wet season, “excess” storm water is passed through the canals and out to tide when it should be stored and used during the dry season. Without sufficient storage, it has been difficult to have water available during the dry season without causing flooding during the wet season.

Water users within the urban areas argue that the Lower East Coast is largely self-sufficient and efficient because the ground water seeping through the Lower East Coast would eventually reach coastal waters were it not withdrawn by the utilities. The SFWMM illustrates how this works. As demands increase, the volume of water that reaches coastal waters decreases. In the SFWMM, at Snake Creek, north of Miami, 121,000 ac-ft of water was lost through groundwater seepage during the wet season in the 1995 base. That amount decreased to 114,000 ac-ft in the 2050 base as urban water supply demand increased. In the Miami River, in the 1995 base, over 192,000 ac-ft was unrecoverable (wet and dry season total). In the 2050 base, only 121,000 ac-ft was unrecoverable.

Others argue that the urban area is far from self-sufficient. While the pattern described above occurs during wet seasons and during normal rainfall years, during extremely dry years, no water reaches the coast and the urban wellfields depend heavily on the WCAs, (including the ongoing seepage from these areas), the canals, and Lake Okeechobee for water supplies. Even during normal dry seasons when flood releases are minimal, the high demands on the system from urban water supply may be withdrawing water from the natural environment that should be kept in the system for late winter and spring biological rejuvenation. In addition, during drought years, the urban and agricultural areas create additional demands as the need for irrigation increases. Also, a significant percentage of the per capita use of water goes towards landscape maintenance, primarily watering lawns from shallow wells.

In a related issue, one concern is that, at present, the flow of water along the eastern protective levee is from the wetlands to the coast. Some argue that keeping the water levels high west of the Atlantic coastal ridge, and keeping levels low to the east of it, results in large groundwater losses from the remnant Everglades throughout the year. This situation might severely reduce the coastal groundwater flows into estuaries like Biscayne Bay and has made it necessary to import regional water to the Lower East Coast to maintain adequate coastal groundwater levels to prevent saltwater intrusion.

The amount of water needed to recharge urban wellfields is small compared to the tremendous volumes needed to prevent saltwater intrusion. Preventing saltwater intrusion is important for several reasons. For example, if significant saltwater intrusion occurred even once, the easternmost wellfields would be contaminated indefinitely and would be replaced with wells further west. This situation has already occurred in Metro-Dade County.

Although significant, the amount of water needed to prevent saltwater intrusion is much less than the wet season coastal releases. It is possible that those flows alone, if captured and stored, would be more than sufficient to maintain the dry season salinity barriers without the need to take water from the natural system. Also, retaining coastal outflows near the coast and maintaining higher groundwater levels along the coastal ridge would allow large quantities of regional water to be used for dry-season environmental benefits.

Within the Lower East Coast, there are also ecological benefits in maintaining groundwater levels. Lower groundwater levels can and have had serious negative effects on estuaries. Biscayne Bay for example, has suffered the consequences of both ground and surface water losses, including increased salinity, lower visibility, and lower water quality. Alternative 3 simulated cutting off groundwater seepage from the WCAs, which reduced flows to Biscayne Bay from 20 percent to 55 percent. In south Miami-Dade County, lowered groundwater levels have caused wetland desiccation and produced shifts in vegetation types.

J.1.11 Socio-Economics

The economic system is connected with the natural ecosystem and in general is ultimately dependent upon it for survival. Changes in the economic system can cause change in the natural ecosystem and vice versa. It is significant, therefore, to describe and understand the general economic and social environment within which such changes could take place.

Economic and demographic data for the study area, comprised of 16 south Florida counties (parts of some, others in entirety), can be viewed from a variety of vantagepoints. No matter how viewed, the picture which emerges is that of higher average incomes, and greater economic and population growth than for the rest of the state and the nation. This is particularly true of southeast Florida, and while true in terms of the overall study area, some localities do not share in this overall trend. Other key important features are agricultural activity, fishing, tourism, and recreation.

The south Florida study area is home to just over 6 million people, about half of Florida's population. This relationship between the study area's population and the state population is likely to continue. Population growth continues to exceed the national rate, although growth is slowing.

Strong wholesale and retail trade, government and service sectors characterize Florida’s economy. Florida's warm weather and extensive coastline attracts vacationers and other visitors and helps to make the State a significant retirement destination for people from all over the country. Agricultural production and fisheries are also important sectors of the state's economy, and are especially significant to portions of the study area. In comparison to the national economy, the manufacturing sector has played less of a role in Florida. High technology manufacturing has begun to emerge as a significant sector in the State over the last decade.

Most of the population and economic activity in the study area is concentrated along the Lower East Coast (Miami-Dade, Broward, and Palm Beach Counties). Per capita income (PCI) for the study area as a whole is above that for the state. The Lower East Coast, three-county area's PCI is even higher. The remaining area is by comparison sparsely populated and is the location of important natural environment and agricultural areas, as well as Seminole and Miccosukee Native American tribal lands.

J.1.11.1 Population

The 16 south Florida counties that make up the study area had a 1990 population of 6.3 million, accounting for nearly half (almost 49 percent) of Florida's total. This share has changed very little over the past 20 years and recent United States Department of Commerce projections predict it will remain stable over the next 50 years. Over 60 percent of this south Florida population is in the three southeast coast counties of Palm Beach, Broward, and Miami-Dade.

Florida is the fourth most populated state in the nation, with a 1990 estimated 12.9 million total residents. Its past is marked by rapid post World War II growth, which accelerated Florida's share of the United States population from just under 2 percent in 1950 to just over 5 percent in 1990. This trend is expected to continue, although at a more modest rate, so that over 6 percent of the U.S. population will be in Florida by 2040. The state population is expected to grow another 50 percent by 2040, reaching nearly 19 million. Growth rates for both the state and the C&SF Project counties have averaged close to three times the average annual percent growth rates for the United States as a whole during recent decades. Future growth rate differences are expected to diminish.

The Lower East Coast three-county area comprises about 9.5 percent of the state's land area, but is home to 3 percent of Florida's population. Population growth is fueled by in-migration, as it continues to be both a leading location for retirement as well as a haven for Hispanic and Caribbean immigrants. By contrast, the group of primarily agrarian counties bordering the shores of Lake Okeechobee (Glades, Highlands, Martin, Okeechobee, St. Lucie, and Hendry Counties, but excluding Palm Beach County), while similar in size to the Lower East Coast counties, contain only about 6 percent of the study area's population.

J.1.11.2 Economy

The 16-county study area had a 1990 per capita personal income about 8 percent above that for the state as a whole, while the Lower East Coast area (Palm Beach, Broward, and Miami-Dade Counties) is about 15 percent higher. Florida's per capital personal income is less than 1 percent higher than the national average. About half of the study area's counties have per capita incomes greater than either the state or the nation. Slightly over half of Florida's employment and earnings takes place in the study area. Nearly two thirds of this is concentrated in the populous Lower East Coast three county area. Excluding the northernmost counties of Polk, Orange, and Osceola, which are technically part of the study area, but which realistically fall outside of the main focus of this study, the three-county Lower East Coast area accounts for about 80 percent of the regional aggregate socio-economic activity for the study area.

Employment and income in the south Florida study area has continued to grow in recent decades at about half again faster than the national average. Growth has been significantly greater in the southwest counties and the Florida Keys (taken as a group--Monroe, Collier, Hendry, Lee, and Charlotte), and in the counties around Lake Okeechobee (Glades, Highlands, Martin, Okeechobee, and St. Lucie) than elsewhere in the study area.

The economy of south Florida is based on services, agriculture, and tourism. While manufacturing has not traditionally played a major role in the economy, this sector has experienced significant growth in recent years.

The service industry is associated with the over-65 population that constitutes nearly one-fourth of the residents of Broward and Palm Beach Counties and sixteen percent of Miami-Dade's population. These individuals have incomes independent of employment and require additional medical, financial, and household services. This relatively strong services part of the south Florida economy is reflected in percent of total employment and income in the services industry, which is consistently higher than for the state as a whole. The exception to this tendency is for those counties whose economic profiles reflect their heavy agricultural orientation. For example, in Hendry, Glades, Highlands, and Okeechobee Counties, the relative share of farm earnings and employment is roughly 20 to 30 times what it is for the other counties, while the relative share of the services industry tends to be smaller for these counties.

Agricultural production in the region, excluding the Everglades Agricultural Area, is virtually all in winter vegetables, tropical fruits and vegetables, citrus and nursery crops. Florida is the national leader in citrus fruit production and the manufacture of processed citrus products, accounting for over 80 percent of the nation's citrus production. Florida is the world leader in the production of grapefruit, accounting for nearly a third of the world's annual supply, and ranks second to Brazil in the world production of oranges, accounting for almost one fifth of the world's supply. Florida produces 100 percent of the nation's tangelos and over 95 percent of its limes. Florida also is the second ranking state in the production of fresh vegetables. South Florida shares significantly in this agricultural productivity. All but three of the top thirteen Florida agricultural production counties, as measured by total cash receipts in 1991 are within the study area. All but two of the study area's sixteen counties are in the top half of Florida's counties, as ranked this way.

The Everglades Agriculture Area economy is based largely on agriculture, the primary focus for the economies of the area's towns of Clewiston, South Bay, Belle Glade, and Pahokee. Besides being the residences of most of the permanent labor force, they support much of the agriculturally related supply and processing activities and are the headquarters of many of the agricultural enterprises. They also support the recreation industry in south Lake Okeechobee. A seasonal influx of agricultural workers increases the population of towns in this area during the winter sugarcane harvest and vegetable seasons. For instance, the City of Belle Glade estimates that its population increases by about 6,000 (plus one-third) during this period. This trend used to be more significant when sugar cane harvesting was largely a labor intensive activity. This activity is now mechanized.

Agriculture in the Everglades Agriculture Area relies on over 580,000 acres of muck soils irrigated, drained and under cultivation (B. Boyd, pers. comm.). This acreage produces sugarcane, vegetables, sod and rice. Farm employment in the Everglades Agriculture Area is very seasonal, because of the seasonal nature of the sugar cane harvest and the seasonal nature of vegetable production. Year round farm employment (as of the late 1980's) is about 4,000 full time employees.

While the vegetables are packed and shipped fresh and are not subject to extensive processing, sugar cane is locally processed, which adds considerably to its value and the output of the industry. Six sugar mills in the Everglades Agriculture Area process all the cane produced in south Florida, both inside and outside the Everglades Agriculture Area. All sugar cane is grown under contract for processing at these mills. The mills produce raw sugar, molasses and other by-products. A portion of the raw sugar receives further processing at the sugar refineries located in the Everglades Agriculture Area. A large portion of the raw sugar is processed outside of Florida.

Farm earnings as a percent of total earnings for the counties comprising the Everglades Agriculture Area ranges from 3.3 percent to 47.2 percent (3.3 percent for Palm Beach, 35.2 percent for Hendry, 47.2 percent for Glades, 17.9 percent for Highlands, 16.6 percent for Okeechobee, 7.6 percent for St. Lucie, and 8.3 percent for Martin). In comparison, farm earnings nationwide are only 1.5 percent of total earnings, and for the State of Florida this figure is 2 percent. The story is similar for farm employment for these counties.

There are also strong per capita income differences between the urbanized Lower East Coast and the agricultural areas. Compared to the state and the nation, the Lower East Coast counties have higher per capita income, while the agricultural counties bordering Lake Okeechobee (with the exceptions of Martin and Palm Beach) have lower per capita income.

In the Everglades National Park area, small-scale agricultural activities existed historically. Much of the marginal land was abandoned from the 1940's to the 1960's, and all agriculture had ceased by 1975. Prior to the official creation of Everglades National Park in 1947, there existed some small scale lumbering and logging, hunting and fishing. The Park's land use activities have been directed at preservation of the natural environment. Some low impact human activities are allowed, involving education, research, and recreation. These activities are the basis for Everglades National Park's contribution to the Florida economy.

The economic activity of the Florida Keys/Florida Bay area is somewhat indicated by its land use patterns, which illustrate a predominance of residential activities oriented toward the water and commercial activities along the main (and only) highway. Residential growth and development is occurring at a rapid rate. The rapid growth within the Keys is a result of the warm climate and extensive diversity of the natural environment.

Primary activities in the Monroe County-Florida Keys area are tourism and fishing. Both are related to some extent to conditions in Florida Bay, about which there has been growing concern. Many observers feel that these changes have been related to decreases in freshwater inflow from the Florida mainland (the Everglades), due at least in part to C&SF Project drainage and flood control features constructed in recent decades.

The relationship between tourism and fishing and the environmental health and vitality of Florida Bay is fairly obvious. These are mainstays of the Monroe County/Florida Keys economy, as reflected by the relative domination of economic activity there in the following sectors: services; retail trade; and fisheries ("agricultural services, forestry, fisheries & other"). Monroe County plays a strong role in Florida's well-developed commercial fishing industry, accounting for about 20 percent of the state's total in recent years. Shrimp has historically been the most valuable species caught, accounting for over 40 percent of total sales in the state. There is widespread concern that recent precipitous declines in commercial fish landings in conjunction with degrading conditions in Florida Bay are causally related to these changes, and that continuation of these trends will result in even more fishery declines. Earnings in the economic sector that includes commercial fishing account for nearly 4 percent of Monroe County earnings, a dramatically higher share than for the United States, and also significantly higher relatively than for the state overall. Employment in this sector accounts for over 8 percent of total employment in the county, with similar relative comparisons to the state and nation.

J.1.12 Land Use

The existing use of land within the study boundaries varies widely from agriculture to high-density multi-family and industrial urban uses. A large portion of south Florida remains natural, although much of it is disturbed land. The dominant natural features are the Federally protected Everglades National Park and Big Cypress National Preserve at the southernmost tip of the peninsula, Lake Okeechobee, and the state protected water conservation areas in the westernmost reaches of the Lower East Coast counties. Generally, urban development is concentrated along the Lower East Coast from Palm Beach County to Miami-Dade County, in the central Florida/ Orlando area, and on the Lower West Coast from Fort Myers to Naples.

Most of the interior of the study area is in agricultural use, which includes sugar cane (the dominant crop) and vegetable farms in the Everglades Agricultural Area of western Palm Beach County and Hendry County; the Agricultural Reserve Area of Palm Beach County; and the south Miami-Dade agricultural area where vegetable crops dominate, especially tropical varieties. There are citrus groves in every county, but citrus is concentrated in St. Lucie and Martin counties on the east coast and Hendry, Highlands, Collier, and Glades counties on the west. Cattle and dairy farms predominate in Glades, Highlands, and Okeechobee counties.

In the northern portion of the system, around Orlando, tourism and its attendant service-oriented land uses (for example, hotels / motels, convenience stores, souvenir shops) make up a significant portion of the landscape. Agriculture, however, continues to play an important role in the region, with over two million acres being farmed, half of which is pastureland. The area surrounding Lake Okeechobee, the second largest freshwater lake within the contiguous United States, is largely rural, with agriculture the prevailing land use. There are over 580,000 acres of irrigated farmland in the Everglades Agricultural Area (B. Boyd, pers. comm.). Farm products produced there include sugarcane, the predominant crop, rice, row crops, and sod. There is also extensive pastureland both west and north of the lake. Directly south of the Everglades Agricultural Area lie the water conservation areas. The conservation areas cover 1,372 square miles and consist mainly of sawgrass marshes and tree islands. The 1948 C&SF Project created the WCAs for the conservation of water supplies for the Lower East Coast.

The Upper East Coast is comprised of St. Lucie and Martin counties; the landscape is dominated by agricultural uses. Significant natural resources, the St. Lucie Estuary and Indian River Lagoon, are also contained within this area. Urban land use, which makes up 17 percent of the Upper East Coast, is mainly concentrated along the seaboard coastal and lagoon shorelines. The Lower East Coast extends approximately 100 miles through the coastal portions of Palm Beach, Broward, and Miami-Dade counties. Being the most densely populated area in the state, the Lower East Coast is home to one third of the state's population, more than 4.5 million people. The area is primarily an urban megalopolis, but it also contains substantial agricultural acreage, particularly in southwestern Miami-Dade County (90,000 acres) and western Palm Beach County (29,000 acres). Rapid population growth and land development practices have resulted in notable western urban sprawl; the predominant land use is single-family residential. The once significant rural population in the western areas of the counties, especially Miami-Dade and Broward, has practically disappeared, resulting in an urbanized makeup in population. Palm Beach County is not far behind.

The Florida Keys are made up of over 1,700 islands that encompass approximately 100 square miles and contains the largest reef system in the United

States. While a majority of the county is designated as conservation land, due to the land falling within either Everglades National Park, the Big Cypress National Preserve, or the National Key Deer Refuge, land use is primarily either residential or geared towards supporting the region's main industry (tourism). The county's fragile natural resources and vulnerability caused the State of Florida to designate the area as an Area of Critical State Concern in 1975; such designation is intended to protect such resources from degradation by strictly regulating development.

The southwestern counties of Collier and Lee are the fastest growing in terms of population in the state. Population growth is mainly due to the in-migration of retirees, not a high birthrate. The coast has become highly urbanized, with development spreading eastward into agricultural and natural lands. Agriculture is however, a major industry, especially in Lee County where citrus predominates.

J.1.12.1 Agricultural Land Use

The general agricultural conditions in each of the C&SF Project physiographic regions are summarized below. Because agricultural statistics are reported by county, best approximations of region boundaries were made along county lines. The information is based upon data compiled and distributed by the National Agriculture Statistical Service, and also data from the 1995 Florida Statistical Abstract. The data used are from the 1992 to 1996 time period.

Kissimmee River

Osceola, Polk, Highlands, and Okeechobee Counties were included in this region. More than two million acres in these counties are farmed, with more than half of this area devoted to pastureland (UFBEBR, 1995). This region is characterized by large farms with relatively low productivity per acre. These four counties are among the top five counties in Florida for cattle production, both beef and dairy (FASS, 1996a). More than 200,000 acres are used for citrus production. Approximately 11,000 people are employed in agricultural production and services representing a payroll of approximately $21 million (UFBEBR, 1995). The market value of all agricultural products in this region totals approximately $575 million (UFBEBR, 1995). Almost a quarter of a million acres in the Kissimmee River Basin are irrigated (UFBEBR, 1995), requiring a dependable water supply.

Lake Okeechobee

Lake Okeechobee has traditionally been a key source of water supply for irrigated crops around the lake including the Everglades Agricultural Area, the Caloosahatchee River Basin, and Martin and St. Lucie Counties (Upper East Coast). Continued access to this source of water is considered vital to sustaining agriculture in the surrounding regions.

Upper East Coast

Martin and St. Lucie Counties are included in this region. Almost one half million acres are farmed (UFBEBR, 1995). St. Lucie and Martin Counties rank first and eighth, respectively, among Florida counties for number of acres of citrus (FASS, 1996b). Although this area is known primarily for its citrus production, many acres are used for pastureland. Farms average 600 acres in size with moderate productivity per acre (UFBEBR, 1995). More than 7,500 people are employed in agricultural production and services with a payroll of approximately $9.5 million (UFBEBR, 1995). The market value of all agricultural products in this region totals approximately $362 million (UFBEBR, 1995). Approximately 200,000 acres are irrigated (UFBEBR, 1995) requiring a dependable water supply. Lake Okeechobee has traditionally been the water source for this region.

Everglades Agricultural Area

The Evergaldes Agriculture Area contains all or parts of: Palm Beach County and Hendry County. Most of Hendry County lies within the Big Cypress region, so it was discussed in that section of the report. More than 600,000 acres are farmed in Palm Beach County (UFBEBR, 1995), and sugarcane was harvested from about half of that acreage in 1996 (FASS, 1996d). Sugarcane receipts accounted for 68 percent of total field crop sales in Florida in 1996 (FASS, 1996c). The Everglades Agriculture Area is known for its sugarcane production and sugar processing, but Palm Beach County also ranks 15th among Florida counties for acres of citrus (FASS, 1996b). This region is characterized by mid-size farms averaging 690 acres each with high productivity of more than $1,300 per acre (UFBEBR, 1995). More than 18,000 people are employed in agricultural production and services representing a payroll of more than $26 million (UFBEBR, 1995). Total market value of agricultural products in Palm Beach County is almost $900 million, ranking it first among counties in the state of Florida (UFBEBR, 1995) and third among U.S. counties (FDACS, 1994).

The Everglades Agriculture Area is highly dependent upon the system of canals running through the region to provide necessary drainage of excess water during the wet season as well as supplemental water supplies for irrigation during the dry season. Approximately two thirds of the land farmed in the Everglades Agriculture Area is irrigated, totaling more than 580,000 acres (B. Boyd, pers. comm.). The Everglades Agriculture Area has traditionally relied upon Lake Okeechobee for its water supply, and looked to the Water Conservation Areas to the south to receive their excess drainage.

Continued agricultural production in the Everglades Agriculture Area has become increasingly controversial. Some of the factors that may affect Everglades Agriculture Area agriculture include water quality concerns, soil subsidence, and encroachment of urbanization. The water quality concerns, particularly phosphorus loading, are being addressed through implementation of best management practices, construction of storm water treatment areas, the growing use of organic farming practices, and rice cultivation in rotation with sugarcane production. Prevention of continued soil subsidence will depend on maintaining high ground water levels to prevent further oxidation of the soil profile. This, in turn, will require development of more water-tolerant sugarcane varieties and/or increased rice cultivation. A strong agricultural economy in the Everglades Agriculture Area, based on profitable crop production is the best defense against conversion of agricultural land to urban land.

Water Conservation Areas

No agricultural production takes place in the Water Conservation Areas, however these areas are an important resource to the surrounding agricultural regions. The WCAs provide water storage for excess water drained from the Everglades Agriculture Area.

Lower East Coast

Broward and Miami-Dade Counties are included in this region. Although Palm Beach County is also a part of this region physiographically, agriculture issues for Palm Beach County were addressed within the Everglades Agriculture Area region. More than 100,000 acres are farmed in Broward and Miami-Dade Counties (UFBEBR, 1995). This region is characterized by small farms averaging less than 50 acres, with very high productivity of more than $3,500 per acre (UFBEBR, 1995). A variety of crops are produced including vegetables, tropical fruits, and nursery plants. Hurricane Andrew, which struck southern Miami-Dade County in 1992, caused significant damage to agricultural areas. Many fruit tree orchards were damaged or destroyed. Statistics from 1996 indicate that avocado production had recovered, but mango and lime orchards had not yet recovered from the hurricane damage (FASS, 1997b). Total acres of tropical fruit production in Miami-Dade County remain approximately 7,000 less than pre-hurricane levels (FASS, 1996e). Foliage plant production is also a major business in Broward and Miami-Dade counties. More than 120 million square feet were devoted to the foliage crop in Broward, Miami-Dade, and Palm Beach Counties in 1996 (FASS, 1997a).

Agricultural production and services employ approximately 18,000 people in this region representing a $23 million payroll (UFBEBR, 1995). The total market value of agricultural products from this region is almost $400 million (UFBEBR, 1995). Miami-Dade County ranks second in the state for total market value of agricultural products (UFBEBR, 1995).

Approximately half of the acreage farmed in the Lower East Coast is irrigated (UFBEBR, 1995). This region is highly dependent on the system of canals, levees, and other structures for flood control in the wet season and water supply in the dry season. Providing adequate drainage and flood control to the south Miami-Dade County agricultural area is a serious challenge because the farmland is directly adjacent to Everglades National Park. Evidence suggests that efforts to provide flood control to agriculture have resulted in over-drying the eastern portions of Everglades National Park adversely affecting Park ecology. Agricultural land does, however, provide a buffer between urbanization and Everglades National Park. Farmland is recognized as the preferred neighbor to natural areas because of its minimal impervious areas, open green space, and low population density. A strong agricultural economy in the Lower East Coast region based on profitable crop production is the best defense against conversion of agricultural land to urban land.

Everglades National Park and Florida Bay

Little or no agricultural production takes place in these regions, which includes Everglades National Park, Florida Bay, the Ten Thousand Islands, and Whitewater Bay. However, water management decisions made for these regions may affect other regional farmland and should, therefore, be considered carefully.

Big Cypress

Hendry and Collier Counties are included in this region. More than 800,000 acres are farmed in the Big Cypress region, and almost half of that area is pastureland (UFBEBR, 1995). The region is characterized by moderate to large farms producing more than $600 per acre in market value (UFBEBR, 1995). Hendry County ranks third in the State of Florida for cattle production (FASS, 1996a). Approximately 70,000 acres of sugarcane were harvested in 1996 (FASS, 1996d). Hendry County ranks third in the state for acres of citrus with over 100,000 acres, while Collier County is ninth with over 36,000 acres (FASS, 1996b). Citrus production in the Big Cypress region is currently increasing.

More than 17,000 people are employed in agricultural production and services, and the payroll totals approximately $16 million (UFBEBR, 1995). Agricultural products in this region have a total market value of more than $525 million (UFBEBR, 1995). Hendry and Collier Counties rank third and fourth in Florida for market value of agricultural products (UFBEBR, 1995).

Caloosahatchee River

Glades and Lee Counties are included in this region. Almost one half million acres are farmed in the Caloosahatchee River region, and approximately three-fourths of that area is pastureland (UFBEBR, 1995). The region is characterized by large farms averaging 1800 acres, with relatively low productivity per acre (UFBEBR, 1995). Glades County ranks eighth in the state of Florida for cattle production (FASS, 1996a). Citrus production in the Caloosahatchee River region covers more than 20,000 acres (FASS, 1996b) and is currently increasing.

Almost 5,000 people are employed in agricultural production and services, and the payroll totals approximately $5 million (UFBEBR, 1995). Agricultural products in this region have a total market value of more than $135 million (UFBEBR, 1995).

More than 77,000 acres of farmland are irrigated in the Caloosahatchee River region (UFBEBR, 1995). Reliable water supply is a big concern in this region that has traditionally relied upon water deliveries through the Caloosahatchee River from Lake Okeechobee. Irrigation demands can be expected to increase as additional land is used for citrus production.

J.1.13 Recreation Resources

In order to determine and assess the existing recreation resources within the Restudy, a thorough review of U.S. Geological Survey maps and other available data has been completed. Recreation resource use data and information from the Florida Statewide Comprehensive Outdoor Recreation Plan (SCORP), March 1994 and other information sources has been utilized to help define the resource use rate and importance. The discussion below is a general overview of the existing recreation resources of the ten physiographic regions as defined in Figure J-1.0-1.

The regional breakdowns will help to further define and determine the existing circumstances that influence the quality and use of recreation resources within the specific regional boundaries. Resource availability, and the influence of urbanization, agriculture, infrastructure development, exotic species, and varying water management scenarios are discussed as appropriate, to determine what influence these factors have on the quality of the visiting public's recreational experience.

J.1.13.1 Kissimmee River

Recreation resources in the Kissimmee River region are centered around a chain of connected lakes, public access points for boating and fishing, and adjacent land based recreation. Marinas, fishcamps, and public facilities (boat launching, picnicking, bank fishing) are located around many lakes in the region. Thirty-six miles of the Florida Scenic Trail were designated in June 1990, with additional trail section designations to follow. Lake Kissimmee State Park, Three Lakes, Kissimmee River and Kicco WildlifeManagement Areas, and Prairie Lakes Preserve provide upland and water based recreation resources for the region. The GFC surveyed boat traffic at six locks (20,000 passengers in 1991) and derived 26,000 annual fishing days that include local and tourist users (USACE, 1991). Population of the Kissimmee River region has more than doubled from 1970 to 1990 (Obers

1986 and 1990 Florida Census of Population, United States Department of Commerce, Bureau of Economic Analysis and Bureau of Census). Substantially altered water deliveries to this region could have a detrimental affect on many recreation resources in the area. Overall, existing regional recreation resources receive heavy annual usage and are expected to increase.

J.1.13.2 Lake Okeechobee

Recreation resources in the Lake Okeechobee region are primarily water based within Lake Okeechobee and include boating, fishing, waterfowl hunting and nature interpretation. Lake Okeechobee provides approximately 40 miles of navigable waterway for commercial navigation and many more for recreational boating. Twenty-five U.S. Army Corps of Engineers land and water-based recreational facilities are located along the Lake. The Florida National Scenic Trail encompasses Lake Okeechobee atop the Herbert Hoover Dike (approximately 140 miles long). The annual 3-day “Big O Bike Tour” is a 110-mile bike ride that occurs in the fall. It begins from the city of Okeechobee and heads south around the lake on top of the dike (Kichen, 1998). Approximately 94 percent of the recreation lands available to the public in this region are state or Federal (SCORP, 1994).

Bike riding, hiking, picnicking, camping, and nature interpretation is popular land based recreation activities in the region. Two-hour swampland tours aboard pontoon cruisers begin at the footbridge over the Kissimmee River and traverse the 28,500-acre National Audubon Wildlife Sanctuary on Lake Okeechobee. Substantially altered water deliveries to this region could result in flooding and have a detrimental affect on many natural and recreation resources in the area. The ample water based recreation resources in the Lake Okeechobee region receive extensive use and future demand is anticipated to increase. Many surrounding lakeside communities host annual recreation events that are important aspects of local economies.

J.1.13.3 Upper East Coast

Recreation resources in the Upper East Coast region are diverse, consist of variable quality, and include coastal, inland water and land based resources. The St. Lucie Canal provides approximately 34 miles of navigable waterway with four U.S. Army Corps of Engineers/County recreation facilities that include boating, fishing, camping and day-use facilities (USACE, 1991). An eight mile canoe trail winds through cypress strand lush with ferns and orchids in Jonathan Dickinson State Park (Martha, 1997). The approximately 44 miles of Intracoastal Waterway, within the Upper East Coast, provides many coastal recreational navigation opportunities. Several other river bodies offer recreational opportunities including the north section of the Loxahatchee River in Martin County which is designated a National “Wild and Scenic River” (SCORP, 1994). Substantially altered water deliveries to this region could have a detrimental affect on many recreation resources.

Public beaches in the Upper East Coast region are the most popular forms of recreation in the region. Four State of Florida Aquatic Preserves, and four State Parks and Recreation Areas are within the Upper East Coast region. Five artificial coastal reefs are popular diving and fishing spots. The region also includes high quality recreation opportunities within the Dupuis Reserve State Forest and Wildlife and Environmental Area and the St. Lucie Inlet Preserve. Overall, existing recreation resources in the region receive heavy annual usage that is expected to increase in the future.

J.1.13.4 Everglades Agricultural Area

Recreation resources in the Everglades Agriculture Area region are minimal due to the heavily developed agriculture industry in the region. The landscape is nearly flat with most of the areas under sugarcane production. The region is extensively ditched for water supply. A few community sized city and school playgrounds/parks are located within the Everglades Agriculture Area region. Some City, County, South Florida Water Management District, and U.S. Army Corps of Engineers parks are also found in the region. Recreation resources in are generally rustic and community-based.

J.1.13.5 Water Conservation Areas

Recreation resources in the WCA region are inland water and upland resources that include the Arthur R. Marshall Loxahatchee National Wildlife Refuge, Rotenberger, Holey Land, and Brown's Farm Wildlife Management Areas (SCORP, 1994). These areas provide high quality boating, fishing, and nature interpretation activities. The Miccosukee State Indian Reservation is within the WCA region boundary. Hunting, boating, and fishing occur within the Everglades Wildlife Management area, including the Miccosukee State Indian Reservation. Of note is the fact that the Everglades Wildlife Management Area is the only major natural area that is still open in south Florida for recreational airboating (GFC pers. comm.). Substantially altered water deliveries to this region could have a detrimental affect on many natural and recreational resources in the area. At present, undesirably high water in the Everglades Wildlife Management Area results in the GFC having to close areas for all forms of recreation, except for boating in the perimeter canals (GFC pers. comm.).

J.1.13.6 Lower East Coast

Recreation resources in the Lower East Coast region include an abundance of inland and coastal water resources that provide water and upland recreation opportunities. Many cities, county, State parks and recreation areas and one national recreation area are interspersed within the heavily urbanized boundaries. Approximately 115 miles of urbanized coastline provide popular seaside recreation resources where boating, fishing, swimming, diving and many others opportunities are available. The Intracoastal Waterway provides a diverse water-based recreation resource opportunity in the region.

The DuPuis Reserve State Forest, and the Loxahatchee River – Lake Worth Creek Aquatic Preserve also provide high quality recreation opportunities for boating, fishing, and nature interpretation activities within the Lower East Coast region. Altered water deliveries to this region could have a detrimental affect on many natural and recreational resources in the area. The good quality land and water based recreation resources in the Lower East Coast region receive extensive use and future demand is anticipated to increase.

Biscayne Bay offers among the most diverse quality recreation opportunities within the Restudy project area. Biscayne National Park provides opportunities for birwatching, recreational hiking, boating, fishing, snorkeling, diving and picnicking. The open bay waters are dotted with keys (islands) that add an additional element of interest and opportunity to study nature. Biscayne Bay, Card Sound and Cape Florida are designated Aquatic Preserves (SCORP, 1994). Substantially altered water deliveries to this region could have a detrimental affect on many natural and recreational resources in the region.

J.1.13.7 Everglades National Park

Everglades National Park and Florida Bay offer unique and diverse opportunities for a variety of natural resource and wilderness based recreational activities. Day use and camping (front and backcountry) facilities are available throughout the Park. There are over 150 miles of walking and canoe trails, including 2 miles of elevated boardwalk trails and three campgrounds with over 420 campsites and an additional 48 backcountry campsites in the Park. Recreation activities include: hiking, boating and canoeing, fishing, bird and wildlife viewing, and going on guided interpretive tours.

Everglades National Park has been designated a World Heritage Site, and International Biosphere Reserve, and a Wetland of International Significance. In addition, 86% of the Park is designated Wilderness under the Wilderness Act of 1964. The state of Florida has designated the Park an Outstanding Florida Water. The Park has also been listed as one of the nation's top ten most endangered parks (USACE, 1994).

Diverse ecosystems from sawgrass prairie to pinelands and hammocks to the estuarine environment of Florida Bay area easily accessible from the main park road or the Shark Valley tram road. The main park road ends at Flamingo, a former fishing village, and a main port of entry to Florida Bay, where a variety of self-guided, concession or ranger led walks and boat tours are available. U.S. 29 leads to Everglades City and the Gulf Coast Visitor Center where the island-bay-mangrove ecosystems of the 99 mile Wilderness Waterway and Chokoloskee Bay, Turner River, and the Ten Thousand Islands area can be accessed. At Shark Valley, within the Shark River Slough, there are opportunities for biking, a guided interpretive tram tour, guided interpretive walks, as well as the climb to the top of the observation tower for a spectacular view of the sawgrass prairie. Chekika, (a former state park within the East Everglades Acquisition Area and donated by the state to the Park in 1991) offers a slightly different experience with opportunities for a soak in a sulfur pool as well as for picnicking and hiking.

Recreation resources within Florida and Whitewater Bays, the Ten Thousand Islands, the Wilderness Waterway, West Lake and Nine Mile Pond are characterized primarily by water-based resources and include boating, fishing, bird and wildlife observation, and interpretive programs. The opportunity to enjoy the sounds of nature, solitude, tranquility and wilderness are also part of the recreational aspect of these areas. The Wilderness Waterway and Florida Bay are dotted with backcountry camp sites (by permit only). There are three kinds of backcountry campsites: chickees, ground sites, and beach sites. All offer opportunities for wildlife viewing and experiencing the sounds of nature, solitude, tranquility, and wilderness.

J.1.13.8 Florida Keys

Recreation resources in the Florida Keys region are mostly high quality water-based with some upland shoreline activities. Boating, fishing, diving, and nature interpretation are some of the many recreation opportunities in the region. The Florida Keys National Marine Sanctuary is located here, in addition to five wildlife refuges , the Keys Wildlife and Environmental Area, and one of the busiest state parksin Florida. Several other state parks in addition to John Pennekamp Coral Reef State Park are also within the region (SCORP, 1994). Key Largo National Marine Sanctuary designates protection for the delicate reefs outside of Pennekamp, which is also a popular diving destination. Fort Jefferson National Monument is the most southern point of the continental United States and is one of the most unique monuments in the world because of its setting. Recreation resources depend on the very fragile Florida Keys regional ecosystem. Diving is the most popular recreation activity followed by fishing, and bird watching. The overall region is a delicate natural resource that provides visitors with excellent recreation resources. Altered freshwater deliveries to this region have adversely affected many natural and associated recreational resources in the region. Development pressures could adversely affect the regional water quality and recreation resources.

J.1.13.9 Big Cypress

Recreation resources in the Big Cypress region are primarily wetland based with some upland access and facility use. Air boating, fishing, hunting, and nature interpretation are all very popular recreation activities in the region. Camping facilities are also found within the region. In the heart of the region, the Big Cypress National Preserve and Wildlife Management Area is rivaled in size statewide only by the Everglades Wildlife Management Area. Five state parks and recreation areas are located in the region as is a state preserve. The Panther National Wildlife Refuge is also within the region. Artificial reefs are located in the region's coastal area (SCORP, 1994). National Audubon Society's Corkscrew Swamp Sanctuary offers a 2 mile elevated boardwalk trail through old cypress and to a wood stork rookery.

Major roadways in the region include Alligator Alley (I-75) and Tamiami Trail (SR 41), which transect the region west to east. Several canals range north to south for many miles. Tamiami Canal runs east and west for many miles also. These represent pending concerns due to water quality issues and exotic species transport that could adversely affect recreation resources in the near future. Surrounding development pressures could also be critical to the natural and recreation resources. Substantially altered water deliveries to the Big Cypress region could have a detrimental affect on many recreation resources in the region.

J.1.13.10 Caloosahatchee River

Recreation resources in the Caloosahatchee River region are diverse and include coastal, inland water and land based resources. The Caloosahatchee River provides approximately 67 miles of navigable waterway with ten U.S. Army Corps of Engineers recreation facilities that include boating, fishing, picnicking, and camping. Several other river bodies also offer recreational opportunities in the region. The Caloosahatchee River provides approximately 67 miles of navigable waterway with ten Corps recreation facilities that include boating, fishing, picnicking, and camping. The J.N.”Ding” Darling NWR, a popular birding area, administers Caloosahatchee, Matlacha Pass, Island Bay National Wilderness area and Pine Island National Wildlife Refuge, all located near the region's western edge. Boca Grande Pass is world renowned for record tarpon, Sanibel Island is reported among the top shelling destinations in the Western Hemisphere.

Caloosahatchee State Park and Recreation Area is located near Alva on the Caloosahatchee River. Estero River and Hickory Creek State Canoe Trails are within the region and provide excellent recreation resources. Cayo Costa State Park, Sanibel Island State Park, and State Aquatic Preserves are located in the region. Areas boating, diving and fishing are popular recreational activities. Surrounding development pressures could adversely affect the areas natural and recreational resources. Substantially altered water deliveries have had detrimental affect on natural and recreation resources in the region. Recreation resource use is substantial and anticipated to increase.

J.1.14 Aesthetics

The visual characteristics of the central and south Florida region can be roughly described for the dominant three land use categories: natural areas, such as those areas within the Everglades Protection Area, agricultural lands, and urban areas. Regional aesthetics depends in a large part on one's personal perspective. Where one lives, spends recreational time, makes a living, and who one perceives oneself to be, contributes to a personal perspective and opinion of what is aesthetically pleasing, and what is not.

Very briefly, the natural areas are composed of a variety of upland and wetland based ecosystems including lakes, sloughs, ponds, and vast expanses of marsh and wet prairie with varying vegetative components. Uplands are often dominated by pine, although other sub-tropical and tropical hardwoods such as fig, gumbo limbo, and cypress occur within their ecotone. Overall the land is remarkably flat, with few natural topographic rises such as hills or other geographic undulations. Much of the visible topographic features are man-made, including ubiquitous canals and levees. Additional man-made features of the landscape include pump stations, navigation locks, secondary and primary roads, highways, electrical wires, communication towers, occasional buildings (some abandoned), borrow pits and other features which may or may not detract from the regional aesthetic. Views, when possible from a high perspective such as atop a levee, offer pleasant and unspoiled perspectives on Everglades marsh, often dotted with tree islands, and numerous birds and other wildlife.

One of the most prominent levees in the C&SF Project system is the Herbert Hoover Dike. Over 140 miles of levee surrounds Lake Okeechobee. The impact of this levee on Lake Okeechobee's regional aesthetics has been permanent and profound. What is otherwise a scenic and immense natural water body with a profusion of wildlife along the shoreline is nearly invisible to the casual observer because the Herbert Hoover Dike effectively blocks ones view. This is an example of the types of aesthetic impacts to key regional and local natural resources that the Restudy must strive to avoid.

Other key natural areas of particularly high aesthetic quality include among others, the Loxahatchee Slough in the Upper East Coast region, areas of the Big Cypress, the Ten Thousand Islands, Everglades National Park, Florida Bay, and Biscayne Bay. The Florida Keys and the coral reef tract provide important aesthetic qualities to the state as well as some of the most significant underwater aesthetics in the world.

Agricultural lands occur throughout the system outside of the Everglades Protection Area. They are comprised largely of open pastureland north of Lake Okeechobee, in the Caloosahatchee region and northern Big Cypress region, where dairy and beef cattle operations predominate. The Kissimmee River region for instance is primarily pasture, with patchy natural areas that function to retain water for the regional system. The Lower Basin of the Kissimmee River region is largely undeveloped and presents a panoramic landscape largely untouched by mankind for miles. The C-38 canal is straight and wide and in the process of being "restored". Project earth-moving equipment, as well Avon Park Bombing Range aircraft, break the panoramic scenery and detract from the otherwise high visual quality.

In the Everglades Agriculture Area sugar cane production, and to a lesser extent sod, vegetables and rice lend a uniform and organized appearance to the landscape, largely devoid of trees and other non-agricultural vegetation. The visual aesthetics are rather monotonous and of marginal value. Agriculture in the Upper East Coast and in south Miami-Dade County is somewhat less intensive than the Everglades Agriculture Area and so a more traditional agricultural landscape, with more diverse crops such as citrus and a variety of tropical trees, shrubs and landscape plants occur. Both the natural areas described above, and the agricultural areas are relatively open, with low population density, few buildings and other structures interspersed across the landscape, and are generally quiet.

The urban areas, other than the scattered small to medium sized municipalities characteristic of the interior regions, occur mostly along the highly urbanized east coast. This includes such sprawling, mostly low level cityscapes as Stuart, Fort Pierce, West Palm Beach, Boca Raton, Pompano Beach, and nearby urban areas. Fort Lauderdale and Miami and their surrounding suburban areas epitomize the highly urbanized scene described above, only with significant high rise buildings in the downtown area nearest the coast or on nearby barrier islands. These cities are visually congested with immense residential areas, composed mostly of one or two story buildings, well-trafficked roads, seemingly endless impervious surfaces, parking lots, strip malls, high rise hotels, and industrial and commercial enterprise. The urbanized east coast begins more or less at the Florida Turnpike, and extends eastward to the coast, and includes intensively developed residential communities, highways and heavily used roads, and other development immediately adjacent or nearby to protected natural areas or agricultural lands. Visual aesthetics are marginal except in areas where urban landscaping assumes a high priority.

Along the east coast, the Atlantic Ocean and Atlantic Intracoastal Waterway (IWW) shorelines provide panoramic aesthetic views from many locations. White shoreline sand contrasts sharply with tropical colored waters of the ocean and IWW in the region. High-rise structures, often hotels to serve the tourist industry, restrict visual access to the ocean's panoramic scenery and tend to diminish the visual experience from the shoreline. Visual access to the scenic IWW is also limited.

J.1.15 Cultural Resources

The earliest widely accepted date of occupation of Florida dates from around 12,000 years ago. This earliest cultural period is termed the Paleo-Indian stage and lasted until about 7500 B.C. Few Paleo-Indian archeological sites are recorded in Florida, and because sea level was as much as 35 meters (115.5 feet) lower then, a large number of coastal and riverine sites are presumed to now be inundated. However, professional investigations at Nalcrest, in Polk County, and Little Salt Springs, and Warm Mineral Springs, have helped to define the period. Until recently, Paleo-Indians were thought to be widely ranging nomadic hunters and gatherers, exploiting now extinct Pleistocene megafauna. Recently developed models of human behavior now suggest that Paleo-Indians led a more sedentary lifestyle.

The Archaic stage, (ca. 7500 B.C. - ca. 500 B.C.), is thought to be a reflection of man's adaptation to the changing environment at the start of the Holocene, when our basically modern climate and biota were established. Archaic Indians exploited a wider range of resources than Paleo-Indians, probably utilized a more restricted territory, and may have led a more sedentary existence. Seasonally available food resources, including deer and small game, hardwood nuts, freshwater snails, and marine shellfish were used during the Archaic. The Archaic is further subdivided into the Early Archaic (7500B.C. to 5000 B.C.), Middle Archaic (5000 B.C. to 3000 B.C.) and Late Archaic (3000 B.C. to 500 B.C). Few Early or Middle Archaic period archeological sites are recorded in south Florida and known sites are clustered along the Atlantic and Gulf coasts and inland waterways. Foraging and hunting are the main subsistence activities throughout the archaic stage, with Late Archaic people exploiting a larger territory and wider range of aquatic and terrestrial food resources. Archaic sites become more numerous during the Late Archaic period, when essentially modern climatic conditions had been established. Crude fiber-tempered pottery first appears in the Late Archaic. The end of the Late Archaic is characterized by changes in technology and lifestyles. By 500 B.C. sand replaces or augments fiber as a ceramic-tempering agent. A profusion of stone tool types and ceramic styles indicates increased population movement and social interaction, and more complex political and religious community organization.

Regional cultural diversity becomes apparent in the archeological record by 500 B.C. The clearest indication is that distinctive styles of pottery were made in different parts of the state. The Okeechobee Basin and Glades regions are distinct regional culture areas in south Florida through time. The St. Johns Region and the central peninsular Gulf coast region are other recognized cultural regions peripheral to the C&SF Project area which have at some points in time influenced the culture history of southern Florida.

In the Okeechobee Basin, the Belle Glades culture sequence (ca. 500 B.C. - A.D. 1500) is subdivided into four periods. Ceramic technology progresses from fiber tempered to fiber and sand tempered to sand tempered ceramics, with St. Johns ceramic types also being used during the Belle Glades culture sequence. Hunting and collecting subsistence strategies are thought to have been supplemented by maize agriculture practiced on circular and linear earthworks. A complex political system practiced by the Calusa was recorded in the late Belle Glades sequence. Objects of Spanish origin obtained from European contact or shipwreck salvage have been recovered from sites dating to the late periods of the Belle Glades.

In east and central Florida, the St. Johns culture begins about 500 B.C. and lasts into the historic period about A.D. 1500. The St. Johns has been subdivided into six temporal periods, based on changes in ceramics and other material remains. Changes in ceramic technology appear to reflect variations in the degree of interaction with indigenous groups from northern Florida through time. Limited horticulture was assumed established by the beginning of the St. Johns, although abundant marine food resources appear to be the staple throughout the 2000-year time span. Formal agricultural practices, if present, made only a minor contribution to the subsistence base.

The Caloosahatchee River is often identified as a separate cultural area. During the pre-Columbian period, the river likely served as a vital transportation route to the Okeechobee Basin and the Glade culture areas. Throughout the pre-Columbian period cultural and political boundaries were probably blurred or non-existent at times, but a ceramic chronology is recognized in the archeological record, subdivided into five sub-periods. Large shell mound and shell midden sites characterize the Caloosahatchee coastal area. Sand burial mounds and shell and earth middens are typically found inland along the river. Smaller dirt middens are found on interior hammocks near freshwater marshes.

During the early historical period, beginning with the first Spanish colonial period (1513 - 1763), European contacts were limited to the coastal areas. It is estimated that approximately 10,000 Calusas inhabited southern Florida prior to contact with Europeans. The Calusas were hunters and gatherers concentrated primarily in coastal areas, subsisting by fishing, collecting shellfish, and gathering wild plants for food.

Interaction between Spanish and French explorers and the Calusas occurred during the 16th century. The European settlers attempted to convert the Native

Americans to Christianity and alter their social structure. The Spanish retreated from Florida in the 1570's, leaving the Calusas undisturbed during the 1600's. Approximately 6,000 Calusas remained, but disease and occasional European invaders continued to reduce the population.

The Miccosukees are descendants of the Hitchiti-speaking Lower Creeks, and the Seminoles of the Muskogee-speaking Upper Creeks. These groups migrated to Florida in the 18th and 19th centuries from Georgia and Alabama. Then as now, the ethnic distinction between the Miccosukees and Seminoles stems mainly from a difference in language.

By the early 1800's, the migrant Native American population of Florida had grown to about 5,000. Miccosukee and Seminole Indians settled primarily in northern Florida originally. Removal and relocation of many Native Americans to reservations west of the Mississippi River occurred as a result of the Seminole Wars of the 1800's and the Indian Removal Act of 1830. Following the United States government policy of Native American removal, General Zachary Taylor led a force down the Kissimmee River valley during the Second Seminole War in 1873. The remaining Miccosukees and Seminoles moved farther south and established themselves in the Everglades, Big Cypress Swamp, and the Ten Thousand Islands areas. Most of the people lived on upland tree islands (hammocks), and used dugout canoes for transportation, hunting, and trading. Dwellings, called chickees, were constructed of cypress logs and palm fronds. The traditional lifestyle endured for the remainder of the century and still endures to a certain extent.

The first efforts to drain and reclaim the Everglades began in 1881. Agriculture began in the Everglades, south of Lake Okeechobee, after drainage projects of the 1906-1927 era. During this period, the first settlements, Okeelanta and Glade Crest were established just south of the lake. By 1921, there were 16 settlements on or near Lake Okeechobee, with a total estimated population of 2,000. Settlement and agricultural activities escalated during the subsequent decades.

By the early 20th century, hundreds of sport and commercial hunters were exploiting the Everglades resources. The opening of Tamiami Trail in 1928 ensured easy access for hunters and trappers to the southern Everglades. Permanent homes were rare, and the isolation and harsh environment compelled people to be self-reliant. Although soils in the area were fertile, it was the exploitation of fishery resources, along with animals and birds for skin and feathers, which was most economically important. Lumbering and charcoal making were also attempted (USDI, 1991). In 1947, most of the southern Everglades was incorporated as Everglades National Park.

Today, the Miccosukee and Seminole Indian Tribes are Federally recognized Indian Tribes living in south Florida. The Miccosukees have two main reservation areas, the 333 acre Tamiami Trail Reservation that is a permit area from the NPS; and the 76,800 acre Miccosukee Federal Indian Reservation in Broward County. Currently, none of the approximate 550 Tribal members reside at the 76,800-acre Reservation in Broward County.

The Seminole Tribe of Florida occupies Federal trust lands in five Florida locations, including the Big Cypress, Hollywood, and Brighton reservations, and the Immokalee and Tampa Indian communities. The present total population of the Seminole Tribe is estimated at 1,800.

Biscayne National Park has archeological sites both on land and underwater. A partial survey of submerged lands identified over 100 locations representing archeological remains. The earliest identified submerged site that has been discovered in Everglades National Park dates back to the mid-18th century. However, historical records indicate that European exploration of this region began in the early 16th century, so it is possible that more ancient remains exist. The region containing shipwrecks and other submerged examples of maritime casualties are listed in the National Register of Historic Places as an archeological district. This listing is currently in the process of being updated and expanded in scope and boundary (Adams, pers. com.).

The keys of BNP include numerous prehistoric archeological sites. The earliest site discovered so far is located on Sands Key. It is a midden dating back to 1000 AD. On the lands immediately adjacent to the mainland of the park lies the Cutler Fossil site dating back to 8000 BC. The presence of this site suggests that there is a potential for the existence of earlier sites located in BNP (Adams, pers. com.).

The Keys also contain more recent cultural resources. Boca Chita Key is listed on the National Register as a historic district for its ten historic structures as well as the ruins of several other structures. Elliott Key contains another archeological district, the Sweeting Homestead, which contains the remains of the first pioneering homestead on these keys. In addition to the previously mentioned sites, several other historic and prehistoric sites exist on other keys within the BNP (Adams, pers. com.).

J.1.16 Hazardous, Toxic, and Radioactive Wastes

A Phase I Hazardous and Toxic Waste (HTRW) Site Assessment was conducted in conformance with the scope and limitations of ASTM Practice E 1527. The findings and conclusions provided below reflect existing HTRW conditions based on a HTRW database search, aerial photography, review of available records, site inspections and interviews. These findings and conclusions are of existing conditions as they revealed at this time. The project conditions assume that any

HTRW found during any phase of the project would be remediated in accordance with local, state and Federal laws. Therefore, it can be assumed that the project condition will be contamination free or of low levels, which would include de minimis conditions that generally do not present a material risk of harm to public health or the environment. This assessment of existing conditions is not intended to be site specific in that definitive sites for the placement of most project features have not been decided. In some instances, tasking involved assessment of a certain area, or areas which were identified as possible conceptual locations for a project feature, subject to change, pending future detailed planning.

Several site visits were conducted over the past few years, with the most recent survey having been performed during the month of August 1998. The HTRW database search was performed on the entire study area and it indicated that overall, the majority of the proposed project areas are free of hazardous and toxic waste. Most of these properties are very remote and were farms, vacant land, or natural areas. The most common type of HTRW, hydrocarbons, was found along state highways in which the majority of the gasoline stations had leaking underground storage tanks. The leaking underground storage tanks are found on roads crossing proposed project areas at the Kissimmee River, Lake Okeechobee perimeter road, Upper East Coast roads, and Lower East Coast roads.

The database also revealed that several locations are not just leaking underground storage tanks, they are on the National Priority List (NPL). These sites are located in the Palm Beach Agricultural Reservoir, North and Central Lake Belt Storage area, in the vicinity of S-9 Structures and the Water Preserve Area south of Alligator Alley (I-75). Contaminants originating at these NPL-listed sites, which are on the edge of the proposed project, may be migrating into the project area through the movement of leachates.

There are numerous undocumented tanks and landfills that may be present in these proposed project areas which were not included in the database. These HTRW locations may be due to illegal dumping or may have simply not been documented. The project implementation requires that any HTRW problems revealed during the real estate acquisition or actual project construction be fully remediated. The following is a brief summary of existing HTRW conditions based on the ten physiographic regions that comprise the project area.

J.1.16.1 Kissimmee River

Several site visits were conducted over the past few years, with the most recent HTRW survey having been performed on 12 August 1998. The HTRW database review of the existing condition found the site to be free of hazardous and toxic materials and waste. The property surrounding the proposed project appears to be vacant land. One possible site for the 20,000 acre storage reservoir has potential sources of contamination located on the highway (underground storage tanks), however, these pose a low HTRW risk.

J.1.16.2 Lake Okeechobee

Several site visits were conducted over the past few years, with the most recent HTRW survey having been performed on 12 August 1998. The HTRW database, aerial photography review and site assessment of the existing conditions found the potential of HTRW contamination. The immediate property surrounding Lake Okeechobee consists of the Herbert Hoover Dike (dike) which was free of discolored soil or stressed vegetation, or any other indicator which may indicate contamination levels requiring clean-up on the dike. However, close to the dike, several locations have the potential of being a source of contamination. In Pahokee, on the east end of the Lake, businesses and private residences approach very close to the back toe of the Herbert Hoover Dike. It appears that the dike has been used as the "backyard fence". In some instances, private residences have installed a property fence creating a secure backyard boundary, the dike. This may have caused residents in the neighborhood to store materials close to the dike. Although no obvious contamination was observed, the potential of having past spills in these areas does exist. The physical inspection was performed by random spot check and driving along the road in the vicinity of the dike. It should be noted that rainfall and the high seepage rates in the area would have flushed-out most hydrocarbon, or smaller molecule chemical spills. Large molecule (PCB's), and metals may be less mobile and these spills may still measure residual levels. During real estate procurement and project construction further evaluations will be required. The perimeter road has several leaking underground storage tanks and several reported spills around Lake Okeechobee. All of these potential contamination problems are located within towns or along the highways that runs very close to the dike.

J.1.16.3 Upper East Coast

Several site visits were conducted over the past few years, with the most recent survey having been performed on 12 August 1998. The HTRW database review of the existing conditions found the site to be free of hazardous and toxic materials and waste. The property surrounding one possible project site appears to be vacant land and agricultural land. However, several of the roads that cross the C-44 basin storage reservoir have above ground storage tanks and underground storage tanks located on the roads within the project area. These appear to be gasoline stations. The potential of HTRW risks at these sites is low.

J.1.16.4 Everglades Agricultural Area

Several site visits were conducted over the past few years, with the most recent survey having been performed the week of 12 August 1998. The HTRW database review of the existing conditions found the site to be free of hazardous and toxic materials and waste. The property surrounding a possible project site did not have discolored soil or stressed vegetation, or any other indicator that may discover contamination levels requiring clean up. No hazardous substances in connection with identified uses were observed. However, the database search did reveal that the road adjacent to a possible site for the proposed 60,000-acre storage site did have a toxic release to the north of the northernmost 20,000-acre storage cell. This spill poses a low risk to the site.

J.1.16.5 Water Conservation Areas

Several site visits were conducted over the past few years, with the most recent survey having been performed on 12 August 1998. The HTRW database review of the existing conditions found the site to be free of hazardous and toxic materials and waste. The property surrounding the proposed project is natural vegetation.

J.1.16.6 Lower East Coast and Biscayne Bay

Several site visits were conducted over the past few years, with the most recent survey having been performed during the week of 12 August 1998. The HTRW database review of the existing conditions found one possible site to be free of hazardous and toxic materials and waste. The HTRW database has identified several locations within the Lower East Coast and Biscayne Bay region that are on the National Priority List. Throughout the study area many HTRW issues have been revealed. These sites are located in the Palm Beach Agricultural Reserve, North and Central Lake Belt Storage area, in the vicinity of the S-9 Structure, and the proposed Water Preserve Areas south of I-75. Contaminants originating at these NPL-listed sites, which are on the edge of the proposed project, may be migrating into the project area through the movement of leachates.

Within the Lower East Coast and Biscayne Bay project area, eight National Priority Listed sites exist. They are located within or are just adjacent to the proposed sites. These NPL sites described above do not include the NPL sites clustered just the south of the Central Lake Belt Storage Reservoirs.

J.1.16.7 Everglades National Park and Florida Bay

Several site visits were conducted over the past few years, with the most recent survey having been performed the month of August 1998. The HTRW database review of the existing conditions found the site to be free of hazardous and toxic materials and waste. The remoteness of this region and limited access has helped to keep this site free of HTRW. The adjoining area consists of agricultural land, former agricultural lands or are natural areas.

J.1.16.8 Florida Keys

Several site visits were conducted over the past few years, with the most recent survey having been performed on 12 August 1998. The HTRW database review of the existing conditions found this region to have a low risk of widespread hazardous waste contamination being present. Leaking underground storage tanks have been documented to exist along the highway connecting the islands to Key West.

J.1.16.9 Big Cypress

Several sight visits were conducted over the past few years, with the most recent survey having been performed on 12 August 1998. The HTRW database review of the existing condition found the site to be free of hazardous and toxic materials and waste. The area has limited access and is surrounded by natural vegetation or vacant land.

J.1.16.10 Caloosahatchee River

A sight visit to the project area was conducted on 12 August 1998. The HTRW database review of the existing condition found the project area to be free of hazardous and toxic materials and waste. Within the area negligible activities have been documented which would result in HTRW contamination. However, one possible site investigated for the proposed 20,000-acre storage reservoir has a landfill on the southern portion of the proposed project area. This landfill has also been listed on the National Priority List. There is a high probability that the southern portion of the proposed project area is contaminated.

J.2 KISSIMMEE RIVER REGION

The Kissimmee River Basin is covers 3,013 square miles, and extends from Orlando southward to Lake Okeechobee (refer to ***Figure J.2-1***). The watershed, which is the largest providing surface water to Lake Okeechobee, is about 105 miles long and has a maximum width of 35 miles.

Project works in the basin for flood control and navigation were constructed by the U.S. Army Corps of Engineers as part of the C&SF Project. Upper Basin works consist of channels and structures that control water flows through 18 natural lakes into Lake Kissimmee. The Lower Basin includes the channelized Kissimmee River (C-38) as a 56-mile earthen canal extending from Lake Kissimmee to Lake Okeechobee.

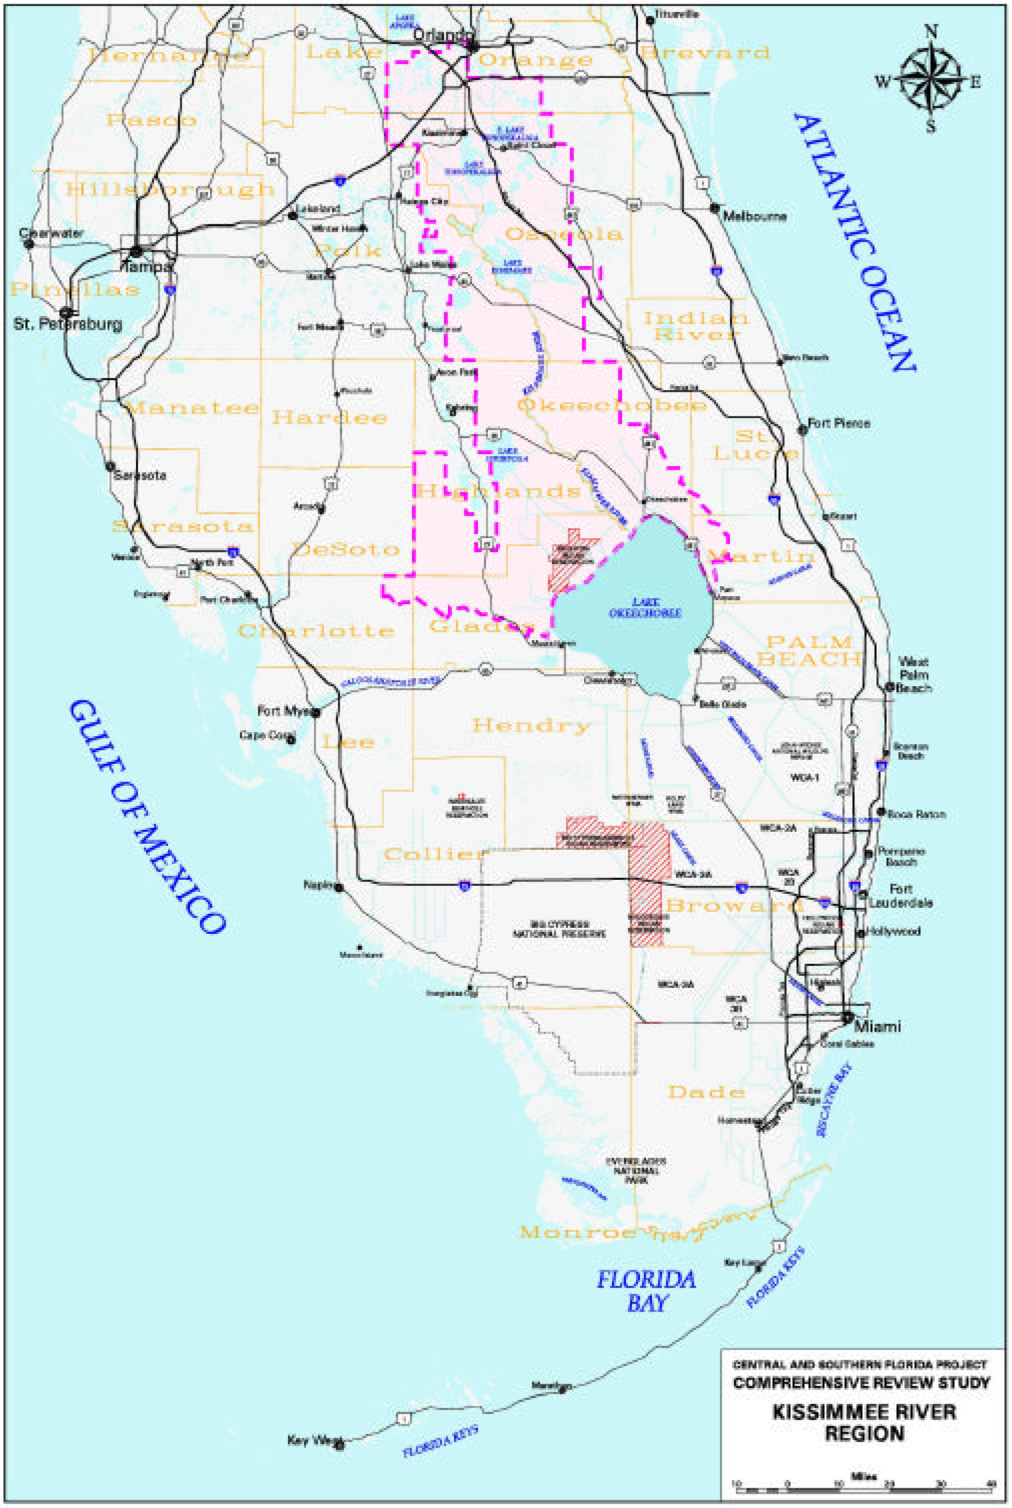

Figure J.2-1 Kissimmee River Region

The northern portion of the basin is comprised of many lakes, some of which have been interconnected by canals. This large sub-basin often termed the “Upper Basin” or “Chain of Lakes”, is bounded on the southern end by State Road 60, where the largest of the lakes, Lake Kissimmee, empties into the Kissimmee River.

The Upper Basin covers 1,633 square miles, including Lake Kissimmee and the east and west chain of lakes are in Orange and Osceola Counties. A 758-square-mile Lower Basin includes the tributary watersheds of the Kissimmee River between the outlet in Lake Kissimmee and Lake Okeechobee. The 622-square-mile Lake Istokpoga area provides tributary inflow to the Lower Basin.

J.2.1 Vegetation

The littoral zones of the lakes are among the most significant resources in the Upper Kissimmee River Basin. The distribution of plants is a result of a history of inundation, fire, grazing, nutrient input and soils. Cypress swamp, shrub swamp or emergent fresh water swamp make up the dominant vegetation communities in the littoral zones.

Flooding stage and duration are the dominant influences on vegetation composition. Flood control regulation has impacted environmental resources in the Upper Basin. Because the range of water level fluctuations and maximum annual lake stages have been reduced (***Figure J-2.1-1***), the outer fringe of littoral wetlands surrounding the lakes has been drained and associated fish and wildlife values have diminished.

The lakes are generally surrounded by pine flatwoods, dry and wet prairies, and cypress domes. The tributaries are bordered by swamp hardwood and in the case of Reedy Creek, swamp hardwood bottomlands extend for more than 25 miles to the north.

Where the cypress swamp occurs, it exists in pure stands in peripheral parts of the lakes, with little understory vegetation. The shrub swamp is dominated by willow (*Salix* spp.), buttonbush (*Cephalanthus occidentalis*), Carolina bay (*Persea* sp.) and primrose willow (*Ludwigia peruviana*). The emergent marsh is dominated by various grasses: torpedo grass (*Panicum repens*), maidencane (*Panicum hemitomon*), and cord grass (*Spartina bakeri*). Smartweed (*Polygonum* spp.), pickerelweed (*Pontederia cordata*), arrowhead (*Sagittaria latifolia*), sawgrass (*Cladium jamaicense*), cattail (*Typha* spp.), various rushes (Juncus spp.) and sedges compete with the grasses. Deeper parts of the littoral zone contain water lily (*Nymphaea odorata*), spatterdock (*Nuphar luteum*), bulrush (*Scirpus* spp.), and cattail. Hydrilla (*Hydrilla verticillata*) is a dominant submerged aquatic plant, and American lotus (*Nelumbo lutea*) is locally abundant.

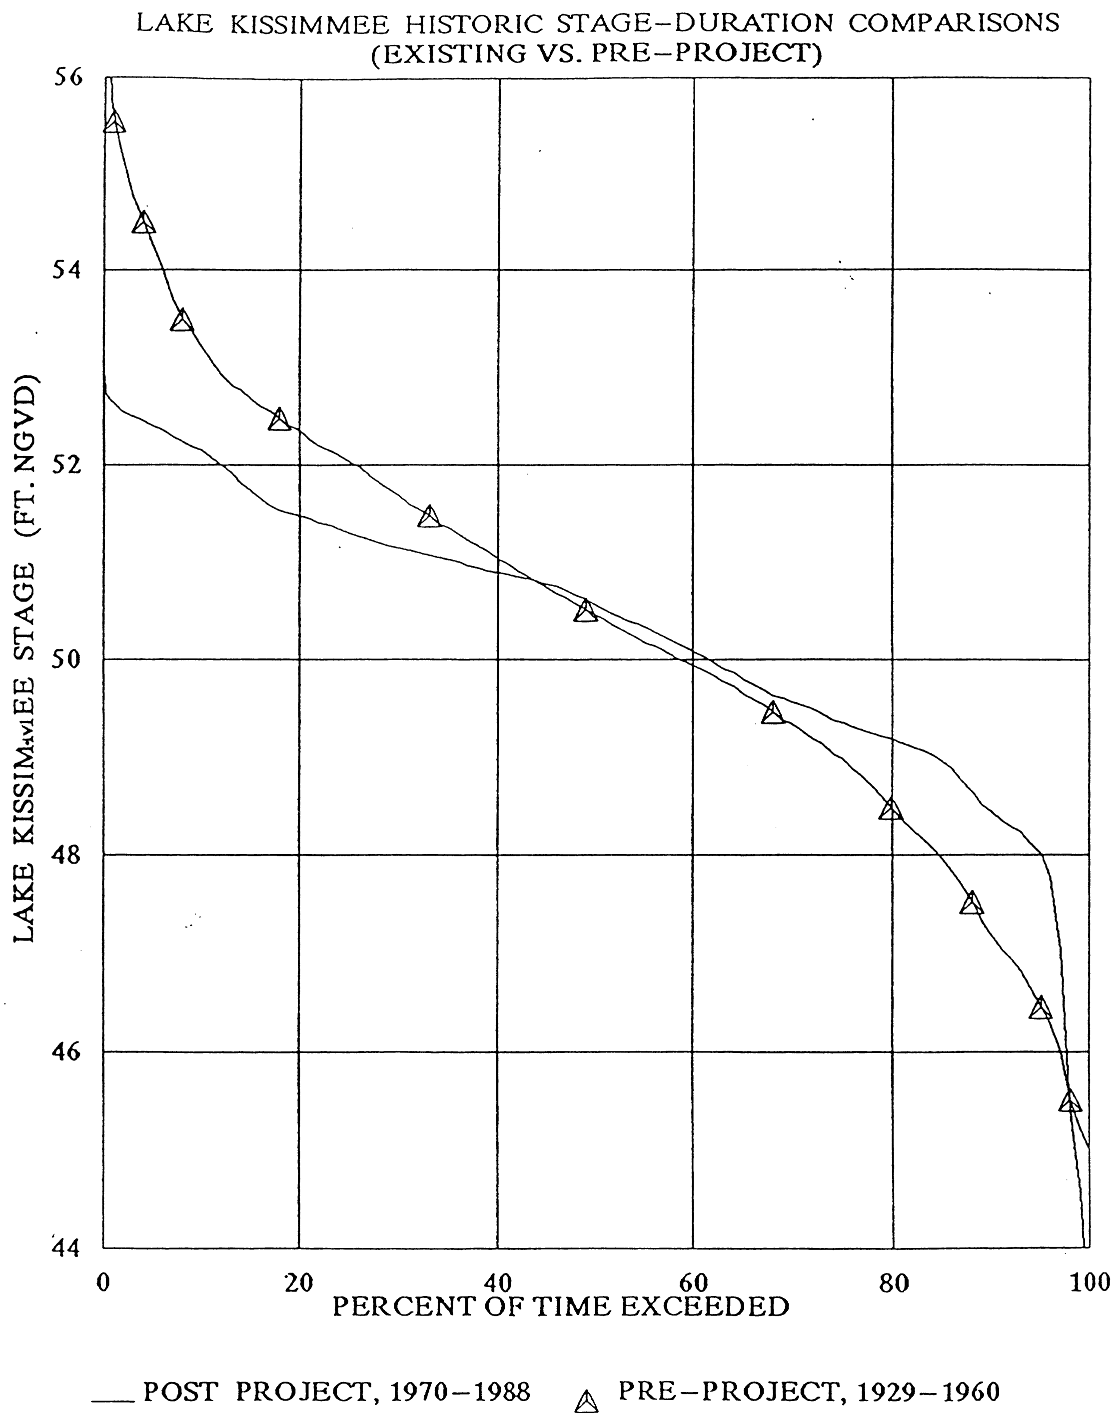

Figure J-2.1-1 Lake Kissimmee Stage Duration Comparisons

The zone around the present emergent marsh is largely pasture land dominated by short-growing carpet grass, with little cordgrass, and is subject to cattle grazing. Where cattle are excluded, the area is dominated by other grasses, such as torpedo grass. If the upper marsh has not been burned and cattle are excluded, it is dominated by broomsedge (*Andropogon virginicus*), dog fennel (*Eupatorium capillifolium*), sesbania (*Sesbania punicea*), goldenrod (*Solidago fistulosa*), and wax myrtle (*Myrica cerifera*).

The wet prairie is typically inundated about 1.5 months to 5 months each year. It is dominated by grasses and rushes, such as *wiregrass (Aristida stricta*), maidencane, spikerush (*Eleocharis* spp.), beakrush (*Rhynchospora microcarpa*), and cordgrass.

Reduced or eliminated water level fluctuations have been implicated by many authors as a major cause of undesirable changes in lake and wetland communities (Perrin, 1982). Such changes involve the accelerated accumulation of unconsolidated bottom sediments, declines in dissolved oxygen, nutrient enrichment, vegetation changes in the upper littoral zone, and ultimately the reduction of fish and wildlife populations.

In six places, on the east and west shore of Lake Kissimmee, on the southwest, northwest and east shore of Lake Hatchineha, and on the northwest shore of Lake Cypress near C-35, land owners have constructed farm levees to reduce flooding of pasture land. The levees inhibit flooding of about 3,000 acres that, historically, were marsh, contiguous with the lakes during high water periods.

This reduction in the size of the littoral zone marshes has reduced the total area for recruitment of forage to the in-lake fishery and diminished the shallow, useful zone for wading bird foraging. The present day marsh zone is approximately 16,000 acres. This is approximately a 71 percent reduction in marsh area compared to the historical extent of wetlands surrounding these lakes.

On occasion these lakes are drawn down several feet in cooperation with the GFC as a fisheries management measure to consolidate organic sediments and to permit removal of muck and debris from the littoral zones. They attempt to hold water levels down for at least 90 days, starting February 1. For Lake Kissimmee, water levels should remain below 45 feet for a minimum of 90 consecutive days for effective treatment. Extreme drawdowns were completed for Lake Tohopekaliga in 1971, 1974, and 1987, and East Lake Tohopekaliga in 1989. A drawdown of Lake Kissimmee was completed in 1977 and 1996.

Historically, the Kissimmee River floodplain was approximately one to two miles wide and sloped gradually to the south from an elevation of about 51 feet at Lake Kissimmee to about 15 feet at Lake Okeechobee.

> "*The marshes along the Kissimmee River floodplain historically occupied around 5000 km² [2,000 mi²]. Prior to its channelization in the 1960's, the river followed a 160-km [100 mi] meandering course from its headwaters at Orlando to its terminus in Lake Okeechobee. Undulating topography within the Kissimmee Valley created numerous isolated swale marshes, which blended into drier grasslands known as the Kissimmee Prairie.* (Kushlan in Myers and Ewel, 1990.)"

Based on the U.S. Fish and Wildlife Service's (1991) interpretation of 1954 photography of the Lower Kissimmee river Basin the historic flood plain contained approximately 35,000 acres of wetlands. "One of the largest marshes in the Kissimmee complex was the 12,000 ha [30,000 acre] Istokpoga (or Indian) Prairie, which originated at Lake Istokpoga and then drained southward to Lake Okeechobee. It was once covered by shallow marsh, embedded with numerous deeper marshes. Similar marshes dot the swamp forests within the Fisheating Creek basin, located southwest of the Kissimmee River valley." (Kushlan in Myers and Ewel, 1991).

Major plant communities found within the Kissimmee River wetlands included maidencane and beakrush wet prairies, broadleaf marsh, and woody shrub. Other plant communities common in the wetlands, but not distributed extensively, included wetland hardwoods, cypress stands, oak-cabbage palm hammocks, switchgrass, sawgrass, and floating mats or tussocks (Pierce et al., 1982).

Distribution and maintenance of the plant communities within the flood plain was influenced by inundation periods and seasonally fluctuating water levels (Dineen et al., 1974; Toth, 1991). A fluctuating hydroperiod, along with the undulating topography of the flood plain, a meandering river channel, oxbows, and natural discontinuous levees, enhanced and maintained habitat diversity, including a mosaic of intermixed vegetation types (Perrin et al., 1982).

The 35,000 acres of wetlands that existed prior to channelization in the Lower Basin are estimated to have declined to about 14,000 acres in the existing condition (U.S. Fish and Wildlife Service, 1991). As during prechannelization, the dominant post-channelization wetland communities are broadleaf marsh, wet prairie and wetland shrub.

J.2.2 Fish and Wildlife

The fluctuating waters of the lake littoral zones of the upper basin are important for overwintering waterfowl, which utilize these lakes during migrational periods. Coots (*Fulica americana*), ring-necked ducks (*Aythya collaris*), American widgeon (*Anas americana*), pintails (*Anas acuta*) and blue-winged teal (*Anas discors*) are the major species (Joe Carroll, USFWS. Pers. Comm., 1992). The native Florida, or mottled duck (*Anas fulvigula*) also breeds and is resident in the shoreline marshes. Normally, the common snipe (*Gallinago gallinago*) is also found in these areas in the fall and winter months.

Post-regulation waterfowl use in the Upper Basin, i.e., Lakes Kissimmee, Hatchineha and Cypress, has averaged 3,405 waterfowl days based on eight surveys between 1965 and 1980. Pre-regulation waterfowl usage, based on three surveys between 1954 and 1957, had a mean of 4,360 waterfowl days. This is a 22 percent decrease in waterfowl day usage since lake level regulation was imposed on the lakes (Perrin et al., 1982). Presently, i.e., 1994-1995, a mid-winter waterfowl survey by the Florida Game and Fresh Water Fish Commission (GFC) on lakes Kissimmee, Cypress, Hatchineha and Tohopekaliga estimated approximately 56,402 individuals were utilizing the lakes. This would represent an increase of approximately 16,000 individuals over the historic peak of 40,000 individuals since lake level regulation has been imposed. However, in comparing the data found in Perrin et al. (1982) against the 1994-95 mid-winter survey by GFC this increase is attributed to the significant increase in the populations of coots on the lakes. Lake Kissimmee had a pre-regulation (1954-1957) population mean of 2,532 ducks and 959 coots during winter surveys, while the post-regulation (1965-1980) mean population had changed to 1,437 ducks and 1,203 coots. The GFC found in their mid-winter survey of Lake Kissimmee that ducks numbered approximately 3,185 whereas coots had increased to 14,010. This change in species abundance from ducks to coots is exhibited on all the lakes of the Upper Basin. The changes in duck and coot populations on the lakes has occurred following implementation of regulated water level schedules. One of the main factors related to these changes would be the decrease in the zone of fluctuation surrounding the headwater lakes. The zone of fluctuation which provides important waterfowl habitat was reduced by 5,600 acres for all upper basin lakes following water level regulation (Huber et al., 1976). Due to topographical characteristics, the reduction of high water stages had greater impacts upon the low lying marshes bordering Lakes Kissimmee, Hatchineha and Cypress than the other lakes of the Upper Basin. The vegetation change resulting from regulated water level schedules and construction of local farm levees has resulted in conditions that favor coot utilization over ducks.

Wading birds use the littoral zone as important feeding habitat. The great egret (*Casmerodius albus*), snowy egret (*Egretta thula*), great blue heron (*Ardea herodias*), tricolor heron (*Egretta tricolor*), and little blue heron (*Egretta caerulea*) are among those that benefit from the littoral zone. White ibis (*Eudocimus albus*) and glossy ibis (*Plegadis falcinellus*) also feed there. All are dependent on forage organisms produced in the littoral zone; i.e., fishes, reptiles, amphibians and invertebrates. One of the main reasons for recent declines in wading bird populations has been attributed to nesting failures due to inadequate food production (Ogden 1978). Ultimately, this lack of food production is attributed to increased marshland destruction and alteration of hydrological patterns (Kushlan and White 1977, Ogden 1978). Based on aerial surveys conducted over the upper and lower Kissimmee Basins by GFC from November 1978 through October 1980, wading bird population levels in the survey area seemed to reflect the degree to which wetlands habitat had been degraded. Number of species, density, and diversity of wading birds generally were lower in the Lower Basin (Kissimmee River) system than in the lake marshes of the Upper Basin.

Sport fishing constitutes the largest recreational use in the Upper Basin area. The primary quarry sought by anglers on Lake Kissimmee is the largemouth bass (*Micropterus salmoides*). From 1987 to 1991, anglers exerted 59 percent of the total fishing effort on bass, 24 percent on black crappie (*Pomoxis nigromaculatus*) and 17 percent on bream (*Lepomis* spp.). Miscellaneous species, such as channel catfish (*Ictalurus punctatus*), brown bullhead (*Ictalurus nebulosus*) and chain pickerel (*Esox niger*) also were targeted. The effects of stabilized water levels, loss of littoral wetland habitat and the increased nutrient loadings are displayed in the accumulation of muck in the littoral zones. Increased rates of organic matter deposition and flocculation of decaying plant matter have reduced the food availability for fish, limiting the habitat for fish spawning and larval and juvenile fish.

The American alligator (*Alligator mississippiensis*) is a dominant reptile in both the upper and lower basins. The alligator scavenges for carcasses of birds and hunts for fish in the deep water canals and ponds within the marsh zone.

The lower basin has experienced a substantial decline in largemouth bass and the loss of six indigenous fish species (Perrin et al., 1982). This decline has been attributed to low dissolved oxygen levels in the canal, the drainage of wetlands which have reduced food and foraging habitat for river fish species, and the lack of river habitat diversity on the channelized waterway (Toth 1990). Game and Freshwater Fish Commission data indicate the rough fish (gar and bowfish) to game fish ratio presently is about three-to-one.

During and since construction of the Kissimmee Flood Control project, several wading bird counts were made (Toland, B. 1991) and summarized (Montalbano et al., 1979; Perrin et al., 1982). An interpretation of Toland's work yields an estimate of an average population of 3,500 birds on the flood plain, exclusive of cattle egrets (2,500-4,500 range est. by Toland, B. 1991). One species, the wood stork, is Federal listed as an endangered species. Three other species are listed by the Florida Game and Fresh Water Fish Commission as endangered or as a species of special concern: tri-colored heron (endangered), little blue heron (species of special concern), and snowy egret (species of special concern). The South Florida Water Management District Demonstration Project resulted in a 1,000 percent increase in the aquatic wading bird utilization of the area (Toland, 1990).

The present waterfowl population estimate is about 140 in the Lower Basin (Toland, 1991); available winter water is estimated to be about 27,000 acre-days annually. A study by the Florida Game and Fresh Water Fish Commission (Perrin et al., 1982) reported that about 80 percent of the wintering waterfowl population utilized the Upper Basin while use of the river flood plain accounted for the remaining 20 percent. This study also disclosed that coot and water-fowl usage of the flood plain decreased by over 90 percent after channelization of the Kissimmee River. This was partly a result of shifts in continental population of waterfowl. A significant exception was Paradise Run, which is influenced by periodic water level fluctuation and hence has habitat conditions that are more attractive to waterfowl, and which had substantially more waterfowl utilization than any of the five pools of C-38.

J.2.3 Water Management

The system of water control works now in place in the Kissimmee Basin conforms closely with the general plan outlined in the 1948 report to Congress and authorized for construction in 1954. The project was designed to provide flood damage prevention for thirty percent of the standard project flood (SPF). This equates to protection against a five-year flood event. Water levels within the basin are controlled by a complex system of canals and control structures that are managed by the South Florida Water Management District in accordance with regulations prescribed by the Secretary of the Army.

The major lakes of the “Headwaters” area, (the Upper Basin) are connected by channels. Most of the channels were excavated by private interests in the 1880’s and subsequently enlarged to varying degrees under the congressionally authorized plan. Nine control structures regulate water levels and flows in the lake system. For more details on the existing flood control project, refer to the U.S. Army Corps of Engineers Kissimmee River, Florida – Final Feasibility Report and Environmental Impact Statement (1985). Operational criteria for both basins can be found in the Water Control Plan for the Kissimmee River-Lake Istokpoga Basin (1991). From time to time, operations may temporarily deviate from the water control plan. These temporary deviations may be conducted for various purposes such as control of nuisance aquatic vegetation, lake drawdowns, or construction.

Prior to the project, lake outlets within the “Headwaters” region had been dredged for drainage and navigation, but were uncontrolled, and over-drainage often occurred. Dredged outlets did not provide adequate flood control and the Upper Basin did not have enough outlet capacity (sometimes termed “get away” capacity) to remove flood waters within a “reasonable” time frame to avoid flood impacts.

To provide adequate outlet capacity from the Upper Basin, approximately 15 miles of canal, the outlet channel, was required immediately downstream of Lake Kissimmee. This length is a function of canal size, the size of the Lake Kissimmee outlet structure size (S-65), and the very flat terrain immediately downstream of the lake.

An earlier project, the Herbert Hoover Dike around Lake Okeechobee, had modified the original lower end of the Kissimmee River with a borrow area immediately upstream of Lake Okeechobee. This eight mile section of canal, known as Government Cut, was modified and enlarged during construction of C-38, and is inside the Lake Okeechobee containment levee. This section of the canal diverted flow from a downstream portion of the Kissimmee River, creating an isolated remnant of the river known as Paradise Run. Paradise Run, immediately west of Government Cut, retains most of its original topography; however, diversion of natural flows has lowered water levels and former wetland areas have been converted to grazing and pasture land.

Between the outlet channel at the upper end of the Kissimmee River (C-38), and Government Cut at the lower end, approximately 33 miles of the river and flood plain, referred to as the central reach, also was provided flood control. Some consideration was given to non-structural approaches (e.g., levee the uplands from the flood plain); however, channelization was determined to be more cost effective at that time. Combined with Government Cut, the new canal provided complete channelization of the entire 56-mile river-flood plain from Lake Kissimmee to Lake Okeechobee.

The natural fall of the land from Lake Kissimmee to Lake Okeechobee is about 36 feet. Construction of Canal 38 (known as C-38) included six water control structures, S-65, 65A, 65B, 65C, 65D, and 65E from north to south, which form a series of five pools between S-65 and Lake Okeechobee.

The S-65 structures act as dams, and were located to step the canal water level down in increments of about six feet. In doing so, the natural slope of the river was removed, and flat pools (impoundments) resembling stair-steps were created. The water level of each pool generally is held constant, with little fluctuation or slope. This action has lowered water in the northern reach of each pool, and has created flooded marsh in the southern or lower end of each pool. A water surface area of approximately 7,600 acres is included within these pool areas under the existing regulation schedules.

C-38 is generally 30 feet in depth, but varies in bottom width from 90 feet near Lake Kissimmee to 300 feet above S-65D. The canal's length, width, and water level vary in each pool. The head, or difference in water level above and below each structure, varies from structure to structure and with rate of discharge, but is typically about six feet.

During construction of C-38, a temporary easement was used to obtain areas adjacent to the canal for deposition of dredged material. The material was hydraulically deposited in linear alignments covering some 8,000 acres along the canal, with elevations averaging 15 feet above pre-project topography. The material consisted of hydraulically sifted subsoil sands and clays with limited organic fraction, and high percolation rates. The material became part of the property upon which it was deposited. A number of landowners subsequently used the material to fill low areas on their property; and, at two locations in Okeechobee County, flood free, fly-in, residential subdivisions were built on the material. Where material was left undisturbed, xeric vegetation emerged on many of these deposits.

The CS&F Project works improved navigation opportunities originally provided in the Congressional Act of 1902. Each water control structure along C-38 includes a 30-foot by 90-foot navigation lock, which can accommodate boats with drafts up to 5.5 feet. The canal provides continuous navigation; however, inter-pool navigation is limited to daylight hours of lock operations.

The approximately 68 miles of river oxbows that exist within the five C-38 pools represent secondary channels of widely varying water depths. Many of these channels are very shallow, but only those that receive tributary inflows have any substantial base flow. Culverts within the tieback levees at Structures S-65B, 65C, and 65D provide modest amounts of circulation flow in the existing river channels below the levees.

Approximately 50 tributaries provide inflow into the Lower Kissimmee Basin. These tributaries are characterized by relatively constricted central channels with pasture lands usually extending along the channel. Most channels are covered with vegetation.

J.2.4 Water Supply

The Kissimmee River Basin contributes about 30 percent of the water input to Lake Okeechobee and is second only to rainfall in the lake's water budget. Prior to channelization, the Kissimmee Basin, which included the Istokpoga Basin, contributed an average annual inflow of about 4,300 acre feet/day (2,200 cfs) at its outlet.

The volume of water reaching the Lower Kissimmee Basin has declined in recent years. The majority of the decline has occurred in the Upper Basin, where, for example, the mean discharge has declined from 1,241 to 722 cubic feet per second at the gage site near S-65. A small portion of the decline may be attributable to an increase in water supply withdrawals, and current water management practices; however, this reduction is most likely the result of a reduction in basin rainfall compared to pre-project rainfall conditions (Obeysekera and Loftin, 1990). In the Lower Basin below Lake Kissimmee, the basin yield, after adjusting for Lake Istokpoga outflow, has remained virtually unchanged.

Since 1970, the south Florida region has experienced an apparent change in rainfall characteristics, and most basins in the region have received less than normal annual rainfall. The Kissimmee River Basin has had about 10 percent less rainfall compared to pre-1970 records. Land use in the Kissimmee Basin also has undergone substantial change over the last thirty years. Combined effects of upland drainage and construction of the basin's flood control works, have changed the hydrologic response from upland/flood plain retention and slow runoff, to upland/flood plain drainage with rapid runoff. The flow regime has undergone a major shift from predominantly baseflow runoff, to surface (direct) runoff with increased volume discharged at a faster rate during flood events (Huber et al., 1976, Obeysekera and Loftin, 1990).

The net hydrologic effect of the canal and control structures was to shorten the residence time of water in the basin during periods of high water (floods) and to increase residence time during low-flow (drought) periods. Based on a review of historical U.S. Geological Survey data under similar hydrologic conditions, the overall volume of water delivered to Lake Okeechobee from the Lower Kissimmee River Basin via the canal was found to be relatively the same as those volumes experienced under pre-project conditions. The timing of those water deliveries has been changed, however, which is reflective of current water management practices for flood control and water conservation purposes within the basin.

J.2.5 Socio-Economics

The six counties that make up the study area of this report are Glades, Highlands, Okeechobee, Orange, Osceola, and Polk. Population growth and economic activity within the study area and in the state overall has influenced and is expected to continue to influence the socio-economic trends and characteristics of the Kissimmee Basin. The State of Florida began showing tremendous population growth after World War II. The state's population grew from 2,771,300 in 1950 to 12,937,900 in 1990 primarily because of migration. Over this period the state's share of the U.S. population increased from 1.8 to 5.2 percent.

Within the six-county Kissimmee River Basin study area, the 1990 population totalled 1,296,251. The majority of the population resided in Orange County, with Orlando being one of the nation's leading tourist areas. There are no major urban areas within the Lower Basin. The largest urban concentration in the area is Okeechobee, located within the Taylor Creek-Nubbin Slough sub-basin.

J.2.6 Land Use

Orlando, at the headwaters of the Kissimmee River Basin, is the primary economic and transportation center in the study area. Once the center of the state's orange production, the local economy of Orlando and the surrounding area now focuses on tourism. Kissimmee, located in Osceola County, is located eight miles east of Disney World and seventeen miles south of Orlando, and is influenced largely by tourism activities in the Orlando area. The other major incorporated area of Osceola County, the city of St. Cloud, is primarily a retirement community.

Land uses in the Upper Basin around the perimeters of Lakes Kissimmee, Hatchineha, Cypress, Rosalie, Tiger and Jackson are primarily pasture, some agriculture, and a large amount of wetlands. Marinas, fish camps, and various public facilities, such as boat launching sites and picnic areas, are located around the lakes. Lake Kissimmee State Park is on the extreme northwestern periphery of Lake Kissimmee, and the Three Lakes Wildlife Management Area and Prairie Lakes Preserve border the southeastern half of Lake Kissimmee. Small residential and commercial areas are also scattered around most of the lakes. Development is more intense upstream of Cypress Lake, particularly in the Lake Tohopekaliga – East Lake Tohopekaliga (Toho) chain.

Agriculture continues to play an important role in the region. In the Lower Basin, most of the area between Lake Kissimmee and Lake Okeechobee is in fewer than fifty large, private land holdings and several hundred subdivided property holdings. Agriculture remains the primary land use activity within the Lower Basin, being dominated by extensive beef cattle production and dairy activities.

The Avon Park Air Force Bombing Range is located within the Polk County portion of the Lower Basin. This 107,000-acre Federal facility is used both as a training facility for Armed Forces personnel, and as a management area for wetlands adjacent to the Kissimmee River.

Table J-2.6-1 provides generalized land use categories found within the Lower Kissimmee River Basin. Lower Basin lands have undergone substantial change over the last twenty years. Most notable is the conversion of unimproved pasture land to improved pasture at an accelerated pace during the period 1958 to 1972.

In the Upper Basin, most of the development susceptible to flood damage is urban, where damage is primarily a function of the depths of flooding inside structures or the stage of flooding. Single family residential land use is the primary type of development affected by flooding in the Upper Basin. Major affected areas are located around the towns of Kissimmee and St. Cloud, which cover only six

Table J-2.6-1 Land Use Lower Kissimmee River Basin			
Land Use	**1958**	**1972**	**1980**
Urban	0	1,300	3,100
Crops	300	1,600	5,400
Improved Pasture	32,900	223,200	187,100
Unimproved Pasture*	280,600	133,200	141,500
Citrus	1,300	1,000	1,700
Forest	3,200	7,500	35,800
Marsh	133,700	84,200	54,900
Total	452,000	452,000	438,500

(Source: Obeysekera and Loftin, 1990)
Most of the unimproved pasture was wet prairie.
** Area for 1980 does not include the sub-basin below S-65E.

percent of the damage susceptible flood-prone area but account for almost half of the basin's standard project flood damage. Other affected areas include Lake Hart, Lake Mary Jane, Pells Cove, Hidden Lake, Lake Hatchineha, Lake Alligator, Lake Rosalie, and the area west of the southern part of Lake Kissimmee. Existing average annual equivalent flood damages in the Upper Basin are estimated to be $1,226,100 (8 ¾ percent rate).

In the Lower Basin, mobile homes located around Pool E are the primary areas that would be affected by flooding. Although this land use would account for most of the damages from a standard project flood and 100-year event, it is not susceptible to damage during smaller floods. Other damages occur due to the duration of flooding on pasture land. Although agricultural use is the primary land use in the Lower Basin, flood damages are relatively minor for this activity due to the short duration of flooding, a result of the existing project works. Existing average annual equivalent damages in the Lower Basin are estimated to be $97,700 (8 ¾ percent rate).

J.2.6.1 Agriculture

Osceola, Polk, Highlands, and Okeechobee Counties were included in this region. More than two million acres in these counties are farmed, with more than half of this area devoted to pastureland (UFBEBR, 1995). Much of this acreage is likely categorized as unique farmland based upon its location, growing season, and high value crops, including citrus. Almost a quarter of a million acres in the Kissimmee River Basin are irrigated (UFBEBR, 1995), requiring a dependable water supply. This region is characterized by large farms with relatively low productivity per acre. These four counties are among the top five counties in Florida for cattle production, both beef and dairy (FASS, 1996a). More than

200,000 acres are used for citrus production. Approximately 11,000 people are employed in agricultural production and services representing a payroll of approximately $21 million (UFBEBR, 1995). The market value of all agricultural products in this region totals approximately $575 million (UFBEBR, 1995).

J.2.7 Recreation Resources

The three counties in which the upper Kissimmee Basin is located are in two different regions according to the State Comprehensive Outdoor Recreation Plan, published in 1989. Orange and Osceola are in Region VI; Polk is in Region VII. The large urban populations around Orlando, the Tampa Bay area, and the central coastal cities are all within a one- to two-hour drive from the project area. The main highways leading to the project area are heavily traveled and well maintained. The main constraint to access lies with the condition of the secondary service roads leading from the main highways to the upper chain of lakes and the large amount of private property which is in agricultural use around some of the lakes.

Recreation in the upper Kissimmee River basin is moderate to heavy with emphasis on Recreational Vehicle (RV) camping, general boating, and boat and bank fishing. Channelization and water control provide year-round navigable water levels for recreational boating, canoeing, and fishing. During high water conditions, airboats are able to traverse many of the marshes and flooded pastures around the chain of lakes.

Marinas, fish camps, and various public facilities such as boat launching sites and picnic areas are located around the lakes. There are six public and 14 commercial boat ramps around the upper chain of lakes, which occur within the region affected by headwaters revitalization. The commercial boat ramps are associated with RV parks, marinas and fish camps located on the lakes. All but two of these commercial operations charge fees for use of their launching facilities.

Lake Kissimmee State Park encompasses over 13,000 acres along the extreme northwestern periphery of Lake Kissimmee. Lake Kissimmee State Park, located on the shores of Lakes Kissimmee, Tiger and Rosalie, offers outstanding fishing and water access, picnicking, bird watching and boating. Thirty campsites with water and electrical hookups are available. The park has 13 miles of hiking trails, which offer hikers the possibility of seeing whitetail deer, bald eagles, sandhill cranes, turkeys and bobcats. Plans to rework the park boat ramp are being developed by the State.

The Three Lakes Wildlife Management Area, located in Osceola County, is an 59,000 acre tract of land adjacent to Lakes Kissimmee, Jackson and Marian. This area is traversed by the Florida Trail. Picnicking facilities are available and primitive camping is allowed at designated campsites along the trail except during established hunting seasons for the area. Camping permits are required, but these are issued at no cost to the camper. This area has a boat ramp which can provide access to the Kissimmee chain of lakes via Lake Jackson. Parking at the ramp should not be affected by higher water conditions. The access road into the site may be subject to overtopping, however.

The Kicco and Kissimmee River Wildlife Management Areas also provide recreational amenities in this region. Kicco Wildlife Management Area comprises 7,427 acres on either side of River Ranch Resort, and Kissimmee River Wildlife Management Area is composed of eight units along both sides of the Kissimmee River and currently totaling 8,581 acres. Kissimmee River Wildlife Management Area is expected to expand as new tracts are acquired (GFC pers. comm.).

A large number of out-of-state visitors bring their boats with them to spend the winter in this portion of the State. During their stay, they participate in fishing and boating activities in and around the interconnected chain of lakes in the Upper Kissimmee Basin. Rental boats are available at many of the fish camps and marinas found along the edge of many of the lakes. Resident boat owners intensify the use of these lakes. The combined acreage of the Upper Basin lakes, plus the miles of waterways in between, offer recreational boating and fishing unlimited opportunities for residents and visitors alike.

Heaviest boat usage occurs within the Lake Kissimmee and Lake Okeechobee areas, located at the northern and southern ends of C-38. This is most likely the result of the larger numbers of boat owners who keep their boats at marinas on these lakes, more waterfront property owners with their own moorage facilities, and more convenient access to these larger water bodies than to the river. Although fishing occurs on a year round basis, heaviest fishing use occurs during the four to five months from late fall to early spring.

Recreational fishing is the largest use of species in the lakes. Based on creel data collected by the GFC, effort expended to fishing in Lake Kissimmee over the five year period, 1987-1991, averaged 451,582 hours per year. The primary quarry sought by anglers on Lake Kissimmee is the largemouth bass. From 1987 to 1991, anglers exerted 59 percent of the total fishing effort on bass, 24 percent on black crappie and 17 percent on bream. Miscellaneous species, such as channel catfish, brown bullhead and chain pickerel also were targeted. The only creel survey conducted in Lakes Hatchineha and Cypress was during the spring of 1986. The total fisherman effort was 40,832 hours at Hatchineha and 18,007 hours at Lake Cypress. As a comparison, fishermen in Lake Kissimmee fished for 213,921 hours during the same spring quarter (February 21 to May 15, 1986). Lakes Rosalie and Tiger are also popular with fishermen, but no creel census on these waters were available for this report. Lake Jackson has been a popular fishing spot in the past, but aquatic vegetation problems periodically cause fishing effort to be low. Hunting is also a very popular recreational activity in the Kissimmee River Region, particularly in terms of hogs, deer, and waterfowl.

The lakes are drawn down several feet on occasion to consolidate organic sediments and to permit removal of muck and debris from the littoral zone. Water levels are lowered for several months at a time during the draw down period. During this period the major problem in affected lakes is temporary loss of navigational access due to low water. The organized Kissimmee Boat-A-Cade utilizes the Kissimmee channel for an annual floating pilgrimage in December from the City of Kissimmee through Lake Okeechobee to the coast. The 1995 Boat-A-Cade was canceled because of a drawdown underway on Lake Kissimmee.

Recreation within the Lower Kissimmee River Basin has increased substantially in recent years, and both public and private facilities have been developed or expanded to accommodate the increasing demand for recreational opportunities. Public facilities include Okee-Tanti Park, located at the mouth of the Kissimmee River, which provides camping, picnicking, boat ramps, and restrooms with showers. Other public facilities include Lake Kissimmee State Park, located upstream of the channelized Kissimmee River, and the Avon Park Bombing Range, the latter offering camping, picnicking, hiking trails, and hunting. The Bombing Range is utilized during the week by several military bases throughout the state for practice flights. As a result, the number of low-flying jet aircraft using the range tends to disrupt the audible aesthetics of the river.

Private facilities include the River Ranch Resort located at the upper end of the Kissimmee River, which offers a marina, and multi-purpose recreational opportunities. An additional seven privately-owned fish camps are located between State Highways 60 and 70, offering boat ramps and other services along the waterway.

Recreational use in the Lower Basin is primarily concentrated at each end of C-38, with emphasis on camping, general boating, boat fishing, and bank fishing. There is limited access to the river on C-38 for bank fishing, but boaters have access to almost any point along the waterway from existing boat ramps. However, available facilities are not used at full capacity. Most of the land along the river remains in private ownership. Those using the area for fishing, hunting, and wildlife observation may only utilize the river banks and adjacent lands with permission of the landowners.

Thirty-six miles of the Florida National Scenic Trail were dedicated in June 1990 along the flood plain of the Kissimmee River. Additional sections of trail will be developed as contiguous parcels of land are acquired by the state under the Save

Our Rivers program. According to the South Florida Water Management District, the long range plan is to extend the trail the full length of the river.

A 1978-1980 fishing census by the Florida Game and Fresh Water Fish Commission found about 26,000 fishing days annually. Effort by species was 43 percent for bass, 41 percent for crappie, and 16 percent for panfish. Non-residents accounted for 28 percent of the fishing. Boat traffic through the six locks is 20,000 passages per year (1991).

Prior to construction of the C&SF Project in the Kissimmee Basin, efforts were made by local recreational boating interests to demonstrate the need to continue navigation on the river. As a result of this interest in the maintenance of navigation, locks were included in the Federal project with the local sponsor responsible for maintenance of the navigation portion of the project. The South Florida Water Management District has continued to operate and maintain the navigation locks which are used by recreational craft.

The existing flood control project modified the Congressionally-authorized 3-foot navigation project, and the waterway now provides daylight only year-round navigation from Lake Kissimmee to Lake Okeechobee. Navigation is now primarily along the canal (C-38), instead of the meandering alignment of the original river. The waterway provides opportunity for day use recreational boating, canoeing, and fishing. The organized Kissimmee Boat-A-Cade currently utilizes the channel for an annual floating pilgrimage of some 300-400 boats from the city of Kissimmee through Lake Okeechobee to the coast.

Field observations of boaters using the channelized Kissimmee River indicate that recreational powerboats are dominant crafts using the waterway. Annual lockage data for the six navigation locks on the Kissimmee also indicates to some extent the utilization of the system.

Although portions of the original river are presently unnavigable, many of the original river oxbows remain intact and are accessible via small boats or canoes. Some 60 miles of oxbow and meander area of the original river are accessible by canoe, bass boat, jon boat, and similar shallow-draft craft.

J.2.8 Aesthetic Resources

The Headwaters lakes exhibit a patchwork development pattern with numerous subdivisions as well as commercial enterprises and agriculture dotting the lakeshores. Large tracts of undeveloped land used by wildlife for roosting, feeding and nesting are interspersed along stretches of the lakes, and are more extensive than the developed shorelines. This patchwork type of development allows those who use the lakes the opportunities to view a tremendous variety of wildlife from short distances away from shorelines. The Upper Chain of Lakes provides an excellent example of the contrasts between development and a more natural lacustrine environment.

With the exception of developed areas around major road crossings, and near the various locks, the Lower Basin is largely undeveloped and presents many miles of water in which boaters can travel without seeing signs of human habitation. However, the canal offers little in the way of vegetative or scenic interest. The canal is wide and straight, and this contributes to the lack of variety.

The remnants of the old river are associated with the large, older trees and denser vegetation, as well as submerged and emergent plants. These have not established themselves on the canal cut because of deeper water and steep sides. The taller trees overhanging the oxbows provide shade which is missing from the main canal.

The aesthetics are adversely affected in the vicinity of the Avon Park Bombing Range, which is used during the week by several military bases throughout the State of Florida for practice flights. The planes approach the range from any direction at low altitudes and at high speeds with the resulting noise associated with such low flying aircraft. This has a tendency to shatter the audible aesthetics of the river.

J.2.9 Hazardous, Toxic, and Radioactive Wastes

The U.S. Army Corps of Engineers performed a HTRW Civil Works Audits in conformance with ER 1165-2-132. These audits covered property impacted by both the upper and lower restoration projects. Aerial photographs were reviewed for the purpose of delineating the actual property for detecting any signs that would indicate past activity that could have resulted in the existence of a current hazard. A south Florida Water Management District Environmental Audits determined that two inactive cattle dipping vats were identified on the concerned property.

J.3 LAKE OKEECHOBEE

Lake Okeechobee (***Figure J.3-1***) is the second largest freshwater lake within the contiguous United States, measuring 700 square miles (576,000 acres) in area, with approximately 150 square miles of littoral zone. The lake is shallow with a mean depth of 9 feet, subtropical, and eutrophic. Its storage capacity of 1.05 trillion gallons makes it the center of south Florida's water supply and flood control system. Lake Okeechobee provides water for a variety of consumptive demands, including urban drinking water, irrigation for agricultural lands, and recharge for wellfields. Habitat conditions inside and outside the lake also depend on this water supply. The lake's littoral zone supports a renowned recreational sport fishery, commercial

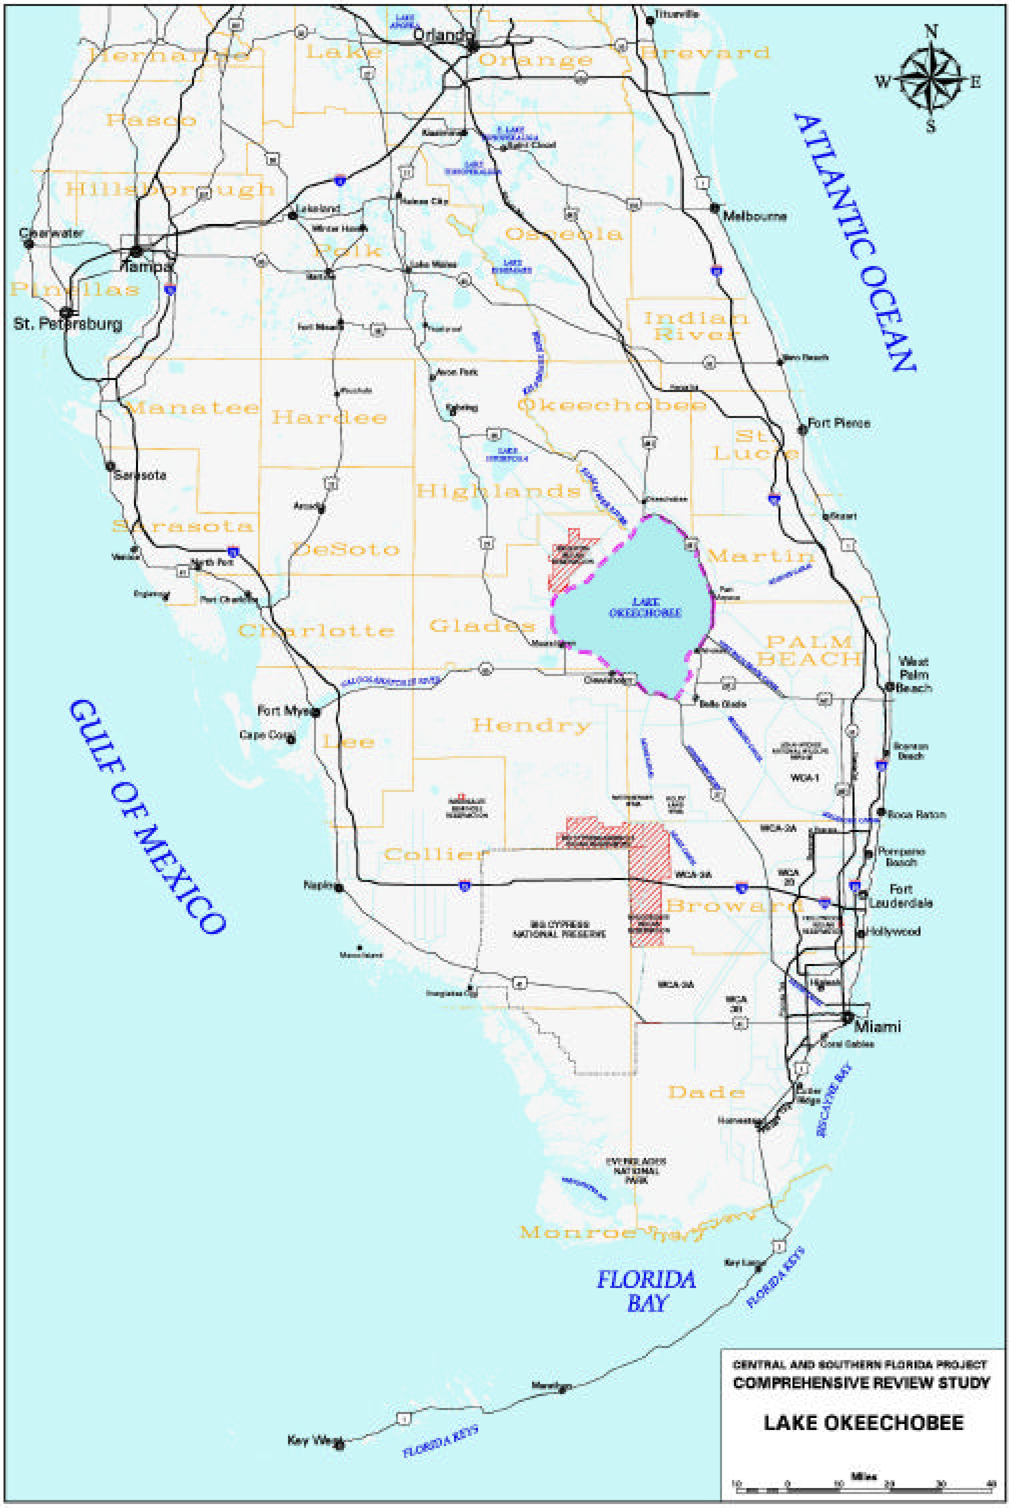

Figure J.3-1 Lake Okeechobee Region

fishery, wading bird breeding and foraging, resident and migratory waterfowl, and endangered species. Lake Okeechobee is an important source of freshwater to the Everglades, and discharges control the ecology of the St. Lucie and Caloosahatchee estuaries.

J.3.1 Vegetation

The vegetation and cover types within the Lake Okeechobee region have been greatly altered during the last century. Historically, the natural vegetation was a mix of freshwater marshes, hardwood swamps, cypress swamps, pond apple forests, and pine flatwoods. The freshwater marshes were the predominant cover type throughout, but especially along the southern portion of the Lake where it flowed into the Everglades. These marshes were vegetated primarily with sawgrass (*Cladium jamaicense*) and scattered clumps of carolina willow (*Salix caroliniana*), sweetbay (*Magnolia virginiana*), and cypress (*Taxodium* sp.). Hardwood swamps dominated by red maple (*Acer rubrum*), sweetbay, and sweet gum (*Liquidambar styraciflua*) occurred in riverine areas feeding the Lake, while cypress swamps were found in depressional areas throughout the region. Pine flatwoods composed of slash pine (*Pinus elliottii*), cabbage palm (*Sabal palmetto*), and saw palmetto (*Serenoa repens*) were prevalent in upland areas especially to the north.

Lake Okeechobee has an extensive littoral zone that occupies approximately 400 km^2 (about 25 percent) of the lake's surface. Littoral vegetation occurs along much of the lake's perimeter, but is most extensive along the southern and western borders (Milleson 1987). The littoral zone plant community is composed of a mosaic of emergent, submergent and natant plant species. Richardson and Harris (1995) refer to a total of 30 distinguishable vegetative community types in their digital cover map study. Emergent vegetation within the littoral zone is dominated by herbaceous species such as cattail (*Typha* spp.), spike rush (*Eleocharis cellulosa*), and torpedo grass (*Panicum repens*). Other emergent vegetation observed includes bulrush (*Scirpus californicus*), sawgrass (*Cladium jamaicense*), pickerelweed (*Pontederia cordata*), duck potato (*Sagittaria* spp.), beakrush (*Rhynchospora tracyi*), melaleuca (*Melaleuca quiquenervia*), wild rice (*Zizania aquatica*), arrowhead (*Sagittaria latifolia*), button bush (*Cephalanthus occidentalis*), sand cordgrass (*Spartina bakeri*), fuirena (*Fuirena scirpoidea*), primrose willow (*Ludwigia peruviana*), southern cutgrass (*Leersia hexandra*), maidencane (*Panicum hemitomon*) white-vine (*Sarcostemma clausum*), dogfennel (*Eupatorium capillifolium*), mikania (*Mikania scandens*) and carolina willow (*Salix caroliniana*).

The submergent vegetation is composed almost entirely of hydrilla, pondweed (*Potamogeton illinoensis*), bladderwort (*Utricularia* spp.),and tape-grass (*Vallisneria americana*).

The natant, or floating, component of the littoral zone consists of lotus lily (*Nelumbo lutea*), fragrant water lily (*Nymphaea odorata* and *N. mexicana*), water hyacinth (*Eichhornia crassipes*), water lettuce (*Pistia stratiotes*), duckweed (*Lemna* sp.), rush (*Scirpus cubensis*), coinwort (*hydrocotyle umbellata*), and ludwigia (*Ludwigia leptocarpa*).

The most recent vegetation mapping of the western littoral zone and marsh, conducted by the South Florida Water Management District, clearly depicts the dynamic state of vegetative succession within the littoral zone and the spread of less desirable and invasive exotic species into new areas.). Results of this vegetation mapping show extensive areas of melaleuca along the rim canal, and nearshore, spike rush, particularly in the Moonshine Bay area, cattail, mostly interspersed in smaller stands, hydrilla (*Hydrilla verticillata*), where large monotypic floating and submergent mats dominate in Fisheating Bay, and large stands of torpedograss, which largely outcompete other species at most water levels.

Hydrilla is one of several problem species discussed below which occur on Lake Okeechobee. It seems to provide good fish habitat, but its prolific growth, as evidenced in Fisheating Bay, causes navigation and possibly water quality problems. There has also been observed a significant expansion of cattail in the littoral zone by GFC staff.

Melaleuca, a resilient species, found in a variety of habitats is one of the principal species of concern on the Lake. Melaleuca is capable of displacing native vegetation, including sawgrass marsh (Hofstetter and Parsons 1983, Stocker and Sanders 1980, Laroche and Ferriter 1992), and has been observed to displace native species in other marsh types, cypress-hardwood forests, and pine savanna (Schmitz and Hofstetter 1994). Ewel (1990) described melaleuca sites in south Florida as having hydroperiods of 6-9 months. Shomer and Drew (1982) noted that melaleuca colonization rates appeared to be inversely proportional to the length of the hydroperiod. Melaleuca may be observed adjacent to the rim canal, on spoil islands peripheral to the Herbert Hoover Dike, in wetland pockets behind the dike, and in the western littoral zone, where it has penetrated into the marsh over a mile from the rim canal near Moorehaven.

Brazilian pepper (*Schinus terebinthifolius*) is frequently associated with ditch banks (Barber 1994) and is commonly found along canal banks within the Lake. Very little is known about its hydroperiod requirements, but Duever et al. (1986) found that it thrives in areas with three to four month hydroperiods, while Doren and Jones (1994) stated that it rarely grows on sites flooded longer than three to six months, and is absent from deeper wetland communities.

Australian pine is a major invader of short hydroperiod areas where it can be found in dense stands, which preclude establishment of native species. One of the species (*Casurina quinquenervia*) is intolerant of extended inundation, but another (*C. glauca*) invades sawgrass marsh and burned hardwood hammocks in the Everglades (Doren and Jones 1994). Australian pine is commonly found along the rim canal and in monotypic stands on the berm of the Herbert Hoover Dike and in areas behind the dike.

Other exotics that continue to plague resource managers throughout Lake Okeechobee include torpedograss, which is believed spreading rapidly into areas of spike rush, forms dense rooted mats and appears to be tolerant of a wide variety of hydroperiods. There was an estimated 14,000 acres of torpedograss within the marsh as of 1992 (Schardt and Schmitz 1992), although that figure may be too low according to recent empirical data (C. Hanlon pers. comm.). Other species include waterhyacinth, native to South America, that clogs waterways and is found primarily in canals and backwater areas; and waterlettuce, found in canals and may root in wet soil. These latter two species, along with hydrilla, pose navigation problems for boaters and fisherman, flood control and water supply challenges for water managers, and are among the principal species targeted by eradication efforts by the USACE (D. Kinard, pers. comm.).

J.3.2 Fish and Wildlife

The area around Lake Okeechobee includes a wide variety of habitat opportunities for wildlife, including wading and migratory birds, many mammals, amphibians, and reptiles, as well as prey species such as crayfish, prawns, apple snails, and aquatic insects. The U.S. Fish and Wildlife Service (USFWS) has designated five species of wildlife as threatened or endangered and likely to occur around Lake Okeechobee. There are also state-listed species present within the lake, including several of the wading bird species that are not on the Federal list. The U.S. Army Corps of Engineers has conducted for the past two years, a wildlife survey within the western littoral zone of the lake, sampling key habitat types for reptiles, amphibians, and all migratory and resident birds. The study results, thus far, are briefly summarized in this section.

The study area is home to a large number of fish species, some of which are valued as commercial and sportfish, and others serving as part of the cornerstone of the littoral zone food web. In the areas being sampled as part of the wildlife utilization study, numerous small fish species, including the Cyprinodontids such as the golden topminnow (*Fundulus chrysotus*), the least killifish (*Heterandria formosa*), and the Florida flagfish (*Jordanella floridae*) have been collected and are known to be important food resources for wading birds, amphibians, and reptiles.

Additionally, Furse and Fox (1994) revealed that numerous sportfish occur in the littoral zone. The largemouth bass (*Micropterus salmoides*) is one of the most popular gamefish in the state of Florida, and is a major predator of small fish, amphibians, birds, and reptiles. Additionally, the black crappie *(Pomoxis nigromaculatus*), bluegill (*Lepomis macrochirus*), and redear sunfish (*Lepomis microlophus*) are sportfish found in high numbers in the littoral zone.

Macroinvertebrate diversity in the western littoral zone provides yet another vital component to the food web. Macroivertebrate species incidentally sampled during U.S. Army Corps of Engineers (1997) sampling of the western littoral zone included the apple snail (*Pomacea paludosa*), an important food resource of the everglade snail kite, crayfish (*Procambarus* spp.), grass shrimp (*Paleomonetus paludosus*), and Dytiscid beetles (*Dytiscidae*).

Lake Okeechobee supports a valuable commercial and sport fishery. Trawl samples taken by the GFC from 1987 to 1991 collected twenty-five fish species from the limnetic zone. Threadfin shad (*Dorosoma petenense*) were most abundant, and black crappie, most abundant in terms of biomass. These two species, and Florida gar (*Lepisosteus platyrhincus*), gizzard shad (*Dorosoma cepedianum*), white catfish (*Ameirus catus*), redear sunfish, and bluegill represented 98 percent of the total catch in terms of number and weight in the trawl study (Bull et al. 1995). Channel catfish area also considered commercially important on the lake.

Lake Okeechobee also supports a valuable commercial fishery. Over a five year period (1987-1991) mean annual commercial harvest was 2,008 metric tons (Fox et al. 1992, 1993). Commercially important fish species include white catfish, bluegill, and redear sunfish.

The area of critical concern to the life cycle of most fish and wildlife is the western littoral zone and marsh, thus the description below will focus on this area.

The western littoral zone provides tremendous foraging and nesting habit for a wide range of avifauna. Previous studies (Smith and Collopy, 1995; David, 1994) have documented birds including the endangered wood stork (*Mycteria americana*), the Federally and state endangered snail kite (*Rostrhamus sociabilis*), great blue heron (*Ardea herodias*), white ibis (*Eudocimus albus*), pied-billed grebe (*Podilymbus podiceps*), great egret (*Casmerodius albus*), snowy *egret (Egretta thula*), little blue heron (*E. caerulea*), tricolor heron (*E. tricolor*), and common moorhen (*Gallinula chloropus*) have commonly been observed utilizing the study area.

Other birds that may utilize the littoral zone include the threatened bald eagle (*Haliaeetus leucocephalus*), black skimmer (*Rhyncops niger*), brown pelican (*Pelecanus occidentalis*), double-crested cormorant (*Phalacrocorax auritus*), and anhinga (*Anhinga anhinga*).

According to rangemaps presented in Conant and Collins (1991), herpetofaunal diversity should be quite high in littoral and marsh area. Studied species on Lake Okeechobee include the american alligator *(Alligator mississippiensis*) (L. Hord, pers. comm.) and the Florida soft-shelled turtle (*Apalone ferox*) (P. Moler, pers. comm.). Currently, no published inventories are available on the diversity of herpetofauna inhabiting the western littoral zone of Lake Okeechobee.

During a U.S. Army Corps of Engineers (1998) wildlife survey of the western littoral zone, species such as the greater siren (*Siren lacertina*) have been sampled in high numbers along with the green water snake (*Nerodia floridana*) and the banded water snake (*Nerodia fasciata*). Additional common species included frogs such as the southern leopard frog (*Rana utricularia*), the green tree frog *(Hyla cinerea*), and the squirrel tree frog (*H. squirrela*). The american alligator was the only listed species of reptile recorded in the study area and there are no listed species of amphibians currently known to utilize the study area.

Of additional interest is the possibility of colonization of exotic amphibians and reptiles within Lake Okeechobee. Several reports from local residents have confirmed sightings of non-native species of lizards, such as the green iguana (*Iguana iguana*), the spiny-tailed iguana (*Ctenosaura pectinata*), and the brown basilisk (*Basiliscus vittatus*). Established populations of such species could be extremely harmful to native herpetofaunal populations.

Lake Okeechobee also provides major resources for mammalian species. The Okeechobee Waterway, a designated channel that runs around the perimeter of the lake, as well as across the lake, provides habitat for the endangered West Indian manatee (*Trichechus manatus latirostris*). Additionally, river otters (*Lutra canadensis*), bobcats (*Felis rufus*), and the Florida water rat (*Neofiber alleni*), a species of special concern as listed by the Florida Committee for Rare and Endangered Plants and Animals, have been observed within the Lake.

J.3.3 Threatened and Endangered Species

The USFWS has identified eighteen Federally listed plant and animal species as being present in the C&SF Restudy study area, and likely to be effected by alternative plans. Of these eighteen, five animal species, and one plant species are known to occur or are likely to occur within the area of Lake Okeechobee. These include the wood stork, West Indian manatee, bald eagle, snail kite, and eastern indigo snake. The American alligator, although not identified by the USFWS as a species likely to be effected by Restudy alternatives, is an important keystone species present in the Lake. The Okeechobee Gourd is a Federally listed (endangered) plant species, which is known to occur within the Herbert Hoover Dike, on the souteast side of the Lake.

J.3.4 Water Management

Historically, water levels in Lake Okeechobee were probably much higher than they are today, perhaps as high as 6.1 m (20 feet) NGVD (Brooks 1974). Prior to large scale development, and construction of the Herbert Hoover Dike, the Lake had no channeled outflows, and water overflowed the Lake as sheet flow to the south and east. This resulted in a much larger and broader littoral zone and marsh ecosystem to the north and west than the existing one. Today, as the primary reservoir of the Central and Southern Florida Flood Control Project, Lake Okeechobee is capable of storing 2.7 million acre-feet of water between stages of 3.2 m (10.5 ft) above msl and the top of the regulation schedule at 5.3 m (17.5 ft) above msl.

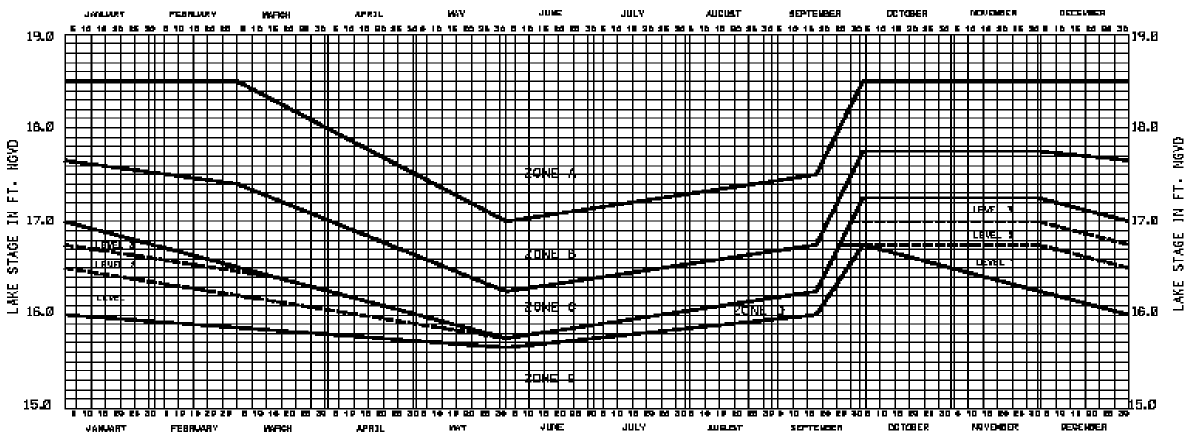
Water levels in the Lake are managed according to a regulation schedule that was developed by the South Florida Water Management District and the U.S. Army Corps of Engineers. The schedule is designed to maintain a low level of 4.7 m (15.5 ft) during the wet season in order to provide storage capacity for excessive amounts of rainfall and to prevent flooding in surrounding areas. The stage at the end of the wet season is regulated at a maximum of 5.3 m (17.5 ft) in order to store water for the dry season. The Caloosahatchee and St. Lucie canals are the primary outlets for release of flood waters when the Lake is above regulation stages.

A series of structures are situated around the Lake, which provide flood protection, control drainage, and facilitate navigation. The U.S. Army Corps of Engineers operates the primary structures and navigation locks around the Lake and is responsible for maintenance of the schedule. The South Florida Water Management District operates and maintains the secondary water control structures and pump stations.

Historically Lake Okeechobee's regulation schedule was developed primarily to meet flood control and water supply objectives, the primary purposes for construction of the C&SF Project. The environmental concerns for the lake's littoral zone and wildlife habitat and the downstream estuaries have generally been compromised in order to meet the water supply needs of south Florida.

Trimble and Marban (1988) performed an analysis of the Lake Okeechobee regulation schedule which incorporated a trade off analysis framework and resulted in the recommendation of an improved schedule known as "Run 25", which is the regulation schedule now in use (***Figure J-3.4-1***). This recommended schedule reduced the water quality impacts associated with regulatory discharges to the St. Lucie and Caloosahatchee estuaries by reducing the need to discharge large volumes of freshwater from the lake, without significantly impacting existing flood control, water supply and environmental benefits provided by the previous (15.5-

Figure J-3.4-1 Run 25-3 Regulation Schedule



RELEASE THROUGH OUTLETS AS INDICATED

ZONE	AGRICULTURAL CANALS (2)	CALOOSAHATCHEE RIVER (2)	ST. LUCIE CANAL
A	PUMP MAXIMUM PRACTICABLE TO WCA'S	UP TO MAXIMUM CAPACITY AT S-77	UP TO MAXIMUM CAPACITY AT S-80
B (1)	MAXIMUM PRACTICABLE TO WCA'S	6500 CFS AT S-77	3500 CFS AT S-80 (3)
C (1)	MAXIMUM PRACTICABLE TO WCA'S	UP TO 4500 CFS AT S-77	UP TO 2500 CFS AT S-80 (3)
D	MAXIMUM PRACTICABLE TO WCA'S	MAXIMUM NON-HARMFUL DISCHARGES TO ESTUARY WHEN STAGE RISING	MAXIMUM NON-HARMFUL DISCHARGES TO ESTUARY WHEN STAGE RISING (3)
E	NO REGULATORY DISCHARGE	NO REGULATORY DISCHARGE	NO REGULATORY DISCHARGE

NOTES: (1) RELEASES THROUGH VARIOUS OUTLETS MAY BE MODIFIED TO MINIMIZE DAMAGES OR OBTAIN ADDITIONAL BENEFITS.
(2) SUBJECT TO FIRST REMOVAL OF LOCAL RUNOFF.
(3) EXCEPT WHEN EXCEEDED BY LOCAL INFLOW.

CENTRAL AND SOUTHERN FLORIDA
INTERIM REGULATION SCHEDULE
LAKE OKEECHOBEE
DEPARTMENT OF THE ARMY, JACKSONVILLE DISTRICT
CORPS OF ENGINEERS, JACKSONVILLE, FLORIDA
DATED: 27 DEC 1994

RUN 25

17.5 feet) schedule approved in 1978. This schedule was approved by the District's Governing Board in December 1991 and approved on a two year interim basis by the U.S. Army Corps of Engineers in May of 1992. Regulatory releases are to occur at lower lake stage and at lower and more environmentally sensitive rates of discharge than the previous schedule. The lower rates of discharge are made in a "pulse" fashion, which simulates a natural rainstorm event within the St. Lucie (C-44) Basin. Each pulse takes 10 days to complete. This method is designed to allow estuarine biota to tolerate changes in salinity and the discharges to remain within the natural range of freshwater flow to the estuary.

J.3.5 Water Quality

Lake Okeechobee may be considered a naturally eutrophic water body that is tending to become hypereutrophic, due primarily from nutrient inputs from the Kissimmee River and the Taylor Creek basins. Water quality conditions in the upper Kissimmee River appear to be improving, primarily due to re-routing of wastewater flows from the river to reuse and ground-water discharge sites.

However, large quantities of nutrients are still discharged from Lake Toho to Lake Kissimmee and other downstream areas. Water quality improves from Lake Kissimmee to near Lake Okeechobee, where the channel flows mostly through unimproved rangeland; however, pollutant loadings increase as cattle and dairies grow more numerous near the lake. Because the lake's phosphorus is internally recycled and a vast reservoir of the nutrient is stored in ground water as well as wetland and canal sediments, phosphorus within the lake may not reach acceptable levels for many decades or even a century.

According to the 1996 305(b) report (FDEP, 1996) for Lake Okeechobee, the major pollution sources for the lake include runoff from ranch and dairy operations in the north where pollution has elevated phosphorus and coliform bacteria concentrations and created a continuous algal bloom. In the south, historic backpumping of runoff from row crops and sugar cane has elevated nutrient and pesticide levels. The backpumping has mostly ceased but still occurs when water in the primary canal of the Everglades Agricultural Area reaches 13 feet (flood-control levels). As a result, depending on location and seasonal rainfall or drought, the lake receives varying amounts of nutrients, substances creating high biological oxygen demand (BOD), bacteria, and toxic materials. Other pollutants include high levels of total dissolved solids, unionized ammonia, chloride, color, and dissolved organic chemicals.

Biological sampling indicated variable but generally eutrophic conditions. In recent years, several widespread algal blooms (one covering about 100 square miles) and at least one major fish kill -- all of which were widely publicized -- launched the environmental community and governmental agencies into intense investigation and analysis of the lake's problems. The Lake Okeechobee Technical Advisory Committee, formed to assess the situation and recommend solutions, determined that phosphorus from dairies and agriculture was a major cause of the noxious algal blooms and that levels should be reduced by 40 percent. A few others contended that the secondary cause of increased phosphorus is the flooding of hundreds of acres of perimeter wetlands after the SFWMD decided in the late 1970's to raise the lake's water level. The higher level also reduced valuable fish-spawning grounds and waterfowl feeding and nesting habitat.

In general, the water quality trends for the lake are stable at six sites, improved at two sites, and degraded at two sites. The best water quality observations were noted for the flow entering Fisheating Creek and along the west near wetlands, while the worst water quality conditions occurred in the south by agricultural areas, and to the northeast by Taylor Creek, Nubbin Slough and the St. Lucie Canal. The reported major pollution sources in this basin were dairies and agriculture. A generalized assessment of the lake shows the lake as having fair water quality conditions, except for Myrtle Slough which was shown to have poor water quality, and the extreme south-southwest section of the lake where good water quality conditions are described by the 305(b) report (FDEP, 1996).

J.3.6 Water Supply

Lake Okeechobee functions as a multipurpose regional reservoir. The once natural fluctuations of the lake have been altered under the C&SF Flood Control Project to serve several objectives. These include: (1) flood control, (2) agricultural water use, (3) urban and industrial water supply, (4) protection of wetland and estuarine systems, and enhancement of fish and wildlife resources, (5) prevention of saltwater intrusion, (6) navigation, (7) recreation, (8) wellfield recharge and, (9) water supply for Everglades National Park. Lake Okeechobee stores vast quantities of water during the wet season for later use by agricultural and urban users. Storage is also required to provide adequate water during the dry season to meet service area demands for agricultural irrigation and regional demands for supplemental water deliveries to the water conservation areas, urban areas of Florida's southeast coast, and Everglades National Park. Other entities, such as the Seminole Tribe of Florida and Miccosukee Tribe of Indians of Florida, also rely upon water from Lake Okeechobee.

Water storage capacity is limited by the height of the Herbert Hoover Dike, which surrounds the lake and protects local communities from flooding caused by hurricane force winds. Water levels in Lake Okeechobee are closely monitored to protect the structural integrity of the dike, and ensure that sufficient storage capacity is available to prevent local flooding of cities and farms. A further constraint on the Lake Okeechobee storage capacity is the need to protect littoral zone habitat. Extended high lake stages have been found to be harmful to the littoral zone ecosystem (Milleson, 1987), while large regulatory releases of fresh water are harmful to estuarine biota (Haunert and Startzman, 1985). Major projects currently underway, such as Everglades Restoration, are also expected to have a significant impact on water supply planning from Lake Okeechobee. Because the eight functional objectives of the lake are often competing with each other, it has not always been possible to manage Lake Okeechobee to satisfy all demands.

J.3.7 Socio-Economics

The following discussion of socio-economic existing conditions focuses on the principal social and economic forces of the Lake Okeechobee region. They include: commercial navigation via the Okeechobee Waterway, agriculture in the area immediately surrounding the Lake, urban municipalities, recreation and sport fishing, and commercial fishing.

J.3.7.1 Commercial Navigation

The Lake Okeechobee Waterway connects Stuart on the Atlantic Ocean with Ft. Meyers on the Gulf of Mexico. It includes 154 miles of navigation channel and five lock and dam structures. The Port Mayaca and Moore Haven locks connect the lake to the St. Lucie canal and Caloosahatchee River respectively. Commercial navigation on this waterway has been stable over the past 10 years, with substantial year to year variation (USACE 1998). The Lake Okeechobee Waterway was used to transport 430,000 tons of freight in 1995. Petroleum products were the predominant commodities transported (USACE 1998). There are no commercial shipping lines that regularly pass through the waterway, rather traffic consists primarily of special barge traffic which takes advantage of the shortcut across the Florida peninsula, saving about 3-5 days of travel.

J.3.7.2 Agriculture

The immediate area surrounding Lake Okeechobee is largely rural, with agriculture being critical to the local and regional economy. There are estimated to be over 700,000 irrigated acres of farm land in the Lake Okeechobee Service Area (LOSA), which includes the Everglades Agriculture Area. The Everglades Agricultural Area alone, accounted for over $750 million in agricultural production, and provided employment for over 20,000 full time workers in 1989 (Snyder and Davidson, 1994). Agricultural production consists predominantly of sugarcane, as well as rice, row crops, and sod. There is also extensive improved and unimproved pastureland, particularly west and north of the Lake. The St. Lucie and Caloosahatchee basins, which also receive irrigation water from the Lake, also cultivate an estimated 138,000 and 49,000 acres, respectively of citrus crops, sugarcane, vegetables, sod, and ornamentals (USACE 1998). During prolonged droughts, significant volumes of water are also required by the agricultural community in the Lower East Coast (Lower East Coast). Row crops such as truck vegetables, are the predominant crop type in the Lower East Coast.

J.3.7.3 Urban

The urban landscape surrounding Lake Okeechobee includes the incorporated municipalities of Belle Glade, Clewiston, Moore Haven, Okeechobee City, Pahokee, and South Bay. These communities range in population from approximately 1,439 (Moorehaven) to 16,656 (Belle Glade). Residential and commercial water users depend on lake water supply for wellfield recharge, drinking water, and industrial processes.

J.3.7.4 Recreation and Sport Fishing

Lake Okeechobee is the largest recreational resource in the region. The lake provides a wide variety of water based recreation including fishing, boating, picnicking, sightseeing, camping, swimming, hunting, airboating, and hiking. The littoral zone, along the Lake's western shore, provides valuable habitat for the Lake's popular sport fishery. Lake Okeechobee is recognized as supporting one of the best recreational fisheries in the nation. A variety and abundance of sport fish, including largemouth bass black crappie, bluegill, and redear sunfish are targeted by sportfisherman from around the country. Consequently, sport fishing is a major activity on the Lake. There are also several major sportfishing tournaments held on Lake Okeechobee annually, which bring significant revenues to the marinas, fishing guides, hotels, and support industries along the Lake. It should be noted that the Lake supports several commercial finfishing endeavors, including fisheries for bullhead catfish, gizzard shad, striped mullet (*Mugil cephalus*), and gar (*Lepisosteus* spp.).

Heavy seasonal waterfowl utilization of the Lake attracts tourists and recreational enthusiasts, such as hunters. Common waterfowl species include ring-necked duck (*Aythya collaris*), American wigeon (*Anas americana*), Northern pintail (*Anas acuta*), green-winged teal (*Anas crecca*), blue-winged teal (*Anas discors*), lesser scaup (*Aythya affinis*), and Florida duck (*Anas fulvigula*).

The Lake has also been a historic tourist destination for purely aesthetic reasons. Airboat rides are popular tourist activities on the Lake. In 1996 recreation levels at Lake Okeechobee were estimated at over 64,000 visitor-hours, with an annual value of over $78,000,000 (USACE 1998).

J.3.7.5 Commercial Fishing

The commercial fishing industry in Lake Okeechobee utilizes primarily haul seines to catch bluegill, redear sunfish, and catfish. Catfish are also caught by trot lines, and wire traps. Bullhead, shad, gar, mullet, and tilapia are also caught, although since the net ban, mullet are no longer considered a commercial species. There are also reports of commercial turtle trapping on the Lake, mostly in the canals (GFC pers. comm.). The annual wholesale value of the commercial fishery was estimated in 1998 (USACE) to be approximately $2,326,932, employing about 210 fisherman and landside workers.

There are also commercial fisheries on the Lake, which harvest the American alligator and the Florida soft-shell turtle (Diemer and Moler, 1995). Alligators are harvested from the Lake population to supplement the stock in alligator farming operations. Soft-shell turtles are harvested by commercial fishermen, with some individual yields in excess of 13,640 kilograms (30,000 pounds) annually. The majority of the harvest is prepared for shipment to Japan, or sold locally, primarily to the Miccosukee tribe.

J.3.8 Land Use

The following section will address the general land use within the immediate area of the Lake. The area is rural in character, with most lands dedicated to agriculture, very generally sugar cane is the predominant crop in the south, row crops and sugar cane in the east and pastureland with dairy production in the north. Urban areas, which are generally few and modest in population, service the agriculture sector, as well as the tourists who come to the Lake to fish, hunt, and enjoy other recreational pursuits.

J.3.8.1 Urban

A significant use of land outside the agricultural context is for urban development. Six incorporated communities are situated around the Lake and range in population from approximately 1,400 to 16,000 (***Table J-3.8.1-1***).

Table J-3.8.1-1
1996 Population Estimates For Communities Surrounding Lake Okeechobee (Usbc, 1997)

Community	Population	County
Belle Glade	16,656	Palm Beach
Clewiston	6,645	Hendry
Moore Haven	1,439	Glades
Okeechobee City	4,831	Okeechobee
Pahokee	6,993	Palm Beach

The Brighton Seminole Indian Reservation occupies a large area of land west of the Lake in Glades County. The southern end of this reservation is near the Herbert Hoover Dike just north of Lakeport.

Major transportation corridors around the perimeter of Lake Okeechobee include several highways and railroads. County Road 78 parallels the Lake along its western and northern shores from Moore Haven to Okeechobee. From Okeechobee, State Highway 98/441 follows the northern and eastern portion of the Lake to Pahokee. County Road 715 then follows the Herbert Hoover Dike from Pahokee to Belle Glade, where State Highway 27 follows the southern Lake area back to Moore Haven and County Road 78. In many cases, these highways are within 1.6 km (1 mile) of the Herbert Hoover Dike, and are often within 15 m (50 ft).

Railroad corridors in the Lake Okeechobee area include the Florida East Coast Railway and the South Central Florida Railroad. The East Coast Railway is located along the eastern part of the Lake where it comes very near to the Herbert Hoover Dike. The South Central travels along the southern end of the Lake, where it comes within 1.6 km (1 mile) of the Herbert Hoover Dike.

J.3.8.2 Agriculture

The primary land use in the Lake Okeechobee region is agricultural. Sugar cane plantations, cattle ranching, ornamental nurseries, vegetable production, and citrus make up the majority of agricultural land use in this area. Farmland within the counties that surround Lake Okeechobee (Glades, Hendry, Martin, Okeechobee, and Palm Beach), occupies from 50 to 76 percent of the total land area.

Other common land use types in the Lake Okeechobee region are frequently associated with agriculture. Sugar cane refineries, produce packaging and shipping plants, and other support activities constitute a significant use land along with direct agriculture (Purdum, 1994).

Lake Okeechobee has traditionally been a key source of water supply for irrigated crops around the lake including the Everglades Agricultural Area, the Caloosahatchee River Basin, and Martin and St. Lucie Counties (Upper East Coast). Continued access to this source of water is considered vital to sustaining agriculture in the surrounding regions.

J.3.9 Recreation Resources

Recreation resources in the Lake Okeechobee region are primarily water based within Lake Okeechobee and include boating, fishing, and nature interpretation. Lake Okeechobee provides approximately 40 miles of navigable waterway for commercial navigation and many more for recreational boating. Twenty-five U.S. Army Corps of Engineers built land and water-based recreational facilities are located along the lake. The Florida National Scenic Trail encompasses Lake Okeechobee atop the Herbert Hoover Dike (approximately 140 miles long). Approximately 94 percent of the recreation lands available to the public in this region are state or Federal (SCORP, 1994). Bike riding, hiking, picnicking, camping, and nature interpretation are popular land based recreation activities in the region. Substantially altered water deliveries to this region could result in flooding and have a detrimental affect on many natural and recreation resources in the area. The ample water based recreation resources in the Lake Okeechobee region receive extensive use and future demand is anticipated to increase.

J.3.10 Aesthetic Resources

The Lake Okeechobee region is characterized by two types of scenery: open lake views, characterized by a vast expanse of water with a vanishing horizon, and littoral zone viewsheds, characterized by various types of marshes, serving as a backdrop for wildlife. Hardwood swamps are found landward of the HHD, primarily on the west side of the lake. Significant exotic and invasive vegetation species (melaleuca, Australian pine, torpedograss, cattail) are intruding into stands of native species that tends to diminish biological diversity and existing aesthetics in those areas. In the Indian Prairie region of the lake, expansion of torpedograss and cattail particularly have affected aesthetic qualities of the lake.

Some remnants of the historical willow swamp vegetation still can be found (Lodge, 1994). The Herbert Hoover Dike sideslopes are generally well grassed but contain some exotic and or dead vegetation that degrades the distant uniform appearance. However, the dike affords a panoramic view of the lake from its crest, which can be magnificent during a sunset or sunrise. Shoreline trees generally enhance the rim canal aesthetics when viewed from a distance.

Melaleuca control programs have left hundreds of acres of dead melaleuca forest standing, which effects the overall aesthetic north of the Old Moorehaven Canal. Also, vast expanses of torpedograss, in the Indian Prairie region, and in significant areas south of Fisheating Creek where it enters the Lake, have had a detrimental effect on the areas aesthetic appeal. Substantially altered water levels to this region could have a detrimental affect on many aspects of the region’s littoral aesthetic resources. Substantially altered water levels could have a detrimental effect on many aspects of the region's viewable resources. Development is a nominal aesthetic impact to this region’s aesthetics at the present.

J.4 UPPER EAST COAST AND INDIAN RIVER LAGOON

The Upper East Coast (Upper East Coast) and Indian River Lagoon (IRL) collectively make up this geographic planning unit (***Figure J-4-1***). The Upper East Coast Planning Area covers over 1,100 square miles and has an average elevation of 20 feet. Average seasonal temperatures range from 64^{o}F degrees during the winter to about 81^{o}F degrees during the summer (University of Florida, 1993). Annual average rainfall in the Upper East Coast region is about 51 inches. About 72 percent of the annual rainfall occurs during the May through October wet season.

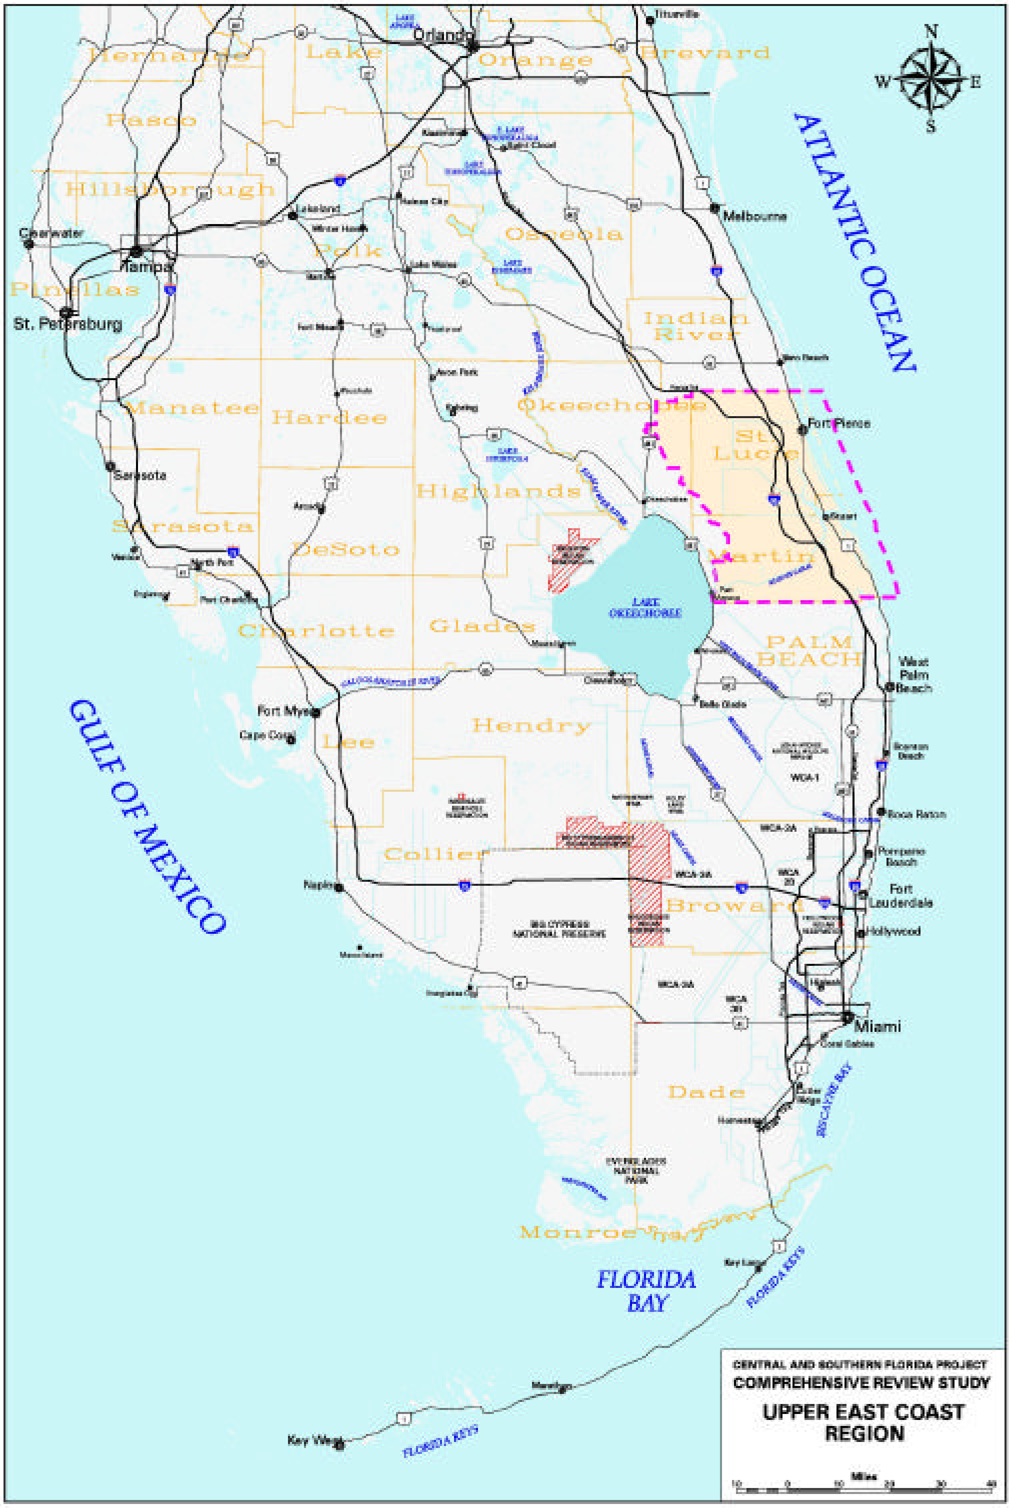


Figure J-4-1 Upper East Coast and Indian River LagoonRegion

The Upper East Coast Planning Area is characterized by three principal physiographic zones, which generally trend from east to west. These zones are identified by White (1970) as: (1) the Atlantic Coastal Ridge, (2) the Eastern Valley, and (3) the Osceola Plain. The Atlantic Coastal Ridge, made of relict beach ridges and sand bars, parallels the coast and has a width ranging from several hundred feet to a couple of miles. The ridge varies in elevation from sea level to a high of 86 feet above sea level in the sandhills of Jonathan Dickinson State Park.

West of the Atlantic Coastal Ridge is the Eastern Valley, which is a flat relict beach ridge plain. Most of the planning area lies within the Eastern Valley. The valley is generally lower than the ridge, with land elevations ranging from 15 to 30 feet above mean sea level, and an average width of 30 miles. These areas are characteristically pocketed with shallow lakes and marshes and have limited natural drainage. Prior to development and construction of canals, the valley drained by a slow drift of water through multiple sloughs to the St. Lucie River, the Loxahatchee River and the Everglades. This area contains the Savannas State Park, Pal-Mar, Loxahatchee Slough, and the Allapattah, St. Lucie and Osceola Flats.

The Osceola Plain lies west of the Eastern Valley in St. Lucie County and intrudes into the Eastern Valley in Martin County, where it terminates at Indiantown. The elevation of the plain in Martin County is approximately 40 feet.

The St. Lucie Estuary (SLE) is located on the southeast coast of Florida, encompassing portions of both Martin and St. Lucie counties within the watershed. The two forks of the St. Lucie Estuary, the North Fork and South Fork, flow together near the Roosevelt Bridge at the City of Stuart, and then flow eastward approximately six miles to the Indian River Lagoon and Atlantic Ocean at the St. Lucie Inlet. Tidal influences in the North Fork reach 15 miles north of Stuart in Five-Mile Creek, and to a water control structure on Ten-Mile Creek just west of the Florida Turnpike at Gordy Road. Tidal influences in the South Fork extend about eight miles south of Stuart to the St. Lucie Lock and Dam on the St. Lucie canal. Tidal influence also extends into the extremes of the nearby Old South Fork tributary (Morris, 1987).

The Estuary is divided into three major areas, the inner estuary, composed of the North and South Forks; the mid-estuary, consisting of the area from the juncture of the North and South Forks to Hell Gate, and the outer estuary extending from Hell Gate to the St. Lucie Inlet. The main body of the North Fork is about four miles long, with a surface area of approximately 4.5 square miles and a total volume of 998.5×10^6 cubic feet at mean sea level. The South Fork is approximately half the size of the North Fork with a surface area of about 1.9 square miles and a volume of 468.7×10^6 cubic feet. The mid-estuary extends approximately five miles from the Roosevelt Bridge to Hell Gate and has an area and volume similar to the North Fork (4.7 mi^2 and 972.7 x 10^6 cubic feet) (Haunert and Startzman, 1985).

Surface sediment composition within the estuary has been mapped by the South Florida Water Management District (Haunert, 1988). Sediment composition within the SLE is influenced by hydrodynamics and is somewhat correlated to depth. Sand substrates, with little organic content, are found along the shallow shorelines of the estuary and in the St. Lucie canal. This reflects the impacts of wave turbulence and rapid currents. Substrates comprised of mud and moderate quantities of sand are present in areas that are more typically low energy environments, but subjected to occasional high energy events. Mud substrates are found in low energy areas such as dredged areas and the deeper portions of the estuary. These mud sediments often contain high concentrations of organic materials.

While the Estuary encompasses about 8 square miles, the watershed covers an area of almost 775 square miles. The watershed is divided into eight basins; five major basins and three minor ones. Three of these major basins, the C-23, C-24, and C-44, represent basins now linked to the estuary by components of the Central and South Florida Flood Control Project. In addition to drainage from within the C-44 basin, the C-44 canal (St. Lucie Canal) also conveys flood control discharges from Lake Okeechobee to the St. Lucie Estuary. The other two major basins, the North Fork, and Tidal Basin, include numerous connections to the St. Lucie estuary.

J.4.1 Vegetation

The major plant communities found in the Upper East Coast are described below. These plant communities or associations of community types are based on those that are being mapped statewide as part of the Florida Game and Freshwater Fish Commission's project to develop a comprehensive statewide habitat system for Florida and the Florida Land Use, Cover and Forms Classification System (FLUCCS) Plant associations found in the region include hardwood hammocks, pine flatwoods, sand pine scrub, dry prairie, cypress swamps, hardwood swamps, mangrove swamps, salt marsh, sloughs, and estuarine SAV communities.

A number of wetland complexes exist in the Upper East Coast. These complexes include: a) isolated creeks, ponds, hammocks, sloughs, and wet prairies within the Allapattah Slough, b) isolated ponds, cypress areas, and wet prairies in cane slough, c) 21,875 acres of wet prairie, cypress domes ponds and remnant everglade marsh in the DuPuis Reserve, d) 37,314 acres of wet prairie ponds interspersed within a pine flatwood community in the Pal-Mar tract, e) St. Lucie County's remaining wetland systems including the Savannas; wetlands associated with Five Mile, Ten Mile, Cow, Cypress, and Van Swearingen creeks; remnant portions of the St. Johns marsh,; and the floodplain of the North Fork of the St.

Lucie River, f) In Okeechobee County the Upper East Coast has tracts of forested and emergent wetlands that dominate the landscape and continue into St. Lucie County.

J.4.1.1 Exotic Species

Exotic plants in the Upper East Coast include: Australian pine (*Casuarina equisetifolia)*, Brazilian pepper (*Schinus terebinthifolius)*, climbing fern (Lygodium microphyllum), melaleuca (*Melaleuca quinquenervia*), lather leaf (*Colubrina asiatica)* and calophyllum (*Calophyllum inophyllum*).

Many of the wetlands in the region have suffered decreases in water levels, changes in water quality, changes in frequency and seasonality of burning, physical damage from vehicles or wild pigs (introduced from Europe by man) or other kinds of disturbance. The most visible sign of stress in these wetlands is vegetation change with increases in the numbers of weedy native species, such as cattail and primrose willow, and exotic species, such as melaleuca and Brazilian pepper. At the same time, many native plants disappear, either directly because of the disturbed environment, or because they are crowded out by weeds.

J.4.2 Fish and Wildlife

The Indian River Lagoon system is a biogeographic transition zone, fed by the St. Lucie Estuary, rich in habitats and species, with the highest species diversity of any estuary in North America (Gilmore, 1977). Approximately 4,315 different plant and animal species have been identified in the lagoon system. Included are 2,965 species of animals, 1,350 species of plants, 700 species of fish and 310 species of birds (IRL Program). Species diversity is generally high near inlets and toward the south, and low near cities, where nutrient input, freshwater input, sedimentation, and turbidity are high and where large areas of mangroves and seagrasses have been lost. For biological communities and fisheries, seagrass and mangrove habitats are extremely important (Virnstein and Campbell, 1987). Much of the habitat loss has occurred as the result of the direct effects of shoreline development, navigational improvements, and marsh management practices.

Seagrass beds support some of the most abundant fish populations in the Lagoon, with large species diversity. Pinfish and several species of mojarra are very abundant in the seagrass habitat. These species are known to feed on seagrasses and on the epiphytes and epifauna of the seagrasses, providing a critical link in the food chain between the primary producers and the higher level consumers such as the common snook and spotted seatrout. Gilmore (1977) describes the fish community of the Indian River Lagoon System. Many seagrass beds are in decline due to various environmental problems, including Johnson's seagrass (*Halophila johnsonii*), recently listed as threatened by the National Oceanic and Atmospheric Administration.

The seagrass habitat is also a critical resource for the Florida manatee. This marine mammal depends on seagrasses for a major part of its food supply (Lain, 1978; Van Meter, 1989; Provancha and Hall, 1992). It has been reported that manatee grazing may result in up to a 68 percent decrease in seagrass biomass (Virnstein, 1987; Provancha and Hall, 1991a), illustrating the importance of seagrasses as manatee forage. Juvenile sea turtles have also been documented as foraging on turtle grass and other seagrasses in the Indian River Lagoon (Mendonca, 1981; Mendonca and Ehrhart, 1982).

The major rivers, creeks, and canals entering the Indian River Lagoon complex from the mainland provide lotic (flowing water) conditions with varying degrees of tidal influence depending upon their size, discharge, and proximity to ocean inlets. Currents in these streams vary from sluggish to moderate. The margins are usually covered with dense vegetation (unless denuded by human activity). Various types of submerged, emergent, and floating aquatic vegetation are usually present, with the species composition varying according to flow, substrate type, and other physical factors. Tributary streams and canals are much more prevalent in the southern portions of the Lagoon system, especially the southern third.

Most of the predominantly freshwater fishes recorded from the Lagoon system, such as minnows (Cyprinidae), bullhead catfishes (Ictaluridae), and sunfishes (Centrarchidae) are found mainly or exclusively in the tributary streams including the streams feeding the St. Lucie. Examples of other species in this habitat include all of the ubiquitous forms mentioned above as well as Florida gar (*Lepisosteus platyrhincus*); gizzard shad (*Dorosoma cepedianum*); flagfish (*Jordanella floridae*); bluefin killifish (*Lucania goodei*); mosquitofish (*Gambusia affinis*); least killifish (*Heterandria formosa*); sailfin molly (*Poecilia latipinna*); inland silverside (*Menidia beryllina*); gulf pipefish (*Syngnathus scovelli*); leatherjack (*Oligoplites saurus*); gray snapper (*Lutjanus griseus*); Irish pompano (*Diapterus auratus*); silver jenny (*Eucinostomus gula*); fat sleeper (*Dormitator maculatus*); bigmouth sleeper (*Gobiomorus dormitor*); and lined sole (*Achirus lineatus*). Fish species that specialize in creek-mouth habitats include yellowfin menhaden (*Brevoortia smithi*); gafftopsail catfish (*Bagre marinus*); timucu, a needlefish (*Strongylura timucu*); gulf killifish (*Fundulus grandis*); striped killifish (*F. majalis*); mosquitofish; sailfin molly; lined seahorse (*Hippocampus erectus*); chain pipefish (*Syngnathus louisianae*); gulf pipefish; tarpon snook (*Centropomus pectinatus*); Atlantic bumper (*Chloroscombrus chrysurus*); leatherjack; lookdown (*Selene vomer*); gray snapper; Irish pompano; silver jenny; great barracuda (*Sphyraena barracuda*); fat sleeper; emerald sleeper (*Erotelis smaragdus*); frillfin goby (*Bathygobius soporator*); darter goby (*Gobionellus boleosoma*); naked goby (*Gobiosoma bosc*); clown goby (*Microgobius gulosus*); bay whiff, a flatfish (*Citharichthys spilopterus*); gulf flounder (*Paralichthys albigutta*); lined sole;

planehead filefish (*Monacanthus hispidus*); striped burrfish (*Chilomycterus schoepfi*); southern puffer (*Sphoeroides nephelus*); bandtail puffer (*S. spengleri*); and checkered puffer (*S. testudineus*).

Besides marine faunal communities, the Upper East Coast contains a number of terrestrial habitats including hardwood hammocks, pine flatwoods, sand pine scrub, dry prairie, cypress swamps, hardwood swamps, marshes, and sloughs. Cypress swamps, hardwood swamps and slough communities are forests in a marsh or wet prairie matrix, and as such are surrounded by emergent vegetation of low stature and longer hydroperiod. These habitats can be used as roosting or nesting sites contiguous to surrounding marshes used for foraging. Common breeding birds utilizing this habitat include the anhinga (*Anhinga anhinga*), the green-backed heron (*Butorides striatus*), the black-crowned night heron (*Nycticorax nycticorax*), and the boat tailed grackle (*Quiscalus major*) (SFWMD, 1992). Other common vertebrates include raccoons (*Procyon lotor*), opossums (*Didelphis marsupialis*), the river otter (*Lutra canadensis*), white tailed deer (*Odocoileus virginianus*), water snakes (*Nerodia* spp), and the green anole (*Anolis carolinensis*) (SFWMD, 1992).

Marshes are longer hydroperiod wetlands that may be made up predominantly of sawgrass or mixed graminoid marshes. General resident organisms utilizing this habitat include the rice rat (*Oryzomys palustris*), cotton mouse (*Peromyscus gossypinus*), hispid cotton rat (*Sigmadon hispidus*), marsh rabbit (*Sylvilagus palustris*), king rail (*Rallus elegans*), red-winged blackbird (*Agelaius phoeniceus*), American bittern (*Botaurus lentiginosus*), long billed marsh wren (*Cistothorus palustris*), yellowthroat (*Geothlypis trichas*), squirrel tree frog (*Hyla squirella*), and the green anole. These areas have more open water components and are extremely important to wading birds and some mammals. Although sawgrass marshes are generally poorer habitat some animals utilize them seasonally. Animals utilizing sawgrass marshes include the American bittern *(Botaurus lentiginosa*), the long-billed marsh wren (*Cistothorus palustris*), the limpkin (*Aramus guarauna*), and the American alligator (*Alligator mississippiensis*).

Marsh habitats other than sawgrass marshes are utilized by a variety of water birds and wading birds. These birds include the wood stork (*Mycteria americana*), great egret (*Casmerodius albus*), snowy egret (*Egretta thula*), white ibis (*Eudocimus albus*), glossy ibis (*Plegadis falcinellus*), great blue heron (*Ardea herodias*), green-backed heron (*Butorides striatus*), tri-colored heron (*Hydranassas tricolor*), black-crowned night heron (*Nycticorax nycticorax*), least bittern (*Ixobrychus exilis*) and American bittern. Other animals important in these marshes include the snail kite (*Rostrhamus sociabilis*), the pig frog (*Rana grylio*), cricket frog (*Acris grylio*), water snakes, peninsular newt (*Notophthalmus viridescens*), and several sirens.

Pine Flatwood and sand pine scrub are upland areas containing a number of vertebrates including the pine woods tree frog (*Hyla femoralis*), oak toad (*Bufo quercicus*), southern leopard frog (*Rana sphenocephala*), box turtle (*Terrapene carolina*), pine woods snake (*Rhadinea flavilata*), eastern diamondback rattlesnake (*Crotalus adamanteus*), black racer (*Coluber constrictor*), bobcat (*Lynx rufus*), grey fox (*Urocyon cineroargenteus*), striped skunk (*Mephitis mephitis*), raccoon, cotton mouse, hispid cotton rat (*Sigmadon hispidus*), marsh rabbit, white tailed deer, red shouldered hawk (*Buteo lineatus*), great blue heron, barred owl (*Strix varia*), blue grey gnat catcher (*Polioptila caerulea*). None of the mammals are found exclusively in this region, but the fox squirrel (*Sciurus niger*) is often found in flatwoods with open understory.

Dry prairies are the main habitat for the crested caracara (*Polyborus plancus*), burrowing owl (*Athene cunicularia*), and the Florida Sandhill crane (*Grus canadensis*). Additional species of interest include the box turtle, black racer, turkey vulture (*Cathartes aura*), black vulture (*Coragyps atratus*), common nighthawk (*Chordeiles minor*), least shrew, cotton rat, eastern harvest mouse (*Reithrodon tomys humulis*), and eastern spotted skunk (*Spilogale putorius*).

Ponds and creeks have the longest hydroperiod of the freshwater habitats available. They are generally wet in all but the driest of drought years. General resident organisms utilizing this area include the round tailed muskrat (*Neofiber alleni*), rice rat (*Oryzomys palustris*), otter, wading birds, black crowned night heron (*Nycticorax nycticorax*), anhinga, turkey vulture, purple gallinule (*Porphyrula martinica*), boat tailed grackle (*Quiscalus major*), American alligator, water snakes (*Nerodia spp*), Florida softshelled turtle (*Trionyx ferox*), two toed amphiuma (*Amphiuma means*), pig frog, southern leopard frog (*Rana sphenocephala*), and peninsula newt. Large salamanders, turtles, and snakes inhabit these aquatic systems. Water levels of these areas affect their usage by birds. Wading birds use sloughs depending upon the time in the water year. During periods of high water, birds such as the common moorhen (*Gallinula chloropus*), the pied-billed grebe (*Podilymbus podiceps*), anhinga and the limpkin utilize this habitat. Common mammals in this habitat include the river otter and the round tailed muskrat while many others may use the edges during dry conditions.

J.4.3 Water Management

Agricultural drainage and residential development have extensively modified the watershed of the entire St. Lucie Estuary. One major effect of these man-made alterations in the landscape and water management practices is increased drainage, manifested by a lowered groundwater table and dramatic changes in how stormwater runoff is introduced to the estuary. Typically, when a watershed is highly drained like the St. Lucie Estuary watershed, all three runoff factors (quality, quantity and timing) are negatively affected. From a yearly cycle perspective, the quantity of water drained to the Estuary is increased, the water quality is degraded and the seasonal distribution of runoff is altered such that dry season flows are of less magnitude and frequency and wet season flows are of greater magnitude and more frequent. The vast majority of runoff occurs within the first three days after a rainfall event rather than over an extended period of time. Water quality is degraded, especially by increased amounts of nutrients and suspended solids. The increased nutrients in the St. Lucie Estuary have increased primary productivity within the system to the point where unhealthy levels of dissolved oxygen occur on a regular basis in the inner estuary. The dramatic increase in sediment load has contributed significantly to the build-up of muck throughout the system. The sandy sediment loads like those that build up in the Palm City area are from primarily high discharge events. However, it is the increased organics coming from high levels of Chlorophyll a and floating aquatics introduced from the canals combining with high organic fine suspended sediments that flocculate out at the fresh-salt interface that lead to the formation of muck. As a result, the benthic environment of the estuary is a favorable habitat for mostly pollution tolerant organisms. In addition, the rapid introduction of freshwater causes salinity fluctuations that are not conducive to developing or maintaining a healthy estuarine plant and animal community. The overall result of these changes is the loss of important habitats.

The St. Lucie estuary has received increased inflows over the last 100 years because of these modifications to the watershed. Extreme salinity fluctuations and ever-increasing inflows have contributed to major changes in the structure of the communities within the estuary such as seagrass and oyster losses. Phillips (1961) described the marine plants in the St. Lucie Estuary. At the time, mangroves were abundant in the North and South Forks and seagrasses, although stressed, were still found in many areas of the estuary. Today, the presence of seagrasses is severely limited and ephemeral. Oyster populations in the Estuary are virtually nonexistent due to the continual exposure to low salinities and lack of suitable substrate (clean hard objects) for larval recolonization (Haunert and Startzman, 1980, 1985).

Regulatory discharges from the C-44 canal have been documented to adversely impact the St. Lucie Estuary by depressing the salinity range far below the normal range, and by transporting large quantities of suspended materials into the estuary. Sedimentation problems in relation to C-44 discharges were recognized as early as the 1950's (Gunter and Hall,1963). While current monthly average flows from the watershed to the SLE seldom exceed 2500 cfs, regulatory releases from the C-44 alone have produced flows in excess of 7000 cfs. The quantity of suspended solid material passing structure S-80 has reached a peak of 8000 tons a day when daily discharges reached near 7000 cfs in 1983. Much of this material passes through the estuary and into the Indian River Lagoon or Atlantic

Ocean (Haunert, 1988). It was recognized then that these discharges transported sand as well as very fine, organic rich suspended material to the estuary.

J.4.3.1 Surface Water Resources

Prior to development, most of the Upper East Coast Planning Area was characterized by nearly level, poorly drained lands subject to frequent flooding. The natural surface drainage systems included large expanses of sloughs and marshes such as St. Johns Marsh, Allapattah Slough (also referred to as Allapattah Flats), and Cane Slough. Drainage systems with higher conveyance included the North and South Forks of the St. Lucie River, Ten Mile Creek, Five Mile Creek, the Loxahatchee River and Bessey Creek. Minor creeks include Danforth, Fraiser, Hidden River, Willoughby, Krueger, Mapps, and Warner. Most of these surface water systems, especially those with poor drainage, have been altered to make the land suitable for development and to provide flood control.

Since the early 1900s, numerous water control facilities have been constructed to make this region suitable for agricultural, industrial, and residential use. The St. Lucie Canal (C-44) was constructed between 1916 and 1924 to provide an improved outlet for Lake Okeechobee floodwaters. From 1918 to 1919, the Fort Pierce Farms Drainage District (FPFDD) and the North St. Lucie River Drainage District (NSLRDD) were formed to provide flood control and drainage for citrus production in east-central and northeastern St. Lucie County. The C-25 Canal (also known as Belcher Canal) provided a drainage outlet for the FPFDD, as well as limited flood protection for western areas of the basin. The C-24 Canal (also known as the Diversion Canal) provided drainage and limited flood protection west of the NSLRDD protection levee. The C-23 Canal provided water control in Allapattah Flats during the dry season. However, large areas continued to be under water for months at a time during the wet season.

Although the primary function of the C&SF Project was for flood control and drainage, the drainage network formed by the Project canals and the secondary canals and ditches has become an important source of irrigation water and frost protection for agriculture. In general, water stored in the canals is replenished by rainfall, ground water inflow, and withdrawals from the FAS when needed.

Prior to the large-scale expansion of citrus in the 1960s, storage in the drainage network in St. Lucie County was adequate to meet irrigation demands. However, the drainage and development of the large marsh areas in western St. Lucie County have depleted much of the surface water storage. The lowering of water tables also reduced the amount of water in ground water storage. The reduction of surface and ground water storage coupled with increased acreages of citrus have resulted in inadequate supplies of surface water to meet demands during droughts. Therefore, an equitable distribution of the available surface water in the C-23, C-24 and C-25 basins is maintained by limiting the invert elevation of irrigation culverts and the intake elevation of pumps to a minimum of 14.0 feet NGVD. Artesian well water from the FAS is used as an irrigation supplement when surface water supplies become limited. Due to the high mineral content of the Floridan Aquifer, this water is generally blended with surface water before it is used as irrigation water.

J.4.3.2 Surface Water Inflow and Outflow

Within the Upper East Coast Planning Area basins, essentially all surface water inflows and outflows are derived from rainfall. The exception to this is the St. Lucie Canal (C-44), which also receives water from Lake Okeechobee. In addition, most of the flows and stages in the region's canals are regulated for water use and flood protection. The amount of stored water is of critical importance to both the natural ecosystems and the developed areas in the Upper East Coast Planning Area. Management of surface water storage capacity involves balancing two conflicting conditions. When there is little water in storage, drought conditions may occur during periods of deficient rainfall. Conversely, when storage is at capacity, flooding may occur due to excessive rainfall, especially during the wet season. Management of surface water systems is one of the main factors affecting movement of water through the regional hydrologic cycle.

C-25 Canal

The C-25 canal is the northwestern sub-basin in the south segment of the Indian River Lagoon. A complex system of canals exists in this basin for agricultural drainage. Under natural conditions, however, this basin would not discharge into the Indian River Lagoon. Generally, runoff from the eastern portion of this sub-basin flows east through the S-99 structure on the C-25 canal. Stormwater originating in the western portion of this sub-basin can be discharged into the C-24 canal through S-311.

North St. Lucie Sub-basin

The North St. Lucie sub-basin extends from Ft. Pierce Inlet southward to the St. Lucie Inlet and westward to C-24 canal. There are several drainage areas within this sub-basin. Although this sub-basin naturally discharged into the Indian River Lagoon, agricultural canals have greatly improved drainage. This sub-basin occasionally receives inflow from the C-24 canal.

The North St. Lucie Drainage District drainage area drains primarily into the North St. Lucie River. The North St. Lucie Drainage District is located in the northern portion of this area and drains to the C-25 canal from the north and to the C-24 canal from the west. South and east of the North St. Lucie Drainage District are several urban developments, of which the City of Port St. Lucie is the largest.

The Indian River Lagoon/Ft. Pierce Inlet to St. Lucie Inlet area is bordered by the barrier island to the east and the coastal hills on the west. Very little development has occurred on the barrier islands in this area with the exception of the Florida Power and Light Company's nuclear power plant on Hutchinson Island. The mainland portion of this area is very narrow and has experienced some development.

C-24 Canal Sub-basin

The C-24 canal sub-basin is located west of the North St. Lucie basin and is mostly outside the area that would naturally discharge into the Indian River Lagoon. This sub-basin discharges into the North St. Lucie River through the S-49 structure. Agricultural canals have greatly improved drainage. Besides discharge into the C-24 canal from within the sub-basin, C-24 also receives water from the western portion of the C-25 sub-basin and the western portion of the North St. Lucie Drainage District.

C-23 Canal Sub-basin

The C-23 canal sub-basin is located south of C-24. Under natural conditions much of this area would not have drained into the Indian River Lagoon. Agricultural canals have improved drainage from the area. Discharge from C-23 canal in this sub-basin is controlled by the S-97 structure, which is located just west of Florida's Turnpike.

South St. Lucie River Sub-basin

The South St. Lucie River sub-basin is the natural drainage for the South St. Lucie River and contains several drainage areas. The City of Stuart lies in the northeastern portion of this sub-basin between the South St. Lucie River and the Indian River Lagoon.

Bessey Creek is a natural creek that is located south of the C-23 canal. The S-96 structure is a weir within C-23 canal that is located immediately upstream of the confluence of C-23 canal and Bessey Creek. The eastern portion of Bessey Creek drainage area contains scattered pockets of residential development, while the western portion is mostly agricultural. Although drainage improvements have occurred, these have been less extensive than improvements that have occurred in the northern sub-basins.

The Tidal St. Lucie drainage area is the major natural drainage into the Indian River Lagoon from the South St. Lucie River. The City of Stuart lies in the northeastern portion of this basin. Although some drainage improvements have occurred in this area, there are still many of the natural isolated wetlands in the southern portion. The S-80 structure, which is the control structure for C-44 canal into the St. Lucie River, is located about one mile west of Florida's Turnpike.

The Non-Tidal St. Lucie is a small drainage area that historically would have discharged into C-44 canal just above the S-80 structure. However, drainage from this area has been blocked, causing the area to be isolated from the Indian River Lagoon basin.

The Indian River Lagoon/St. Lucie Inlet to Jupiter Inlet is the southernmost drainage area of the Indian River Lagoo. Many residential developments occur on both the barrier island and the mainland portions of this area. The major developments occur in the north, around the City of Stuart.

St. Lucie Canal

The St. Lucie Canal (C-44) sub-basin contains the C-44 canal which is a part of the major navigational route between the east and west coast of Florida, connecting Lake Okeechobee to the South St. Lucie River. The S-308 structure controls flow from Lake Okeechobee into C-44. This sub-basin has many agricultural developments, mostly pasture, which have improved drainage. However, these agricultural areas are interspersed with areas of natural, poorly drained wetlands.

The C&SF Project canal and control structures in the C-44 Basin have five functions: (1) to provide drainage and flood protection for the C-44 Basin, (2) to accept runoff from the S-153 Basin and discharge this runoff to tidewater, (3) to discharge water from Lake Okeechobee to tidewater when the lake is over schedule, (4) to supply water to the C-44 Basin during periods of low natural flow and (5) to provide a navigable waterway from Lake Okeechobee to the Intracoastal Waterway. Excess water is discharged to tidewater by way of S-80 and C-44A. Under certain conditions, excess water may backflow to Lake Okeechobee by way of S-308. Regulatory releases from Lake Okeechobee are made to C-44 by way of S-308. Water supply to the basin is made from Lake Okeechobee by way of S-308 and from local rainfall. Both S-80 and S-308 have navigation locks to pass boat traffic.

Lockages are performed on an "on-demand" basis at S-80, except when water shortages have been declared or maintenance and repairs to the structure are taking place. Although there is no water shortage plan for S-80, the U.S. Army Corps of Engineers will curtail lockages at the request of the District. Maintenance and repairs that result in stoppage of lockages are done on an as-needed basis, usually occurring every three to five years (phone conversation January 29, 1993 with Bill Mason, Lockmaster at S-80, USACE, Stuart, FL). Each lockage at S-80 releases over 1.3 million gallons of water. The average number of lockages at S-80 varies monthly. Between 1987 and 1991, there were an average of 15 lockages per day, with maximum and minimum monthly averages ranging between 19 and 11 lockages per day (facsimile received February 1, 1993 from James Vearil, Hydraulic Engineer, USACE, Jacksonville, FL.).

The S-80 structure in the Tidal St. Lucie Basin has three functions: (1) to accept flow from C-44 and to discharge those flows to tidewater in the St. Lucie River, (2) to provide a navigable waterway from the St. Lucie Canal to the Intracoastal Waterway, and (3) to provide drainage for portions of the Tidal St. Lucie Basin.

C-44 and S-80 were designed to pass the Standard Project Flood from the C-44 Basin and the S-153 Basin and to pass regulatory discharges from Lake Okeechobee to tidewater. The S-308 and S-80 control structures are operated to maintain an optimum canal stage of 14.5 feet NGVD within the Tidal St. Lucie Basin.

J.4.3.3 Ground Water Resources

A distinctive feature of south Florida's hydrologic system is the aquifer system and its use for water supply. Two vast aquifer systems, the Surficial Aquifer System (SAS) and the Floridan Aquifer System (FAS), underlie the Upper East Coast Planning Area. Ground water inflows from outside the planning area form an insignificant portion of recharge to the SAS. Rainfall is the main source of recharge, and because of this, long-term utilization of this source must be governed by local and regional recharge rates. The FAS, on the other hand, receives most of its recharge from outside of the Upper East Coast Planning Area. This fact must also be incorporated into long-term planning decisions. Within an individual aquifer, hydraulic properties and water quality may vary both vertically and horizontally. Ground water supply potential varies greatly from one place to another.

J.4.4 Water Supply

Although Lake Okeechobee is potentially a large water source, there are competing users of this water elsewhere within the Lake Okeechobee Service Area and the Lower East Coast and Lower West Coast planning areas. During periods of water shortage in the lake, water supply allocations are determined through procedures described in the Lake Okeechobee Supply-Side Management Plan. The Lake Okeechobee Supply-Side Management Plan is implemented if the projected lake stage falls below 11.0 feet NGVD at the end of the dry season, or below 13.5 feet NGVD at the end of the wet season.

Water demand in Martin County grew significantly in the 1980s, reflecting the increase both in agricultural acreage and population. Both agriculture and population in the Upper East Coast are anticipated to continue growing through the year 2050, causing the increase in water demands shown in ***Table J-4.4-1***.

Table J-4.4-1. UEC M&I Demands (Million Gallons Per Day)	
End Use	2050 Range of Unrestricted to Restricted Demand
Residential	83.6 –70.1
Commercial & Industrial	33.5 – 31
Public & Other	8.7 - 7.9
Total	125.8 – 108.9

Public utilities served 57 percent of the residential demand in 1990, accounting for just over 8 percent of the total water use. This is expected to increase to just 11 percent of water usage by 2010, with the total number of persons utilizing public utilities as their source of water nearly doubling. The urban areas of Martin County have never experienced a declared water shortage, unlike other areas of the South Florida Water Management District.

J.4.5 Socio-Economics

The commercial fisheries harvesting sector based in the Indian River Lagoon has contributed a substantial portion of both the value of the Florida east coast (65 percent dockside value) and statewide fisheries catch (21.7 percent dockside value) over the past several years (National Marine Fisheries Service, 1985). Seafood processing, the wholesale and retail sector of the commercial fisheries industry, is another current use of the lagoon. The sector generates added value to the dockside value through processing and handling, wholesale and retail sales, and expenditures for supplies and equipment. The total primary economic impact was estimated at $73 million in 1983 for seafood processing and wholesaling (Yingling, 1987).

The recreational fishing industry and the marine service sector are also major users of the lagoon. These industries include such associated user services as boat sales, rentals, engine and hull repair, launch facilities, dockage, commercial and recreational fishing bait, tackle and supplies, charter and head boats, yacht clubs, marine resort areas, and other facilities and services. The economic impact of these activities is significant. For example, in 1984, recreational saltwater fishing was estimated to account for over $46 million in expenditures in the Indian River Lagoon region (Yingling, 1987).

One of Florida's deepwater ports is located in the Upper East Coast. In terms of combined import and export values, Ft. Pierce ranked tenth, among Florida's twelve major ports in 1984. The Port of Fort Pierce exports one-third of the citrus from Florida.

J.4.6 Land Use

The record of human existence in the Upper East Coast region spans approximately 8,000 years. The lagoon system provided the Indians and early settlers with food, materials for tools and their major means of transportation. In the late 1800s, the Indian River Lagoon region was already established as a major area of commerce (tourism, fisheries, shipping and agriculture). The lagoon was used for safe harbor and transportation of cargo, especially citrus.

At present, The dominant land use in the basin is agriculture (covering approximately 45 percent of the basin). Agricultural activities include 228,000 acres of citrus, 211,000 acres in range and citrus, and 9,500 acres of vegetable crops (SCS, 1994). The present urban land use (17 percent of the basin) is concentrated along the coast and the lagoon shorelines. Urban growth is rapidly extending westward, replacing agricultural land. Future land use patterns indicate that this trend will continue as urbanization intensifies along the coast, especially in the southern counties (Swain and Bolohassen, 1987). Present forested uplands and wetlands comprise 11 and 18.8 percent of the basin, respectively.

J.4.6.1 Agriculture

Martin and St. Lucie Counties are included in this region. Almost one half million acres are farmed (UFBEBR, 1995). Of this total approximately 200,000 acres are irrigated requiring a dependable water supply. Lake Okeechobee has traditionally been the water source for this region. St. Lucie and Martin Counties rank first and eighth, respectively, among Florida counties for number of acres of citrus (FASS, 1996b). Although this area is known primarily for its citrus production, as many acres are used for pastureland. Farms average 600 acres in size with moderate productivity per acre. More than 7,500 people are employed in agricultural production and services with a payroll of approximately $9.5 million. The market value of all agricultural products in this region totals approximately $362 million (UFBEBR, 1995).

J.4.7 Recreation Resources

Recreation resources in the Upper East Coast region are diverse, consist of variable quality, and include coastal, inland water and land based resources. The St. Lucie Canal provides approximately 34 miles of navigable waterway with four U.S. Army Corps of Engineers/County recreation facilities that include boating, fishing, camping and day-use facilities (USACE, 1991). An eight mile canoe trail winds through cypress strand lush with ferns and orchids in Jonathan Dickenson State Park (Marth, 1997). The approximately 44 miles of Intracoastal Waterway provides many coastal recreational navigation opportunities. Several other river bodies offer recreational opportunities including the north section of the Loxahatchee River in Martin County which is designated a National “Wild and Scenic River” (SCORP, 1994).

Public beaches in the Upper East Coast region are the most popular form of recreation in the region. Four State of Florida Aquatic Preserves, and four State Parks and Recreation Areas are within the Upper East Coast region. Five artificial coastal reefs locations are in the Upper East Coast region as diving and fishing are very popular. The region also includes high quality recreation opportunities within the DuPuis Reserve State Forest and the St. Lucie Inlet Preserve. Overall, existing recreation resources in the Upper East Coast region receive heavy annual usage that is expected to increase in the future.

J.4.8 Aesthetic Resources

The Upper East Coast regional aesthetic overview is comprised of many components throughout its varied landscape. Waterways, canals, and roadways epitomize corridors where aesthetics are more specifically outlined, smaller in scale, and are bounded by walls of vegetation or bank sideslopes. Corridor widths, textures, colors, and wildlife are notable aspects of the region’s aesthetics. Some remnants of the historic cypress tree strands can still be found in the region (Lodge, 1994). Open pastoral settings are found where farming or grazing activities occur. Much of the interior region is ditched for farming or range practices that have altered the natural vegetation and aesthetic resources of those areas. Many of the regional rural areas possess good scenic quality on a small scale.

The coastal segments of the region possess more urban development than the interior and a completely different aesthetic quality and character. The sand shorelines of the Intracoastal Waterway and Atlantic Ocean provide a striking contrast with the tropical colored waters of those resources. Many locations offer panoramic vistas that are spectacular in some instances. Coastal underwater aesthetics are quality resources of the region. The few state parks within the region are found in the coastal section and provide pocket oasis of high quality aesthetics. Occasional air traffic is the one overriding aesthetic impediment that cannot be escaped. Future urban development could continue to pose a threat to the region’s aesthetic resources. Future water delivery schedules could adversely affect aesthetics of the region.

J.5 EVERGLADES AGRICULTURAL AREA

The historic Everglades contains the largest known contiguous body of organic soils in the world (Jones, 1948; Stephens, 1984). The area known as the Everglades Agricultural Area, located south of Lake Okeechobee within eastern Hendry and western Palm Beach counties (***Figure J-5-1***), encompasses an area totaling approximately 718,400 acres (1,122 sq mi.) of highly productive agricultural land comprised of rich organic peat or muck soils. A small portion of Everglades Agricultural Area mucklands is also found in western Martin County. Approximately 77 percent of the Everglades Agricultural Area (553,000 acres) is in agricultural production. The area is considered one of Florida's most important agricultural regions. It extends south from Lake Okeechobee to the northern levee of WCA-3A. Its eastern boundary extends to the L-8 Canal. The L-1, L-2 and L-3 levees represent its westernmost limits.

J.5.1 Vegetation

The Everglades Agricultural Area, covering 1,122 square miles south of Lake Okeechobee is the largest contiguous area of historic Everglades cover that has been converted by land use practices. The Everglades Agricultural Area historically consisted of several different plant communities. A dense swamp of pond apple, willow and elderberry formed broad bands along the southern rim of Lake Okeechobee. The remainder of what is now the Everglades Agricultural Area was dominated by sawgrass marshes. The Everglades Agricultural Area today contains primarily agricultural cropland. Approximately 77 percent or 553,000 acres support crops including sugar cane, vegetables, sod, rice and citrus. Sugar cane is the primary crop of the Everglades Agricultural Area.

Several large tracts of land at the south end of the Everglades Agricultural Area were never directly converted to agricultural lands, although their hydropattern has been greatly altered by water management practices. These areas are known as the Holey Land, Rotenberger, and Brown's Farm Wildlife Management Areas. These three areas comprise approximately 18 percent of the Everglades Agricultural Area and retain much of their historic sawgrass marsh and associated plant communities, although the plant cover has been altered by hydroperiod changes, fires, soil subsidence and invasion of exotic plant species.

The Holey Land Wildlife Management Area (aproximately 35,026 acres) has been managed for hydroperiod restoration by the South Florida Water Management District since 1990. The Florida Game & Fresh Water Fish Commission has been monitoring the growth of cattails in the Holey Land area since 1990. According to the GFC, cattail growth has increased significantly over the five year period 1990-1994. Table ***J-5.1-1*** presents the results of cattail surveys completed from 1990 through 1994.

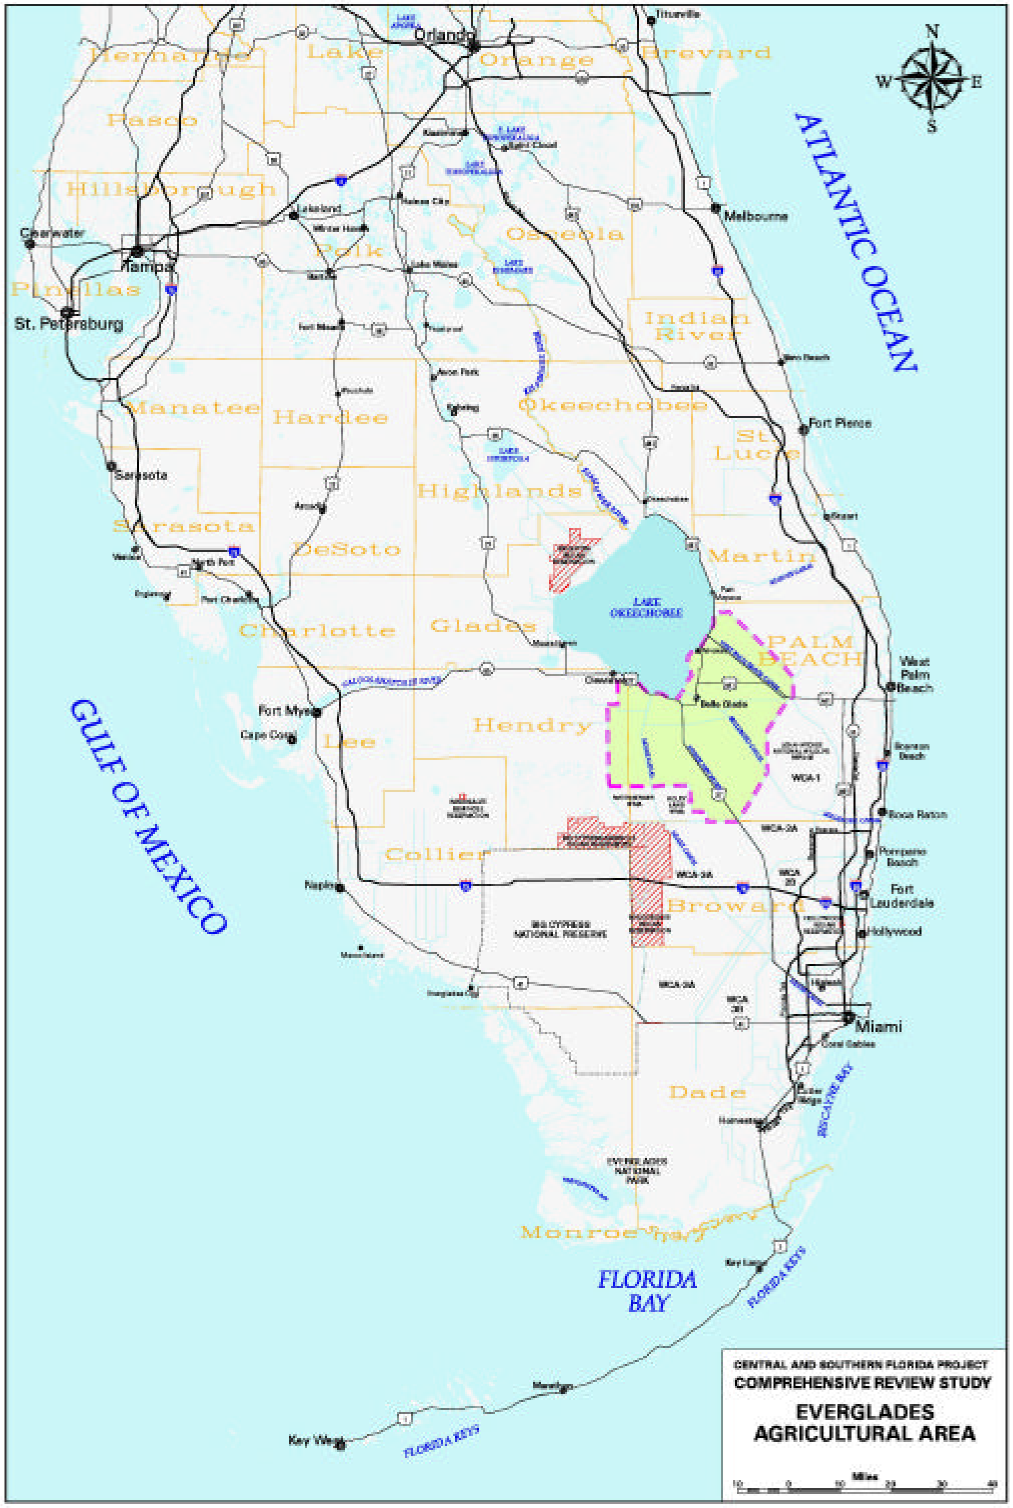

Figure J-5.-1 Everglades Agricultural Area Region

Table J-5.1-1 Holey Land Area Cattail Growth	
Year	**Acres with some cattail coverage**
1990	100
1991	538
1992	1,417
1993	3,414
1994	5,402

The cause for this increase is not completely understood. Phosphorus input from the Miami canal (the water source for hydroperiod restoration), residual phosphorus in Holey Land soils, and the hydroperiod regimes are factors contributing to the proliferation of cattails.

The Everglades Agricultural Area is bordered on the northeast by the western fringes of the Dupuis Reserve, and the Corbett Wildlife Management Area. These areas contain pine flatwoods and wet prairie plant communities. The North perimeter of the Everglades Agricultural Area is Lake Okeechobee. The west perimeter of the Everglades Agricultural Area consists of agricultural and range lands of eastern Hendry County. To the southeast and south, the Everglades Agricultural Area is bounded by the WCAs.

The natural cover of the C-139 Basin in southeastern Hendry County is of pine flatwoods, cypress domes, aquatic sloughs, and freshwater marshes. About 27 percent of the basin is considered to be wetlands (ESE, 1992). About 7 percent of the basin remain as pine flatwoods. The remaining areas of the basin have been converted to pasture and cropland.

J.5.2 Fish and Wildlife

Populations of many animal species have experienced declines throughout the Everglades. Factors that have led to population decreases include loss of habitat by land conversion, intensive harvest, altered hydroperiods, and altered fire patterns. Some wetland animal populations have been jeopardized by water management actions that have affected various aspects of their life histories (SFWMD, 1992).

Wildlife habitat within the Everglades Agricultural Area is mostly limited to the canal systems. Flooded and cultivated agricultural fields attract feeding birds, especialy waders. The Holey Land, Rotenberger, and Brown’s Farm Tracts located at the south end of the Everglades Agricultural Area are wildlife management areas that support populations of wading birds, deer, hogs and waterfowl.

J.5.3 Water Management

The existing drainage/irrigation system within the Everglades Agricultural Area is a complicated network of canals, levees, control structures and pumps. The original six major canals, (West Palm Beach, Hillsboro, Miami, North New River, Cross and Bolles canals, built in the 1920's) still serve to drain the Everglades Agricultural Area although each canal underwent major improvements during the 1960's. Historically the Everglades Agricultural Area has depended upon the flood storage capacity of Lake Okeechobee to the north and the Everglades WCAs to the south as a means of removing excess drainage water from the Everglades Agricultural Area. Prior to adoption of the IAP in 1979, the northern one-third of the Everglades Agricultural Area was routinely backpumped directly into Lake Okeechobee through Pump Stations S-2, S-3, and S-4 located on the south shore of the lake. The eastern and southern two-thirds of the Everglades Agricultural Area drained water south to the WCAs via Pump Stations S-5A, S-6, S-7, S-8.

Under the current IAP, the S-2 and S-3 Basins are now also routed south to the WCAs. Approximately 82 percent of the Everglades Agricultural Area land area (i.e. S-2, S-3, S-5A, S-6, S-7 and S-8 Basins) now pump excess drainage waters into the three WCAs via Pump Stations S-5A, S-6, S-7 and S-8. Nine much smaller Chapter 298 Drainage Districts also currently discharge surface water runoff into Lake Okeechobee. As a result the Everglades Agricultural Area depends on the flood storage capacity of the Water Conservation Areas, and to a lesser extent, on Lake Okeechobee, as a means to remove water from the basin.

The growers remove runoff water from their lands by pumping to the six C&SF Project canals serving the Everglades Agricultural Area. Growers in general are allowed a maximum removal rate that is determined by a runoff formula and is almost always in excess of the basin wide design rate of three-quarters of an inch of runoff per day (Cooper, 1989). This amount was based on three considerations: (1) that not all land in the basin would be in agricultural production at one time, (2) that some of the land would be planted to water tolerant crops, and (3) that the canals in the basin have some storage capacity. Although the capacity of the canal system is not large enough to handle all the water discharged from the Everglades Agricultural Area at one time, it was assumed that not all of the growers' pump stations would be pumping or pumping to capacity at any given time (Cooper, 1989).

J.5.4 Water Supply

Historically, the Everglades Agricultural Area has depended upon the flood storage capacity of Lake Okeechobee to the north and the Everglades WCAs to the south as a means of removing excess drainage water from the Everglades Agricultural Area. Prior to adoption of the IAP in 1979, the northern one-third of the Everglades Agricultural Area was routinely backpumped directly into Lake

Okeechobee through pump stations S-2, S-3, and S-4 located on the south shore of the lake, while the eastern and southern two-thirds of the Everglades Agricultural Area moved water south to the WCAs via pump stations S-5A, S-6, S-7, S-8.

Concerns over the accelerated rate of eutrophication in Lake Okeechobee led to a decision to change the relative distribution of flood or drainage water pumped from the Everglades Agricultural Area north to Lake Okeechobee on an average annual basis. The redistribution was called the IAP. Under this plan, 95 percent of all flood water and water released from Lake Okeechobee for water supply purposes are pumped from the Everglades Agricultural Area into the WCAs. Only an estimated 5 percent is pumped north to Lake Okeechobee during flood or drought emergency conditions. The S-2 and S-3 Basins are now also routed south to the WCAs. Approximately 82 percent of the Everglades Agricultural Area land area (i.e. S-2, S-3, S-5A, S-6, S-7 and S-8 basins) now pump excess drainage waters into the three WCAs via pump stations S-5A, S-6, S-7 and S-8. Nine much smaller Chapter 298 Drainage Districts currently discharge surface water runoff into Lake Okeechobee.

Primary Hydrologic Basins

The primary hydrologic basins of the Everglades Agricultural Area regulated under the Chapter 40E-63 Rule include the S-2, S-3, S-5A, S-6, S-7, and S-8 Basins. For the balance of this discussion, the S-8 and S-3 Basins are combined. The S-7 Basin is divided into those areas generally tributary to the North New River Canal and to the Hillsboro Canal. That part tributary to the North New River Canal is combined with the S-7 Basin; that part tributary to the Hillsboro Canal is combined with the S-6 Basin. As a result of those combinations, four primary hydrologic basins are defined:

- The S-5A Basin.
- The S-6/S-2 Basin.
- The S-7/S-2 Basin.
- The S-8/S-3 Basin.

Previous analyses of discharges from the above four basins were prepared for a period of record including water years 1979-1988 (Everglades Protection Project, Conceptual Design, 1994). The combined contributing areas for the four primary hydrologic basins are:

- S-5A: 126,910 acres.
- S-6/S-2: 121,009 acres.
- S-7/S-2: 142,160 acres.
- S-8/S-3: 133,642 acres.

A summary of the historic average annual discharge volumes from the Everglades Agricultural Area to various receiving waters is presented in ***Table J-5.4-1.***

Table J-5.4-1 Historic Everglades Agricultural Area Runoff 1979-1988 Average Annual Discharge	
Basin	**Volume (acre-feet)**
S-5A	275,537
S-6/S-2	194,394
S-7/S-2	274,245
S-8/S-3	298,068
TOTAL	**1,042,243**

298 Districts and 715 Farms

The Everglades Agricultural Area includes a number of special drainage districts and other areas that discharge at least some of their runoff directly to Lake Okeechobee. These areas include the South Florida Conservancy District, South Shore Drainagr District, East Beach Water Control District, East Shore water Control District, and the 715 Farms Area.

The five basins discussed herein encompass a total of approximately 32,081 acres along the south and east shores of Lake Okeechobee, and are situated primarily in Palm Beach County (the westerly two miles of the South Florida Conservancy District are situated in Hendry County).

South Florida Conservancy District

The South Florida Conservancy District is situated on the south shore of Lake Okeechobee immediately west of the Miami Canal, and includes a total of approximately 9,775 acres. The South Florida Conservancy District is served by a total of three pumping stations. Pump Station P-5-E is located on the west bank of the Miami Canal, and discharges to the Miami Canal. Pump Station P-5-W discharges to the Industrial Canal (in the S-4 Basin) at the west line of the South Florida Conservancy District. Pump Station P-5-N is located on the south bank of Lake Okeechobee, and discharges directly to the Lake. This station is presently operated only when the combined capacity of stations P-5-E and P-5-W is inadequate to prevent flooding in the District. While station P-5-W does not technically discharge directly to Lake Okeechobee, the majority of its discharges are eventually routed to the Lake through the Industrial Canal (and Canal C-21) via Hurricane Gate No. 2 (and Pump Station S-4).

South Shore Drainage District

The South Shore Drainagr District is located on the south shore of Lake Okeechobee, extending generally between the Miami Canal and the North New River Canal, and includes a total of approximately 4,230 acres. The South Shore Drainagr District is presently served by a total of two pumping stations. The Bean City Pump Station is located on the south shore of Lake Okeechobee, and discharges directly to the Lake. The South Bay Pump Station is located on the west bank of the North New River Canal and discharges to the canal.

East Beach Water Control District

The East Beach Water Control District is located on the east shore of Lake Okeechobee south and west of the West Palm Beach Canal, and includes a total of approximately 6,542 acres. The East Beach Water Control District is presently served by three pumping stations. Pump Station 1 is located on the east shore of Lake Okeechobee and discharges directly to the Lake. Pump Station 2 is located on and discharges to the West Palm Beach Canal. Discharges from the East Beach Water Control District are conveyed to Pump Station 2 through the C-4 Canal. Pump Station 3 is located on the C-4 Canal at the easterly boundary of the East Beach Water Control District, and discharges to the C-4 Canal at the easterly boundary of the East Beach Water Control District, and discharges to the C-4 Canal. Its discharge is subsequently routed through Pump Station 2 to the West Palm Beach Canal.

East Shore Water Control District

The East Shore Water Control District is situated between the West Palm Beach and Hillsboro Canals, and is abutted on the west by the 715 Farms area, which physically separates the East Shore Water Control District from Lake Okeechobee. It is abutted on the north by the Pahokee Water Control District, and on the east by the Highland Glades Drainage District. It includes a total of approximately 8,136 acres. The East Shore Water Control District is presently served by a single pumping station on the east shore of Lake Okeechobee that discharges directly to the Lake. Runoff from the East Shore Water Control District is carried to the pumping station through a conveyance canal following the south line of the 715 Farms area.

715 Farms

The 715 Farms are (also known as Closter Farms) consists of approximately 3,398 acres of agricultural lands. This area abuts the east shore of Lake Okeechobee, and is served by a single pumping station that discharges directly to the Lake.

Record data on discharges to Lake Okeechobee from the 298 Districts and the 715 Farms area was furnished by the Florida Department of Environmental Protection. The following is a summary of the average annual historic discharge volumes from these districts to Lake Okeechobee.

South Florida Conservancy District; 17,500 acre-feet per year.
South Shore Drainagr District; 5,199 acre-feet per year.
East Beach Water Control District; 5,383 acre-feet per year.
East Shore Water Control District; 8,555 acre-feet per year.
715 Farms; 7,820 acre-feet per year.

A portion of the runoff from these districts is delivered to the primary canal system. Volume of flow is not available, however the majority of the runoff from these districts is delivered to Lake Okeechobee.

C-139 Basin

The C-139 Basin is the most northerly of the four primary hydrologic basins forming the Western Basins; other basins include the Feeder Canal Basin, the L-28 Basin, and the L-28 Tieback Basin. These basins are all tributary to the EPA. The conceptual plan for the Everglades Protection Project directly addresses only the C-139 Basin.

The total area of the C-139 Basin, based on historical boundaries established by the District, is approximately 169,500 acres. The primary canals within the C-139 Basin consist of the L-1, L-2, and L-3 Borrow Canals. There are a total of five outfall locations for the C-139 Basin. All drainage eventually outfalls to WCA-3A. The total average annual volume from the C-139 Basin during the period water years 1979-1988 is estimated to be 98,000 acre-feet (C-139S – 87,000 ac-ft, C-139N – 11,000 ac-ft).

L-8 Basin

The L-8 Basin encompasses 171 square miles in northwestern Palm Beach County (168 square miles) and southwestern Martin County (2 square miles). The balance of the L-8 Basin (42 square miles) is considered to be ineffectively drained and not significantly contributing to L-8 Basin runoff.

Over a nine-year period of record including water years 1980-1988, the average annual runoff from the L-8 Basin was calculated to be 187,039 acre-feet. Runoff from the L-8 Basin can be delivered to a variety of receiving water bodies. A summary of historic runoff volume by receiving water body from the L-8 Basin over the period water years 1980-1988 is presented in ***Table J-5.4-2***.

Table J-5.4-2
Average Water Year
L-8 Basin Runoff And Receiving Waterbody
(Acre-Feet)

Lake Okeechobee	M Canal	C-51 via S-5AE	WCA-1	S-5A Basin	Total*
22,141	48,821	36,379	60,565	19,132	187,039*

May not add up exactly due to rounding.

Water users in the L-8 Basin can receive water not only from L-8 Basin runoff, but also from sources external to the L-8 Basin, including Lake Okeechobee (via Culvert #10A) and WCA-1, the S-5A Basin, and the C-51 West Basin via the S-5A complex. ***Table J-5.4-3*** summarizes both gross and net supplemental inflows to the L-8 Basin from Lake Okeechobee and the S-5A complex. The gross supplemental inflows represent a summation of all inflows to the L-8 Basin from the indicated source, the net inflow is the difference between inflows to the basin and discharges from the basin at the same point.

Table J-5.4-3
Average L-8 Supplemental Inflows
Supplemental Inflow By Source
(Acre-Feet)

Lake Okeechobee		S-5A Complex		Total	
Gross	Net	Gross	Net	Gross	Net
28,912	6,771	5,806	(108,316)	34,718	(101,545)

C-51 West Basin

The overall C-51 Basin has an area of approximately 164.3 square miles and is located in eastern Palm Beach County. The basin is comprised of two sub-basins, C-51 West (73 square miles) and C-51 East. State Road 7 is generally the boundary between the basins. This discussion is focused on the C-51 West sub-basin. Gauge data for runoff from the C-51 West Basin exists only at Structure S-5AE, and represents but a small fraction of the total runoff from the basin. The Jacksonville District, U.S. Army Corps of Engineers, in connection with its studies of the C-51 Basin, developed a watershed simulation model calibrated to available gage data in the C-51 Basin as a whole. That simulation model is structured to permit separate identification of runoff from the C-51 West sub-basin. That simulation model was developed and applied to the period encompassing water years 1961-1985. The calculated runoff from the C-51 West Basin resulting from application of the model is summarized in ***Table J-5.4-4*** (Everglades Protection Project, Conceptual Design, 1994).

Table J-5.4-4
Average C-51 West Basin Water Balance
(Ac-Ft)

C-51 West	Discharge at S-5AE		Discharge at S.R. 7*	
Basin Runoff (ac-ft)	**Inflow (ac-ft)**	**Outflow (ac-ft)**	**Net (ac-ft)**	**(ac-ft)**
119,002	112,489	4,264	108,225	227,226

*Includes both discharges to the east of S.R. 7 and any withdrawals from the C-51 West canal for water supply.

J.5.5 Land Use

The vast majority of land within the Everglades Agricultural Area is used for agricultural production. A significant amount of land is also set aside for wildlife management and a lesser amount for urban development.

J.5.5.1 Agriculture

Palm Beach County is included in this region. A portion of Hendry County also lies in the Everglades Agricultural Area. Also, Palm Beach County is not entirely within the Everglades Agricultural Area, but it is assumed that the majority of agricultural production is within the Everglades Agricultural Area because the remaining portion of the county is primarily urbanized.

More than 600,000 acres are farmed in Palm Beach County (UFBEBR, 1995), and sugarcane was harvested from about half of that acreage in 1996 (FASS, 1996d). Much of this acreage is likely categorized as unique farmland based upon its location, growing season, and high value crops, including sugarcane and vegetables. Sugarcane receipts accounted for 68 percent of total field crop sales in Florida in 1996 (FASS, 1996c). The Everglades Agricultural Area is known for its sugarcane production and sugar processing, but Palm Beach County also ranks 15th among Florida counties for acres of citrus (FASS, 1996b). This region is characterized by mid-size farms averaging 690 acres each with high productivity of more than $1300 per acre (UFBEBR, 1995). More than 18,000 people are employed in agricultural production and services representing a payroll of more than $26 million (UFBEBR, 1995). Total market value of agricultural products in Palm Beach County is almost $900 million, ranking it first among counties in the state of Florida (UFBEBR, 1995) and third among U.S. counties (FDACS, 1994).

The Everglades Agricultural Area is highly dependent upon the system of canals running through the region to provide necessary drainage of excess water during the wet season as well as supplemental water supplies for irrigation during the dry season. Approximately two thirds of the land farmed in the Everglades Agricultural Area is irrigated, totaling more than 400,000 acres (UFBEBR, 1995). The Everglades Agricultural Area has traditionally relied upon Lake Okeechobee for its water supply, and looked to the Water Conservation Areas to the south to receive their excess drainage.

Continued agricultural production in the Everglades Agricultural Area has become increasingly controversial. Some of the factors that may affect Everglades Agricultural Area agriculture include water quality concerns, soil subsidence, and encroachment of urbanization. The water quality concerns, particularly phosphorus loading, are being addressed through best management practices, storm water treatment areas, and growing use of organic farming practices and rice cultivation in rotation with sugarcane production. Although sugarcane cultivation in the Everglades Agricultural Area has come under some sharp criticism in recent years, sugarcane is recognized as the most appropriate crop for this region. Sugarcane requires less phosphorus fertilizer than other crops grown in the Everglades Agricultural Area (Sanchez, 1990), and sugarcane has been found to remove 1.79 times more phosphorus than was applied as fertilizer (Coale et al., 1993). Florida sugarcane only requires small amounts of pesticides due to disease resistant and tolerant cultivars, and cultivation instead of herbicides for weed control. Sugarcane also tolerates greater variability in water table levels, allowing for more flexible water management strategies (Glaz, 1995).

Soil subsidence has become a potential threat to long-term crop production in the Everglades Agricultural Area. The average historic rate of subsidence of 1 inch per year has slowed to 0.56 inches per year since 1978 (Shih et al., 1997). They attributed the lower rate to several factors including higher water tables and an increased proportion of land planted to sugarcane. Surveys conducted by Shih et al. (1997) in 1997 found an average of 1.62 feet to 4.36 feet of soil remaining over 11 transects. Prevention of continued soil subsidence will depend on maintaining high ground water levels to prevent further oxidation of the soil profile. This, in turn, will require development of more water-tolerant sugarcane varieties and/or increased rice cultivation. This research is currently underway and showing promising results (Glaz, 1997). A strong agricultural economy in the Everglades Agricultural Area based on profitable crop production is the best defense against conversion of agricultural land to urban land.

J.5.5.2 Rotenberger and Holey Land Wildlife Management Areas

The Holey Land Tract (35,026 acres) is managed by the GFC as a state wildlife management area. The South Florida Water Management District as been managing the hydroperiod since completion of a perimeter levee and pump station in 1990. The Rotenberger Tract (23,970 acres) and Brown's Farm Tract (4,460 acres) are also managed by the GFC as state wildlife management areas. Lake Harbor Waterfowl Management Area is operated by GFC for management of waterfowl. The land is under rice production for both harvest and wildlife habitat.

J.5.5.3 Urban

The remaining 5 percent of the Everglades Agricultural Area includes the communities of Pahokee, Belle Glade, South Bay and Clewiston, several sugar mills, roads, canals and water control features.

J.5.5.4 C-139 Basin

Land use within the C-139 Basin of eastern Hendry County is predominantly agricultural. The land use in the basin is approximately 62 percent agricultural, 4 percent urban, and 34 percent native land cover. This rural area is primarily pasture land for cattle grazing, with increasing amounts of land being converted to citrus groves. Agricultural land uses include vegetable farms, citrus groves, improved pasture, and unimproved pasture (Mock Roos, 1993).

J.5.6 Recreation Resources

Recreation resources in the Everglades Agricultural Area region are minimal due to the heavily developed agricultural industry in the region. The landscape is nearly flat with most of the areas farmed in sugarcane. The region is extensively ditched for water supply. A few community sized city and school playgrounds/parks are located within the Everglades Agricultural Area region. Some City, County, WMD, and U.S. Army Corps of Engineers parks are also found in the region. Recreation resources in the region are minimal at best.

J.5.7 Aesthetic Resources

The aesthetic overview is one of an extensively altered landscape that is nearly flat with most of the land in agricultural production. Few areas if any of the historical, pond apple or sawgrass marsh plant communities remain in their natural state. The region is extensively ditched for water supply to farm sugarcane and appears lush and green when the cane is ready for harvest. The cane fields are burned off just before the cane is harvested which produces a huge cloud of smoke visible for miles that smells awful. Once the cane is harvested the fields appear dark black before planting and through much of the early growing cycle. Minimal aesthetic resources exist in the Everglades Agricultural Area region however some non-farmed pocket areas do possess better aesthetic quality. Agricultural development and fluctuations in the water supply and quality are concerns of the downstream properties of the Everglades system. The Everglades Agricultural

Area region affects the water quality, vegetation and aesthetics of the downstream regions.

J.5.8 Hazardous, Toxic, and Radioactive Wastes

The U.S. Environmental Protection Agency and Florida Department of Environmental Protection databases were reviewed to determine if previously reported areas of environmental concern exist in the vicinity of the proposed STAs and other Everglades Construction Project project features. The U.S. Environmental Protection Agency database includes the Comprehensive Environmental Response Compensation and Liability Information System (CERCLIS), Facility Index System (FINDS), National Priorities List (NPL), and Resource Conservation and Recovery Information System (RCRIS) lists. The CERCLIS database includes information on sites identified by the U.S. Environmental Protection Agency as abandoned, inactive, or uncontrolled hazardous waste sites that may require cleanup. The FINDS database contains facility information and suggestions for other sources of information, e.g., RCRIS, CERCLIS. The NPL database is a subset of CERCLIS, which identifies sites scheduled for priority cleanup under the Superfund Program. RCRIS includes information on sites which generate, transport, store, treat, and/or dispose of hazardous waste as defined by the Resource Conservation and Recovery Act (RCRA).

The Florida Department of Environmental Protection, Bureau of Information Systems, Stationary Tank Inventory System Report includes sites which have reported petroleum product spills in accordance with state regulations. The Florida Department of Environmental Protection, Groundwater Management System report includes sites which have the potential to affect groundwater. Such sites include those with stormwater ponds, dredge and fill permits, wells, etc.

J.6 WATER CONSERVATION AREAS

The Water Conservation Areas (WCAs) cover 1,372 square miles, consisting primarily of sawgrass marshes, associated wetland communities and tree islands. The WCAs are contained by perimeter levees (***Figure J-6-1***). WCA-1, also known as Loxahatchee National Wildlife Refuge, includes 227 square miles of Everglades wetland habitat. WCA-1 represents a remnant of the northern Everglades. WCA-2, the smallest of the three WCAs, encompasses approximately 210 square miles. The area is divided in two cells by a levee constructed in 1961. The north cell, WCA-2A,

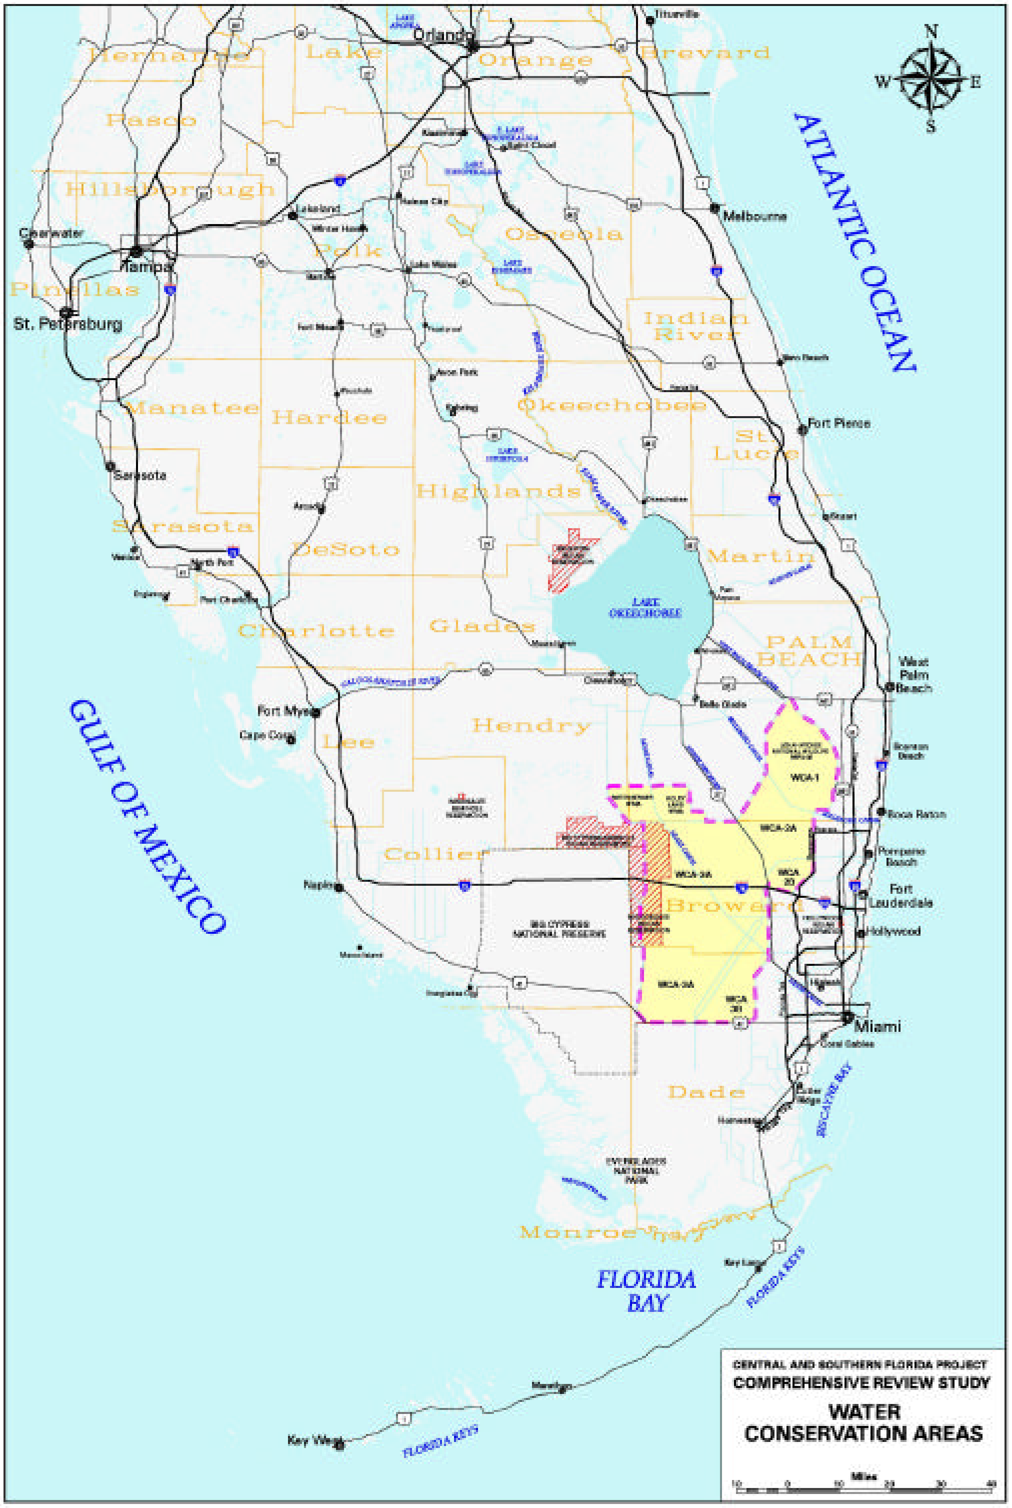

Figure J-6-1 Water Conservation Areas Region

Covers 173 square miles, and the south cell, WCA-2B, covers 37 square miles. WCA-3, the largest of the WCAs covers an area of 915 square miles.

The coverage of the Water Conservation Areas includes descriptions of existing conditions for the Holey Land Wildlife Management Area and the Rotenberger Wildlife Management Area. These two areas, located northwest of Water Conservation Area 3A, between 3A, the Everglades Agricultural Area, and the Big Cypress region, are remnant sawgrass planes and are managed by the Florida Game and Fresh Water Fish Commission. The Miami Canal is their common boundary. Their inclusion in the Water Conservation Area region is purely for organizational purposes for this report and they are not, strictly speaking, part of the Water Conservation Area system. The description of existing conditions for this region, presented below, is drawn largely from the Florida Game and Fresh Water Fish Commission, Fish and Wildlife Coordination Act Report, submitted to the U.S. Army Corps of Engineers on August 6, 1998. This Coordination Act Report is available in entirety in Annex A.

J.6.1 Vegetation

Almost all of the Water Conservation Areas are graminoid wetlands interspersed with tree islands (hammocks) and willow strands. Tree islands are a unique feature of the Everglades ecosystem. Tropical hardwoods are found on some of the relatively unaltered tree islands in the southern portion of the area.

J.6.1.1 Dominant plant communities

The dominant plant communities are listed below. Each community description is followed by a list of plant species common to that community.

Basin Marsh

This plant community type develops in broad, shallow to intermediate depth basins with peat substrate. Flooding is seasonal. Climate is temperate or subtropical; fire is frequent. Dominant plant cover is sawgrass and/or buttonbush and/or mixed emergents. In general, there are three recognizable types of basin wetland communities present:

Sawgrass marsh, composed of sawgrass (*Cladium jamaicense*), with cattail (*Typha* spp.), maidencane (*Panicum hemitomon*), arrowhead (*Sagittaria lancifolia*), pickerelweed (*Pontederia cordata*), willow (*Salix caroliniana*), button bush (*Cephalanthus occidentalis*), wax myrtle (*Myrica cerifera*), and saltbush (*Baccharis glomeruliflora*).

Wet prairie, composed of beak rush (*Rhynchospora tracyi*), spike rush (*Eleocharis spp.*), maidencane (*Panicum hemitomon*), string lily (*Crinum americanum*), and white water lily (*Nymphaea odorata*).

Aquatic slough, composed of white water lily, floating heart (*Nymphoides aquatica*), spatterdock (*Nuphar luteum*), bacopa (*Bacopa caroliniana*), and bladderwort (*Utricularia* spp.).

Strand Swamp

A strand is a broad, shallow channel with peat over a mineral substrate; seasonally inundated by flowing water; tropical or subtropical. Fire is occasional or rare. Vegetation is characterized by cypress and/or willow.

The following species are associated with this community: pond cypress (*Taxodium ascendens*), bald cypress (*Taxodium distichum*), willow (*Salix* spp.), buttonbush (*Cephalanthus occidentalis*), wax myrtle (*Myrica cerifera*), sawgrass (*Cladium jamaicense*), and royal fern (*Osmunda regalis*).

Hydric Hammock

This is a wetland forest community that occurs in lowlands over sandy, clay organic soil, often over limestone. Its water regime is; mesic to hydric; climate is subtropical or temperate; and fire is rare or not a major factor.. Vegetation is characterized by water oak, cabbage palm, red maple, bays, hackberry, hornbeam, needle palm, and mixed hardwoods. The following species are associated with this community: sweet bay (*Magnolia virginiana*), red bay (*Persea borbonia*), cocoplum (*Chrysobalanus icaco*), strangler fig (*Ficus aurea*), wax myrtle (*Myrica cerifera*), willow (*Salix* spp.), elderberry (*Sambucus simpsonii*), hackberry (*Celtis laevigata*), cabbage palm (*Sabal palmetto*), red maple (*Acer rubrum*), royal fern, dicliptera (*Dicliptera assurgens*), false nettle (*Boehmeria cylindrica*), water oak (*Quercus nigra*), hornbeam (*Carpinus caroliniana*), and needle palm (*Rhapidophyllum hystrix*).

J.6.1.2 C&SF Project Effects

Many areas of the WCAs have been affected by construction and operation of the C&SF Project. The Project has caused some areas of the northern Everglades to become overdrained, while other areas of the marsh have been subjected to deep water or stabilized water level conditions. These hydrological modifications of the original overland sheetflow system have played a major role in determining the present day vegetation characteristics of the area (Loveless *et al.*, 1970; Dineen, 1972; McPherson, 1973; Alexander and Crook, 1984). The following discussion identifies the vegetation characteristics of each WCA and points out those areas of the marsh that have been most affected by hydroperiod changes.

Water Conservation Area-1

Vegetation within WCA-1 consists of a matrix of wet prairies, sawgrass prairies, and aquatic slough communities. Tree islands are interspersed throughout the area. Plant community cover within WCA-1 has shifted as a result of impoundment of the marsh by perimeter levees and alteration of hydroperiods by operation of the C&SF Project. The southern, lower elevation areas of WCA-1 have been flooded for long periods of time, while the northern portions of the area have experienced more frequent drying. Areas which have experienced shortened hydroperiods have experienced shifts to woody vegetation (wax myrtle and willow), while lower elevations have experienced shifts to more aquatic flora. In addition, WCA-1 currently includes approximately 6,000 acres (4 percent total cover) of cattail marsh that was not present prior to the early 1960's. A number of factors influence establishment of cattails in the Everglades. These include physical disturbance of underlying soil profile by canal construction activities, proximity to seed sources, fire, hydrologic changes and the availability of nutrients. Exotic vegetation that was uncommon prior to 1965 is a growing problem. Melaleuca and Brazilian pepper are both rapidly spreading along the perimeter and into the interior marsh. In 1988, total coverage of Melaleuca was estimated to be near 4,000 acres (2.8 percent).

Water Conservation Area-2A

Detailed descriptions of the plant communities that existed within WCA-2A prior to impoundment of the area are provided by Davis (1943a,b) and Loveless (1959). Vegetation that was characteristic of the area prior to impoundment included tree islands, sawgrass and extensive communities of beakrush (*Rhynchospora tracyi*), maidencane (*Panicum hemitomon*) and spikerush (*Eleocharis cellulosa*). The wet prairie communities occurred primarily in the central and eastern portions of WCA-2. A generalized 1956 vegetation map of WCA 2 showed more than 50 major tree islands in what is now WCA-2A (SFWMD, 1978). During the 1960s and 1970s, WCA-2A was managed as a regional water storage area. The water regulation schedule for WCA-2A during this period ranged seasonally between 13.0-14.5 ft. NGVD. Stabilization of water levels resulted in the elimination of the natural flood-drought cycle. This stabilization, combined with an increased frequency of flooding, increased water depths, reduction of the frequency of fire and high nutrient loading associated with agricultural runoff, produced a number of ecological changes. Changes include the elimination of wet prairie communities, drowning of tree islands, loss of sawgrass communities along slough edges and accumulation of a flocculent layer of plant detritus (up to 14 inches deep) in sloughs. The detritus level in the sloughs caused high oxygen demand and periodic fish kills. Wading bird feeding habitat was also lost (Dineen, 1972, 1974).

Major plant communities in WCA-2A now consist of remnant drowned tree islands, open water sloughs and large expanses of sawgrass, and sawgrass intermixed with dense cattail (*Typha domingensis*) stands. Remaining tree islands are found primarily at higher ground level elevations, located in the northwest corner of WCA-2A. Remnant (drowned) tree islands, dominated primarily by willow, are found scattered throughout the central and southern sections of WCA-2A. In recognition of these problems, the South Florida Water Management District initiated several experimental drawdown studies of WCA-2A for the purpose of stimulating more natural drying conditions that would promote the re-growth of wet prairie vegetation and tree island communities. An experimental drawdown was conducted in 1973, which allowed WCA-2A to dry out for 71 days before summer rains refilled the area. Many areas of the marsh failed to dry out due to the late timing of the drawdown. Some success was observed in consolidating the flocculent layer of organic detritus as well as stimulating the re-growth of a few species of wet prairie and woody tree island vegetation (Dineen, 1974). Wading birds (white ibis, herons and wood storks), migratory waterfowl and snail kites were observed utilizing WCA-2A on a more frequent basis during the drawdown as compared to years when the higher water level schedule was in effect (Kushlan, 1974).

In 1980, a second attempt was initiated to achieve a drawdown of the area over a four-year period (1980-1984). The second drawdown reduced the regulation schedule from 13.0-14.5 ft. NGVD to 9.5-12.5 ft. NGVD. The initial 1980-81 drawdown coincided with a regional drought. Concerns for regional water supplies suspended the drawdown during 1982 until the late dry season. The result was that only a partial drying of the marsh was accomplished. The dry seasons of 1983 and 1984 were unusually wet and prevented the planned drying of the system. In large part due to extreme climatic conditions, the drawdown effort overall was only partially successful. Lowered water levels created favorable conditions that allowed for some expansion of wet prairie communities and increased sawgrass densities (Worth, 1988).

Concerns have focused on the problems of nutrient-enrichment and cattail expansion in the northwest portion of WCA-2A. The increase in cattails in WCA-2A over time is supported largely by long-term field observations by government scientists (Davis and Harris, 1978; Reeder and Davis, 1983; Davis, 1982, 1984 1989, 1991; Swift, 1981; Swift and Nicholas, 1987; Toth, 1987, 1988; Worth, 1983; 1988; Urban, 1984) who conducted water quality and environmental studies within WCA-2A from 1977 to 1989. These researchers noted an increase in cattail abundance downstream from water control structures S-10C and S-10D in areas that were originally dominated by sawgrass, (where cattail was typically observed as rare or absent). Field observations noting increases in cattail distribution also coincided with observed increases in surface water nutrient concentrations measured downstream from these two water management structures. Scientists documented the existence of a defined nutrient gradient downstream of S-10C (Swift, 1981; Swift and Nicholas, 1987). A set of seven sampling points arranged in a straight line south of S-10C was established in 1978 and labeled "Transect B". High concentrations of nutrients existed at sites dominated by cattail (sites B-1 through B-3) while low concentrations of nutrients existed at sites dominated by sawgrass vegetation (Sites B-5 through B-7). In a follow-up study, conducted from 1980 - 1982, Swift and Nicholas (1987) reported that the nutrient gradient had shifted further south, affecting the microbiology (periphyton community) of site B-5, located 3.7 km downstream of S-10C. These data provide evidence that nutrients had penetrated the marsh interior several kilometers further downstream than originally observed in 1978-1979.

The most current data available (Richardson, C. as cited in LOTAC-II, 1988, Planning Document) concerning the present distribution of cattails in WCA-2 show 4,400 acres in which cattails represent more than 50 percent of the vegetation in coverage and 24,000 acres of mixed or scattered cattail (<50 percent coverage) present in the northeast portion of WCA-2A. Since this survey was conducted in the middle of a long-term regional drought, the species composition data presented in this study may be unrepresentative of average conditions. At the time there was an extensive invasion by pigweed (*Amaranthus* sp.) and temporary thinning of cattails, resulting from extremely dry conditions. There is a relationship between the occurrence of cattail stands in WCA-2A and phosphorus loadings through the three S-10 discharge structures. A similar relationship is noted downstream of pump station S-7.

Several studies conducted within WCA-2A show that cattails out-compete sawgrass in their ability to absorb nutrients. There is increased cattail production during years of high nutrient inflows (Toth, 1988; Davis, 1991). Cattails are considered a high nutrient status species that is opportunistic and highly competitive, relative to sawgrass, in nutrient-enriched situations (Toth, 1988; Davis, 1991). Davis (1991) concluded that both sawgrass and cattail increased annual production in response to elevated nutrient concentrations, but that cattail differed in its ability to increase plant production during years of high nutrient supply.

Infestation of melaleuca, an introduced exotic, in WCA-2A is considered to be relatively light (scattered single or small clumps of outlier trees), and currently covers less than 10 percent (<11,000 acres) of the sawgrass marsh (Melaleuca Task Force, 1990). Low numbers of trees are thought to be related to the higher water levels that were maintained in the area prior to 1980, as well as an experimental melaleuca control program. Existing melaleuca trees are generally restricted to higher ground elevations such as tree islands and sawgrass ridges (Worth, 1983). Control of melaleuca was initiated in 1980 as part of a larger environmental study to evaluate the effects of a drawdown of WCA-2A. Efforts were directed at eradicating or controlling the existing melaleuca seed sources to prevent further spread as a result of the drawdown effort (Worth, 1983, 1988).

Water Conservation Area-2B

Due to the highly permeable nature of the aquifer underlying WCA-2B, it has been difficult to maintain historic water levels within this impoundment. As a result, no water regulation schedule is currently maintained for WCA-2B, although the area should not be allowed to exceed 11.0 ft. NGVD unless the outlet structure is open. Impoundment of WCA-2B by construction of L-35B in 1972 resulted in a lowered water table and a shortened hydroperiod, setting the stage for melaleuca invasion throughout WCA-2B. Since 1980, the hydrology of WCA-2B has changed considerably. Drawdown efforts in WCA-2A during the 1980's resulted in increased volumes of water being diverted to WCA-2B. These efforts have somewhat helped to slow down the invasion of melaleuca.

In the south end of WCA-2B there still exists an extensive wet prairie community dominated by spikerush (*Eleocharis cellulosa)* and maidencane (*Panicum hemitomon*) which has been reported to serve as a important feeding area for wood storks, snail kites and other wading birds over the last several years. Approximately 30 snail kites were observed utilizing the south end of WCA-2B in 1987.

Heavy infestations of melaleuca (large heads and solid forests) occur throughout WCA-2B, and threaten to dominate the marsh within the next several decades. 1990 estimates indicated that about one-quarter of WCA-2B (10,000 acres) was heavily infested by this introduced exotic (Melaleuca Task Force, 1990).

Water Conservation Area-3A

The original plant communities of WCA-3A were first described by Davis (1943a,b) and Loveless (1959). Many areas of WCA 3A still contain vast tracts of Everglades habitat consisting of tree islands, sawgrass marsh, wet prairies and aquatic sloughs, that are very similar in appearance to the descriptions provided by these early studies. However, a number of major changes have occurred as a result of canal and levee construction and impoundment of the area.

WCA-3A North. The community structure and species diversity of Everglades vegetation located north of Alligator Alley (WCA-3A North) is very different from the wetland plant communities found south of the trans-Everglades highway (WCA-3A South). Improvements made to the Miami Canal and impoundment of WCA-3A by levees have over-drained the north end of WCA-3A and shortened its natural hydroperiod. These hydrological changes have increased the frequency of severe peat fires that have resulted in loss of tree islands, aquatic slough, and wet prairie habitat that were once characteristic of the area prior to construction of the C&SF project. Today, northern WCA-3A is largely dominated by sawgrass and lacks the natural structural diversity of plant communities seen in southern WCA-3A.

Over drainage of the northwestern portion of WCA-3A has allowed the invasion of a number of terrestrial species such as salt bush (*Baccharis halmifolia*), dog fennel (*Eupatorium capillifolium*), and broom sedge (*Andropogon* spp.). Melaleuca has become well established in the southeastern corner of WCA-3A North, and is spreading to the north and west.

WCA-3A South. Everglades vegetation located in the central and southern portion of WCA 3A South probably represents some of the best examples of original, undisturbed Everglades habitat left in south Florida. This region of the Everglades appears to have changed little since the 1950's, and contains a mosaic of tree islands, wet prairies, sawgrass stands, and aquatic sloughs similar to those reported by Loveless (1959).

Although the majority of vegetation within WCA-3A south can be described as typical Everglades habitat, several localized problem areas exist. Construction of Alligator Alley (State Road 84) in 1967 cut off sheet flow to the central and southern portions of WCA-3A. The construction of canals and the roadbed has resulted in excessive drainage of the marsh both north and south of the highway. Areas of the marsh located several miles south of the highway and west of the Miami Canal have experienced a shortened hydroperiod, and an increased frequency of peat fires. Severe peat fires during the droughts of 1981, 1985, and 1989 burned tree islands down to bare rock in many places, causing the loss of tree islands north and south of Alligator Alley as well as increasing soil subsidence rates in WCA-3A (Zaffke, 1983; Schortemeyer, 1980). Two environmental enhancement structures, S-339 and S-340 were constructed on the Miami Canal (C-123) in 1980 to divert canal water across WCA-3A north and WCA-3A south in an effort to prolong the marsh hydroperiod, increase water table levels, and reduce flow rates to the south end of WCA-3A (Zaffke, 1983).

The east-central portion of WCA-3A South, located upstream from pump station S-9, has few tree islands and is covered primarily by aquatic slough and sawgrass vegetation. Large stands of cattail exist in this general area. This area, located south of Alligator Alley and east of the Miami Canal, periodically experiences prolonged deep-water conditions as a result of S-11 inflows during the wet season. There are several canals that converge in this area, bringing inflows from the S-11s, and other upstream inflows influenced by agricultural drainage. The S-9 contributes a mix of urban and rural runoff from rapidly developing west central Broward County. The multiple hydrologic connections to this area make it difficult to clearly identify specific sources of influences on vegetation patterns. Apparent impacts to vegetation also have been noted in the western portion of

WCA-3A, along C-60 downstream from pump station S-140, and at the terminus of the L-28 Interceptor Canal.

Completion of L-29 across the southern end of WCA-3 in 1962, coupled with improvements to several major canals (Miami Canal, L-67A Canal, L-29 Canal, and L-38W Canal) interrupted the historic flow of water southward, causing the ponding of water at the extreme south end of WCA-3A. This construction resulted in longer periods of inundation and relatively deeper water levels in the southern portion of WCA-3A as compared to the central portion of the marsh. These hydroperiod changes resulted in a loss of wet prairie habitat, with an increase in aquatic slough communities which may have benefited snail kite populations in this area by providing favorable habitat for the production of apple snails, the primary food source of this endangered species.

Water Conservation Area-3B

Plant communities within WCA-3B exhibit typical Everglades vegetation consisting of a mosaic of tree islands, wet prairies, sawgrass stands, and aquatic slough communities. This area has changed little since the enclosing levees were completed in the early 1960s. Tree islands in this area, however, are threatened by the invasion of melaleuca, which has become firmly established as a seed source within the Bird Road/Pennsuco wetlands located just east of WCA-3B in western Miami-Dade County.

Holey Land Wildlife Management Area

The Holey Land Wildlife Management Area is an extensive sawgrass marsh. The plant communities that occurred historically in the area experienced marked changes in the past due to increased drainage, decreased hydroperiod, drought and fire. The area is now beginning to recover from this damage in response to the restoration project, but problems remain. The Holey Land Wildlife Management Area is located in the north end of the Everglades ecosystem, in an area that has historically been dominated by nearly monospecific plains of sawgrass. Since drainage projects were initiated in the late 1800s, 74 percent of these sawgrass plains have been lost to agriculture. Holey Land Wildlife Management Area represents nearly 23 percent of the remainder of this important component of the original Everglades habitat. The following plant associations can be recognized.

The natural tree island association has been reduced by muck fires and soil subsidence. This association exists on elevated sites and is composed of varying quantities of red maple (*Acer rubrum*), dahoon holly (*Ilex cassine*), wax myrtle (*Myrica cerifera*), elderberry (*Sambucus simposonii*), and willow (*Salix caroliniana*). Fifty-four artificial tree islands were created in the southwest portion of the area in the early 1970s and are now mostly vegetated.

The weed and brush association occurs on slightly less elevated sites and along the borders of the area. The overstory vegetation is primarily salt bush *(Baccharis halimifolia*) and wax myrtle. The understory consists of fennels (*Eupatorium* spp.), goldenrods (*Solidago* spp.), Southern fleabane (*Erigeron quercifolius*), thistles (*Cirsium horridolum*), asters (*Aster* spp.) and loosestrife (*Lythrum lineare*). This area had expanded in response to the overdrainage that Holey Land had experienced, but since hydropattern restoration was achieved in 1991, brush has been greatly reduced, especially along the northern and southern borders of the area.

The sawgrass/wet prairie association occupies wetter sites on the area. The predominant species in this association are sawgrass (*Cladium jamaicensis*) and maidencane (*Panicum hemitomon*). Other species that occur in reduced numbers include cattails (*Typha* spp.), arrowhead (*Sagittaria lancifolia*), pickerel weed (*Pontederia lanceolata*) and smartweed (*Polygonum* spp.). The Holey Land has experienced an explosion of cattail growth since hydroperiod restoration in 1991. Aerial surveys begun in 1990 found only about 100 acres of cattails, but by 1995 this had grown to 6,480 acres. The cattails were initially found in the deep-water sloughs and expanded outward from these bases. A small fringe of cattails found along the distribution canal may be the result of increased nutrient levels, but high water levels are believed to be responsible for most of the cattails in Holey Land.

The willow/shrub association has been greatly reduced due to higher water levels, and is now found mostly in a sparse band running from the northwest to the southeast across the north-central portion of the area and around solution holes. It is composed of willow brush or trees with almost no understory.

The muck burn-barren association consists of areas where muck soils have been oxidized or burned to the limestone substrate. Vegetation is very sparse, consisting mainly of algae and bladderworts (*Utricularia* spp.). During periods of drought, bare rock is apparent.

Exotic vegetation and other undesirable plants have invaded the area. Melaleuca seedlings are regularly found in the southern half of the area, though no permanent stands have yet taken hold. Brazilian pepper is common along levees, spoil banks, and several artificial islands. Wax myrtle and other brush species hare found along levees in a thick band. The 54 artificial islands built in Holey Land in 1974-75 were planted with a variety of species at the time of construction, but it appears that in some cases, these plantings have failed. At least 5 of these islands have been invaded with Brazilian pepper. A series of spoil banks about a mile in length associated with the northern distribution canal have been taken over by Brazilian pepper.

Rotenberger Wildlife Management Area

The Rotenberger Wildlife Management Area is an extensive sawgrass marsh. The plant communities that occurred historically in the area experienced marked changes due to increased drainage, decreased hydroperiod, drought, and fire. The natural tree island association has been reduced by soil subsidence and muck fires in the 1970s and in 1981. This association exists on elevated sites and is composed of varying quantities of red maple (*Acer rubrum*), dahoon holly (*Ilex cassine*), wax myrtle (*Myrica cerfera*), elderberry (*Sambucus simposonii*), and willow (*Salix caroliniana*). Florida Game and Fresh Water Fish Commission personnel have planted almost 450 trees and bushes of varying sizes on seven remnant islands since 1990. The following plant associations can be recognized.

The old field-weed and brush association occurs on slightly less elevated sites along the borders of the area and in the abandoned Cousin's Ranch and Holper properties. The overstory vegetation is primarily salt bush (*Baccharis halimifolia*) and wax myrtle. The understory consists of fennels (Eupatorium spp.), goldenrods (*Solidago* spp.), Southern fleabane (*Erigeron quercifolius*), thistles (*Cirsium horridolum*), asters (*Aster* spp.), and loosestrife (*Lythrum lineare*). This area has expanded in response to drainage of surrounding lands.

The sawgrass/wet prairie association occupies wetter sites on the area. The predominant species in this association are sawgrass (*Cladium jamaicensis*) and maidencane (*Panicum hemitomon*). Other species that occur in reduced numbers include cattails (*Typha* spp.), arrowhead (*Sagittaria lancifolia*), pickerel weed (*Pontederia lanceolata*), and smartweed (*Polygonum* spp.).

Approximately 3,600 acres of the Rotenberger Wildlife Management Area is covered with cattails, mostly in an area that experienced a severe muck fire in 1981. The areal extent of this cattail invasion has remained relatively constant since yearly vegetative surveys began in 1990. However, depending upon the quality of water provided to the area, and other hydrological factors, cattails may increase following hydropattern restoration until cattail control efforts can be implemented.

The muck burn-barren association is mostly found in the northwest corner of the Rotenberger Wildlife Management Area in the vicinity of a 1995-muck fire. It consists of areas where muck soils have been oxidized or burned to the limestone substrate, resulting in sparse vegetation, consisting mainly of algae and bladderworts (*Utricularia* spp.).

Changes in historic hydropattern have impacted vegetative communities in the Rotenberger Wildlife Management Area. Shorter hydropatterns have permitted brush to invade much of the area, allowed wildfires to damage tree islands, and provided the conditions for muck fires to convert several thousand acres of sawgrass to cattails. Exotic plants have invaded the area and undesirable plant coverage has expanded. Melaleuca seedlings are regularly found in the southern half of the area, though no permanent stands have yet taken hold. Brazilian pepper is common along levees and other disturbed areas. Wax myrtle has invaded former agricultural land, and is found near levees and in the southwestern corner of the area.

J.6.2 Fish and Wildlife

The American alligator, more than any other species, is most often identified with the Everglades and its unique wetland ecosystem. The alligator has made an impressive comeback in terms of population numbers since the 1960s, when the reptile was placed on the endangered species list by the USFWS. Today, alligator populations in the WCAs and throughout Florida have increased in sufficient numbers to support a controlled harvest program (Florida Game and Fresh Water Fish Commission, 1986). Due to concerns over mercury contamination however, alligator harvesting is not permitted within the Water Conservation Areas.

Alligators have been cited to serve an important ecological function by maintaining "gator holes", or depressions, in the muck, which are thought to provide a refuge for aquatic organisms and constitute a concentrated food source for wading birds and other Everglades predators during drought (Kushlan, 1974, 1976a). The validity of this concept is currently being questioned.

Water levels represent the important factor influencing nesting success of alligators in the WCAs. High water levels during the period of nest construction, which occurs from June to early July (Woodward *et al.,* 1989), decrease the availability of nesting sites, which in turn results in decreased nesting efforts (Joanen and McNease, 1979). Optimum nesting effort and success is observed when water levels remain stable or decrease throughout the nesting season (June - September). Significant nest loses due to increasing water levels during the nesting season have been reported by several workers (Joanen, 1969; Jacobsen and Kushlan, 1986; Hines *et al.,* 1968). Joanen *et al.* (1977) reported total submergence of eggs for 48 hours resulted in mortality.

Low water levels during the spring have been associated with decreased nesting (Joanen and McNease, 1972a, b, c; Palmisano *et al.*, 1973; Schemnitz, 1972). Aerial nest surveys were conducted in WCA 2 and WCA 3 in 1988 and 1989 (L.J. Hord, Feb. 8, 1990, Florida Game and Fresh Water Fish Commission comments on Nov. 8, 1989 SWIM Plan). Three hundred and fifty nests were observed in 1988. Only 75 were found in 1989 when the WCAs experienced low water levels in the spring. A water management scheme that promotes maximum habitat and species diversity, while maintaining adequate water levels in the spring, and minimizes water level increases from June through September, would be most beneficial to alligator nesting success (Florida Game and Fresh Water Fish Commission comments on Nov. 8, 1989 Everglades SWIM plan).

Colonial wading birds (Order Ciconiformes) are a conspicuous component of the wildlife communities that utilize the WCAs as both feeding and breeding habitat. These include 11 species of herons and egrets, two species of ibis, the wood stork, and the roseate spoonbill (Robertson and Kushlan, 1984). Historically, white ibis (*Eudocimus albus*) has been the most abundant colonial wading bird species within the Everglades WCA study area. Surveys indicate that the great egret *(Casmerodius albus)* is the second most abundant species (Frederick and Collopy, 1988). The great blue heron (*Ardea herodias*), little blue heron *(Egretta caerulea)*, tricolored heron *(E. tricolor*), green backed heron *(Butorides striatus*), snowy egret *(E. thula*), cattle egret (*Bubulcus ibis*), black crowned night heron *(Nycticorax nycticorax*), and yellow crowned night heron (*N. violacea*), are also common wading bird species found throughout the WCAs. The roseate spoonbill *(Ajaia ajaja)*, a state species of special concern, and the wood stork *(Mycteria americana)*, a Federally listed endangered species, both occur within the study area.

Most wading bird species utilizing the Everglades exhibit seasonal changes in numbers, being, more abundant during the dry season than during the wet season. The majority of species nest in late winter or early spring, although a few, such as the great egret, are reported to nest at different times throughout the year (Kushlan and White, 1977a). The WCAs support additional aquatic avifauna, such as the limpkin *(Aramus guarauna)*, two bitterns *(Ixobrycus exilis* and *Botarus lentiginosus*), the anhinga *(Anhinga anhinga)*, as well as a number of resident and migratory waterfowl.

The reproductive cycle of most Everglades wading birds is tightly linked with seasonal water level fluctuations within the marsh. During the rainy season, when water levels are high, fish and invertebrate prey species repopulate the newly flooded marsh and begin to increase in abundance. As water levels recede during the dry season, the density of these prey species (topminnows, mosquitofish, killifish, crayfish, freshwater prawns and insect larvae) increase as they concentrate in remnant pools and along the edge of the drying marsh. Concentration of aquatic prey species during the dry season provides an easily harvested food source for wading birds. It has been estimated that the standing stock of fish increases from about 50 kilograms per hectare to about 500 kilograms per hectare between the rainy season and the dry season (Kushlan *et al.*, undated). Concentration of these food resources has been shown to be a major factor in the initiation of nesting for the wood stork (Kahl, 1964) as well as for other wading bird species.

Loss of habitat and man-induced changes in the natural hydrologic cycle (i.e. distribution of historical water flows and the timing of seasonal drying of the marsh) are thought to represent the major factors affecting the decline of colonial wading bird species in south Florida. Historically, the Everglades WCAs supported large numbers of wintering and breeding wading birds (Robertson and Kushlan, 1974). South Florida wading bird populations have suffered two major declines in this century. Plume hunting at the turn of the century nearly wiped out several species. Most scientists agree that Federal protection measures enacted in 1910 allowed wading bird populations to rebuild to healthy levels by the 1930s (Allen, 1964; Robertson and Kushlan, 1974; Ogden, 1978; Kushlan and Frohring, 1986; Frederick and Collopy, 1988). Sometime between the late-1940s and the mid-1960s, numbers of breeding wood storks, tricolored herons, snowy egrets, and white ibis declined several orders of magnitude (Kushlan and White, 1977a; Ogden, 1978; Kushlan *et al.*, 1984; Kushlan and Frohring, 1986; Frederick and Collopy, 1988). Kushlan and Frohring (1986) suggest that the decline of the wood stork population coincided with changes in the regional water management system initiated in the 1960s, rather than the gradual declines observed since the 1940s (Sprunt and Kahl, 1960). Although the extent of the population decline is a subject of controversy, much of it has occurred since construction of the regional water management system, largely completed in 1962. The physical compartmentalization of the Everglades by levees and canals has caused major changes in historical flow patterns, water depths, the natural timing of water level fluctuations, and the distribution of water within the WCAs and Everglades National Park (Kushlan, 1987). Water bodies in some areas of the system are now much deeper than they were historically, while other areas of the system are substantially drier. Under both conditions, the natural timing of these water level fluctuations has been altered (Kushlan, 1987). Implementation of the minimum delivery schedule for delivery of water to Everglades National Park in 1970 and the addition of the L-67 extension canal and associated levee has exacerbated these timing and delivery problems, and is thought to be directly related to the poor nesting success of wood storks within Everglades National Park (J. Ogden, pers. com.).

Loss of wading bird habitat due to the conversion of seasonal wetlands to agriculture has also been cited as an important factor. Browder (1976) reported that wading bird feeding habitat south of Lake Okeechobee has been reduced by 35 percent since the turn of the century, resulting from the conversion of sawgrass wetlands to sugarcane farming. It is generally believed that the combined effects of habitat destruction, loss of feeding areas and disruption of historical hydroperiod patterns represent the primary factors affecting the decline of wading bird populations in south Florida.

The majority of wading bird species require shallow water for efficient feeding. White ibis rarely forage in waters deeper than 6 inches, while almost all of the smaller heron species are too short to wade in waters deeper than 8 inches (Custer and Osborne, 1978; Kushlan, 1974). Construction of water management canals and levees have rendered many areas of the WCAs unsuitable as wading bird feeding habitat due to the ponded, deep-water conditions that prevail in these areas.

Regardless of whether a wading bird is a tactile or sight feeder, all species rely heavily on receding water levels during the dry season and the associated concentration of prey species (crustaceans and fish) for optimum reproductive success. The physical concentration of prey species produced by the natural drying of these wetlands is essential for the nesting success of such tactile feeders as the wood stork and white ibis (Kahl, 1964; Kushlan, 1974; Kushlan, 1976a; Frederick and Collopy, 1988). The wood stork is considered to be highly sensitive to seasonal water level fluctuations. Successful nesting requires that a concentration of fish be present within a certain distance of its nesting colony for the entire length of its nesting period (Kahl, 1964). Nesting may not be initiated if there is insufficient concentration of fish due to poor fish production during the rainy season, or due to high water levels during the dry season. Similarly, nest failure is likely if water levels rise before the end of the nesting period. Of all colonial wading birds, the wood stork exhibits the most dramatic response to water level changes. The nesting success of wood storks parallels many other colonial wading bird populations, and is considered a good indicator of the effects of water level changes on colonial wading bird populations in the Everglades. Poor feeding conditions and poor nesting success result from changes in the natural hydrologic cycle (i.e. timing of the seasonal drying of the marsh). Increased or rising water levels during the nesting season cause wood storks, white ibis, and small herons to abandon their nests (Frederick and Collopy, 1988). Slow drying, interrupted drying rates, or late drying of the marsh relative to the normal nesting period all contribute to poor reproductive success of colonial wading birds (Frederick and Collopy, 1988). Stabilized water levels, extended hydroperiods or long term, deep-water conditions provide poor foraging habitat for the majority of Everglades wading birds. The duration of optimal feeding conditions is also an important factor in wading bird nesting success. Prime feeding conditions must be available during the entire nesting period to achieve maximum reproductive success. Optimum conditions for successful breeding would be a long, protracted drying of the marsh that would encompass the entire breeding cycle (nesting and providing forage for fledgling and juvenile birds (Frederick and Collopy, 1988).

White ibis, the most abundant wading bird found in the WCAs, feeds primarily on crayfish (*Procambarus alleni*). This crustacean makes up about 66 percent of its diet by energy content, with other invertebrates comprising 25 percent (Kushlan and Kushlan, 1975). In contrast, wood storks feed almost exclusively on fish (Ogden *et al.,* 1976). Although both species are tactile foragers, differences in prey preference and foraging strategies allow both species to utilize drying wetlands with minimum competition. The diet of sight- feeding wading birds (herons and egrets) generally includes forage fish (topminnows, killifish and mosquitofish), small reptiles (snakes and lizards) and frogs, crustaceans (crayfish, fresh water prawns), snails and insect larvae.

Aerial surveys (Systematic Reconnaissance Surveys or SRF flights) are being conducted to determine the foraging habitat requirements and to map the movement of colonial wading birds (herons, egrets, wood storks and ibis) within the WCAs. Results of these surveys have indicated that white ibis, great egrets, great blue herons, wood storks, little blue herons, snowy egrets, cattle egrets, and glossy ibis are the most common wading bird species utilizing the WCAs, with populations varying widely in relationship to seasonal water level fluctuations. Peak wading bird use of the WCAs often occurs in January in synchrony with receding water levels, with over 121,000 birds being observed at times. Lowest counts have occurred during August with less than 15,000 birds counted. The white ibis is typically the most abundant wading bird observed, with total monthly counts varying as the birds move in and out of the WCAs in response to changing water levels. Great egrets represented the second most abundant species of wading birds observed.

Population estimates showed two residency patterns. Great blue herons and great egrets are residents in the WCAs during the dry season, with consistent population sizes during this period. White ibis, wood storks, and small white and dark herons fluctuate in numbers in response to rising and falling water levels. Peak populations occur during the winter months (often during March), with numbers declining in the spring. These birds leave the WCAs during the wet season. The WCAs provide an important staging habitat for ibis, wood storks, and small white and dark herons prior to their migration to the north.(Hoffman *et al*., 1989).

White-tailed deer (*Odocoileus virginianus)* have lived in the Everglades for centuries, long before the marsh was impounded by a system of levees and water control structures. Information collected in recent years indicates that Everglades deer herds fluctuate widely in response to flood and drought cycles. However, little information is available on the original carrying capacity of the system prior to construction of the present day water management system. In the past, deer populations were generally described as a "boom or bust" proposition, increasing during an extended dry period, and decreasing during prolonged wet periods, depending on water levels. (Florida Game and Fresh Water Fish Commission, 1983).

During high water periods, deer concentrate on tree islands, levees and spoil banks. This creates intense competition for available forage and resting areas, increases the transmission of diseases and parasites, and causes physical and behavioral stress to the animals. If high water levels persist, the food supply becomes exhausted and malnutrition develops, resulting in a large-scale die-off of the herd.

Newly born fawns and crippled or diseased animals are usually the most susceptible individuals within the population. Highest fawning activity occurs in February. If high water levels are experienced during this critical time, then fawn mortality is high. Regression analysis shows a strong negative correlation (r = 0.7) between herd recruitment and marsh water levels. High recruitment is experienced during low water, while low recruitment is typical during high water periods.

The Florida Game and Fresh Water Fish Commission manages essentially four separate deer herds within the WCAs. These are identified as WCA-2A and 2B (managed as one unit), WCA-3A north, WCA-3A south, and WCA-3B. Assessment of these four areas in 1987 indicated that the WCA deer herd was healthy and in good condition based on analysis of percent kidney fat and counts of liver fluke and stomach parasites (Ault, 1989). Prior to 1979, the deer population fluctuated widely from year to year, with higher numbers of animals maintained in the area as compared to levels maintained since 1982.

In 1979 and 1982, two highly publicized water-related die-offs occurred in WCA-3A. The die-off in 1982 required a controversial Special Emergency Deer Hunt (July, 1982) to protect the remaining herd and minimize the extent of deer mortality (Florida Game and Fresh Water Fish Commission,1983). Since 1982, the Commission's policy has been to maintain deer herd size at a carrying capacity that will prevent the large scale die-off experienced in 1982, resulting from prolonged high water levels. The strategy developed to meet this objective was to establish an index (Norton-Griffins index) of the deer population that could survive prolonged high water conditions without having much effect on the overall health of the herd, while keeping the adult sex ratio between 1:2 and 1:3. The population index objectives established for each of the four deer management areas located within the WCAs were 1,000 for WCA-3A north, 1,500 for WCA-3A south, 500 for WCA-3B and 250 for WCA-2A and 2B.

Since 1983, the Florida Game and Fresh Water Fish Commission has collected data and tested management practices, demonstrating that it is possible to control both herd size and adult sex ratios. From 1983 to 1986, the primary short-term objective was to control the sex ratio and herd size. This was achieved by regulating the doe harvest. However, because of this emphasis, herd size remained below the Florida Game and Fresh Water Fish Commission population objectives. In 1987, the Commission initiated a number of management practices designed to allow for an increase in herd size up to the objective. Justification for these actions were based on the following: (1) Only a small die-off resulted from the high water events recorded in the summer of 1986; (2) Herd size was below Florida Game and Fresh Water Fish Commission objectives for each management zone; (3) Sex ratios were at desired levels with the Florida Game and Fresh Water Fish Commission demonstrating their ability to regain control of the population if ratios become skewed; and (4) Increased herd size provides more hunting opportunities.

In 1987, the primary management action taken to increase herd size up to the carrying capacity of these wetlands was to reduce the number of doe tags issued by 83 percent. This strategy however, has not yet produced the desired result, with 1987 and 1988 experiencing below average recruitment. Low recruitment may also be related to the time lag required for herd composition changes to show up in older age class individuals. For 1989, the Commission recommended (a) continuing the restricted doe harvest; and (b) moderate hunting pressure on the buck population to increase recruitment levels.

The Everglades fish community has adapted to a number of severe environmental conditions such as periodic drying of the marsh, high temperature extremes, low dissolved oxygen concentrations, and generally poor water quality experienced during low water periods. Native Everglades fish have developed physiological and behavioral adaptations to accommodate extremes in water level fluctuations and water quality (Dineen, 1974; Schomer and Drew, 1982). Several forage fish species are able to extract oxygen from the water surface, and are therefore not affected by periodic anaerobic conditions. Flagfish, mosquito fish, and the sailfin molly (*Poecilia latipinna*) have been found to be extremely hardy species tolerant of very poor water quality conditions (Dineen, 1974). Many of these fishes have developed reproductive strategies, that allow them to reproduce rapidly to repopulate a newly flooded marsh.

Kushlan (1980 and 1976a) reported that the number and size-class distribution of fishes within the Everglades WCA study area is determined by the annual pattern of water level fluctuations. The seasonal water level variation results in a community dominated by small-bodied, omnivorous fishes with high reproductive potential. Kushlan (1976a) also reported that when natural water level fluctuations are stabilized, there is a shift in the community structure towards a population dominated by larger-bodied, carnivorous fishes, and predation replaces hydrology as the dominant factor influencing community structure.

An accumulation of organic flocculent (dead plant material), can build up as a result of plant growth and mortality during periods of extended high water. This material interferes with fish spawning. Degradation of this material exerts a large biological oxygen demand, which has been correlated with the occurrence of fish kills within the WCA-2A marsh (Dineen, 1972; Worth, 1988).

Generally, Everglades sport fish are harvested from the borrow canals that surround the marsh. As water levels in the canal and marsh rise, fish populations disperse into the interior marsh and reproduce with minimum competition and predation. As water levels recede, fish concentrate into the deeper waters of the surrounding canals, where they become available as prey for wildlife and fishermen. In some instances, the canal fishery has experienced major fish kills due to overcrowding and oxygen depletion.

Studies conducted by the Florida Game and Fresh Water Fish Commission in WCA-2A during 1987 found the abundance and distribution of fish species within the interior marsh and perimeter canals to be quite different. Morello *et al.* (1988) sampled fish populations in the southern portion of the WCA-2A interior marsh and within the L-35B Canal that separates WCA 2A from WCA-2B. Total standing crop of fish in the marsh was low, averaging 24 pounds per acre, but density was extremely high, averaging 24,000 fish per acre. Two small forage fish, the Florida flagfish and bluefin killifish, accounted for 86 percent of the total fish density. Juvenile largemouth bass were collected in the marsh, indicating successful reproduction for the second consecutive year. Higher minimum water levels implemented in 1986 improved spawning habitat for these fish. Between 1982 and 1987, fish standing crop in the marsh varied from 10 to 70 pounds per acre.

The L-35B Canal supported a higher standing crop, but lower densities, of fish as compared to the interior marsh. Total fish biomass and density in the canal averaged 347 pounds and 1,400 fish per acre, respectively. Sport fish were 64 percent of all fish collected. Since 1983, fish standing crop and density were highly variable and dependent on water level. When water levels were low in 1983, standing crop and density averaged 3500 pounds and 8,000 fish per acre, respectively. Similarly during the following five years, there was an negative relationship between water level and electroshocking catch-per-unit effort for density (r = -0.96) and weight (r = -0.97). Under drought conditions, fish become highly concentrated in WCA canals, and at times the Florida Game and Fresh Water Fish Commission removed or greatly increased creel limits as low oxygen levels became critical to fish life (Morello *et al.*, 1988).

The WCAs provide a valuable sport fishery to south Florida. In WCA-2A, 65 percent of the fisherman sought largemouth bass and 22 percent preferred to catch sunfish (Morello *et al.*, 1988). Success rates were high compared to other water bodies in Florida; catch-per-hour for largemouth bass, sunfish, and oscar was 0.66, 2.55, and 3.12 respectively in 1987-88. However, a 34 percent decline in angler use was noted between 1986-87 and 1987-88. During the six-month survey in 1987-88, largemouth bass anglers spent an estimated $265,000.

In WCA-3A, fish sampling in 1988 within the L-67A Canal indicated that gar and bowfin (rough fish species) dominated the sample collection by weight (64 percent) (Morello *et al.*, 1988). Largemouth bass, sunfish, and catfish were also collected. Angler effort for largemouth bass was four times greater in WCA-3A compared with WCA-2A. However, success for largemouth bass, sunfish, and oscar were 0.26, 0.67, and 1.23 fish-per-hour, lower than that observed for WCA-2A.

Besides supporting a valuable recreational fishery for the region, WCA-fish communities provide a major food source for Everglades wading birds, alligators, and other carnivorous reptiles and mammals. Fish community structure and abundance is highly dependent on water levels. Consequently, fishing success by humans or wildlife is also dependent on water levels (Dineen, 1974).

A diversity of mammals, birds, reptiles and amphibians are known to occur in the Holey Land Wildlife Management Area. The species present are indicative of those found in a sawgrass marsh ecosystem. Many of the terrestrial species have been reduced in numbers as a result of hydroperiod restoration, and animals more associated with Everglades marsh habitat have returned to Holey Land Wildlife Management Area.

Several game species occur on the area white-tailed deer (*Odocoileus virginianus*), common snipe (*Capella gallinago*), and marsh rabbit (*Sylvilagus palustris*). Blue-winged teal (*Anas discors*), mottled ducks (*Anas fulvigula*) and other game waterfowl are found in the sloughs of the northeast corner.

A diversity of non-game mammals birds, reptiles, and amphibians are known to occur in the Rotenberger Wildlife Management Area. The species present are indicative of those found in a sawgrass marsh ecosystem. Several game species occur on the area white-tailed deer (*Odocoileus virginianus*), (*Capella gallinago*), marsh rabbit (*Sylvilagus palustris*), feral hogs (*Sus scrofa*) and various waterfowl species.

J.6.3 Water Management

WCA-1 is encircled by 56 miles of levees and canals. A network of pump stations, levees and water control structures, controls water levels. WCA-1 is the only conservation area completely encircled by canals. The water management facilities hydrologically are connected with Lake Okeechobee, the Everglades Agricultural Area, WCA-2, WCA-3 and the Atlantic Ocean. Rainfall represents the major source of water inflow into WCA-1, accounting for about 54 percent of the refuge's water budget. Pump station S-5A, located at the northern tip of the refuge near 20-Mile Bend, moves water into the refuge from the West Palm Beach Canal, accounting for approximately 30 percent of the inflow water. Pump station S-6, located on the refuge's western border, pumps water from the Hillsboro Canal into the southwest portion of the refuge, accounting for about 15% of WCA-1 inflow water. Approximately 45% of the WCA-1 water inflow originates as drainage from agricultural land located north and west of WCA-1. Two small pumps operated by the Acme Improvement District are located in the L-40 levee on the northeastern boundary of the refuge. These pumps drain primarily residential/urban lands (Wellington) and can move water in and out of the refuge. Acme represents only a minor fraction (<1%) of the refuge's water budget. Four water control structures (S-10A, S-10C, S-10D, and S-10E) exist along WCA-1 on the southern levee of L-39 (Hillsboro Canal). The S-10 structures allow water to flow southward out of the Hillsboro Canal and WCA-1 into WCA-2A if so desired. The Hillsboro Canal (L-39), located in the extreme southeast corner of the refuge, drains WCA-1 to the east through S-39, which provides water supply to urban areas and discharges drainage waters to tide water. To the north, the S-5A structure can be used to move water north out of the refuge into the L-8 canal. There are four other small privately operated structures in the L-40 levees; one of these is operated by the USFWS. These structures constitute less than 1% of the refuge's annual water budget. Water management operations for WCA-1 are governed by a water regulation schedule adopted in 1994 (***Figure J-6.3-1***).

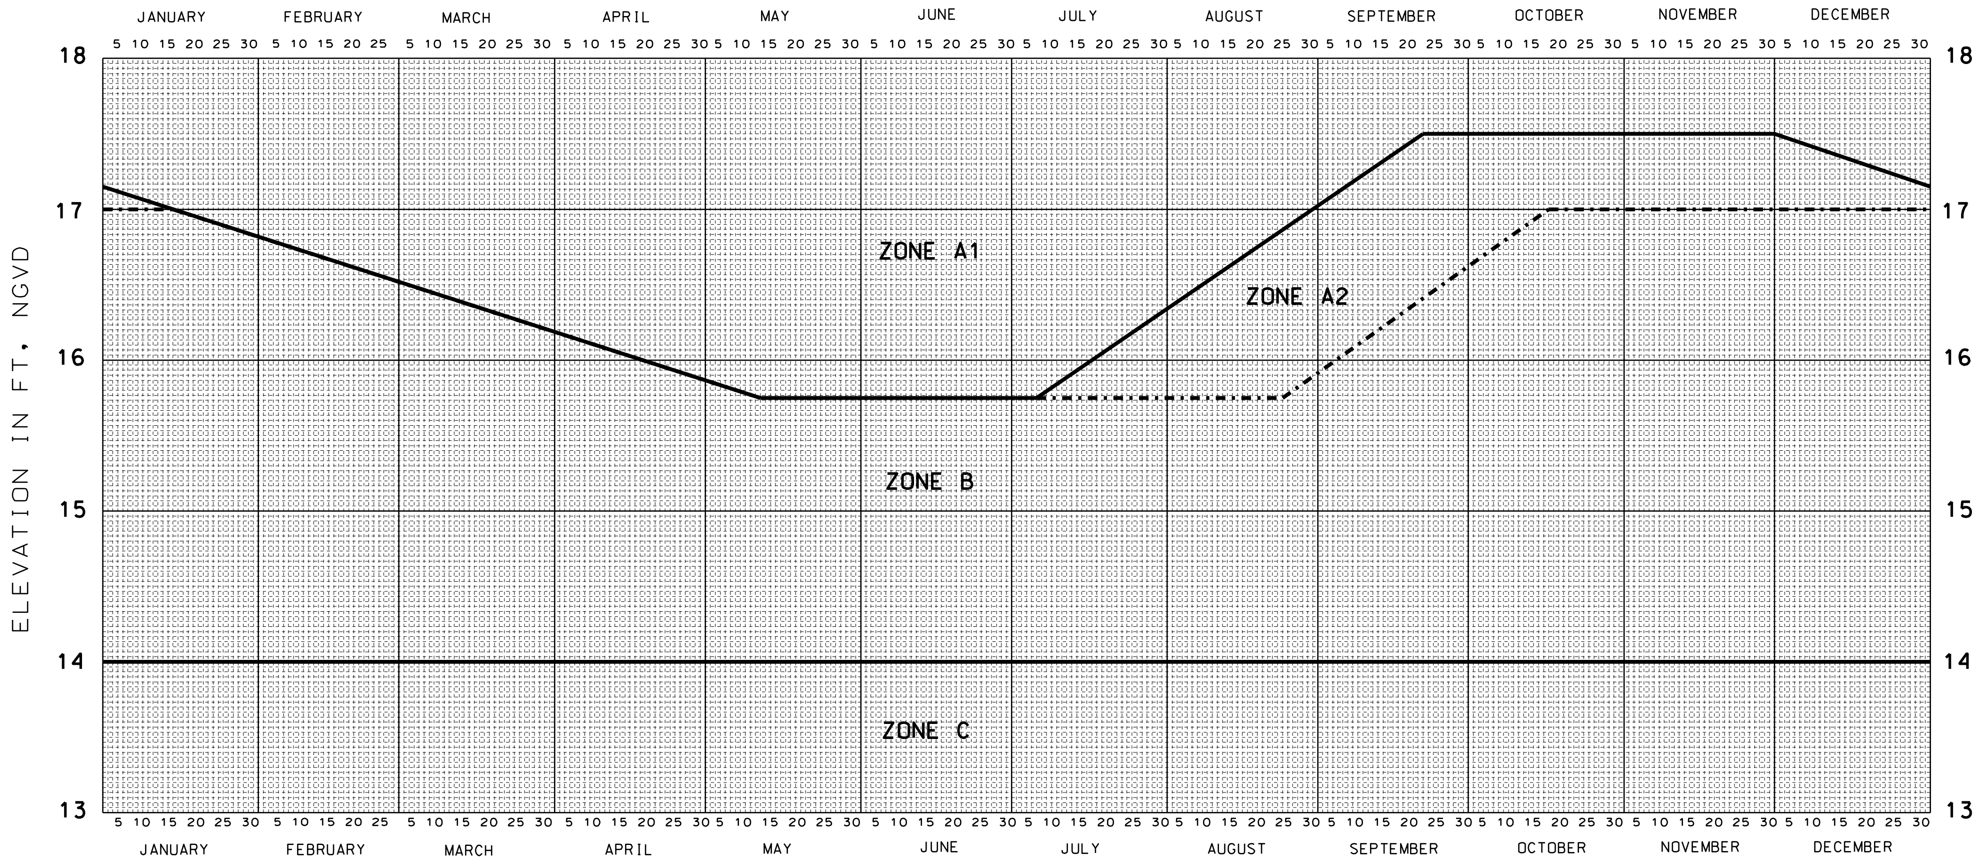
Major developments in the WCAs have been the construction of canals, levees, water control structures and roads. WCAs-2 and 3 are almost completely enclosed by a levee and canal system that is approximately 150 miles in length. The only portion of the area not completely enclosed by the levee system is WCA-3A where a seven-mile section of the western border remains hydrologically connected to the Big Cypress Preserve. Four canals and their associated levees pass through the WCAs: the Miami Canal, L-35B Canal, L-67A Canal, and L-67C Canal.

Many water control structures have been constructed to move water throughout the WCAs. Facilities designed to provide flow into the area include the S-6, S-7, S-8, S-9, and S-140 pump stations, and a series of gated spillways referred to collectively as the S-10 structures. Water is moved from WCA-2A to WCA-3A via the S-11 structures and through WCA-3A via the Miami Canal and a series of bridged openings under Alligator Alley (I-75). Water is released from WCA-3A through the S-12 and S-333 structures and the Pompano and North New River canals. The canals, levees, and water control structures were constructed and are currently operated by the U.S. Army Corps of Engineers and the South Florida Water Management District. The WCAs were constructed primarily to provide flood protection to adjacent agricultural and urban areas, and to serve as a source of fresh water for the heavily populated Lower East Coast. Secondary considerations were the need to manage the areas to benefit fish and wildlife, and to provide public recreation.

Water regulation schedules represent water level targets that govern the operations to store and release water from the WCAs. The water regulation schedule for WCA-2A was originally set too high to support Everglades habitat, and has been the subject of extensive research and experimentation. The original 1961 schedule called for water levels to fluctuate from 12 to 14.5 feet. The schedule was revised even higher in 1970 to a range of 13 to 14.5 feet with only a 30-day period at the lower end. Observed changes in the ecology of WCA-2A caused scientists in the early 1970s to initiate efforts to lower the water schedule and provide for annual drying of the interior marsh. Extended high water killed significant stands of trees, eroded islands, and caused other undesirable vegetation changes in the area (Dineen, 1972, 1974; Worth, 1988). In 1980, the schedule was revised to an interim plan of 9.5 to 12.5 feet, an extreme drawdown that was in place for eight years. Extensive research during this time led to an interim schedule of 11 to 13 feet, which was adopted in 1989 (***Figure J-6.3-2***).

The regulation schedule for WCA-3A is perhaps the most complicated and difficult schedule to describe or implement. The schedule ranges from 9.5 to 10.5 feet, but includes a series of five zones to modify discharges to Everglades National Park when water levels are above or below the optimum target (***Figure J-6.3-3***). The size of WCA 3A and the number of inflow and discharge points preclude intensive management of water levels in the area. Discharges at the southern end of the area flow directly into Everglades National Park. These discharges were modified three times in the past decade to alleviate problems resulting from too little discharge in the early years, and heavy flood discharges during the dry season, which impacted nesting wading birds and other wildlife during the 1970s and early 1980s. The original schedule was set shortly after Everglades National Park and the South Florida Water Management District's predecessor agency was created. In 1970, Congress adopted an Everglades National Park-backed plan to establish a minimum monthly volume of water to be delivered to Everglades National Park. This resulted in significant flood damages from dry-season floodwaters, which were discharged from WCA-3A when the water schedule was exceeded. In 1983, Congress authorized an Experimental Program of Water Deliveries to Everglades National Park, which allowed an experiment with water releases based on rainfall and evaporation over the Everglades. This rainfall-based plan distributes water over a broader area than the original operating schedule whenever possible.

Other problems within WCA-3A, primarily overdrainage in the northern end, are not due to the schedule but instead are caused by the design of water-control facilities. These regulation schedules are open to review and change if the agencies involved find better ways of regulating the water levels.



ZONE	RELEASES
A1	UP TO MAXIMUM AT S-10 (AND S-39 WHEN AGREED BETWEEN CORPS AND SFWMD). WATER SUPPLY RELEASES AS NEEDED.
A2	S-10 RELEASES BASED ON CORPS FORECASTS. WATER SUPPLY RELEASES AS NEEDED. IF LAKE OKEECHOBEE STAGE IS ABOVE WCA-1 STAGE OR NO MORE THAN ONE FOOT BELOW WCA-1 STAGE, THEN WATER SUPPLY RELEASES FROM WCA-1 MUST BE PRECEEDED BY AN EQUIVALENT VOLUME OF INFLOW.
B	WATER SUPPLY AS NEEDED. IF LAKE OKEECHOBEE STAGE IS ABOVE WCA-1 STAGE OR NO MORE THAN ONE FOOT BELOW WCA-1 STAGE, THEN WATER SUPPLY RELEASES FROM WCA-1 MUST BE PRECEEDED BY AN EQUIVALENT VOLUME OF INFLOW.
C	NO NET RELEASES FROM WCA-1. ANY WATER SUPPLY RELEASES MUST BE PRECEEDED BY AN EQUIVALENT VOLUME OF INFLOW.

DATES	USE GAGE	CONDITIONS
1 JAN - 30 JUN	1-8 CANAL	ALL
1 JUL - 31 DEC	1-8 CANAL	EXCEPT AS NOTED BELOW

Note:

During droughts, an optimum floor level will be agreed upon for ecological purposes below which no releases from storage are permitted.

CENTRAL AND SOUTHERN FLORIDA
REGULATION SCHEDULE

WATER CONSERVATION AREA NO. 3A

DEPARTMENT OF THE ARMY, JACKSONVILLE DISTRICT
CORPS OF ENGINEERS, JACKSONVILLE, FLORIDA

AUGUST 1960

Currently, Holey Land Wildlife Management Area's water regulation schedule is based upon the initial operating plan agreed to by the South Florida Water Management District and the Florida Game and Fresh Water Fish Commission 28 June 1990. This schedule dictates that water stages in Holey Land Wildlife Management Area vary between a low of 11.5' MSL on May 16 to a high of 13.5' on November 1. When direct rainfall is unable to provide enough water to meet the schedule, water is pumped onto the area from the Miami Canal at the G-200 pump station in the northwest corner of the area. Other water enters the area from the G-201 pump station, which returns water to Holey Land from the exterior seepage canal. Outflow is through three set of culverts along Holey Land's south boundary. In accordance with the 1990 Operational Agreement, after cattail coverage exceeded 2,000 acres, flashboards were placed in the outflow culverts and were set at 13.5' in order to retain water in the area as long as possible to reduce the need for pumping untreated water from the Miami Canal. Detailed topographic data on Holey Land Wildlife Management Area, collected after restoration began, found that average ground elevation was approximately 0.5' lower than previously thought and a verbal agreement was made between South Florida Water Management District and Florida Game and Fresh Water Fish Commission in July, 1993 to change the operational schedule to one that lies between 11-13'. Additional research conducted by Florida Game and Fresh Water Fish Commission and the South Florida Water Management District staffs indicated that high water levels in Holey Land Wildlife Management Area contributed to the explosive growth of cattails in the area after restoration began, and that water levels above 12.5' drove deer from the marsh onto surrounding levees. In response to this information, on January 20, 1995, the Florida Game and Fresh Water Fish Commission proposed that the water schedule be again lowered, to 10.5-12.0', a level that has since been used as a guideline by the South Florida Water Management District. A similar (10.75-12.0') schedule was proposed by the Florida Game and Fresh Water Fish Commission on June 11, 1997, and discussions are currently underway to finalize an agreement recognizing this proposed level. The water management plan is designed to simulate a natural hydroperiod for the purpose of restoring and preserving natural Everglades habitat.

The Rotenberger Wildlife Management Area is located in the north end of the Everglades ecosystem, in an area that has historically been dominated by nearly monospecific plains of dense sawgrass. Since drainage efforts began in the late 1800s, 74 percent of these sawgrass plains have been lost to agriculture. The Rotenberger Wildlife Management Area represents nearly 18 percent of the remainder of this important component of the Everglades. Because of development and drainage of surrounding areas, the hydropattern in the Rotenberger Wildlife Management Area has shortened, causing a shift away from its historically sawgrass-dominated community. The distribution, timing, and depths (hydropattern) of water in the Rotenberger Wildlife Management Area have been dramatically changed by drainage to the north and west, as well as in several parcels inside the boundaries. This development, along with construction of canals and levees, has blocked the sheetflow of water southward from Lake Okeechobee; a process which will probably not be reversed. The Rotenberger Wildlife Management Area itself is drained by a series of culverts linked to the L-4 canal. Several sets of culverts drain farmland on existing inholdings while two sets drain abandoned farms on the eastern border into the Miami Canal.

While the current hydropattern in the Rotenberger Wildlife Management Area does mimic the natural rise and fall associated with the wet and dry seasons, it does not receive enough rainfall to reach historic water levels during the wet season and dries much more quickly than normal due to the culverts mentioned above. The 1983 agreement between the Florida Game and Fresh Water Fish Commission, South Florida Water Management District and the Department of Environmental Regulation calls for the restoration of 0-1' water levels in the area. As part of the Everglades Construction Project, these levels have been used as initial goals of hydropattern restoration within the Rotenberger Wildlife Management Area. Achievement of this goal will be a two stage process. First, all drainage culverts will be closed and the effects of this upon the hydropattern will be assessed. This information will be used to devise an operational schedule for the area which will become effective upon completion of STA 5, and installation of the pumps allowing inflow into the Rotenberger Wildlife Management Area.

J.6.4 Water Supply

The Biscayne Aquifer lies beneath the WCAs. The aquifer is a limestone bed 200 feet thick lying along the Broward/Dade coast, tapering to an edge 35-40 miles inland. It is one of the most porous and productive aquifers in the world. Because of its importance and sensitivity to urban and agricultural systems, it has been designated a "Sole Source" aquifer by the U. S. Environmental Protection Agency. Currently, it is common practice to use the WCAs for water storage during high rainfall years. Conversely, during dry periods water is removed for urban and agricultural water supply. These practices result in a detrimental exaggeration of the natural wet-dry cycle. As the population expands in south Florida, competition for water could leave the WCAs with serious water shortages. WCA-3A is used for water supply to Everglades National Park.

J.6.4.1 Water Conservation Area-1

WCA-1, part of Loxahatchee National Wildlife Refuge, includes 227 square miles of Everglades wetland habitat. WCA-1 is part of a huge freshwater storage area connected by a series of canals and levees built by the U.S. Army Corps of Engineers. The essential water management features of the northern WCA system are shown in ***Figure J-6.4.1-1***. The western boundaries of WCA-1 border the Everglades Agricultural Area. The area east of WCA-1 includes a number of

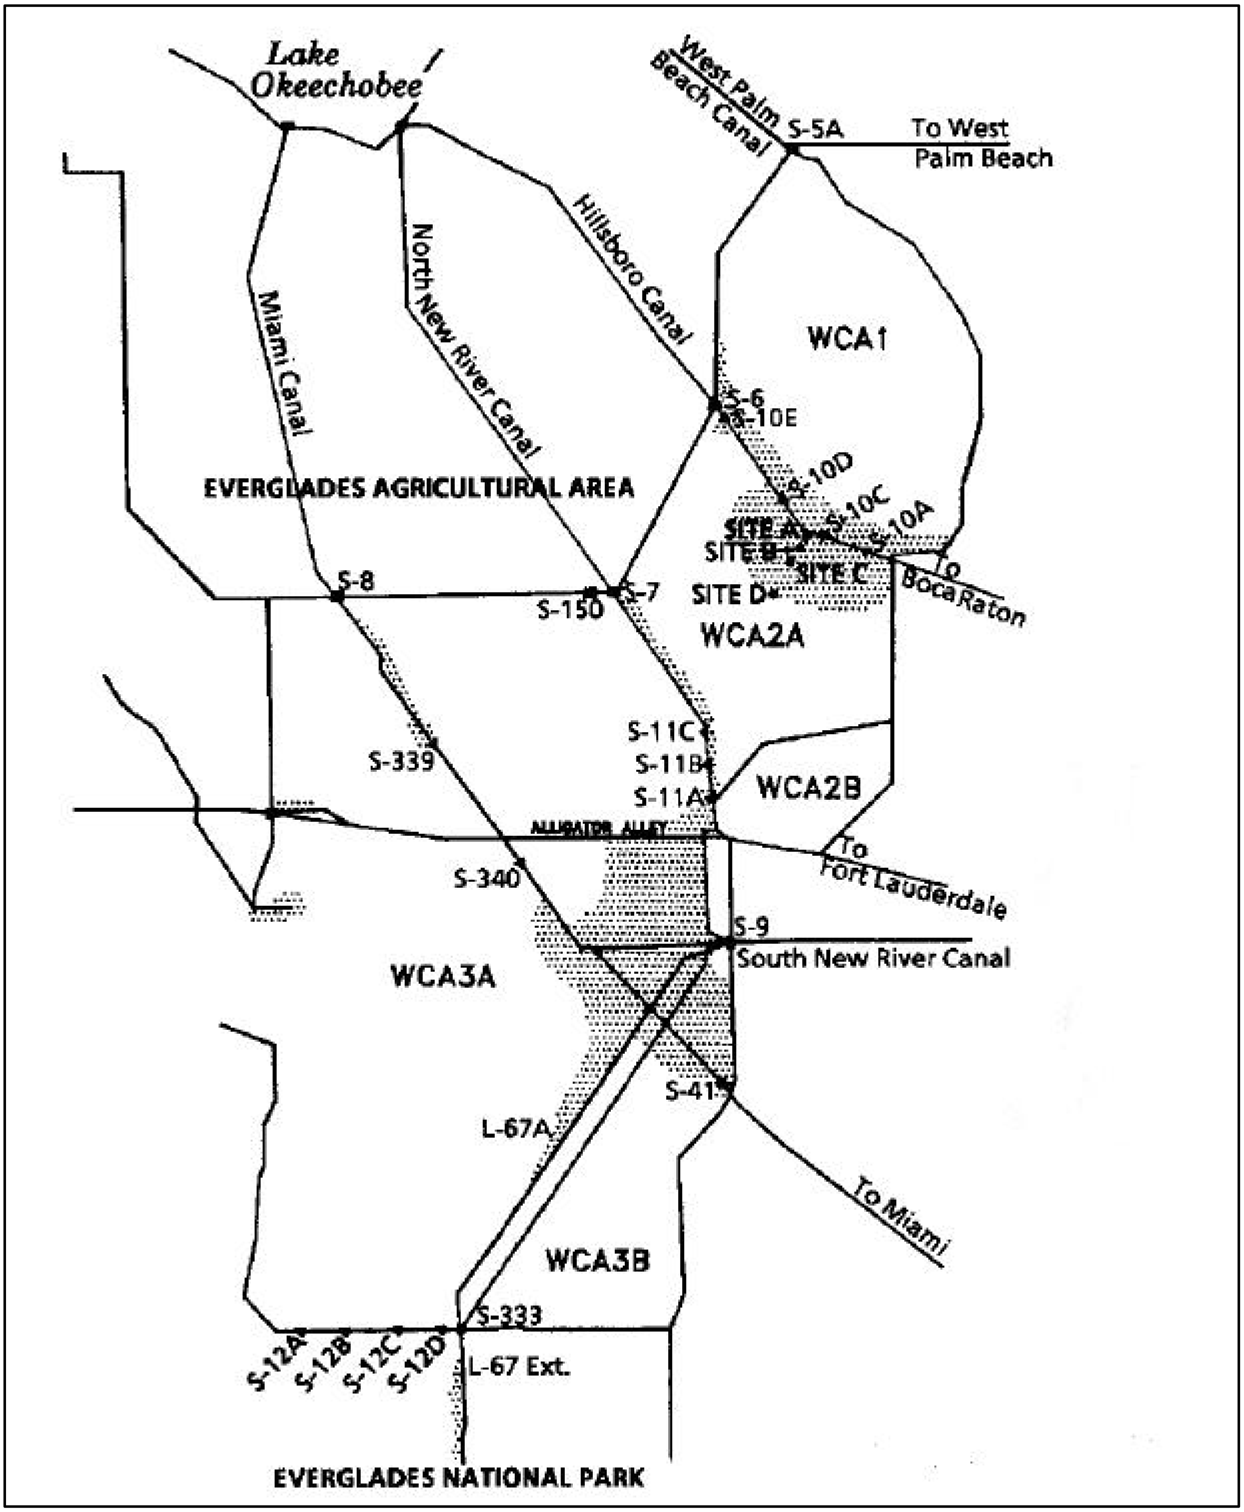

Figure J-6.4.1-1 Cattail Distribution

rapidly expanding urban communities, although several sections immediately adjacent to WCA-1 are undeveloped and contain extensive wetlands. To the south and southwest of the refuge lie WCA-2A and WCA-3A.

WCA-1 is encircled by 56 miles of levees and canals (Everglades SWIM Plan, South Florida Water Management District, 1992). Water levels are controlled by a network of pump stations, levees and water control structures. WCA-1 is the only conservation area completely encircled by canals. The water management facilities hydrologically are connected with Lake Okeechobee, the Everglades Agricultural Area, WCA-2, WCA-3, and the Atlantic Ocean. ***Table J-6.4.1-1*** presents the average annual water budget for WCA-1.

Table J-6.4.1-1
Water Budget For WCA-1
Average Annual Water Volumes
Water Years 1979-1988

Input Source	**Volume (million area feet)**	**Percent of Total**
S-5-A	.314	30%
S-6	.157	15%
Rainfall	.576	55%
Total Input	**1.048**	100%
Output	**Volume**	**Percent**
S-39	.078	7%

Total Output	**1.086**	100%

Source: Everglades SWIM Plan, South Florida Water Management District, 1992

Rainfall represents the major source of water inflow into WCA-1, accounting for about 54 percent of the refuge's water budget. Pump Station S-5A, located at the northern tip of the refuge near 20-Mile Bend, moves water into the refuge from the West Palm Beach Canal accounting for approximately 30 percent of the inflow water. Pump Station S-6, located on the refuge's western border, pumps water from the Hillsboro Canal into the southwest portion of the refuge, accounting for about 15 percent of WCA-1 inflow water. Approximately 45 percent of the WCA-1 water inflow originates as drainage from agricultural land located north and west of WCA-1. Pump Station S-5A lifts water from this area into WCA-1. Two small pumps operated by the Acme Improvement District are located in the L-40 levee on the northeastern boundary of the refuge. The pumps drain primarily residential/urban lands (Wellington) and can move water in and out of the refuge. Acme represents only a minor fraction (<1 percent) of the refuge's water budget.

Four water control structures (S-10A, S-10C, S-10D and S-10E) exist along WCA-1 on the southern levee of L-39 (Hillsboro Canal). The S-10 structures allow water to flow southward out of the Hillsboro Canal and WCA-1 into WCA-2A, if desired. The U.S. Army Corps of Engineers retains operation and maintenance responsibility for the S-10, S-11, and S-12 structures which control water movement into and out of the WCAs. The District operates these structures under contract with the U.S. Army Corps of Engineers and simply carries out the U.S. Army Corps of Engineers's orders with respect to their operation. The Hillsboro Canal (L-39), located in the extreme southeast corner of the refuge, drains WCA-1 to the east through S-39, providing water supply to urban areas and discharging drainage waters to tide. To the north, the S-5A structure can be used to move water north out of the refuge into the L-8 Canal. There are four other small privately operated structures, which constitute less than 1 percent of the refuge's annual water budget (Everglades SWIM Plan, South Florida Water Management District, 1992).

J.6.4.2 Water Conservation Area-2

WCA-2 encompasses an area of 210 square miles and represents the smallest of the three Everglades WCAs. The essential water management features of the WCA system are shown in Figure J-6.4.1-1. The area is bordered on the west by U.S. 27 and WCA-3A, and on the south by Interstate 75. WCA-2 was created as a critical component of the C&SF Project in the early 1960s. This project was designed to provide flood protection, water supply and environmental benefits for the region. Water levels in this area are controlled by a system of levees and water control structures that encircle the WCA-2A marsh. In 1961, a levee (L-35B) was constructed across the southern portion of WCA-2, dividing the area into two smaller units, WCA-2A, (173 sq. mi.) and WCA-2B (37 sq. mi.), in an effort to reduce water seepage losses to the south and to improve the water storage capabilities of WCA-2A.

Approximately 58 percent of the inflow water entering WCA-2A originates from the Everglades Agricultural Area. Nutrient enriched canal water enters the marsh from the north via four water control structures (S-10A, S-10C, S-10D, and S-10E) located on the L-39 levee (Hillsboro Canal), which drain WCA-1 and the Everglades Agricultural Area, and from the west via Pump Station S-7. The absence of an interior perimeter canal along the marsh's northern levee allows nutrient enriched canal water to sheet flow across the marsh. When surface water stages exceed the regulation schedule, water is discharged from the area, principally through the three S-11 structures (S-11A, S-11B, and S-11C) located along the southwestern levee of WCA-2A. Other minor discharges occur through the C-13 and C-14 basins by way of S-38 (gated culvert) to the southeast, and the S-144, S-145 and S-146 structures which discharge to WCA-2B to the south (Cooper, 1990, in press).

Table J-6.4.2-1 presents the average annual water budget for WCA-2. In contrast to WCA-1 and WCA-3A, which receive the majority of their water from direct rainfall, WCA-2A receives the majority of its water (59 percent) from surface water inflows, including drainage from Everglades Agricultural Area lands and outflows from WCA-1. Rainfall accounted for only 41 percent of the inflow to WCA-2A over the period of record, while the four S-10 discharge structures (S-10A, S-10C, S-10D, and S-10E) and S-7 Pump Station represented 37 and 22 percent, respectively, of the source water inflows into the WCA-2A marsh (Everglades SWIM Plan, South Florida Water Management District, 1992).

Forty-one percent of the water lost from WCA-2A is due to evapotranspiration. The S-11 control structures (S-11A, S-11B and S-11C) account for 45 percent of the water leaving the marsh. Other water losses include discharges through S-38 (4 percent) and discharges to WCA-2B through S-144, S-145 and S-146 (9 percent).

J.6.4.3 Water Conservation Area-3

WCA-3, the largest of the three Everglades WCAs, lies to the west and southwest of WCA-2A. Its boundaries are the L-5 levee, the Rotenberger and Holey Land Wildlife Management Areas and the Everglades Agricultural Area to the north; the L-29 levee, Tamiami Trail (US 41) and Everglades National Park to the south; the boundaries to the east are levees L-30, L-33, L-37 and L-38; boundaries to the west are levee L-28, the Big Cypress National Preserve, and the Miccosukee and Seminole Indian reservations.

WCA-3 is over twice the size of WCA-1 and WCA-2 combined, covering an area of 915 square miles. The area is predominantly a vast sawgrass marsh dotted with tree islands, wet prairies and aquatic sloughs. A cypress forest fringes its western border along the L-28 Gap and expands south to Tamiami Trail. WCA-3A is the only WCA that is not entirely enclosed by levees. A 7.1 mile stretch has been left open on the mid-western side of WCA 3A. This opening, the L-28 Gap, allows overland flows to enter WCA-3A from the Big Cypress and other western basins (Leach *et al.*, 1972). WCA-3 is bisected by several interior canal systems. Major inflows include drainage from the Everglades Agricultural Area to the north (Miami Canal) and a combination of agricultural and WCA-2A sheet flow from the northeast (L-67A Canal). In 1962, WCA-3 was divided into WCA-3A and WCA-3B (786 and 128 sq. miles, respectively) by construction of two interior levees (L-67A and L-67C) so that water losses due to levee seepage could be reduced.

Table J-6.4.2-1 Water Budget For WCA-2A Average Annual Water Volumes Water Years 1979-1988

Source: Everglades SWIM Plan, South Florida Water Management District, 1992

Table J-6.4.3-1 presents the average annual water budget for WCA-3. Rainfall is the major contributor of water to WCA-3A, accounting for over 59 percent (1.85 million acre feet) of its measured annual average inflows from 1978-1988. Primary surface water inflows include the following:

1) The S-11A, S-11B, and S-11C (S-11 structures) account for about 17 percent of all inflows to WCA-3A. These three water control structures transfer water from WCA-2A and the L-38E Canal under U.S. 27 into the northeast section of WCA-3A;
2) Pump Station S-8 (10 percent of all inflows) which drains a 178 sq. mile portion of the Everglades Agricultural Area (S-3 and S-8 basins) served by the Miami Canal;
3) Pump Station S-9 (4 percent) which drains urban lands located in the western C-11 basin in western Broward County;
4) The L-3 Canal (2 percent) which drains the northwest portion of the Everglades Agricultural Area and transfers this water to WCA-3A;

5) Pump Station S-140 (3 percent) located on the western L-28 borrow canal, which drains a 110 sq. mi. drainage area served by the L-28 borrow and the L-28 interceptor canals;
6) The S-150 structure (2 percent) located on the L-5 borrow canal which gravity drains a portion of the Everglades Agricultural Area (the S-7 Basin);
7) The L-28 Interceptor Canal (2 percent) which drains lands west of WCA-3A (i.e. Feeder Canal basin);
8) The L-28 gap which receives drainage waters from the Big Cypress and the L-28 Tie back levee borrow canal; and
9) From the North New River Canal by way of G-123 and S-142 (Cooper, 1990, in press).

** = L-3 inflows based on a flow distribution of 75% inflow into the N.W. corner of WCA-3A. PDR 1977-1988; Percents may not equal 100 due to round off error. Source: South Florida Water Management District, unpublished data.

When water levels exceed WCA regulation schedules, water can be discharged to Everglades National Park principally through S-12A, S-12B, S-12C and S-333 to the Tamiami Canal via the S-343 structures; to WCA-3B by way of S-151; and the Big Cypress (BICY). through the S-344 structure. When WCA-3A is being managed for water supply, discharges can be sent to Everglades National Park, southeast Miami-Dade County, South Miami-Dade Conveyance System, WCA-3B, and BICY. Due to the vast size of WCA-3A, nearly three quarters (2.23 million acre-feet) of the water entering the marsh is lost from the system as ET. The S-12 structures (S-12A, S-12B, S-12C and S-12D) located at the extreme southern border of WCA-3A, discharged about 15 percent (0.48 million acre-feet) of WCA-3As water budget into Everglades National Park over the ten-year period of record, while S-333 delivered another 5 percent (0.14 million acre feet). Water control structure S-151 accounted for another 6 percent (0.18 million acre feet) of the water lost from the system.

J.6.4.4 Combined Water Conservation Area Water Budget

Table J-6.4.4-1 presents a detailed summary of the annual water budget prepared for all three WCAs (WCA-1 + WCA-2A + WCA-3A) using a ten year period of record, October 1, 1978 to September 30, 1988 (based on water year). This table includes average rainfall and water volumes for each of the 20 inflow/outflow structures for the entire system.

J.6.5 Land Use

The WCAs are located in western and southwestern Palm Beach, western Broward and northwestern Miami-Dade counties, Florida. They consist of WCAs 1,2 and 3 and encompass approximately 878,000 acres. For management purposes, the area has been subdivided into several units: WCA-1, WCA-2A, WCA-2B, WCA-3A, and WCA-3B. The WCAs are bordered on the east by the Sawgrass Expressway, U.S. Highway 27, and Krome Avenue; on the south by U.S. Highway 41, on the west by the Levee 28 (L-28) and the Miccosukee Tribe of Indians of Florida Federal Reservation; and to the north by L-4, L-5, and L-6.

The WCAs are located near several State and Federal land and water resources. Lake Okeechobee is approximately 25 miles north. State and Federal lands that border the WCAs includes Holey Land Wildlife Management Area, Rotenberger Wildlife Management Area, Miccosukee Tribe of Indians of Florida Federal Indian Reservation, Big Cypress Indian Reservation (Seminoles), Big Cypress National Preserve, and Everglades National Park. The Big Cypress Area of Critical State Concern is adjacent the southwest boundary of WCA 3A.

As part of the Central and Southern Florida Project (C&SF), land and flowage easements were obtained for the construction of the three WCAs. Construction of the required levees and canals began in 1949 and the WCAs became functional in 1962. The U.S. Army Corps of Engineers designed, constructed, and currently participates in the management of the WCAs and the water resource. The South Florida Water Management District (South Florida Water Management District) serves as the local management agent under the direction of the U.S. Army Corps of Engineers. WCA 1 became the Loxahatchee National Wildlife Refuge in 1961, and is managed by the U.S. Fish and Wildlife Service. WCAs 2 and 3 were designated as the Everglades Wildlife Management Area in 1952, and are operated by the Florida Game and Fresh Water Fish Commission (Florida Game and Fresh Water Fish Commission) under the terms of a cooperative management agreement with South Florida Water Management District (formerly Central and Southern Florida Flood Control District). The agreement became effective on 1 March 1952 with an initial term of 25 years and three automatically successive terms of 15 years each.

The South Florida Water Management District holds fee title to approximately 27 percent of the WCAs, and has flowage easements over the remainder. The Board of Trustees owns approximately 55 percent, with other public agencies owning approximately 4 percent. Approximately 14 percent of the area is owned by private landowners. The identity of the private landowners and the location of the inholdings are, for the most part, unknown; Palm Beach, Broward and Miami-Dade counties have little or no land records for lands in the Everglades Water Management Area.

In 1982, an agreement between the Board of Trustees of the Internal Improvement Trust Fund, the Florida Game and Fresh Water Fish Commission, the South Florida Water Management District and the Miccosukees was prepared to clarify the documentation and respective rights and responsibilities of the State and the Miccosukees in the 189,000 acres of reservation lands within WCA 3.

South Florida Water Management District has used "Save Our Rivers" (SOR) funds since 1982 to purchase land in the Everglades Water Management Area. Section 373.59, Florida Statutes, created the SOR program, and established the Water Management Lands Trust Fund that contains monies designated for the purchase of environmentally sensitive riverine lands. Funds for SOR are provided by a portion of documentary stamp tax on properties purchased in Florida. Save Our Rivers legislation calls for the management and maintenance of lands acquired with SOR funds in an "environmentally acceptable manner, and to the extent practicable, in such a way as to restore and protect their natural state and condition." The legislation encourages the use of SOR lands for public outdoor recreational activities compatible with the primary goal of environmental protection and enhancement.

Governor Bob Graham initiated the "Save Our Everglades" program on 9 August 1983. This program was designed to improve environmental conditions in the Everglades system. Two of the seven program initiatives directly affected the management of the Everglades Water Management Area. Initiative 4 required the Florida Game and Fresh Water Fish Commission to manage the Everglades Water Management Area deer herd at a level that could survive moderate flooding conditions. Initiative 5 incorporated hydrological improvements in the conversion of State Road 84 to Interstate 75 (Alligator Alley). The five remaining program initiatives provided secondary benefits to the Everglades Water Management Area by providing for land acquisition and hydrological improvements that enhanced water quality and delivery to the area.

In 1989, 14,720 acres in WCA-3A were purchased from the Seminole Indian Tribe of Florida with funds from the South Florida Water Management District and the CARL Program. This tract was added as an amendment to the Rotenberger Wildlife Management Area lease, which names the Florida Game and Fresh Water Fish Commission as lead managing agency. This amendment has a perpetual flowage easement granted to the South Florida Water Management District. The Seminole Tribe has retained non-exclusive use rights in parts of WCA-3A.

The State of Florida passed the "Everglades Forever Act" in 1994. The legislation was written to address environmental concerns related to the quality, quantity, and timing of waters entering the Everglades system. The act provided for the creation of stormwater treatment areas (STAs), set water quality standards for water entering the Everglades system, and required the agricultural community to implement Best Management Practices to reduce phosphorous inputs into the Everglades drainage basin.

The three major roadways that affect the WCAs are U.S. Highway 27, which separates WCA-2 from WCA 3, U.S. Highway 41 (Tamiami Trail) which borders WCA-3 to the south, and Interstate 75, which bisects WCA-3. The roadways, in combination with the existing levee and water delivery systems, have altered the natural hydroperiod of the area and disrupted sheet flow throughout the Everglades Water Management Area. In the past, there has been substantial environmental damage to the WCAs due to severe flooding and drought caused by these alterations.

The Holey Land Wildlife Management Area is a tract of Everglades marsh comprising 35,350 acres, located in the southwest corner of Palm Beach County. It is located immediately north of WCA 3, on the east side of the Miami Canal. It is 17 miles south of Lake Okeechobee and approximately 43 miles north of Everglades National Park. A large portion of the property came to the Trustees of the Internal Improvement Trust Fund (Trustees) through statehood as part of the Federal Swamp and Overflowed Lands Act of 1850. Some of the property may have been acquired under the Environmentally Endangered Lands (EEL) acquisition fund in the early 1970s. The remainder of the property was purchased in order to facilitate restoration of the hydroperiod for the area, possibly through the Save our Everglades Program. Lease #2343, dated July 30, 1968 and issued by the Trustees, leased the area to the Florida Game and Fresh Water Fish Commission for fish and wildlife management purposes. Since that time, the Florida Game and Fresh Water Fish Commission has managed the area for public hunting, fishing and recreational use. From 1968 until 1975, the area was apparently included as part of the Everglades Wildlife Management Area. In 1975, it was established by the Florida

Game and Fresh Water Fish Commission as the Holey Land Wildlife Management Area. Past uses, prior to 1968, are unknown.

Man-made structures include levees associated with the Miami Canal and the L-5 canal. A series of canals and borrow pits enclose the area's northern and eastern boundaries. Boat ramps are located at the northwest (G-200) and southwest (G-201) pump stations. There are three water gauges (Holey G, Holey 1, Holey 2) within the marsh, with another located in the eastern boundary levee (G-203D). These structures are operated by the South Florida Water Management District in accordance with a management agreement with the Florida Game and Fresh Water Fish Commission. The South Florida Water Management District also maintains public roads associated with the Miami Canal and L-5 levees. The road along the crest of the northern and eastern boundary levee is closed to the public because it is too narrow to accommodate two-way public vehicular use. Florida Power and Light maintains high-tension power lines and support pads on the southern boundary of the Water Management Area, and a small electrical transmission line along the Miami Canal levee. A series of 54 artificial islands were constructed in the south- and east-central portions of the area in 1974 and 1975.

The Rotenberger Wildlife Management Area is an area of Everglades marsh comprising 27,810 acres located in the southwest corner of Palm Beach County. The Rotenberger Wildlife Management Area is located immediately north of WCA 3 on the west side of the Miami Canal. It is 17 miles south of Lake Okeechobee and approximately 43 miles north of Everglades National Park. Holey Land Wildlife Management Area is immediately along the east boundary of the Rotenberger Wildlife Management Area. The area was named for Ray Rotenberger, who constructed a small camp and airfield in the area during the late 1950s or early 1960s. Approximately 6,300 acres of the original Environmentally Endangered Lands (EEL) project were purchased by the State on February 17, 1975. Since that time all but about 3,500 acres have been acquired. Although biologists were performing surveys and checking harvests in the Rotenberger area as early as 1970, and it may have been part of the Sawgrass Hunt Area at this time, the area was not included in the Florida Game and Fresh Water Fish Commission wildlife management area system until August 26, 1975. The Rotenberger Wildlife Management Area has been operated under lease # 3581 dated November 13, 1979 from the Board of Trustees of the Internal Improvement Trust Fund (Trustees) since that time, with 6 major lease amendments (1987, 1989, 1990, 1994). This lease also includes some lands on the east side of the Miami Canal that are managed as part of the Holey Land Wildlife Management Area and some 14,000 acres south of the L-4 in Broward County that are operated as part of the Everglades and Francis S. Taylor Wildlife Management Area (known as the Seminole Indian Lands).

Man-made structures include levees associated with the Miami Canal, Manley Ditch, L-4 Canal, the Florida Power and Light Powerline, the Guerry sugar cane farm (834 acres), and the abandoned Cousin's Ranch (940 acres) and Holper (100 acres) properties. An airstrip (formerly known as the Matthews Airfield) was built in the late 1950s or early 1960s by Ray Rotenberger, and there are several cabins and other structures associated with that camp. There used to be a cabin on Wall's Head, but it was abandoned and fell apart some years ago. Another cabin on Cousin's Ranch near the Miami Canal (Wildlife Officer's Camp) has also been abandoned, but is still standing. Several sets of culverts drain from Rotenberger Wildlife Management Area into the Miami Canal and L-4 Canal, and there are a series of culverts underneath the Powerline road. There are two South Florida Water Management District water gauges in Rotenberger Wildlife Management Area (Rotenberger North and South). Sometime in the late 1950s or early 1960s an exploratory oil well was drilled near the south-central boundary. Using shellrock and material dredged from the wetlands a 2-acre support pad and access road to the L-4 North and Powerline levees was constructed, but this site was soon abandoned.

J.6.6 Recreation Resources

All of WCA-1 and some adjacent lands are operated by the USFWS as The Arthur R. Marshall Loxahatchee National Wildlife Refuge. The refuge consists of 227 square miles of Everglades Wetland Habitat including WCA-1 and several out parcels. Created in 1951, the Refuge has the following management objectives: 1) To provide optimum habitat and wildlife protection for endangered and threatened species of wildlife which are native to the Everglades; 2) To provide wintering habitat for migratory waterfowl; 3) To provide habitat for a natural diversity of wildlife species; and 4) To provide opportunities for environmental education, interpretation and wildlife-oriented activities.

Currently the refuge attracts approximately 500,000 visitors a year for wildlife observation, environmental education, sport fishing, waterfowl hunting and other wildlife oriented activities (SFWMD, 1992).

Responsibility for wildlife management within The Everglades Wildlife Management Area (WCA-2 and WCA-3) is delegated to the Florida Game and Fresh Water Fish Commission under lease from South Florida Water Management District. The WCAs have traditionally been used by the public for a variety of recreational activities including hunting, fishing, frogging, airboating, nature appreciation, and camping. Utilization of the interior marsh is limited due to physical constraints and lack of access. Airboats are the primary mode of transportation, while other boats are generally restricted to the canals. Other off-road vehicles (ORVs: tracked vehicles, swamp buggies, all-terrain vehicles, and airboats) are used to access the area when hydrological conditions permit. Recreational users obtain access to the area at fourteen boat ramps and access sites.

The WCAs provides hunting, fishing, boating, ORV use and camping opportunities. Hunting occurs in the fall and winter. The most popular sportfish are bass and sunfish. The majority of fishing activity occurs in the canals. Frogging is permitted throughout the year and, unlike fishing and hunting, does not require a license unless the person is engaged in commercial activity (capturing for sale). Although most fishing can be done from the banks or from a variety of boats, frogging and most hunting is done from airboats. Swamp buggies and tracked vehicles are also used for hunting. Commercial airboat rides are available throughout much of the WCAs. Many of the approximately 65 camps in the WCAs are used throughout the year as weekend retreats and hunting camps.

Recreational access to the WCAs along I-75 is presently limited to four boat ramps. The combined use by shore anglers, anglers fishing the canals by boat, sightseers, airboaters, and ORV operators has resulted in overcrowded and unsafe conditions at established boat ramps. Overcrowding has been a factor identified in the number of people violating Federal Department of Transportation (FDOT) parking regulations to access the WCAs along I-75. Safety concerns are being addressed by constucting four new boat ramps and a large rest area along I-75. Access for recreation enthusiasts such as walk hunting also exist along the L-5 and L-6 levees.

There are several recreation areas located along the boundary of the WCAs: Loxahatchee Recreation Area, Sawgrass Recreation Area, Everglades Holiday Park, Thompson Park, and Mac's Fish Camp. These facilities, along with several along Tamiami Trail, provide boat ramps, camping facilities, boat rentals, airboat tours, fishing guides, bait and tackle supplies, and food.

J.6.7 Aesthetic Resources

The visual landscape of the WCAs is overwhelmingly flat. Landscape features include typical canals, levees and prairie wetlands communities. Access points to the interior of the areas are limited, as discussed in the preceding paragraph. WCA-1 is operated as a wildlife refuge and offers opportunities for observation of migratory game birds during winter months. Although some of the marshlands have been degraded in visual quality by over-flooding and loss of tree islands, other areas, such as WCA 3A south, still preserve good examples of original, undisturbed Everglades communities, with a mosaic of tree islands, wet prairies, sawgrasss expanses, and deeper sloughs. From the elevated viewpoint of the Eastern Perimeter Levee system, or EPL, the view westward to the marshes is panoramic, though mostly homogenous.

J.7 LOWER EAST COAST AND BISCAYNE BAY

The Lower East Coast region (***Figure J.7-1***) extends about 100 miles in a north-south direction, through the coastal portions of Palm Beach, Broward and Miami-Dade Counties. To the north it is bounded by the Palm Beach - Martin County line. Its western boundary is, from north to south, (1) Lake Okeechobee; (2) the Everglades Agricultural Area; (3) the eastern edges of WCAs 1, 2A, 2B, 3A, 3B; and (4) Everglades National Park. In southern Miami-Dade County its southwestern boundary is the Overseas Highway. Thus, the Lower East Coast region includes the north end of Key Largo, all of Biscayne Bay, and the West Lake and Lake Worth Lagoons. The region includes the cities of West Palm Beach, Ft. Lauderdale and Miami and the urban strip that connects them. This is the most densely populated region of Florida, supporting more than 4 million people. It also includes the protected resources of Biscayne National Park.

The following physiographic provinces are represented in the region: Coral reefs (the northern end of the Florida reef tract), Atlantic barrier islands (beaches and dunes), extensive estuarine lagoons and bays (Lake Worth, West Lake and Biscayne Bay), coastal plains (often mangrove-lined), the Atlantic Coastal Ridge (a slightly elevated limestone outcropping that parallels the coast), the Lakebelt limestone mining area, pine rocklands, and the nearly flat marl or peat marsh lowlands to the west of this ridge (Everglades proper) (Science Sub-Group, 1994).

Of all the regions, the Lower East Coast may present the most extreme contrasts between intense urban development and full exploitation of natural resources, on one hand, and preserved remnants of natural ecosystems, on the other. The freshwater surface drainage has been converted almost completely to a series of artificial canals. In the Lakebelt region, limerock mining has created a series of deep, vertically walled pits that have replaced significant portions of the original marshes. Residential development, especially in and around Miami, has virtually filled all available space, and is now expanding vertically. Miami is a fast-growing metropolis whose demands for horizontal space, water resources and other regional services are felt throughout the region. However, this region still advertises itself as a mecca for outdoor life; showing the watery resources of Biscayne Bay, the glades, the waterbirds and the coastal islands as a backdrop in its promotional material.

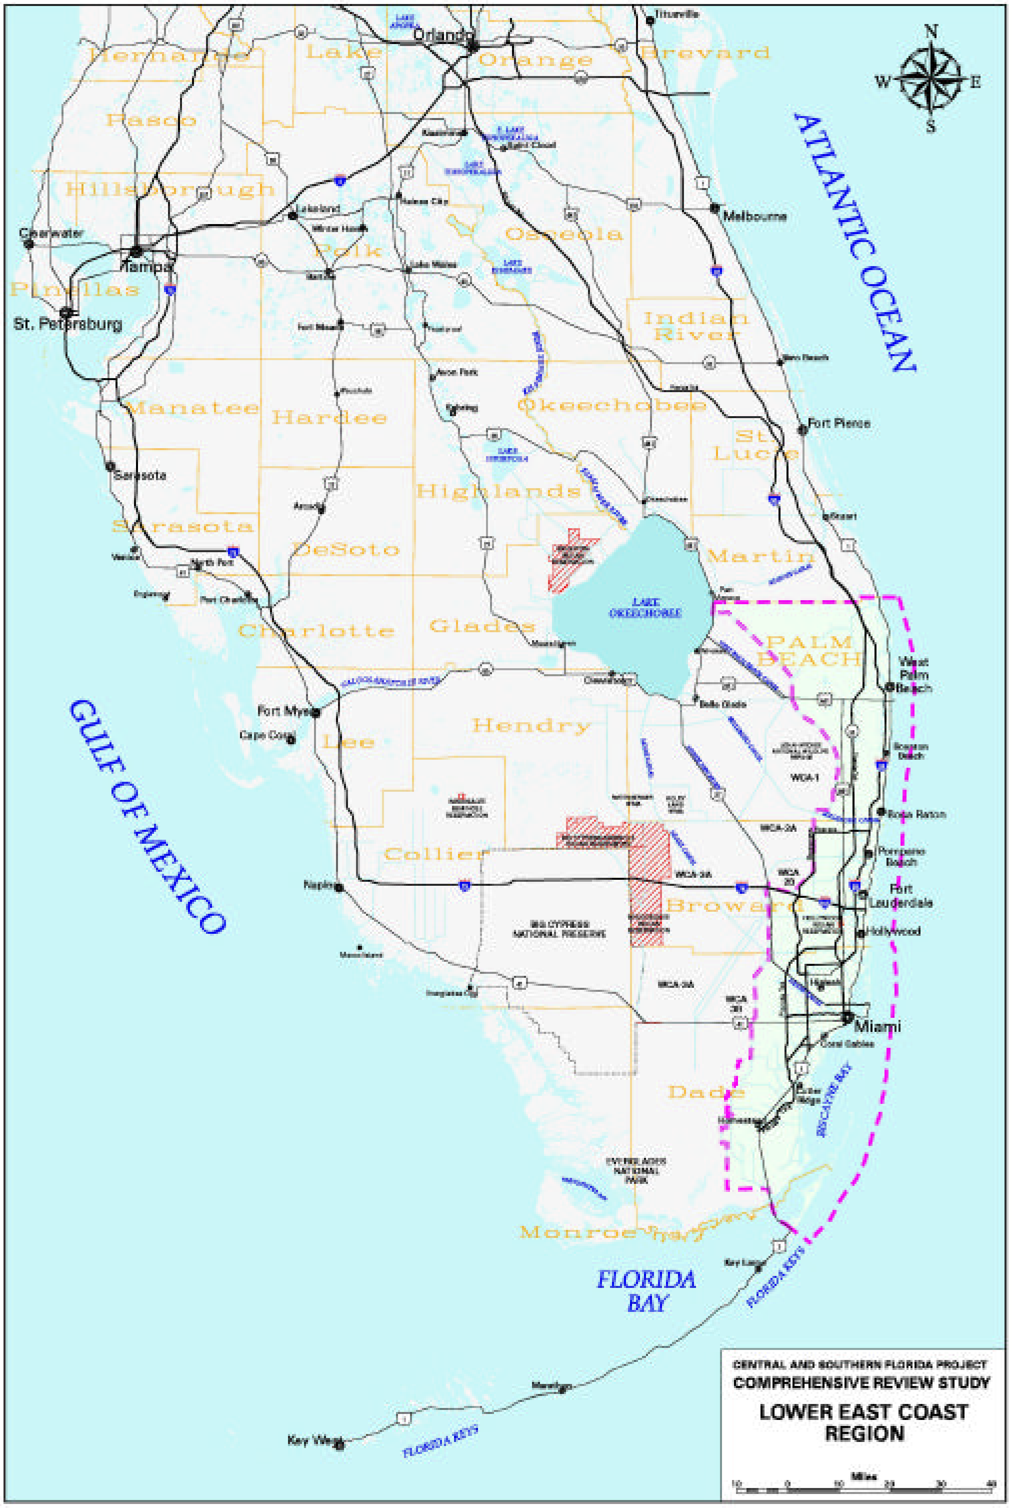

Figure J.7-1 Lower East Coast and Biscayne Bay Region

J.7.1 Vegetation

Plant cover types in the inland zone (behind the coastal ridge) are basically all wetland types. Roughly from west to east, and from north to south, they are: emergent marshes (glades) and wet pine flatwoods in the north, and glades and pine rocklands in the south. The freshwater marshes of the north generally developed over peat and are dominated by sawgrass, (*Cladium jamaicense)*. Toward the south, a second, shorter hydroperiod wetland type, over a marl substrate, is generally dominated by muhly grass (*Muhlenbergia*) and associated species. Smaller fractions of the interior landscape are occupied by hardwood hammocks (tree islands), freshwater sloughs (dominated by floating leaved or floating herbaceous plants), and scrub-shrub wetlands (dominated by willows and buttonbush). Coastal plant communities include mangrove-salt marsh communities, seagrass communities lining the lagoons and bays, dune scrub and coastal hardwood hammocks on the barrier beaches and Atlantic Coast Ridge.

Due to the intense development of the Lower East Coast region, many typical cover types are now represented as tiny relicts in county parks, State or Federal reserves. This is especially true of the least flood-prone types such as coastal hammocks and hardwood hammocks of the Atlantic Coastal Ridge, as well as the pine rocklands and short-hydroperiod rocky glades. Farther north, development has all but eliminated coastal scrub, dune and the drier pine flatwoods communities, leaving only the wetter western pine flatwoods. Examples of upland and coastal plant cover types are preserved in Biscayne National Park, Matheson Hammock County Park, Fairchild Tropical Garden, Crandon Park, Cape Florida and Oleta River State Recreation Areas in Miami-Dade County; John Lloyd State Recreation Area in Broward County, and Spanish River Park and John D. MacArthur State Park in Palm Beach County.

Today, all the natural habitats of the Atlantic coastal area have been so reduced in extent that examples of any natural community in good condition are considered environmentally sensitive areas by county governments. The loss of so much upland and wetland habitat along the Atlantic coast has greatly diminished the abundance and diversity of native plants and animals in southeast Florida. Because important wildlife, particularly birds, move great distances across south Florida, losses in this area clearly affect the WCAs and Everglades National Park.

Many of the wetlands in the region have suffered decreases in water levels, changes in water quality, changes in frequency and seasonality of burning, physical damage from vehicles or wild pigs (introduced from Europe by man) or other kinds of disturbance. The most visible sign of stress in these wetlands is vegetation change with increases in the numbers of weedy native species, such as cattail and primrose willow, and exotic species, such as melaleuca and Brazilian pepper. At the same time, many native plants disappear, either directly because of the disturbed environment, or because they are crowded out by weeds.

The following paragraphs describe the wetland areas that occur in the Lower East Coast and that are considered to be regionally significant. These wetlands may be impacted by changes in regional operations, such as changes in seepage due to higher or lower stages within the WCAs. Some major wetland areas may be examined as potential detention areas for possible backpumping scenarios.

Loxahatchee Slough. The slough, located in northern Palm Beach County, is a diverse area of native wetland habitat interspersed with pineland, oak and subtropical hardwoods. Large portions of this area have been acquired through the Save Our Rivers Program.

Strazzula. This tract is located east of, and adjacent to, the Arthur R. Marshall Loxahatchee National Wildlife Refuge, which is also known as Water Conservation Area 1 (WCA-1). The area is a combination of sawgrass marsh and cypress slough. Water supply to this area comes from rainfall and seepage from WCA-1.

Everglades Buffer Strip. This land is located in Broward County along L-37 and between the North and South New River Canals. Approximately 2,044 acres of the buffer strip have been purchased by the South Florida Water Management District. The area has been impacted by invasion of exotic vegetation and rock mining. Water supply to the area is primarily by rainfall and seepage from WCA-3 under L-37 and L-33.

Dupuis Reserve / J.W. Corbett Wildlife Management Area / Pal-Mar. These areas are contiguous. They are very large areas of natural habitat in Palm Beach and Martin counties. The Dupuis Reserve and the J.W. Corbett Wildlife Management Area are in public ownership. The Pal-Mar tract is under consideration for purchase by Save Our Rivers. Only those portions within Palm Beach County will be considered in this plan. Water supply to these areas is primarily from rainfall.

Bird Drive / Pennsuco / North Trail / Dade-Broward Levee. These areas once were part of the Everglades and are located in the general area of north central Miami-Dade County. These areas are influenced by development, including extensive rockmining, and are in the cone of influence of the Miami-Dade County's Northwest Wellfield. Adjacent canals overdrain portions of these areas.

C-111. A high percentage of the C-111 area wetlands, which are east of Everglades National Park, are undeveloped. Some of the other C-111 wetlands generally are areas that have a low to moderate level of disturbance. The C-111 wetlands provide habitat for several endangered species. Land cover includes pineland remnant, tropical hardwood hammocks and sawgrass glades. Restoration of sheetflow to Florida Bay through the C-111 area is in the planning stages.

Endangered and threatened plant species reported from the Lower East Coast region include crenulate lead-plant (*Amorpha crenulata*), deltoid spurge (*Chamaesyce deltoidea* ssp.), Small's milkpea (*Galactia smallii*), tiny milkwort (*Polygala smallii*), four-petal pawpaw (*Asimina tetramera*), Garber's spurge (*Chamaesyce garberi*), and beach clustervine (*Jacquemonatia reclinata*).

In their natural state, the coastal communities were capable of recovering from disturbances. However, exotic plant and animal species have become prominent on the barrier islands and spoil islands. When areas are disturbed, these species invade and prevent native species from becoming re-established. Many of the exotic species are West Indian or tropical in origin. As such, they are vulnerable to freezes, leaving occasional windows of opportunity for re-establishment of native species.

Nuisance exotic plant species include the common tropical "Australian pine" (*Casuarina equisetifolia*), Brazilian pepper (*Schinus terebinthifolius*), climbing fern (*Lygodium microphyllum*), melaleuca (*Melaleuca quinquenervia*), lather leaf (*Colubrina asiatica*), and calophyllum (*Calophyllum inophyllum*).

J.7.2 Fish and Wildlife

This section contains a brief description of the major faunal groups within the Lower East Coast and Biscayne Bay.

J.7.2.1 Fish

Biscayne Bay contains a large and diverse fish fauna. At least 512 species occur in the bay. Both temperate and tropical species are represented. Tropical species are more prevalent in the summer. and temperate species partially replace them in the winter (SFWMD, 1995). Large number of marine invertebrates inhabit Biscayne Bay. Over 800 species have been documented. The abundant fauna results from the presence of both the tropical West Indian Province and the temperate Carolinian Faunal Province (SFWMD, 1995).

Marine invertebrate diversity on the western side of the bay is greatly affected by canal inputs. Large freshwater pulses into the bay tend to move as masses of low salinity water that do not immediately mix with the marine water. These low salinity plumes can be detrimental to marine invertebrates. Relict oyster shell beds at the mouth of creeks have been documented. Living oyster groups no longer inhabit these areas because of increased salinity. The canals reduce the amount of freshwater in natural creeks thus increasing the salinity levels and killing off the oysters.

Freshwater fish found in south Florida canals include most of the species that are common to the rest of the south Florida region. Mosquitofish and killifish dominate remnant glades and sloughs. Lakes and ponds are often stocked with such gamefish as largemouth bass, bluegill and other sunfish, and black crappie. An interesting fresh water sport fishery has developed around the introduced exotic peacock bass.

J.7.2.2 Wildlife

Major bird rookeries in Biscayne National Park include Chicken Key, Bird Key, the Arsenicker Keys, and the mangrove shoreline on the western bank of the park (SFWMD, 1995). Additional Lower East Coast rookeries include Greynolds Park (North Miami), Fisherman's Island (Lake Worth Lagoon), and islands in the Fort Lauderdale executive airport lakes. Local bird nesting, roosting, and feeding habitat is shrinking due to increased urbanization on lands adjacent to the park. In addition, some colonial nesting shore birds (i.e. ibis) have been targeted for population reduction to make flight traffic safer in south Florida. City, county and state parks, Biscayne National Park, and tree islands in the interior wetlands are vital habitat for migrants that pass through south Florida. In urbanized areas the commonest birds belong to the perching bird group (passerines), and constitue a mix of exotics, such as the rock dove, starling and the English sparrow, and human tolerant natives such as the kingbird and the mockingbird. A very large number of exotic species belonging to the parrot family has escaped and become naturalized in the Lower East Coast region. In agricultural areas west of the urban ridge, cattle egrets and other long-legged wading birds are the most conspicuous group. Other species include typical marsh birds such as the red-winged blackbird, marsh wren, rails, other herons, and bitterns.

Mammal species in the wetland dominated western edge of the region include white-tailed deer, racoon, marsh rabbit, water rat and otter. Mammalian life near urban areas is limited to tolerant speces, including introducted European house mouse and roof rat, bobcat and grey fox, opossum, armadillo, grey squirrel and feral housecats and dogs.

Common amphibians include many species of frogs, including leopard frog, pig frog, bullfrog, green tree frog, fire-bellied newt and dwarf newt. Reptiles are not common in urban areas. In agricultural areas and in the western wet flatwoods and marshes, many species of turtles and snakes, and the American alligator are common. Alligators once seriously threatened by overhunting, are ubiquitous in suburban drainage canals, rainwater detention ponds and canal. Loggerhead, and to a smaller degree, green sea turtles, nest on the Atlantic barrier beaches opportunistically (mostly along stretches of unlighted beach).

Endangered or Threatened wildlife species in the Lower East Coast region include the Stock island tree snail, American crocodile, American alligator, wood stork, eastern indigo snake, Atlantic salt marsh snake, Florida panther, West Indian manatee, loggerhead, leatherback, green, hawksbill, and Kemps Ridley sea turtles, Florida scrub jay, bald eagle, snail kite, Audubon's crested caracara, red-cockaded woodpecker, Kirtland's warbler, Bachman's warbler, and the piping plover.

J.7.3 Water Management

The Lower East Coast functions as a multipurpose canal system with several objectives including: Flood control, urban water supply, industrial water supply, agriculture water use, protection and enhancement of wetland and estuarine systems, prevention of saltwater intrusion, and recreation. The Lower East Coast system is capable of moving vast quantities of water during the wet season as well as supplying water (if available) during the dry season or as needed. Important freshwater canals are, from north to south, C44, C18, C17, C51, Hillsboro canal, North New River canal, Miami canal, New River canal, C9, C8, C7, C4, C100, C100c, C1, C102, C103, C109, C110, C111, and the South Dade Conveyance System.

Approximately half of the acreage farmed in the Lower East Coast is irrigated (UFBEBR, 1995). This region is highly dependent on the system of canals, levees, and other structures for flood control in the wet season and water supply in the dry season. Providing adequate drainage and flood control to the South Miami-Dade County agricultural area is a serious challenge because the farmland is directly adjacent to Everglades National Park. Evidence suggests that efforts to provide flood control to agriculture have resulted in over-drying the eastern portions of Everglades National Park and adversely affecting Park ecology. Agricultural land does, however, provide a buffer between urbanization and Everglades National Park. Farmland is recognized as the preferred neighbor to natural areas because of its minimal impervious areas, open green space, and low population density. A strong agricultural economy in the Lower East Coast region based on profitable crop production is the best defense against conversion of agricultural land to urban land.

The major estuaries in the Lower East Coast are Lake Worth Lagoon in Palm Beach County, West Lake in Broward County and Biscayne Bay in Miami-Dade County. Lake Worth Lagoon was predominantly a freshwater system as recently as 100 years ago but was converted into a marine system with construction of permanent inlets to the ocean. West Lake is 1,400 acres of coastal wetland and mangroves in Hollywood along the Intracoastal Waterway. Biscayne Bay is a subtropical lagoon about 40 miles long that extends the length of Miami-Dade County.

Prior to urban development, freshwater discharge to Biscayne Bay consisted of flows through natural drainageways, overland flow and groundwater discharge from the aquifer. However, the flow has changed from short bursts of rainy season flow through low drainageways, to regulated releases through drainage canals and decreased periods of groundwater discharge (SFWMD, 1995). The construction of the canal system lowered the regional water table and subsequently reduced the amount of groundwater flow into the bay. Groundwater discharge into Biscayne Bay is believed to occur through both seepage and flow through subsurface leakage channels. A zone of seepage occurs around the perimeter of the bay where the water table elevation is higher than sea level. Subsurface flow occurs through natural leakage channels in the rock formations. Prior to the construction of drainage canals, springs flowed along the shore and emanated from the bottom of the bay. However, present day rates of groundwater discharge into the bay are insufficient to produce such flowing springs (SFWMD, 1995).

Surface water flows into Biscayne Bay and Lake Worth Lagoon are primarily controlled by the system of canals, levees, and control structures built as part of the Central and South Florida Flood Control Project. Biscayne Bay receives freshwater surface flows from 17 surface water basins through 12 major coastal structures (SFWMD, 1995). Lake Worth Lagoon's freshwater input is principally from the C-51 canal. The mechanism of surface water flow into Biscayne Bay and Lake Worth lagoon are short, intense pulses of freshwater discharged at discrete locations. This flow has replaced the historic sheet flow through the wetlands adjacent to the bay that existed before development of the canal system. Dry season flows into these water bodies are much lower than pre-drainage levels because most of the discharge into the bay is from storm water release from the canals. The canal discharge can bring sediments, heavy metals, pesticides, fertilizers, herbicides, nutrients and low salinity plumes, which can all adversely affect the biota (SFWMD, 1995).

J.7.4 Water Supply

Water availability in Subregion 9 depends on rainfall and storage capacity in surface and groundwater systems. The Lower East Coast is a producer, as well as south Florida's largest consumer, of fresh water. Florida's heaviest rainfall occurs along the Atlantic Coastal Ridge between Boynton Beach and Miami, where the annual average is as high as 64 inches (1975 data). Rainfall decreases inland and is only 52 inches over Lake Okeechobee (Davis 1943; Klein et al. 1975; McPherson et al. 1976)

The Lower East Coast is dependent on shallow, unconfined surface aquifers for urban and agricultural fresh water. Broward and Miami-Dade counties rely entirely on groundwater. Groundwater accounts for 80-90 percent of Palm Beach County's potable water. Most groundwater (100 percent in Miami-Dade, 90 percent in Broward, 85 percent in Palm Beach) is pumped from depths of less than 46 m. (150 ft.); many wells are much shallower (Alvarez and Bacon 1988; Rodis and Land 1976). The Biscayne Aquifer, the largest and most productive unit of the surface aquifer system, is one of the area's most valuable natural resources. It underlies an area of about 7,770 km^2 (3,000 mi^2), including all of Miami-Dade County and most of Everglades National Park, all of Broward County, and part of south Palm Beach County. The aquifer is composed of sandy limestone and calcareous sandstone with many solution holes and cavities. It is one of the most permeable aquifers ever investigated and probably the most permeable water-table aquifer in the world (Brown and Parker 1945; Kreitman and Wedderburn 1984; Parker et al. 1955; SFWMD 1994a; Schroeder et al. 1958). Aquifer recharge is mainly by direct infiltration from rainfall, supplemented by water carried into the area by canals to supply wellfields and prevent coastal saltwater intrusion during the dry season.

The Biscayne Aquifer was designated a sole-source aquifer for Miami-Dade and Broward counties in 1979 by the EPA under the Safe Drinking Water Act. It is also the primary source of drinking water for Palm Beach County North of Boca Raton, except West Palm Beach, which is supplied by another component of the surficial aquifer that is not as productive as the Biscayne Aquifer. West Palm Beach is the only major municipality supplied by surface water. The source is Clear Lake just inland from the coast (Klein et al. 1975; SFWMD 1992, 1993, 1994a).

Table J-7.4.1-1 lists the total water demand of 1,000.53 MGD for the 3 county area (Miami-Dade, Broward, and Palm Beach) in 1995. Public supply is the primary demand in all three counties.

J.7.5 Socio-Economics

Agricultural land is a prominent feature of the Lower East Coast region. The South Miami-Dade Agricultural area encompasses 90,000 acres in Miami-Dade County. Vegetables are the major products, at 56 percent of total sales. Nurseries and fruit products comprise the balance at 30 and 14 percent, respectively. Agriculture in Palm Beach County covers approximately 29,000 acres in citrus and vegetables. Nurseries are also present and expected to expand in this county. Broward County's agricultural resources are present, but diminishing as residential development expands. Although 34,000 acres were in agriculture in 1935, the amount of agriculture had decreased to 6,000 acres by 1989. This trend is expected to continue with agriculture almost nonexistent by 2010 (Science Subgroup 1996).

Table J-7.4.1-1
Water Use Estimates For Miami-Dade[2], Broward, And Palm Beach Counties (MGD)

Use Category	Palm Beach	Broward	Miami-Dade	Three County Total
Domestic PS	124.85	144.57	245.76	515.18
Commercial PS	28.88	38.56	60.68	128.12
Industrial PS	5.12	6.54	11.93	23.59
Other PS	2.99	2.84	4.24	10.07
Public Use	25.04	29.79	49.92	104.75
Public Subtotal	186.88	222.39	372.53	781.71
Domestic SS	17.19	2.16	12.71	32.06
Comm/Industrial SS	22.95	0.34	43.38	66.67
SS Subtotal	40.14	2.50	56.09	98.73
Golf Courses	43.10	23.44	13.75	80.29
Thermoelectric	0	0.49	1.35	1.84

Total	278.40	277.37	446.76	1000.53

PS – Public Supply SS – Self Supply

[1] Data is from Water Withdrawals, Use, Consumption, and Trends in Florida, 1995, USGS Water Resource Investigation Report 98-4140, and unpublished USGS data.

[2] Miami-Dade county demands includes Florida Keys (Monroe county); the Keys are supplied from Miami-Dade County well fields.

Citrus farming has been practised in the Lower East Coast, but is on the decline. Miami-Dade County lost over 50 percent of its citrus during Hurricane Andrew and by 2020 only 1,667 acres will still be farmed for citrus. By 2020, citrus farming in Broward County is projected to be insignificant and Palm Beach County will have approximately 10,121 acres in citrus production.

Limerock mining is also a substantial industry in the Lower East Coast region. Miami-Dade and Broward County mining operations provide more than half the construction grade rock used in Florida. Rock mining converts three to four hundred acres of land into deep lakes annually (Science Subgroup).

Biscayne Bay is fished both commercially and recreationally. The major economic fisheries include sport fish, such as tarpon, bonefish, snook and permit; food finfish, such as groupers, pompano, snappers, hogfish and mackerels; shellfish, such as shrimp, spiny lobster and crabs; and bait, such as shrimp, pilchard, ballyhoo, pinfish, mullet, thread herring, Spanish sardines and anchovies (SFWMD, 1995).

The dockside value of the commercial fishing industry for the combined years of 1982 and 1983 was estimated at $1.3 million. At the retail level, the commercial catch from the bay excluding lobsters was worth about $2.75 million for the same period. These figures only include the dockside value and do not take into account income which is generated in the fishing industry itself or from sport fishing (SFWMD, 1995).

In 1996 over 573,000 pounds of fish were reported to the Florida Marine Fisheries Commission from commercial fishing as being taken from Biscayne National Park and surrounding waters (Card Sound and Barnes Sound). Bait shrimp accounted for 335,118 pounds of the commercial catch. Finfish accounted for 67,800 pounds, shrimp for 51,194 pounds, and lobster and crab for 115,289 pounds.

In 1996, over 55,000 boats used Everglades National Park with 59 percent engaged in recreational fishing. The areas of the park that were most often fished were those along the reef tract. The second most popular area was inside the bay in the Caesar Creek vicinity. Most of the recreational fishermen were from the local area with less than 0.5 percent from northern Florida or out of state. For the period of April 1996 through March 1997, an estimated 548,297 fish were caught in BNP from hook-and-line fishing, and 16,729 fish were caught from spearfishing. For the spiny lobster season, which lasts from August through March, an estimated 67,329 spiny lobster were caught. This number does not include data gathered from the two-day mini-season, which occurs before the commercial season opens.

In addition to fishing, BNP supports a large tourist industry. Concession-run tour boats leave from Convoy Point daily for snorkeling trips, scuba diving trips, and glass bottom boat tours. People come to see the coral reefs and the associated marine organisms. Tourists are increasingly coming from foreign countries (BNP, 1983). The number of visitors coming into the visitor center as calculated by park staff for 1996 was 25,602 and for 1997 was 33,887. In 1996, 20 environmental education programs were conducted for 517 students. In 1997, the number of programs increased to 75 to accommodate 2,815 students. In addition, 8,565 visitors participated in the 300 public programs, including boat tours, island tours, snorkeling, and diving programs led by park staff in 1996. In 1997, 8,968 visitors took part in 253 public programs.

South Miami-Dade County faces large population increases in the next two decades. Population data from 1994 estimates that south Miami-Dade supports 151,625 people. Between 1994 and 2015, the south Miami-Dade population is expected to increase by 200 percent, supporting about 450,000 residents by 2015.

The region around the former airforce base is expected to support much of this growth, reaching nearly 138,000 people by 2015. The 1994 population distribution in south Miami-Dade was higher east of US Highway 1 on lands closer to BNP.

J.7.6 Land Use

The Lower East Coast supports the densest population in the state of Florida. Population in the Lower East Coast is expected to increase by 35 percent, from 4,518,401 in 1995 to 6,086,700 in 2020. Land use in the Lower East Coast is primarily related to urban activities and the infrastructure (such as transportation and utilities) needed to support this large number of people. Urban demands are expected to increase by 39 percent by 2020. If however, the Lower East Coast experiences a 1-in-10 year drought during the planning period, than the projected urban and agricultural demand will increase about 43 percent.

J.7.6.1 Urban

South Miami-Dade County is defined as the area south of SW 184th St. (Eureka Drive). US Highway 1 bisects the area. West of US 1, land uses are primarily estate and low-density residential uses within the Urban Development Boundary (UDB). Other higher density residential uses, business/office, and industrial uses are found in Homestead and Florida City. The Redlands and other agricultural areas are west across the UDB and make up most of the approximately 55,000 acres of agricultural lands that remain in south Miami-Dade County. The Urban Expansion Area designation identifies agricultural lands in south Miami-Dade County as the next place for development.

Additional Lower East Coast urban-related land uses include the Florida Power and Light nuclear power plant at Turkey Point, landfills, rock mining, Homestead Airforce Base, and a number of marinas scattered throughout Biscayne Bay and Lake Worth Lagoon.

J.7.6.2 Agriculture

Palm Beach, Broward and Miami-Dade Counties are included in this region. More than 100,000 acres are farmed (UFBEBR, 1995). This region is characterized by small farms averaging less than 50 acres, with very high productivity of more than $3,500 per acre (UFBEBR, 1995). A variety of crops are produced including vegetables, tropical fruits, and nursery plants. Hurricane Andrew, which struck southern Miami-Dade County in 1992, caused significant damage to agricultural areas. Many fruit tree orchards were damaged or destroyed. Statistics from 1996 indicate that avocado production had recovered, but mango and lime orchards had not yet recovered from the hurricane damage (FASS, 1997b). Total acres of tropical fruit production in Miami-Dade County remain approximately 7,000 less than pre-hurricane levels (FASS, 1996e). Foliage plant production is also a major business in

Broward and Miami-Dade counties. More than 120 million square feet were devoted to the foliage crop in Broward, Miami-Dade, and Palm Beach Counties in 1996 (FASS, 1997a).

Agricultural production and services employ approximately 18,000 people in this region representing a $23 million payroll (UFBEBR, 1995). The total market value of agricultural products from this region is almost $400 million (UFBEBR, 1995). Miami-Dade County ranks second in the state for total market value of agricultural products (UFBEBR, 1995).

J.7.7 Recreation Resources

Recreation resources in the Lower East Coast region include an abundance of inland and coastal water resources that provide water and upland recreation opportunities. Many City, County, State parks and recreation areas are interspersed within the heavily urbanized boundaries. Approximately 115 miles of urbanized coastline provide popular seaside recreation resources where boating, fishing, swimming, diving and many other opportunities are available. The Intracoastal Waterway also provides a diverse water-based recreation resource in the region.

Biscayne National Park, DuPuis Reserve State Forest, and the Loxahatchee River – Lake Worth Creek Aquatic Preserve also provide high quality recreation opportunities for boating, fishing, and nature interpretation activities within the Lower East Coast region. J.W. Corbett Wildlife Management Area and Southern Glades Wildlife and Environmental Area are large tracts of land that provide recreational ammenities and may be affected by the Restudy. Altered water deliveries to this region could have a detrimental affect on many natural and recreational resources in the area. The good quality land and water based recreation resources in the Lower East Coast region receive extensive use and future demand is anticipated to increase.

Recreational activities of Biscayne National Park include both land and water related activities. During the summer, as many as 1,000 boaters visit the park each day (BNP, 1995). Pleasure boating, sailing, swimming, snorkeling, scuba diving, sunbathing, bird watching, water-skiing, and fishing are some of the water-based recreational activities. Land activities are mostly concentrated on Elliott Key, Adams Key and Boca Chita Key because these islands have facilities. Camping and picnicking accommodations and interpretive/nature trails exist on both Boca Chita and Elliott keys. The historic lighthouse on Boca Chita Key is open to visitors while a ranger is present. Interpretive programs led by park rangers are available throughout the year. Most of the programs emphasize the unique naturalness that BNP provides within the Miami-south Miami-Dade County metroplex.

J.7.8 Aesthetic Resources

The Lower East Coast visual resources include the heavily developed urban strip, with high-rise apartments, hotels and condominiums, extensive pavement and little green space, broad sandy beaches, tropical colored Bay waters, inland marshes and mangroves of Biscayne National Park, and the contrasting low-relief inland agricultural areas, drained by parallel canals, and planted to row crops, tropical fruit trees, or citrus. Many large commercial, industrial, and residential areas in the Lower East Coast are not in optimal condition. Sprawling warehouse and trade zones around Miami Airport exemplify industrial "aesthetics". Residential developments continue to spread and change the visual character of the regional landscape.

The Atlantic Ocean and Intracoastal Waterway (IWW) shorelines provide panoramic views from many locations. White shoreline sand contrasts sharply with tropical colored waters of the ocean and the sound of surf or trade winds are important aesthetic characteristics of the coastal area. However, high-rise structures in many locations restrict visual access to the ocean panorama and tend to diminish the visual experience from the shoreline. Visual access to the scenic IWW is also limited. Heavily used highways intersect the region from Palm Beach to Homestead. Air traffic noise is an increasingly adverse aesthetic impact.

In contrast, Biscayne National Park offers these intangible aesthetic values by providing visitors with an escape from the surrounding metropolitan area. BNP is a place where people can come to enjoy the natural scenery and the quiet of nature. Most of the visitors come to appreciate the picturesque vistas of Biscayne Bay. Others opt to explore the underwater seascape. They are interested in seeing the reefs along with the associated fish and other marine organisms. Glass bottom boats and diving/snorkeling trips give visitors the opportunity to view marine life up close. Aesthetic values are often degraded by aircraft noise and city light intrusion during the nighttime hours.

J.8 EVERGLADES NATIONAL PARK AND FLORIDA BAY

Everglades National Park covers over 2,000 square miles at the southern tip of the Florida Peninsula. It is bounded on the west by the Gulf of Mexico, on the north by Big Cypress National Preserve and Water Conservation Areas (WCAs) 3A and 3B. On the east it is bounded by residential suburbs of Miami and farmlands of Homestead and Florida City. The Park's southern boundary encloses about 85 percent of Florida Bay. Florida Bay includes the waters between the Everglades National Park coastal land and the Florida Keys, from Cape Sable on the northwest to Blackwater Sound, on the east. ***Figure J.8-1*** shows regional boundaries.

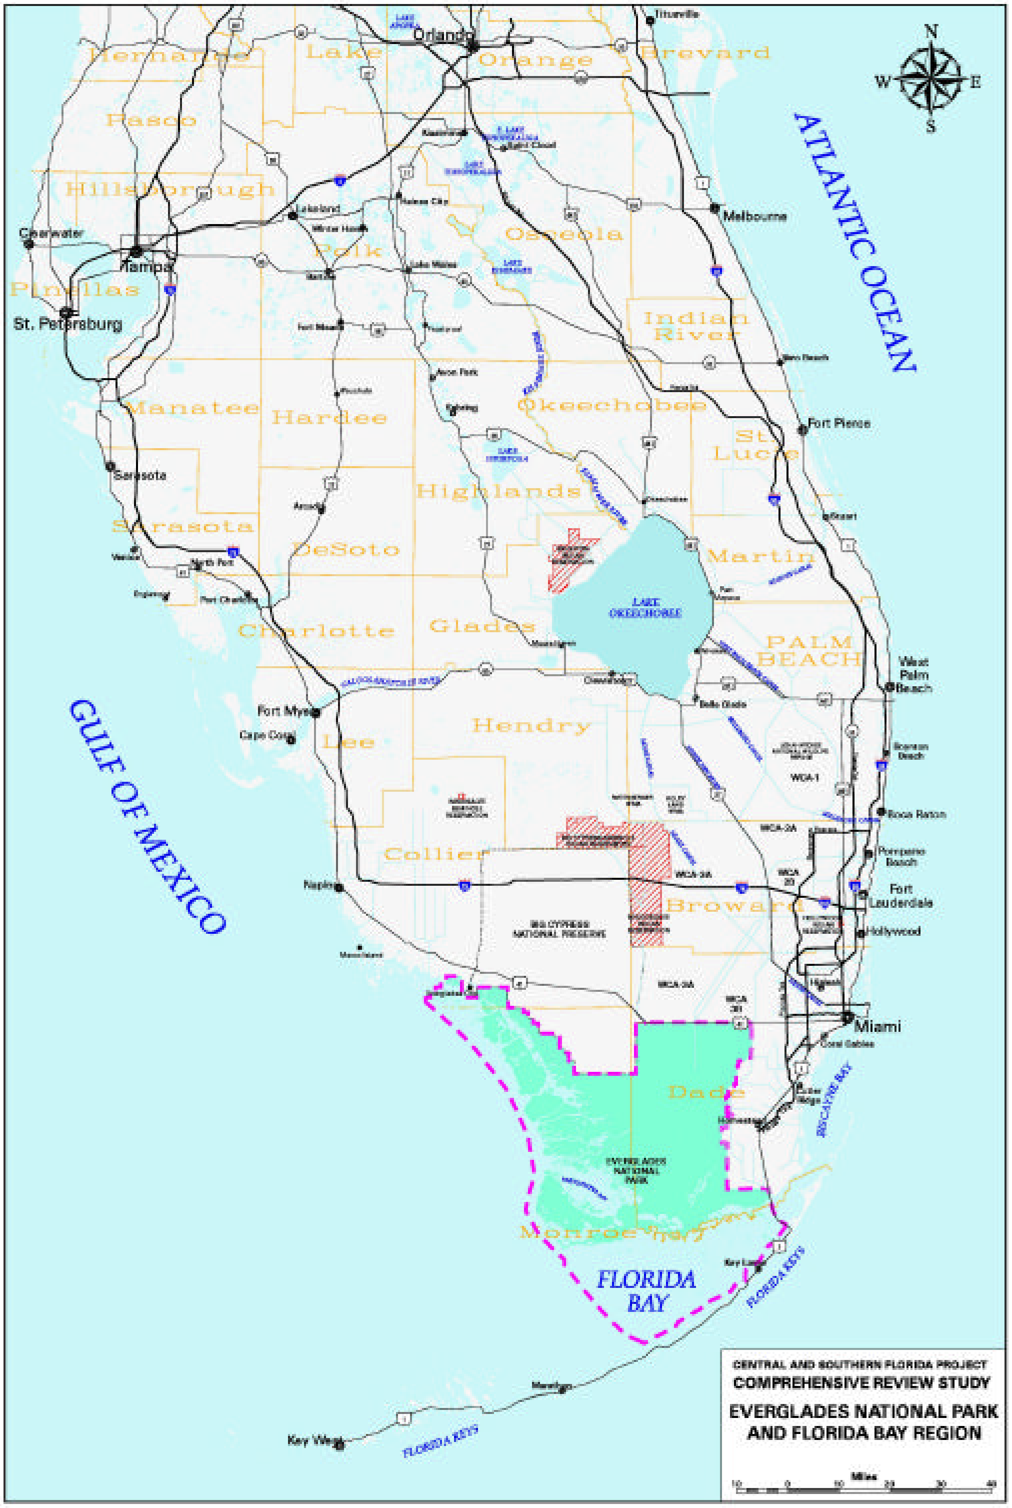

Figure J.8-1 Everglades National Park and Florida Bay Regions

J.8.1 Vegetation and Wetlands Communities

Everglades National Park covers most of the tip of south Florida. It is one of the largest freshwater wetlands in North America. ThePark contains a complex and diverse set of interdependent communities, all driven to a large extent by hydrology and fire (Gunderson and Loftus, 1993). Fire has been recognized as a dominant force in structuring pinelands, forests, and prairie communities. (Additional factors shaping Everglades communities are alligators, which actively keep open water available as refugia during the dry season (Fogarty, 1984); hurricanes (Armentano *et al*. 1995) and prior human use and disturbance. The diverse plant communities comprising the Everglades landscape have been grouped by a variety of methods and conventions. These communities are discussed here according to the conventions used by Gunderson and Loftus (1993).

J.8.1.1 Major Plant Communities

Major plant communities are generally divided between wetland and upland plant communities with further division into freshwater and marine or salt tolerant plants. Benthic communities of Florida Bay are discussed separately.

In the Everglades ecosystem and within Everglades National Park, plant communities are interspersed forming a vegetation mosaic. This heterogeneity is required to sustain the existing natural inter-relationships and natural diversity of Everglades National Park. The following list (***Table J-8.1.1-1***) of the principal plants of the major plant communities is derived from South Florida Water Management District (1992) and Gunderson and Loftus (1993) and was supplemented with other references. Major upland plant communities within Everglades National Park are; pine rockland, tropical hardwood hammock and salt tolerant coastal strand. Major wetland plant communities found within Everglades National Park, ranging from longest to shortest hydroperiod are; ponds, sloughs, sawgrass marsh, wet prairies, Bayhead/swamp Forest, willow heads, cypress forests. Saline wetlands found within Everglades National Park include *Batis* marsh, halophytic graminoid prairie, coastal transition marsh, coastal prairie, salt marsh, mangrove scrub forest, buttonwood scrub forest, mangrove forest, and buttonwood forest. Marine communities include; hard bottom, soft bottom, seagrass, mixed seagrass-macroalgal communities; and plankton (Schomer and Drew, 1982; SFWMD, 1992).

Table J-8.1.1-1 Characteristic Vegetation By Community Type Everglades National Park	
Community Type	**Characteristic Vegetation**
	Freshwater and Upland Communities
Wetland Communities	
Ponds- a. c.	(D) White water lily (*Nymphaea odorata*); (D) Floating heart (*Nymphoides aquatica*) Bladderwort (*Utricularia foliosa*); Water hyssop (*Bacopa caroliniana*) Fire flag (*Thalia geniculata*); Pickeral weed (*Pontederia cordata*);Spatterdock (*Nuphar luteum*)
Sloughs Long hydroperiod a. c.	(D) White water lily (*Nymphaea odorata*);(D) Floating heart (*Nymphoides aquatica*) Bladderwort (*Utricularia spp.*); Spatterdock (*Nuphar luteum*)
Sawgrass Marsh Tall a. c.	(D) Sawgrass (*Cladium jamaicense*); *Justicia angusta*; Spikerush (*Eleocharis cellulosa*) Cattail (*Typha latifolia*)
Sawgrass Marsh Intermediate height a. c.	(D) Sawgrass (*Cladium jamaicense*); Swamp lily (*Crinum americanum*); Arrow arum (*Peltandra virginica*); Spider lily (*Hymenocallis latifolia*);Shy leaf (*Aeschynomene pratensis*); Everglades morning glory (*Ipomoea sagittata*)

J.8.1.2 Physical and Physiographic Features

The Park is composed of two primary physiographic regions, the western Lower Everglades Basin and the more eastern Taylor Slough / Florida Bay Basin (Schomer & Drew, 1982). The Lower Everglades Basin has been further sub-divided into Shark River Slough, the Broad River / Lostman's River area, Coastal Swamps and Lagoons, and 4) Cape Sable. The Taylor Slough / Florida Bay Basin has been modified to include the Rocky Glades as part of this basin. The Taylor Slough / Florida Bay Basin is further sub-divided into six physiographic subzones: Rocky Glades; Taylor Slough Headwaters; Upper, Middle, and Lower Taylor Slough; Taylor Slough Coastal Drainage; Coastal Swamps and Lagoons; and Florida Bay. The Rocky Glades or Rocklands are a transition zone between Taylor and Shark Sloughs.

The two main natural water courses through Everglades National Park are Shark River Slough and Taylor Slough. Shark River Slough is a broad southwesterly trending arc of continuous wetland, interspersed with numerous tree islands. The area of freshwater wetlands to the west of Shark River Slough between the Everglades trough and the Big Cypress Basin is known as the Broad River / Lostmans River Drainage (Schomer and Drew, 1982). Taylor Slough is located east of Shark River Slough. It encompasses more than 158 sq. miles of freshwater marsh and extends approximately 20 miles, from its northern source in the rocky glades to Florida Bay (Van Lent, *et al.* 1993).

Florida Bay is a triangular-shaped bay that lies between the northern Florida Keys chain (to about Long Key) and the southern coast of the Florida mainland. It is a mosaic of banks, basins, and small islands. The general bottom contours grade from a depth of less than 1 meter in the east to 2 meters in the west. Basins are as deep as 3 meters, and are separated by a network of shallow, flat-topped banks. These irregular mud banks are the most conspicuous features of Florida Bay covering nearly 75 percent of western Florida Bay (Wanless and Tagett, 1989), and about 10 percent of the northeastern part of the Bay.

J.8.1.3 Plant Community Descriptions

Upland plant communities are restricted mostly to central areas of the main park and have been converted to agricultural area or residential areas within the East Everglades expansion area (SFWMD, 1992). Upland hammocks are found as a component of the freshwater matrix, in association with some portions of pinelands, and as coastal communities. Freshwater wetland communities include forested associations, graminoid (grassy or grasslike) communities and open water habitats (ponds and sloughs). Salt tolerant communities include saline wetland marshes and saline forest associations (mangroves). These communities are found within Everglades National Park in the southern areas bordering Florida Bay and on the Gulf coast in the Shark Slough – Broad River/Lostman's - Ten Thousand Island drainage. They are characteristic of the coastal swamps and lagoons, the lower Taylor Slough area and Cape Sable. These areas represent the downstream drainages of the major sloughs and water courses of Everglades National Park.

Upland Forests

Upland forest types include pine rocklands, tropical hardwood hammocks a coastal strand.

Pine Savanna or Pine Rocklands

Pine forests of Everglades National Park are characterized as a savanna and have an open overstory of south Florida slash pines (*Pinus elliotti* var. *densa*) (SFWMD, 1992). Pine savannas are fire adapted communities that depend upon fire as a controlling factor (Snyder *et al*., 1990). They are greatly reduced in cover, in comparison to historic cover, within Miami-Dade county (SFWMD, 1992). The largest remaining intact pine forests in the region are found within Everglades National Park (Gunderson and Loftus, 1993). The pine rockland habitat has a high species richness within the understory, with approximately 186 species in this association, so that it is the most naturally diverse community within Everglades National Park (SFWMD, 1992).

Tropical Hardwood Forests

These upland forests are locally called hardwood hammocks. They are dominated by a mix of south temperate and West Indian species and represent the most diverse tree association in Everglades National Park (Snyder *et al*., 1990; Gunderson and Loftus, 1993). Hammocks are found in association with pine forests, occur on elevated outcroppings on the upstream side of some tree islands, and are found in association with the saline areas of Everglades National Park. Their species composition is influenced by regional gradients in rainfall, minimum temperature, fire, hurricanes, salinity gradients, surrounding vegetation types, and elevation and character of the underlying limestone. Royal Palm hammock, found adjacent to Taylor Slough, is one of the largest and most distinct hammocks in Everglades National Park. It is distinguished by emergent royal palm trees, *Roystonea elata* and the fact that it was the first protected as a state park in 1916, which was later expanded to what would become Everglades National Park (Small, 1916; Beard, 1938; SFWMD, 1992). These sites have a history of habitation by native American populations and are often the site of archeological artifacts (Beard, 1938; Davis, 1943a).

At least 120 hardwood hammocks are found in conjunction with the pine forests of Long Pine Key (Johnson *et al*. 1983; Olmsted *et al*. 1983). The dominant overstory trees in the hammocks of Long Pine Key are live oak (*Quercus virginiana*), wild tamarind (*Lysiloma latisiliquum*), and gumbo limbo (*Bursera simaruba*). These trees attain heights of 60 feet (18 meters) and diameters of 6.6 feet (2 meters) (Olmsted *et al*. 1981). Other, less common, tree species in the overstory include sugarberry (*Celtis laevigata*), mastic (*Mastichodendron foetidissimum*), and mahogany (*Swietenia mahogani*)(in the southern hammocks). Trees commonly found in hammocks include willow bustic (*Bumelia salicifolia*), lancewood (*Nectandra coriacea*), many species of stoppers (*Eugenia* spp.), pigeon plum (*Coccoloba diversifolia*), marlberry (*Ardisia escallonioides*) (Gunderson and Loftus, 1993; Snyder et al., 1990). Few plants are found on the ground in intact hammocks due to heavy shading by the dense canopy (Snyder *et al*., 1990). Most of the herbaceous flora are epiphytes, including vines, orchids, and bromeliads (SFWMD, 1992).

Coastal Strand

This vegetation is found on coastal dune located behind the saltmarsh or halophytic zone behind the foredune (Johnson and Barbour, 1990). It is influenced by its proximity to saltwater and exposed coast. This area is characterized by Jamaica dogwood (*Piscidia piscipula*), blackbead (*Pithecellobium keyensis*), and West Indian bluestem (*Schizachyrium semiberbe*) with less frequently occurring sea grape and saw palmetto (Johnson and Barbour, 1990).

Freshwater Wetland Vegetation Complex

Freshwater wetlands of the Everglades include forested and non-forested communities. The forested wetlands include bayheads, willow heads, and cypress forests. The nonforested or herbaceous wetlands of Everglades National Park include sawgrass marshes, wet prairies, ponds, and open water sloughs.

Bayhead/Swamp Forests

The clumps of broad-leafed trees that stand out over the low, flat prairies of the Everglades are collectively called tree islands. Tree islands form over slightly elevated areas of peat, marl or rock, where flooding is less frequent than in the surrounding herbaceous marsh. Average annual flooding duration in these forests is 1 - 4 months. Many of the hardwood species cannot sustain prolonged flooding (Gunderson *et al.* 1988). Tree islands primarily contain wetlands species, although some rocky outcrops of relatively higher elevation support tropical hardwood hammocks. The larger tree islands within Everglades National Park are in the shape of an elongated teardrop, generally oriented with the main axis parallel to the main axis of surface water flow. The bayhead or swamp forest is the most common and abundant forested wetland type in Everglades National Park.

Typically, a two "bay" species are canopy co-dominants in this association, hence the name bayhead. Dominant canopy species include red bay (*Persea borbonia*), swamp bay (*Magnolia virginiana*), dahoon holly (*Ilex cassine*), pond apple (*Annona glabra*), and wax myrtle (*Myrica cerifera*). Other, less common species include willow (*Salix caroliniana*) and strangler fig (*Ficus aurea*). These canopy species attain heights of between 26 to 33 feet (8 to10 meters) (Olmsted *et al.* 1980). A dense shrub layer is generally found beneath the canopy, composed primarily of cocoplum (*Chrysobalanus icaco*) but including smaller individuals of the above mentioned overstory species. Other plants in the shrub stratum include buttonbush, (*Cephalanthus occidentalis*) and the large leather fern (*Acrostichum danaeifolium).* The soils in swamp forests are primarily gandy peat, with measured depths of 1 foot to 6.6 feet (30 to 200 centimeters) (Olmsted *et al.* 1980). The surficial soils are composed mainly of decomposing leaf material from the extant vegetation.

Willow Heads

Stands of southeastern coastal plain willow (*Salix caroliniana*) are also called willow heads. These stands have a monospecific overstory and understory, with willow the dominant woody plant. Other, less common, associated herbaceous taxa include phragmites (*Phragmites australis*), sawgrass, and flag (*Thalia geniculata*). Herbaceous vines such as *Sarcostemma clausa*, hemp-vine (*Mikania scandens*), and *Ipomoea sagittata* are commonly found. Willow heads are found on sites with a history of severe soil disturbance, such as a peat fire, lumbering, farming, or alligator excavation (Craighead, 1968a&b). Willow heads are common in the northern central areas of Taylor Slough (Olmsted *et al.* 1980). Large areas of willow are found along the western edges of the Shark Slough, where severe fires burned through bayheads during the early 1970s (Gunderson *et al.* 1987). Willow is also commonly found around alligator holes or ponds. Craighead (1968b) reports that willow is much more widespread now than in previous times, due to changes in the hydrology and impacts of dry season fires. According to Hilsenbeck *et al.* (1979), willow thickets are ecologically important because they serve as feeding, resting, and roosting habitats for many of the herons, egrets, and other wading birds.

Cypress Forests

Cypress forests are relatively minor features of Everglades National Park, occurring east and west of the Long Pine Key area. Two types of forests occur, domes and cypress prairie (Gunderson and Loftus, 1993). Both are dominated by pond cypress (*Taxodium ascendens*). Domes of pond cypress occur in bedrock depressions in northern Taylor Slough (Rintz and Loop, 1979). The domes are characterized by dense stands of pond cypress with diameters up to 1.6 feet (50 centimeters) and heights to 80 feet (25 meters). The domes with lowest soil surface elevations support little other flora, except perhaps a few aquatic species. Domes with higher soil elevations support many of the hardwood species found in bayheads including red bay, swamp bay, wax myrtle, and cocoplum, and have been called cypress heads (Olmsted *et al.* 1980). Cypress prairies of the Everglades were first described by Small (1932). These forests have also been described as dwarf or hatrack cypress (Craighead, 1971). The cypress trees attain heights of less than 16 feet (5 meters) and diameters of less than 8 inches (20 centimeters). The trees are widely spaced. Understory plants include sawgrass, muhly grass, and other herbs and grasses (Rintz and Loope, 1979).

Herbaceous Wetlands

Herbaceous wetland types include sawgrass marshes, wet prairies, sloughs and ponds. Arranged by hydroperiod, wet prairies have the shortest inundation period and ponds and creeks the longest.

Sawgrass Marshes

Sawgrass (*Cladium jamaicense*) is a characteristic plant of the freshwater everglades marsh. Sawgrass marsh is the dominant cover type of the freshwater Everglades. This association is characterized by primarily monotypic stands of sawgrass. Sawgrass grows best on deep peat soils, which result in tall marsh. When it is found on shallower depths of peat a smaller plant form results (Gunderson and Loftus, 1993). It is well adapted to variable flooding and fire regimes. However if exposed to prolonged high water levels during flood conditions, it looses viability (Gunderson and Loftus, 1993; Davis, 1989; Hofstetter and Parsons, 1979). Sawgrass' low nutrient requirements allow it to survive in the oligotrophic waters of the Everglades (Steward and Ornes, 1975.

Wet Prairies

These communities are a group of low-stature marshes defined by soil type and dominant plant species. They include spikerush (*Eleocharis)* marshes, beakrush (*Rhynchospora)* flats, maidencane (*Panicum hematomon)* flats associations that occur over peat soils while marl prairies are dominated Muhley grass and sawgrass (Gunderson and Loftus, 1993). Wet prairie communities occur in Everglades National Park in the central areas of both Shark and Taylor Sloughs as well as in portions of the park expansion area. Loveless (1959) described the associations over peat as Eleocharis, Rhynchospora, and Maidencane flats. Craighead (1971) described them as spikerush and sedge flats. Common emergent aquatic plants in these wet prairies include spikerush (*Eleocharis cellulosa*), beak rush (*Rhynchospora tracyi),* maidencane (*Panicum hemitomon*), arrowhead (*Sagittaria latifolia*), and pickerel weed (*Pontederia cordata*).

The wet prairies over marl are a conspicuous feature of Everglades National Park. Marl prairies occur on the east and west margins of Shark and Taylor Sloughs and in the east Everglades park expansion area. In these areas bedrock elevations are slightly higher and hydroperiod shorter. These communities have been called the southern coastal marsh prairies (Davis 1943a), southeast saline Everglades (Egler 1952), marl Everglades (Kuchler, 1964), marl prairies (Harper, 1927; Werner, 1976; Olmsted and Loope, 1984) and *Muhlenbergia* prairies (Olmsted *et al.* 1980). Most of the marl prairies in Everglades National Park are dominated by the species muhly grass (*Muhlenbergia filipes*) and sawgrass (SFWMD, 1992). Other locally dominant species in this community include the black top sedge (*Schoenus nigricans*), *Aristida purpurascens*, narrow beardgrass, and *Eragrostis elliotti* (SFWMD, 1992). Beak rush is common in the lower, wetter areas of the marl prairies (Gunderson and Loftus, 1993).

Sloughs

Slough communities are deep water areas dominated by floating aquatic plants. These associations are found on the lowest, wettest sites in the central portions of Shark River and Taylor Sloughs. Dominant plants include white water-lily (*Nymphaea odorata*), floating hearts (*Nymphoides aquatica*), and spatterdock (Gunderson and Loftus, 1993). The remainder of the flora in these associations are composed of submerged aquatics plants, primarily bladderworts (*Utricularia foliosa* and *U. biflora*) and periphyton. These submerged aquatic communities provide structure for attachment by periphyton and are a key component in what is described as the periphyton mat complex.

Ponds and Creeks

Ponds are small, typically less than 2.5 acres (1 hectare), open water areas scattered throughout the Everglades with little or no macrophytic vegetation. The ponds are often bordered by spatterdock (*Nuphar luteum* subsp. *macrophyllum*), water lilies (*Nymphaea* spp.), fire flag (*Thalia geniculata*), pickerel weed (*Pontederia cordata*), and woody plants such as willow or primrose-willow (*Ludwigia peruviana*) (Gunderson and Loftus, 1993). Creeks are open water areas found in the southern portions of the Everglades National Park occurring at the interface of the freshwater and saline zones originating in the freshwater marshes.

Periphyton

"Periphyton" is a general term, which is used here to describe the algal assemblages in the open-water areas of the Everglades. This community is most abundant in sloughs but is found in all marsh and prairie associations of the everglades. Hydroperiod and water chemistry determine the species composition of the periphyton community whose algae precipitate calcium carbonate from water forming the calcitic mud or marl found in marl prairies (Gleason, 1972; Swift, 1984). The algal assemblage of this community is structured by characteristics of the areas in which they occur including; hydroperiod, water chemistry, nutrient availability, and soil composition (Browder *et al*., 1981; Swift, 1984). Calcareous blue-green algae and diatoms dominate the community in shorter hydroperiod sites, which are more alkaline and higher in carbonates (Browder *et al.* 1981). Periphyton provide primary production which forms the basis of the detrital based food web of the Everglades while also influencing oxygen levels in free water and acting as biological mediators in nutrient cycling (Hunt, 1961; Brock, 1970; Wilson, 1974; Wood and Maynard, 1974; Gleason, 1972 Browder *et al.* 1982).

Saline Wetlands

The salt influenced area of Everglades National Park consists of halophytic marshes, prairie, and forest communities. Although most of these area are tidally influenced, soil salinity is believed to be the major determinant of the vegetation (SFWMD, 1992). Salinity in the coastal zone ranges from freshwater in the upland waters during the rainy season, to hypersaline (saltier than seawater) during extreme droughts. Saline wetlands include the areas characterized as coastal swamps and lagoons, Cape Sable, and lower Taylor Slough by Schomer and Drew (1982). This area parallels the coast and reaches a maximum width of 15 miles in the area of Shark River and tapers to the east and west (Craighead, 1971).

Saline Wetland Marshes

The herbaceous communities of the saline zone include *Batis* marshes, coastal prairies, and salt marshes. This area was described by Davis (1943a) as saltmarsh and serves as a transition habitat between the mangroves and the strickly freshwater marshes upstream. The salt marshes include both *Juncus* and *Spartina* marshes. The black rush (*Juncus roemarianus*) and fringe rush (*Fimbristylis castanea*) dominate the *Juncus*-gulf cordgrass marshes. *Spartina* marshes with greater freshwater influences are dominated by sand cordgrass (*S. bakeri*); whereas in the more saline areas gulf cordgrass (*S. spartinae*) dominates. Common plants in the *Batis* marshes include *Batis maritima*, glass wort (*Salicornia virginica*), and sea-purselane (*Sesuvium portulacastrum*). McPherson (1973) described this area as “salt water prairies”. Coastal prairies are dominated by gulf cordgrass and sea-oxeye (*Borrichia frutescens*).

Saline Forest Associations - Mangrove Forests

Three species of mangroves occur in Everglades National Park: red mangrove (*Rhizophora mangle*), black mangrove (*Avicennia germinans*), and white mangrove (*Laguncularia racemosa*). Buttonwood (*Conocarpus erectus*) also occurs in similar habitats and so is considered to be a mangrove associate (Odum and McIvor, 1990). Mangrove forests can occur as monospecific stands dominated by one of these species and also as mixed forests including combinations of these species (SFWMD, 1992). Additional species that may be present in the understory vegetation include: antwood (*Bumelia angustifolia*), joewood (*Jacquinia keyensis*), christmas berry (*Lycium carolinianum*), rubber vine (*Rhabdadenia biflora*), moonflower (*Ipomoea tuba*), and sawgrass (SFWMD, 1992). Scrub mangrove associations are primarily composed of trees 3-6 feet tall (1 to 1.5 meters) (Craighead, 1971). Buttonwood tree islands are scattered throughout the saline mangrove zone growing on soil elevations 1.5-3 feet above high tide (Craighead, 1971).

The mangroves cover extensive areas of coastal swamps and lagoons, higher points on the mud islands of Florida Bay, Cape Sable and the Ten Thousand Island area. Distribution of stand types within the mangrove zone is determined by topography, salinity gradients, lightning strikes, human disturbance (such as lumbering), and hurricanes (Craighead, 1971; Odum and McIvor, 1990)Currently the largest trees are found in the areas along banks of rivers where organic soil depths are greatest. Along the inland (freshwater) margin of the mangrove forests, large areas of stunted red mangroves are found. At these sites, the mangroves only attain heights of 6.6 feet or less. Distribution of buttonwood is controlled primarily by topography, this species is primarily found on higher ground (Odum and McIvor, 1990). Buttonwood is the least salt-tolerant of New World "mangrove" species. The mangrove islands of Florida Bay show a zonation typical of mangrove islets, (Lugo and Snedaker, 1974) with an outer fringe of red mangrove, growing on a raised berm, often encircling a central hypersaline mud flat or lagoon. Succulent salt-tolerant herbs often colonize the inner lagoon or shrubs, including stunted black mangroves or *Batis*.

Benthic Marine Communities

Benthic communities of Everglades National Park are found in Florida Bay, Whitewater Bay, the coastal lagoons of the mangrove fringe of Florida Bay and along the Ten Thousand Island area of Everglades National Park. Benthic communities can be divided into mud, bank top, seagrass (sparse, intermediate, and dense), hard bottom, and submerged macroalgal ("seaweed") communities. Parts of the west coast and interior lake areas have mud bottoms that are bare or sparsely vegetated. Plant cover in these coastal benthic communities is likely controlled by salinity, temperature, hydroperiod (for emergent communities) and interactions among these factors. For instance, hypersaline, shallow areas can develop greatly elevated water temperatures during periods of high sunshine, effectively limiting the species that can colonize and become established there.

Bank habitat is found at depths of less than 2 feet on mud banks throughout Florida Bay. Its plant cover inlcudes including mixed algal - seagrass communities. It is subject to periodic exposure during extreme low tide and wind events (Prager and Halley, 1997a). Turtle-grass (*Thalassia testudinum*) is the dominant species. Shoal-grass (*Halodule wrightii*) and manatee-grass (*Syringodium filiforme*) occur where conditions prevent dense seagrass growth . Hard bottom communities are characterized by less than 5 cm of sediment covering limestone bedrock. Dominant components of this community are gorgonians, sponges, calcareous algae and some stony coral of the genera *Siderastrea* and *Solenastrea* (Prager and Halley, 1997). The macroalgal community is characterized dominance of the following species: *Laurencia* spp., *Batophora* spp., and *Acetabularia* spp. Factors controlling distribution of benthic flora and fauna in Florida Bay include light penetration, temperature, and nutrient availability (Lapoint, 1989).

Since 1987, there has been a significant loss of turtle grass cover in Florida Bay. There have also been frequent occurrences of algal (plankton) blooms, which diminish water clarity. These changes are of concern because of the seagrass beds' importance as habitat for pink shrimp and commercially significant fish. Research on the causes of the massive seagrass die-off is ongoing, but it is believed partly due to spread of a slime mold. This pathogen appears to affect mostly stressed plants, especially in hypersaline areas (Everglades National Park, 1997). Mass mortality of the turtlegrass plants releases nutrients into the water column, which may also be responsible for triggering algal blooms.

J.8.2 Fish and Wildlife

The following section is a discussion of the fish and wildlife resources found within Everglades National Park and Biscayne Bay.

J.8.2.1 Faunal Groups

Fish and wildlife communities are dependent upon habitat types and upon the natural hydrologic cycle for their continued healthy survival. This section contains a brief description of the major faunal groups within Everglades National Park and then a description by habitat type.

Invertebrates

Although the invertebrate community is of primary importance in sustaining the food webs of the Everglades, comparatively little information is available on the invertebrates of the Everglades. Important members of this community include amphipods, dragonflies, mayflies, flies, water beetles and water bugs (Kushlan, 1990). Macroinvertebrates are important components of the aquatic food chains and are represented by prawns, crayfish (*Procambarus alleni*), and snails such as the apple snail (*Pomacea paludosus*) and *Ligus* tree snails.

Fish

The fish fauna of the Everglades is listed as comparatively depauperate with most species derived from the North American temperate freshwater fauna (Kushlan, 1990). Primarily important species are listed by habitat in ***Table J-8.2.1.2-1.***

Reptiles and Amphibians

At least 44 species of amphibians and reptiles occur within the Everglades (Duellman and Schwartz, 1958; Dalrymple, 1988). Most of the herpetofauna are reptiles (30 species), with snakes comprising the majority of these species (16 species) other species include 9 species of turtles and 5 species of lizards (Duellman and Schwartz, 1958; Dalrymple, 1988). Fourteen species of amphibians have been recorded (Duellman and Schwartz, 1958; Dalrymple, 1988).

Birds

Robertson and Kushlan (1984) indicate that even though nearly 400 species of birds have been recorded in southern Florida, the regional avifauna is characterized by about 300 taxa. Of these species listed approximately 60 percent are wintering and migrant birds while about 116 species comprise the native breeding avifauna. A checklist of the birds of Everglades National Park lists 347 taxa (Robertson *et al*. 1984). Toops and Dilley (1986) also provided a broad overview of bird life in southern Florida with emphasis on the Everglades. The heron (*Ardeidae*) and hawk (*Accipitridae*) families are the most speciose groups in Everglades National Park (Gunderson and Loftus, 1993).

Table J-8.2.1.2-1 **Common Fish Species By Habitat Type** (After Gunderson And Loftus, 1993)				
Common Name	Species	Eleocharis Marsh	Ponds	Sawgrass

Uncommon (UC), Common (C)

Mammals

Schwartz (1952) and Layne (1984) listed the mammals that occur within the Everglades National Park. Layne (1984) lists up to 30 species, which have been seen or collected. The most diverse group of mammals is the carnivores, while the most abundant group is the rodents (Layne, 1984). A noted feature of the mammal fauna is the near absence of bats (Layne, 1984).

J.8.2.2 Habitats

Habitat types can be divided based upon hydroperiod since these two components determine animal usage to a large extent. Most animals can use a variety of plant communities and range across the landscape on differing scales depending upon their biology and ecological requirements. Habitats discussed are slightly different from those appearing in ***Table J-8.2.1.2-1*** and are more closely based on hydroperiod. Large portions of this material are derived from the Surface Water Improvement and Management Plan on the Everglades (SFWMD, 1992) and from internal Park information.

Table J-8.2.2-1
Resident Organisms By Habitat
(After SFWMD, 1992)

Species	**Occurrence**
Hardwood Hammock	
Bobcat (*Lynx rufus*)	Resident, widely ranging
Grey fox (*Urocyon cineroargenteus*)	Resident
Striped skunk (*Mephitis mephitis*)	Resident
Raccoon (*Procyon lotor*)	Resident, especially during high water
Opossum (*Didelphis marsupialis*)	Resident, especially at high water
Cotton mouse (*Peromyscus gossypinus*)	Resident
Hispid Cotton rat (*Sigmadon hispidus*)	Resident
Marsh rabbit (*Sylvilagus palustris*)	Resident
White tailed deer (*Odocoileus virginianus*)	Resident, especially at high water
Red Shouldered Hawk (*Buteo lineatus*)	Resident; important nesting site
Great Blue Heron (*Ardea herodias*)	Nests in Bayheads
Barred owl (*Strix varia*)	Resident
Blue-Grey Gnat catcher (*Polioptila caerulea*)	Winter resident
Various warblers (*Parulidae*)	Migrants, some winter residents
Cardinal (*Richmondena cardinalis*)	Resident
Penisula cooter (*Chrysemys floridana peninsularis*)	Uses edges for nesting
Red-bellied slider (*Chysemys nelsoni*)	Uses edges for nesting
Everglades rat snake (*Elaphe obsolet*	Resident

Table J-8.2.2-1 Resident Organisms By Habitat (After SFWMD, 1992)	
Species	**Occurrence**
rossalleni)	
Black racer (*Coluber constrictor*)	Resident
Florida kingsnake (*Lampropeltis getulus floridana*)	Resident
Southern leopard frog (*Rana sphenocephala*)	Breeds along flooded edges
Southern toad (*Bufo terrestris*)	Breeds along flooded edges
Sawgrass Marshes	
Rice Rat (*Oryzomys palustris*)	Resident
Cotton mouse (*Peromyscus gossypinus*)	More common in dry season
Hispid Cotton rat (*Sigmadon hispidus*)	More common in dry season
Marsh rabbit (*Sylvilagus palustris*)	Resident
King rail (*Rallus elegans*)	Resident
Limkin (*Aramus guarauna*)	Seasonal resident
Red-winged blackbird (*Agelaius phoeniceus*)	Resident
American bittern (*Botaurus lentiginosus*)	Winter resident
Long billed Marsh Wren (*Cistothorus palustris*)	Winter resident
Yellowthroat (*Geothlypis trichas*)	Resident
American Alligator (*Alligator mississippiensis*)	Important nesting site
Squirrel tree frog (*Hyla squirella*)	Resident
Green Anole (Anolis carolinensis)	Resident
Wet Prairies And Sloughs	
White tailed deer (Odocoileus virginianus)	Resident
Round tailed muskrat (*Neofiber alleni*)	Resident
Everglades mink (*Mustela vison evergladensis*)	Resident
Otter (*Lutra canadensis*)	Resident
Hispid Cotton rat (*Sigmadon hispidus*)	Resident
Cotton mouse (*Peromyscus gossypinus*)	Resident

Table J-8.2.2-1 Resident Organisms By Habitat (After SFWMD, 1992)	
Species	**Occurrence**
Wading birds (*Egretta* spp. *Ardea*, *Casmerodius*, *Nycticorax*)	Important dry season feeding areas
White Ibis (*Eudocimus albus*)	Feeds and breeds in shallow areas
Wood Stork (*Mycteria americana*)	Feeds in drying marshes
Common moorhen (*Gallinula chloropus*)	Feeds and nests in marshes
Pied-Billed grebe (*Podilymbus podiceps*)	Feeds and nests in winter
Belted Kingfisher (*Megaceryle alcyon*)	Winter resident
Boat tailed grackle (*Quiscalus major*)	Resident
Common grackle (*Quiscalus quiscula*)	Winter resident
Limkin (*Aramus guarauna*)	Resident
American Alligator (*Alligator mississippiensis*)	Resident
Greater Siren (*Siren lacertina*)	Resident
Southern cricket frog (*Acris gryllus gryllus*)	Resident
Pig frog (*Rana grylio*)	Resident, usually near ponds
Water snakes (*Nerodia* spp)	Resident
Wet Prairies (Marl)	
Striped crayfish snake (*Regina alleni*)	Resident
Black swamp snake (*Seminatrix pygemaea*)	Resident
White tailed deer (*Odocoileus virginianus*)	Resident
Hispid Cotton rat (*Sigmadon hispidus*)	Resident
Rice Rat (*Oryzomys palustris*)	Resident
Marsh rabbit (*Sylvilagus palustris*)	Resident
Florida panther (*Felis concolor coryi*)	Resident
Least shrew (*Cryptotis parva*)	Resident
American bittern (*Botaurus lentiginosus*)	Winter resident
Cattle Egret (*Casmerodius albus*)	Resident
Great Egret (*Casmerodius albus*)	Feeds in flooded prairies

Table J-8.2.2-1
Resident Organisms By Habitat
(After SFWMD, 1992)

Species	**Occurrence**
Red-Shouldered Hawk (*Buteo lineatus*)	Resident
King Rail (*Rallus elegans*)	Resident
Common Nighthawk (*Chordeiles minor*)	Summer nester
Eastern Meadowlark (*Sturnella magna*)	Resident, common in dry season
Yellowthroat (*Geothlypis trichas*)	Resident
Cape Sable Seaside sparrow (*Ammodromus maritima mirabilis*)	Resident
Green Anole (*Anolis carolinensis*)	Resident
Southern leopard frog (*Rana sphenocephala*)	Resident
Oak toad (*Bufo quercicus*)	Resident
Narrow-mouthed toad (Gastrophryne carolinensis)	Resident
Ponds And Creeks	
Round tailed muskrat (Neofiber alleni)	Nests along margins
Rice Rat (*Oryzomys palustris*)	Resident
Otter (*Lutra canadensis*)	Occasional
Wading Birds (*Egretta* spp, *Mycteria*, *Casmerodius*, *Eudocimus*)	Feed along margins at low water
Black crowned night heron (*Nycticorax nycticorax*)	Feeds and nests along pond edges
Anhinga (*Anhinga anhinga*)	Feeds and nests near ponds
Turkey Vulture (*Cathartes aura*)	Feeds along edges at low water
Purple Gallinule (*Porphyrula martinica*)	Feeds and nests in marginal vegetation
Boat tailed grackle (*Quiscalus major*)	Feeds and nests in marginal vegetation
American Alligator (*Alligator mississippiensis)*	Digs and maintains ponds
Water snakes (*Nerodia* spp)	Common at low water
Florida Softshelled turtle (*Trionyx ferox*)	Resident
Two Toed amphiuma (*Amphiuma means*)	Resident
Pig Frog (*Rana grylio*)	Resident

Table J-8.2.2-1 Resident Organisms By Habitat (After SFWMD, 1992)	
Species	**Occurrence**
Southern Leopard frog (*Rana sphenocephala*)	Resident
Peninsula newt (*Notophthalmus viridescens*)	Resident

Upland-Rockland Habitats

Upland habitats include primarily tropical hardwood hammocks and rockland pine forests, which together comprise rockland ecosystems. General resident organisms utilizing this habitat are listed in Table J-8.2.2-1. Most truly terrestrial animals are found in these communities, generally utilizing both habitats. Some animals, however, may utilize either tropical hardwood hammocks or rockland pine forests exclusively. Large mammals with the need for broad home ranges such as the Florida panther (*Felis concolor coryi*), the black bear (*Ursus americanus floridanus*) and white-tailed deer (*Odocoileus virginianus*) utilize both upland habitat types as well as other seasonally inundated wetlands. Small rodent utilizing hammocks include the cotton mouse (*Peromyscus gossypinus*), the hispid cotton rat (*Sigmadon hispidus*), and the rice rat (*Oryzomys palustris*). These animals have been documented to occur in densities of 117, 27, and 19 individuals per hectare (Smith and Vrieze, 1979). Other mammal utilizing these tropical hammocks beyond those listed in Table J-8.2.2-1 include shrews (*Blarina* sp.) and the grey squirrel (*Sciurus carolinensis*) (SFWMD, 1992).

Native vertebrate fauna of south Florida rockland ecosystems is primarily derived from southeastern temperate North American fauna (Robertson, 1955; Duellman and Schwartz, 1958; Robertson and Kushlan, 1984; Layne, 1984; Snyder *et al*., 1990). Examples of this fauna include, the southern toad (*Bufo terrestris*), the green tree frog (*Hyla cineria*), the black racer (*Coluber constrictor*), the rough green snake (*Opheodrys aestivus*), the green anole (*Anolis caroliniensis*), the red bellied woodpecker (*Melanerpes carolinus*), the Carolina wren (*Thryothorus ludovicianus*), the pine warbler (*Dendroica pinus*), the northern cardinal (*Cardinalis cardinalis*), the opossum, the hispid cotton rat, the raccoon and the white-tailed deer (Snyder *et al*., 1990; Gunderson and Loftus, 1993). The West Indian vertebrate fauna is limited in the areas of southern Florida and found mostly in the Florida Keys, islands in Florida Bay, and the southern most extent of the peninsula and along the Miami rockridge (Snyder *et al*., 1990). Some examples of this fauna include the black-whiskered vireo (*Vireo altiloquus*), the white crowned pigeon (*Columba leucocephla*), the smooth-billed ani (*Crotophaga ani*), the grey kingbird (*Tyrannus dominicensis*), and the mangrove cuckoo (*Coccyzus minor*) (Snyder *et al*., 1990).

Wetland Forest Habitats

This habitat includes bayheads, cypress forests, willow heads, swamp forests, and pond apple forests. These communities are forests in a marsh or wet prairie matrix, and as such are surrounded by emergent vegetation of low stature and longer hydroperiod. These habitats can be used as roosting or nesting sites contiguous to surround marshes used for foraging. General resident organisms utilizing this habitat are listed in Table J-8.2.2-1. Common breeding birds utilizing this habitat include the Anhinga (*Anhinga anhinga*), the green-backed heron (*Butorides striatus*), the black-crowned night heron (*Nycticorax nycticorax*), and the boat tailed grackle (*Quiscalus major*) (SFWMD, 1992; Gunderson and Loftus, 1993). Other common vertebrates include raccoons, opossums, the river otter (*Lutra canadensis*), white tailed deer, water snakes (*Nerodia* spp), and the green anole (SFWMD, 1992). Kushlan and Kushlan (1977) listed thirty-eight species of birds as utilizing wetland forest habitats, including thirteen species of breeding birds.

Prairies

Prairies are short to intermediate hydroperiod habitats. They comprise an important habitat type within the Everglades and Everglades National Park. General resident organisms utilizing this habitat are listed in Table J-8.2.2-1. These seasonally inundated prairies can occur over marl or peat substrate. Within Everglades National Park these prairies have a relatively high variation in topography with solution holes forming aquatic refugia within the shorter hydroperiod prairies (Loftus and Kushlan, 1987; Dalrymple, 1988). Prairies form an important habitat and support a diverse herpetofauna. Duellman and Schwartz (1958) recorded 46 species of reptiles and amphibians in this habitat. Dalrymple (1988) found the most common reptiles and amphibians in this habitat to be the green anole, the leopard frog, and the oak toad (*Bufo quericus*). This habitat type has had some of the highest development pressure within the system on it. Everglades National Park has a large proportion of the remaining short hydroperiod prairies within the south Florida system. Due to their hydroperiod, they are the first marshes to dry out and as such offer wading birds forage habitat following the drying front. This habitat is extremely important to wading birds, which depend upon it for forage habitat. Wet prairie habitat within Everglades National Park is designated as critical habitat for the Cape Sable Seaside sparrow. The Florida panther also uses the shallow and short hydroperiod portions of these prairies for forage and crosses them regularly.

Marshes

Marshes are longer hydroperiod wetlands which may be made up predominantly of sawgrass or mixed graminoid marshes. General resident organisms utilizing this habitat are listed in Table J-8.2.2-1. These areas have more open water components and are extremely important to wading birds and some mammals. Although sawgrass marshes are generally poorer habitat some animals utilized them seasonally. Animals utilizing sawgrass marshes include the American bittern (*Botaurus lentiginosa*), the long-billed marsh wren (C*istothorus palustris*), the Limpkin (*Aramus guarauna*), and the American alligator (*Alligator mississippiensis*) (Craighead, 1968a; Fogarty, 1984; Kushlan and Kushlan, 1980; Gunderson and Loftus, 1993).

Marsh habitats other than sawgrass marshes are utilized by a variety of water birds and wading birds. These birds include the Wood Stork (*Mycteria americana*), Great egret (*Casmerodius albus*), Snowy Egret (*Egretta thula*), White ibis (*Eudocimus albus*), Glossy ibis (*Plegadis falcinellus*), Great blue heron (*Ardea herodias*), Green-backed heron (*Butorides striatus*), Tri-colored heron (*Hydranassas tricolor*), Black-crowned night heron (*Nycticorax nycticorax*), Least bittern (*Ixobrychus exilis*) and American bittern (Kushlan and Kushlan, 1977; Gunderson and Loftus, 1993). Other animals important in these marshes include the Snail kite (*Rostrhamus sociabilis*), the pig frog, cricket frog (*Acris grylio*), water snakes, peninsular newt, and several sirens (Gunderson and Loftus, 1993).

Ponds and Sloughs

Ponds and creeks have the longest hydroperiod of the freshwater habitats available. They are generally wet in all but the driest of drought years. General resident organisms utilizing this habitat are listed in Table J-8.2.2-1. Many natural ponds are either created or maintained by alligators (Craighead, 1968a &b; Kushlan, 1974). Large salamanders, turtles, and snakes inhabit these aquatic systems (Gunderson and Loftus, 1993). Water levels of these areas affect their usage by birds. Wading birds use sloughs depending upon the time in the water year. Sloughs are used during periods of high water by birds such as the common Moorhen (*Gallinula chloropus*), the pied-billed grebe (*Podilymbus podiceps*), Anhinga (*Anhinga anhinga*) and the limpkin. Common mammals in this habitat include the river otter and the round tailed muskrat while many others may use the edges during dry conditions (Craighead, 1968b).

J.8.2.3 Mangroves and Coastal Ecosystems

Twenty-four species of amphibians and reptiles have been identified in marine, mangrove, wetland and upland habitats (Odum *et al*., 1982). The mangrove and coastal ecosystems are habitat to a variety of amphibians and reptiles including: various species of frogs, the Diamondback terrapin (*Malaclemys terrapin rhizophorarum*) and (*Malaclemys terrapin macrospilota*), the American crocodile (*Crocodylus acutus*), the Eastern indigo snake (*Drymarchon corais couperi*), the Miami black-headed snake (*Tantilla oolitica*), and the mangrove water snake (*Nerodia fasciata compressicauda*) (SFWMD, 1992; Snyder *et al*., 1990).

Odum *et al*. (1982) listed 181 birds that utilize the south Florida mangrove zone, and classified them into six categories based on feeding habits: wading birds, probing shorebirds, floating and diving water birds, aerially searching birds, birds of prey, and arboreal birds. Wading, aerially searching, and floating and diving birds are the most prominent. The tricolored heron (Louisiana heron) (*Egretta tricolor*) and snowy egret (*Egretta thula*) are the most abundant wading birds, while the white ibis (*Eudocimus albus*) and wood stork are found less frequently (Kushlan, 1979; Schomer and Drew, 1982). The double-crested cormorant (*Phalacrocorax auritus*) is the most prominent floating and diving bird. Of the 25 probing shorebird species, only two, the Wilson's plover and willet, are permanent residents of the mangrove zone. Most of the surface and diving birds are present all year (Odum *et al*., 1982). Nesting colonies of aerially searching birds are restricted to the mangrove islands of Florida Bay, but utilize the inland mangrove zone for foraging. Mammals utilizing this habitat include the Manatee (*Trichechus manatus*), the everglades fox squirrel (*Sciurus niger avicennia*), the everglades marsh rabbit (*Sylvilagus palustris*), and the bobcat (Gunderson and Loftus, 1993).

J.8.2.4 Exotic Fauna

Habitat disturbance and introduction of non-native species are known to be primary sources of exotic fauna within south Florida. Much of the exotic fauna within south Florida was either transported unintentionally in international shipments of goods or occurred as part of the trade in exotic species (SFWMD, 1992). These sources have resulted in the survival of reproductively viable colonies of exotic fauna. Some restoration components may affect the existing balance of these organisms. Species of exotic fish known to breed in Everglades National Park are listed in ***Table J-8.2.4-1***. Exotic species within Everglades National Park include wild hog (*Sus scrofa*), house mouse (*Mus muscalus*), nine banded armadillo (*Dasypus novemcinctus*), red fox (*Vulpes vulpes*), jaguarundi (*Felis yagouroundi*), red whiskered bulbul (*Pysnonotus jocosus*), Hill myna (*Gracula religiosa*), five species of parrots, Blue-Grey Tanager (*Thraupis episcopus*), java sparrow (*Padda oryzivora*), starling (*Sturnus vulgaris*), cuban tree frog (*Hyla septentrionalis*), marine toad (*Bufo marinus*), five type of geckos, and five types of anoles (SFWMD, 1992).

J.8.3 Hydrology

The hydrology of Everglades National Park is dependent upon the underlying formations and resulting hydrogeology. This portion of the everglades is underlain by a shallow unconfined surficial aquifer, the Biscayne, and a deep confined brackish aquifer, the Floridan (SFWMD, 1992). The shallow unconfined Biscayne Aquifer serves as the primary source of groundwater to Everglades National Park and is the sole source aquifer for drinking water for Miami-Dade, Broward, and Monroe counties.

Table J-8.2.4-1 Exotic Fish Breeding In Everglades National Park By Habitat			
	Taylor Slough	Shark Slough	Estuarine Zone
Family Clariidae Walking catfish (*Claris batrachus*)	X	X	X
Family Poeciliidae Pike killifish (*Belonesox belizanus*)	X	X	X
Family Cichlidae			
Oscar (*Astronotus ocellatus*)	X	X	
Black acara (*Cichlasoma bimaculatum*)	X	X	
Mayan cichlid (*Cichlasoma urophthalmus*)	X	X	X
Blue tilapia (*Oreochromis aureus*)	X	X	X
Spotted tilapia (*Tilapia mariae*)	X	X	X
Mozambique tilapia (*Oreochromis mozambicus*) *	X		
Butterfly Peacock bass (*Chichla ocellaris*) *		X	

*observed, not known to breed within Everglades National Park

Due to the unconfined nature of the surficial aquifer, surface water and ground water are interchangeable within the area affecting Everglades National Park. Differences in the permeabilities of the sands, limestones, marls, and silts that compose the aquifer system influence the direction and rate of ground water movement. Drawdown in areas outside of Everglades National Park boundary and outside of the defined hydrologic basin affects the hydrology and groundwater resources of Everglades National Park. For this reason, flood protection and conveyance capacity for the adjacent urban areas and the Everglades Agricultural Area affect the management of water, water delivery schedules and operation of structures delivering water to Everglades National Park. Physical structure of the area is based upon the Florida Plateau and the chemical and biological processes leading to deposition and formation of its features as shaped by transgressing and regressing sea level changes (Schomer and Drew, 1982).

J.8.3.1 Groundwater Resources

The hydrogeology of south Florida is extremely diverse. Two aquifer systems are of primary interest, the Surficial Aquifer system and Floridan Aquifer system. The surficial or Biscayne aquifer is of primary importance within Everglades National

Park. This aquifer is the only source of potable water within Everglades National Park and represents the primary source of water for the natural environments of Everglades National Park. The Floridan Aquifer is a regionally extensive, deep aquifer that contains non-potable water throughout south Florida. Jarosewich and Wagner (1985) found two distinct zones within the surficial aquifer system underlying Everglades National Park. These zones consisted of an upper zone of permeable limestones and clastics, and a more heterogeneous lower zone of relatively impermeable fine grained sands and silty sands interbedded with permeable sands, limestones, and shelly marls. Due to the permeability of these two zones, they are considered hydraulically connected as a single surficial aquifer system with the presence of a regionally continuous "green clay bed" of the lower Tamiami Formation defining the base of the aquifer system.

J.8.3.2 Physiographic Subregions of ENP

The area comprised by Everglades National Park has been divided into two physiographic regions by Schomer and Drew (1982), the Lower Everglades Basin and the Taylor Slough/Florida Bay Basin. This division is based on previously published records (Davis, 1943a; Puri and Vernon, 1964; White, 1970; Craighead, 1971)(***Figure J.8.3.2-1***).

Lower Everglades Basin

The Lower Everglades Basin has been further sub-divided into physiographic subzones by Schomer and Drew (1982) which have been modified to include the Rocky Glades as part of Taylor Slough/Florida Bay: 1) Shark River Slough, 2) Broad River/ Lostmans River, 3) Coastal Swamps and Lagoons, and 4) Cape Sable.

Shark River Slough

Shark River Slough is a broad southwesterly trending arc of continuous wetland, interspersed with numerous tree islands. Expansive transitional areas of slightly higher bedrock elevation distinguish its northwestern and southeastern boundaries. The slough is defined by the center of the Everglades trough which is a wide, slightly concave depression in the underlying limestone (White, 1970).

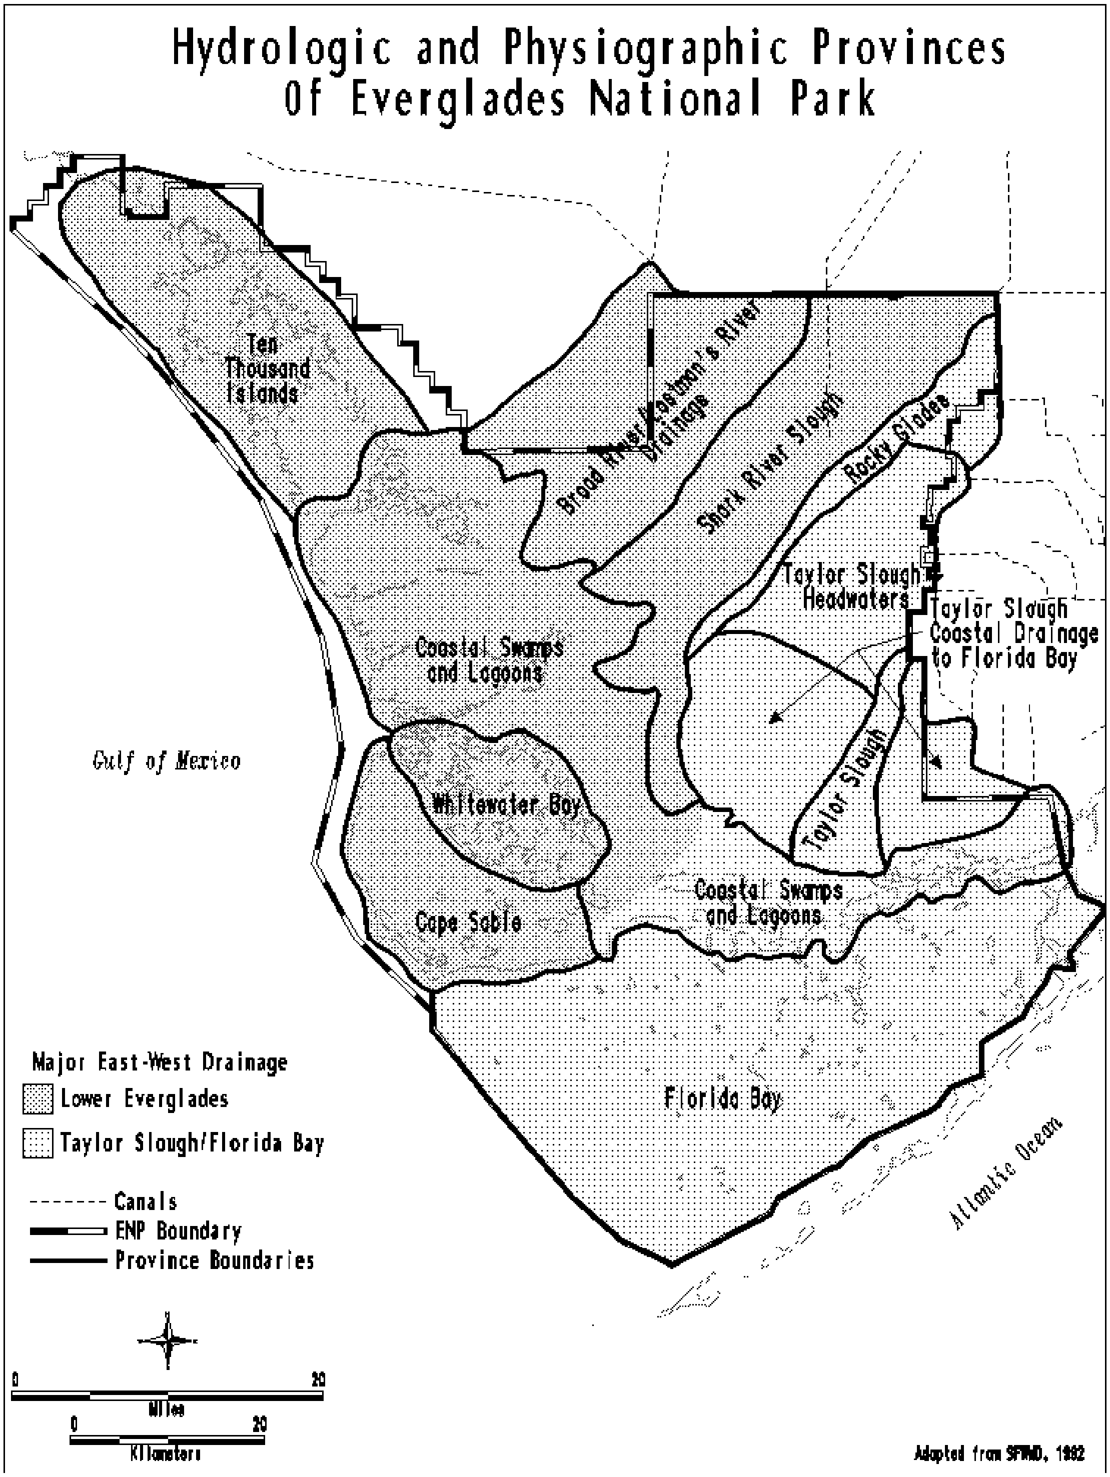

Figure J.8.3.2-1 Everglades National Park Physiographic Regions

Historically natural water movement in Shark Slough depended on the timing, duration, and magnitude of regional and local meteorological events particularly flood and drought conditions. Currently water movement is primarily controlled by the operations of the C&SF Project. Recent isotopic data suggests that groundwater underlying Everglades National Park is derived primarily from recent surface waters, and is heavily affected by recent rainfall recharge, while waters under Alligator Alley in Water Conservation Area 3 is much older and less directly affected by rainfall (Swart 1989, unpublished data).

Broad River/Lostmans River

Northwest of Shark River Slough, the bedrock of the Everglades trough rises gradually toward the Big Cypress Spur, an extension of the Immokalee Rise (Puri and Vernon, 1964; White, 1970). These latter features generally define the Big Cypress Basin. The area of freshwater wetlands located between the Everglades trough and the Big Cypress Basin is known as the Broad River/Lostmans River Drainage (Schomer and Drew, 1982). This transitional area is distinguished from Shark Slough by subtle differences in hydrology, hydroperiod, and geology. Miami Limestone in this area is covered by a veneer of Pamlico sands which encroach upon the Fort Thompson Formation of the Everglades trough (Cooke, 1945). This is area and the Big Cypress Basin form the primary freshwater drainage for the Ten Thousands area of Everglades National Park.

Coastal Swamps and Lagoons

Puri and Vernon (1964) referred to the low mangrove and salt marsh areas at the lower end of Shark Slough drainage as reticulated coastal swamps. These coastal swamps and lagoons extend from the upland limit of periodic salt water influence to the Gulf of Mexico, a distance of about 10 to 25 miles (16 to 40 kilometers). According to Schomer and Drew (1982), the prominent features that delineate the area are:

1) salt marshes, which lie relatively upland;
2) mangrove forests that lie in vast wetland expanses and along shorelines;
3) "back bays" or lagoons--distinct physiographic features that become more prominent north along the coast.

The coastal swamps and lagoons receive most of the surface runoff from the Everglades. Prior to the recent Flandrian sea level rise of the Holocene epoch, a larger area was inundated by freshwater. As surface waters flowed over this area, differential solution of the less-resistant bedrock limestone formed freshwater channels (Schomer and Drew, 1982). Freshwater runoff increased the various peat- and/or marl-forming environments. As sea level rose to its current level, some areas of underlying peat eroded and oxidized, leaving a network of lagoons and "back bays" (Spackman *et al*., 1964; White, 1970).

The largest and most conspicuous of these lagoons is Whitewater Bay. The drainage pattern along the northern edge follows the numerous southeasterly trending channels of Watson River, North River, and Roberts River. The bay to the southeast is confined by an extension of the Atlantic Coastal Ridge that terminates in the "Cape Sable High" (White, 1970). Where the main flow of the Lower Everglades Basin drains to the Gulf of Mexico, conditions are less favorable for the formation of lagoons or back bays (White 1970). Consequently, a wide area of coastline north of Whitewater Bay contains only one small lagoon-like body of water (Tarpon Bay in the Harney River) (Schomer and Drew, 1982).

Cape Sable

Cape Sable is one of the most distinctive features of the southwestern tip of Florida. White (1970) claims that the cape overlies a degenerate westerly extension of Miami Limestone of the Atlantic Coastal Ridge. He refers to the terminal end of this extension as the "Cape Sable High." It is believed that the beaches of Cape Sable first formed as a result of a shallow submarine scarp cut into bedrock (White, 1970). The coastal prairies behind the beaches are composed of a succession of troughs and low dunes (Craighead and Gilbert, 1962). On the upland side of these prairies, the highest elevations support a continuous ridge of hammocks (Craighead, 1971). A series of shallow ponds, the largest of which is Lake Ingraham, extend from the north of the middle Cape to Flamingo. Craighead (1971) considers these ponds remnants of former open waters that have not been completely filled in by marl and peat.

Taylor Slough/Florida Bay Basin

Taylor Slough encompasses greater than 158 square miles of freshwater marsh and extends approximately 20 miles from its northern source in the rocky glades to Florida Bay (Van Lent, *et al*. 1993). Schomer and Drew (1982) separate the Taylor Slough/Florida Bay Basin into six physiographic subzones.

1) Rocky Glades
2) Taylor Slough Headwaters
3) Upper, Middle, and Lower Taylor Slough
4) Taylor Slough Coastal Drainage
5) Coastal Swamps and Lagoons
6) Florida Bay

Rocky Glades

The Rocky Glades or Rocklands are a transition zone between Taylor and Shark Sloughs. They lie southeast of Shark Slough forming portions of the headwaters of Taylor Slough (Davis, 1943a; Schomer and Drew, 1982). The Rocky Glades are formed by solution and differential weathering of bryozoan limestone from the Pleistocene (Schomer and Drew, 1982) The formations resulting from such weathering are also called pinnacle rock and form a unique habitat type within Everglades National Park due to its unusual structure. Geologically, the Fort Thompson Formation underlies much of the Everglades trough as a surface bedrock feature, while the back slope of the Atlantic Coastal Ridge (Miami Limestone) forms the surface rock for the area farther east (SFWMD, 1992). These bedrock features make the Rocky Glades a hydrologic transition between the Shark River Slough drainage to the southwest and the Taylor Slough drainage to the south.

Taylor Slough Headwaters

Historically, sheet flow through the Everglades followed a south by southwest curve, as outlined by the arc of Shark Slough. Some of the sheet flow, however, has been transverse to the main axis of the Miami Rock Ridge, the Everglades Keys, and the Rocky Glades. Erosion of the thin layer of marl soils and solution of the underlying Miami Oolite created a solution-riddled landscape cutting across the limestone toward Taylor Slough.

Upper, Middle, and Lower Taylor Slough

This physiographic subzone originates where L-31W intersects the main channel of Taylor Slough (Olmsted *et al*., 1980). This area is referred to by Olmsted *et al*. (1980) as Upper Taylor Slough. It is a well defined 3.4-mile (5.5-kilometer) long segment running from the intersection of the slough and the canal levee structure L-31W south to State Road 27 (Anhinga Trail). Middle Taylor Slough is defined as the segment of the slough from State Road 27 south 4 miles (6 kilometers) (Olmsted *et al*. 1980). Lower Taylor Slough is defined as the segment lying south of this point and draining to Florida Bay.

Taylor Slough Coastal Drainage

Schomer and Drew (1982) described the areas immediately east and west of Taylor Slough and north of the coastal swamps. This area is referred to as the Taylor Slough Coastal Drainage. The limestone ridges, Long Pine Key and Everglades Keys, that run west/southwest from upper Taylor Slough form a barrier inhibiting sheet flow from Shark River and the lower Rocky Glades.

Coastal Swamps and Lagoons

In the coastal area west of Taylor Slough, Puri and Vernon (1964) distinguish two physiographic provinces lying within the Taylor Slough drainage basin. The first of these provinces refers to the series of lagoons from Seven Palm Lake to West Lake. A broad continuous strip of land covered by coastal prairie occupies the area north of these lagoons, running southeast to the mangroves bordering Madeira Bay. The northern border of these lagoons roughly corresponds to a partial barrier between fresh and saline waters known as the Buttonwood Embankment (Craighead, 1971). A distinct band of pioneer red mangrove (*Rhizophora mangle*) occurs 2 to 5 miles (3 to 8 kilometers) inland of this barrier (Schomer and Drew 1982). The second physiographic province corresponds to black (*Avicennia germinans*) and white (*Laguncularia racemosa*) mangrove communities that occur in the areas south to Florida Bay. This second region is known as Reticulate Coastal Swamps (Schomer and Drew, 1982). On the eastern side of Taylor Slough the coastal lagoons are less prominent, and the surface drainage is better defined. This hydrologic structuring leads to a land and vegetation pattern that radiates out from the surface drainage pattern (Schomer and Drew, 1982).

Florida Bay

Florida Bay is the downstream receiving waters for the Taylor Slough drainage. It is a negative estuary, evaporating more water on an annual basis than falls in rainfall. The Taylor slough drainage is an important source of freshwater for this area.

J.8.4 Water Management

The Everglades National Park drainage basin is described in Cooper and Roy, 1991. The basin has an area of 1684.5 square miles and is located in western Miami-Dade County (886.5 sq. miles), northwestern Monroe county (773.9 sq. miles) and southwestern Collier county (24.1 sq. miles) (Cooper and Roy, 1991). The Park boundaries and the basin boundary are shown in ***Figure J.8.4-1***. The basin includes all of Everglades National Park, the Everglades National Park expansion area, the remainder of the east everglades and portions of the southern Glades Wildlife Environmental Area.

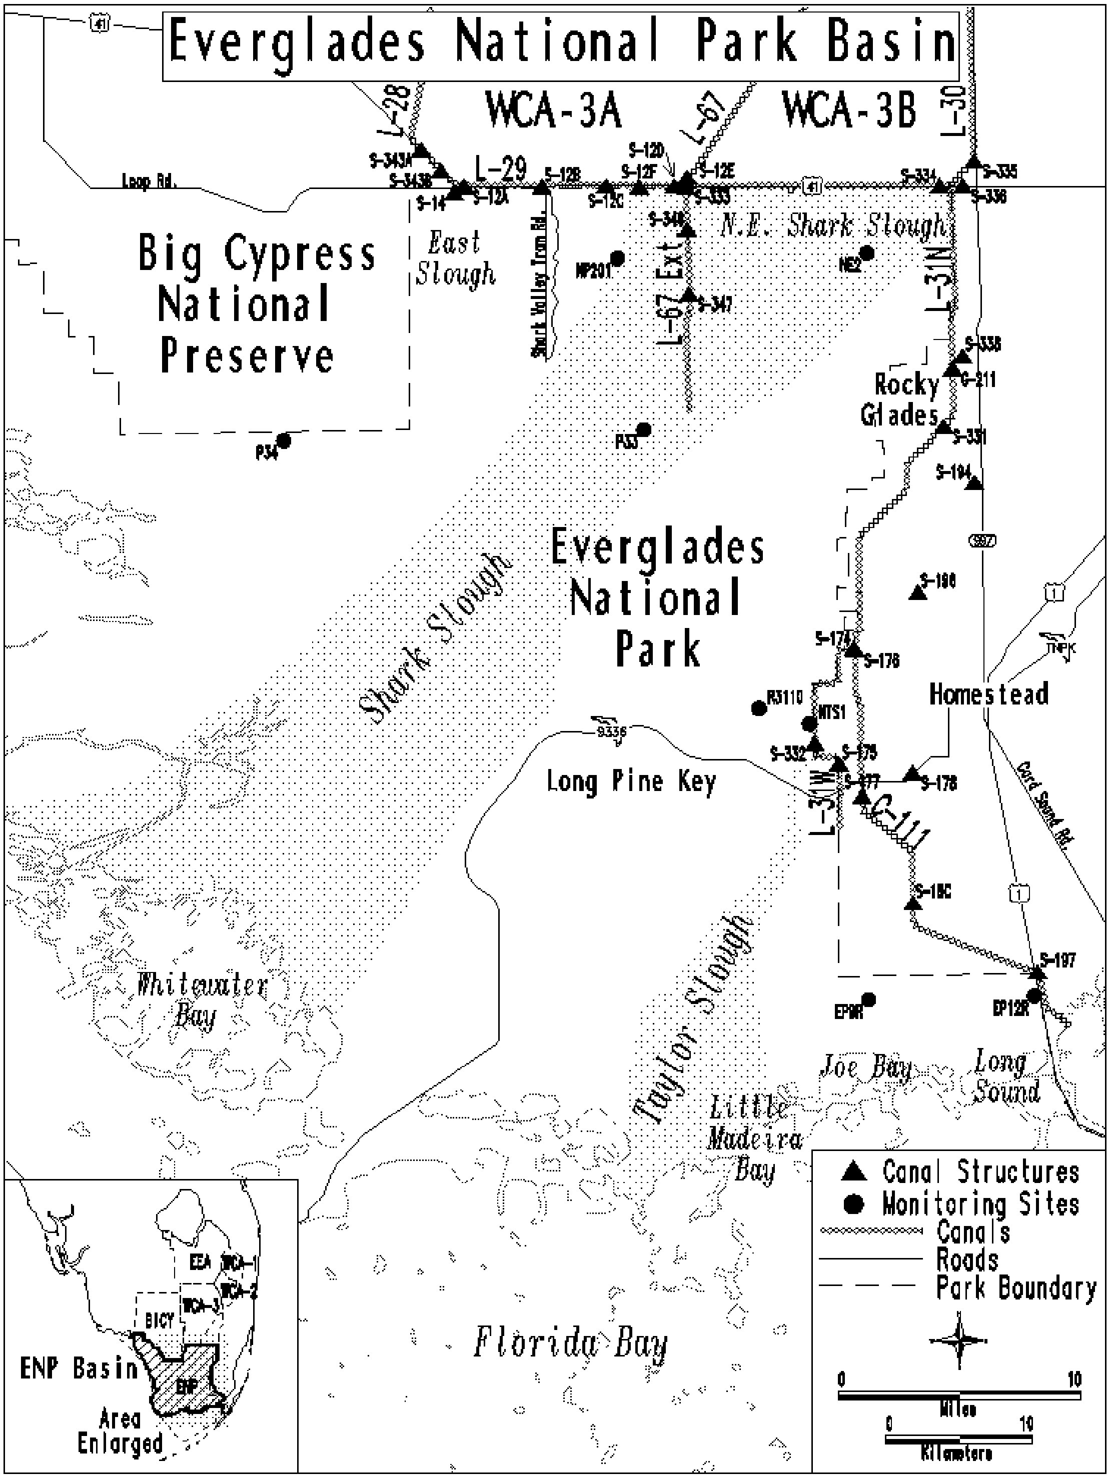

Figure J.8.4-1 Everglades National Park Basin Boundaries

J.8.4.1 Internal Project Structures

The drainage basin for Everglades National Park represents primarily undeveloped land managed for the National Park and its inflows. Central and South Florida Project structures are generally external to the basin and installed primarily for environmental purposes for the National Park or to separate drainage between the National Park and the area to the east of the L-31N and L-31. There are six project structures internal to this basin: the L-67 extension, the plug in the Buttonwood Canal, S-175, S-332, S-346, and S-347. L-67 extension was installed to separate the portions of Everglades National Park, Western Shark Slough from the privately owned lands east, which included the northeastern portions of Shark Slough. The associated canal serves as a getaway channel allowing water to move away from the S-12 structures (Cooper and Roy, 1991). The Buttonwood Canal plug was installed at the mouth of the Buttonwood canal on Florida Bay to prevent further intrusion of saltwater and improve conditions upstream of the canal. The S-175 and S-332 are used to deliver water to Taylor Slough, while S-346 and S-347 are used to control flow in the L-67 extension.

J.8.4.2 External Project Inflows

Managed inflows to Everglades National Park are from the eastern farmland and from the north as an outlet of Water Conservation Area (WCA) 3A and 3B. The managed flows delivered from WCA 3A through the S-12 structures, S-333, and from WCA 3B through G-69. Other inflow points include the L-31W borrow canal through S-332 and S-175 and from the C-111 between S-18C to S-197 as overland flow though the degraded canal berm into the Panhandle of Everglades National Park.

J.8.4.3 Project Structures Controlling Inflow

Project structures controlling flow to the Everglades National Park basin are: S-12A; S-12B; S-12C; S-12D; G-69, S-175; S-18C; S-197; S-332; S-333; and S-334. There are two internal structures controlling flow; the S-346 and S-347, which control flow in the buttonwood canal. There are three project structures, which are located in the basin but are not currently operated; the S-12E, S-12F and S-14. The S-12A, S-12B, S-12C, and S-12D are identical gated spillways located in the L-29 between L-28 and L-67. They connect Water Conservation Area 3A to the Everglades National Park basin. The first connection between WCA-3A and the south Miami-Dade canals occurred in 1978 with the completion of structures S-333 and S-334 in the L-29 Canal. These structures were installed to provide additional dry season water deliveries to L-31N. Structure G-69 connects WCA 3B to the Everglades National Park basin via the L-29 canal. Project works are largely peripheral to the Everglades National Park basin and have as their primary function providing a supply of water to the basin.

J.8.5 Water Supply

Most of the surface flow entering Everglades National Park occurs through the Central and South Florida Project. The primary function of the C&SF Project is to supply water to the basin and to pass floodwater flows from adjacent basins into the Everglades National Park. The first overall plan for flood protection and water control for southern Miami-Dade County was presented in the Survey Review Report on the Central and Southern Florida Project, South Miami-Dade County (USACE, 1961). The L-31W Canal system was not included as part of this plan. The remaining major flood control and water supply facilities for southern Miami-Dade County were addressed in the General Design Memorandum (GDM), South Miami-Dade County (USACE, 1963). The L-31W Canal and control structures S-174 and S-175 were added to the project as part of the memorandum following recommendations by the NPS and the U.S. Fish and Wildlife Service.

Water control works that were constructed immediately adjacent to Shark River Slough, Taylor Slough, the East Everglades and the panhandle of the Everglades National Park allowed water managers to regulate flow across park boundaries. Several water delivery plans were implemented from 1962 to 1982 to meet delivery goals for the Everglades National Park and are summarized in ***Table J-8.5-1.***

Table J-8.5-1
Summary Of Water Delivery Schedules To Everglades National Park

Description	Summary of Operation
Conservation Area 3A Stage (Dec. 1962 – March 1965)	Park only to get excess water once Conservation Areas Filled
Conservation Area 3A Stage (March 1965- March 1966)	• All excess water to Everglades National Park through the S-12's • 3stage zones dictated 3 different monthly delivery schedules. • P-33 served as an over-ride
Lake Okeechobee Stage (March 1966-Feb. 1970)	• 13.5 – 15.5 ft. – 1000 cfs through S-12's • 12.5 – 13.5 ft. 140 to 150 cfs through S-12's • Below 12.5 ft. no delivery
Lake Okeechobee Stage (Feb. 1970-Sept. 1970)	• Above 12.5 ft. – 260,000 acre-ft. through S-12's • Below 12.5 ft. – reduced % of schedule • P-33 as over-ride.
Congressionally mandated Minimum Delivery Schedule (1972 – 1982)	• 260,000 acre-ft. minimum delivery schedule through the S-12's • Provisions for reduction of flow to share adversity in drought.
Rainfall Plan (June 1985 – present)	• Base the amount and timing of water deliveries to Shark Slough on recent rainfall and evapotransporation upstream in WCA-3A • Moderate sudden changes in flow resulting from the minimum delivery schedule • Redistribute flow across the entire width of the slough, restoring flow to the eastern flow section and North East Shark Slough. • Included a flow redistribution component for passing 55% of flow through NESS and 45% through the remainder of Shark Slough.

J.8.5.1 Minimum Delivery Schedule

A minimum delivery schedule was implemented in 1970 as a step towards recognizing the importance of surface water delivery to Everglades wetlands. The minimum allotments for water supply to Everglades National Park were identified as 315,000 acre-feet per year and were divided among the major drainage basins as follows: Shark Slough-270,000 acre-feet, Taylor Slough-37,000 acre-feet, Eastern Panhandle-18,000 acre-feet. ***Table J-8.5.1-1*** provides a summary of water delivery schedules to Shark River Slough for the period 1962 to 1982.

Table J-8.5.1-1
Minimum Delivery Schedule
Shark River Slough, Taylor Slough
And Eastern Panhandle
(Acre-Ft)

Month	Shark River Slough (S-12's) (acre-feet)	Taylor Slough (S-332) (acre-feet)	Eastern Panhandle (S-18C) (acre-feet)
January	22,000	740	1,540
February	9,000	370	630
March	4,000	185	290
April	1,700	185	110
May	1,700	370	110
June	5,000	6,660	340
July	7,400	7,400	510
August	12,200	2,960	860
September	39,000	5,920	2,690
October	67,000	7,770	4,630
November	59,000	3,700	4,060
December	32,000	740	2,230
Total	**260,000**	**37,000**	**18,000**

Source: C&SF Project C-111, EIS, 1994

The effects of this delivery schedule are well documented and summarized as follows:

- The water releases to Everglades National Park, through the four S-12 control structures were still constrained by the needs of other consumers and the requirement for releasing excess water during high water periods,
- Water releases to Everglades National Park were directed to the west side of the historic flow-way,

- Water releases, in conjunction with the construction of the L-67 extension, resulted in abbreviated and lower water levels in the Northeast Shark Slough,

- As consequence of these operations, it has been possible for the relatively high ground along the eastern edge of the Northeast Shark Slough to be developed for agricultural and urban use, and

- Further consequences of these actions has been the continued deterioration of the ecological conditions within the park

J.8.5.2 Experimental Program of Water Deliveries to ENP

Recognition of the adverse effects to Everglades National Park prompted the Congress to enact provisions within the Supplemental Appropriations Act (Public Law 98-181) on November 30, 1984. Section 1302 of this act authorized the Secretary of the Army to conduct a two year experimental program for delivering water to Everglades National Park. This authorization allowed for modifications to the existing schedule of water deliveries from the Central and South Florida Project. Provisions of this law also called for the acquisition of lands in agricultural production which may be adversely affected by the modifications to the delivery schedule. The Secretary was also authorized to construct necessary flood protection measures for the protection of homes in the area affected by the modifications to the delivery schedule.

J.8.5.3 Modified Water Deliveries to ENP

In response to PL 98-181, the Secretary of the Army completed the General Plan for Implementation of an Improved Water Delivery Schedule to Everglades National Park, Florida in January 1985 and approved by the Secretary on February 28, 1985. This document contained two recommendations:

(1) Preparation of a General Design Memorandum (GDM) and an Environmental Impact Statement (EIS) addressing modifications to improve water deliveries to Everglades National Park, and

(2) Extension of the two-year time limit specified in PL 98-181 based on a written agreement between the U.S. Army Corps of Engineers, Everglades National Park, and South Florida Water Management District.

The Shark Slough feasibility report examined the redistribution of waters into Northeast Shark Slough (NESS) with principle study objectives of determining as way to provide more manageable and flexible water delivery system by redistributing flows through NESS into Everglades National Park and Florida Bay.

Six alternatives were examined each involving redistribution of up to 50 percent of the recorded S-12 flows into NESS. These alternatives required both structural and operational changes. Structural modifications included the removal of the bottom 4 miles of the L-67e, additional outflow capacity in L-28 and a 1000 cfs structure in the middle of the L-67 to distribute flow into WCA-3B. Operationally water would be allowed to flow from WCA-3A into L-29 using S-333.

30-day and 90-day field tests were conducted in the period from 1983-1985 for a flow through experiment conducted to provide data to evaluate the effects on adjacent areas of re-inundating NESS. The 30 day test was conducted and the end of the dry season, 1984 during very dry conditions to test the introduction of water into NESS via S-333. The resulting analysis by MacVicar and VanLent (1984) indicated the effectiveness of the flow diversion in reducing the S-12 flows when there is storage in the NESS showing a decrease in water levels in WCA-3A and western Shark Slough.

The U.S. Army Corps of Engineers's General design memorandum for Modified Water Deliveries to Everglades National Park (USACE, 1990) addresses the Shark Slough portion of Water Deliveries and developed a plan for structural improvements to the water delivery system. The GDM authorized in 1985, describes the latest plan to redesign the surface water inflow patterns in an attempt to restore the Shark Slough hydrologic regime.

The Modified Water Delivery and C-111 Programs are the structural components for two different geographic regions encompassing Everglades National Park for redistribution of water to Everglades National Park. The Experimental Water Delivery Program is a series of iterative operational changes in water delivery to Everglades National Park until structural modifications are complete. The resulting Experimental Program of Water Deliveries to Everglades National Park is intended to build upon the results of previous tests as a means to restore more natural water deliveries. The overall goal of the Modified Water Delivery Program is to provide operational flexibility to Everglades National Park for further ecosystem restoration, while maintaining levels and flood protection for other interests in the area (USACE, 1995). This program was intended to provide a mechanism to field test water delivery methods and assess potential impacts to Everglades National Park, to other parts of the C&SF project, and the water supply ability of the U.S. Army Corps of Engineers and the South Florida Water Management District (USACE, 1995). This program is intended to provide a practical means of testing ecosystem responses to water deliveries with the goal of ecologic restoration for the natural systems of Everglades National Park.

The Modified Water Delivery Program and current schedule of Experimental Water Deliveries to Everglades National Park were initiated as a response to the requests outlined in the 7 Point Plan by Everglades National Park. As a response to this request, the U.S. Army Corps of Engineers initiated a series of tests, authorized under Public Law 98-181 Section 1302, to "conduct an experimental program for the delivery of water to the Everglades National Park from such project [the C&SF project] for the purpose of determining an improved schedule for such delivery" (USACE, 1995). These tests of experimental water deliveries to Everglades National Park were divided between schedule changes to both Shark Slough and to Taylor Slough. The first five iterative tests were conducted in the Shark Slough drainage. Test 6 incorporated Taylor Slough into the experimental program for the period beginning June 1993 through October 1995. Test 6, therefore involved changing operating practices for the existing structural features of the C& SF system that affect water deliveries and hydrologic conditions in both Shark Slough and Taylor Slough.

Authorizations for the Modified Water Delivery Program are found under the following statutes:

1) Minimum Water Deliveries to the C&SF project by Congress in 1969 under PL 91-282.

2) The Supplemental Appropriations Act of 1984, which authorized the U.S. Army Corps of Engineers with Everglades National Park and the South Florida Water Management District to deviate from the minimum delivery schedule.

3) PL 98-181, which allowed for land acquisition of impacted agricultural lands that were in agricultural production in 1983.

4) Section 107 of PL 102-104, which amended PL 98-181 to allow continuation of the Experimental Delivery program until modifications to the C&SF Project authorized by sections 104 of the Everglades National Park Protection and Expansion Act of 1989 (PL 101-229) were completed and implemented.

Experimental Water Delivery Program, Test Iteration 7 Features

The C-111 General Reevaluation Report (GRR) recommends that an operational plan be developed for both Shark Slough and Taylor Slough as part of the Experimental Program. Test 7 was designed as a means of examining the impacts of refinements recommended from Test 6. Test 7 is the implementation and examination of the effects of changes recommended at the conclusion of Test 6.

As described by the U.S. Army Corps of Engineers (1995) Test 7 includes:

1) Northeast Shark Slough water deliveries through the S-12 and S-333 structures as an extension of the Test 6 program.

2) Taylor Slough water deliveries changed to maintaining water levels in the L-31W canal between S-174 and S-175 based on a rainfall/canal stage formula developed by Everglades National Park for Taylor Slough.

3) L-31W Flood Conveyance Capacity, where 500 cfs flood conveyance capacity is maintained by the addition of a pump station (S-332D) at S-174.

4) Add up to 125 cfs in additional pumping capacity at S-331.

5) Monitoring: Ecological and hydrological monitoring will be carried out for the period of Test 7.

6) Public acquisition of the Frog Pond, to eliminate the need for planting season drawdowns and allow increased stages beyond design stage in L-31W.

7) Provide plugs in the east-west Aerojet canal south of S-175 and in the north-south S-175 getaway canal.

8) Raise S-18 C operating criteria

9) Adjust S-174 and S-175 operating criteria

10) Test Duration: Test 7 will continuously operate for up to four years and then undergo an evaluation of six months or less in duration to determine whether the test should be continued or a new test implemented.

J.8.6 Socio-Economics

The purpose of this section is to provide an overview of the socio-economic environment of the 5 south Florida Counties (Palm Beach, Broward, Miami-Dade, Monroe and Collier) most intimately tied to Everglades National Park (Park). The Park lies within Collier, Miami-Dade, and Monroe counties. It is, however, affected by conditions within Broward and Palm Beach counties due to urban and agricultural pressure on the entire Everglades ecosystem. This section will also discuss the contributions of Everglades National Park to the region.

J.8.6.1 Population and Demographics

The area under consideration falls within several planning and regulatory jurisdictions. The primary land use planning and regulatory jurisdictions include the south Florida, southwest Florida, and Treasure Coast Regional Planning Councils under the Florida Department of Community Affairs, while the South Florida Water Management District is the primary water management and regulatory agency. The South Florida Regional Planning Council's jurisdiction includes Monroe, Miami-Dade, and Broward Counties. Collier County is included within the Southwest Florida Regional Planning Council and Palm Beach County is part of the Treasure Coast Regional Planning Council. The South Florida Water Management District jurisdiction includes 16 counties: all of Broward, Miami-Dade, Monroe, Glades, Lee, Palm Beach, St. Lucie, Collier, Hendry, and Martin counties and part of Highlands, Osceola, Charlotte, Okeechobee, Orange and Polk counties (SFWMD, 1992). Additionally the water management district has divided their water supply planning into several regions, of particular interest is the Lower East Coast, which includes all of Palm Beach, Broward, Miami-Dade and Monroe Counties (SFWMD, 1997). Collier County primarily falls under the planning auspices of the South Florida Water Management District's Big Cypress Basin Board or the Southwest Regional Planning Council.

Southeast Florida, or the Lower East Coast, defined as Broward, Miami-Dade, Monroe, and Palm Beach Counties, has experienced tremendous growth since 1900. In 1910, the population of southeast Florida was just under forty thousand, half of whom lived in the Florida Keys (Shultz 1991). This growth had begun to dramatically increase by 1920, doubling to 86,000. By 1930 the population had increased to 228,000, by 1940 it had increased to 400,000 and by 1950, about the time that construction of the Central and South Florida Project had begun, there were 700,000 people in the area (Shultz 1991). In 1970, there were 2.3 million people living in southeast Florida and by 1990 the area had a population of 4.1 million people (Shultz, 1991; Bureau of Economic and Business Research, 1995). On the west coast, Collier County, now recognized as one of the fastest growing counties in the state, had a population of 2,883 in 1930, by 1940 it had grown to 5,102, by 1950 to 6,488, and by 1960 the population had more than doubled to 15,753 (Bureau of Economic and Business Research, 1995). ***Table J-8.6.1-1*** shows the average annual rates of population growth in the region in the decades between 1950 to 1995.

Table J-8.6.1-1
Average Annual Rates Of Population Growth
(%)

Period	Broward	Miami-Dade	Monroe	Region	Florida
1950/1960	14.8	6.6	4.8	8.0	6.0
1960/1970	6.4	3.1	0.9	4.0	3.2
1970/1980	5.1	2.5	1.9	3.4	3.7
1980/1990	2.1	1.8	2.1	1.9	2.9
1990/1995 *	1.5	0.6	1.5	1.0	1.8

(*) Projections Source: Bureau of Economic and Business Research, Projections of Florida Population by County, 1993-2020, as presented in SFRPC (www.sfrpc.com/region/prof.peop.htm).

There are now approximately 6 million people in the South Florida Water Management District's 16 county service area. The South Florida Water Management District (1993b) expects population to triple by 2050. ***Table J-8.6.1-2*** shows the University of Florida Bureau of Economic and Business Research’s estimates of the median projected population for the five south Florida counties under review.

Table J-8.6.1-2
Population Projection Estimates
For 5 South Florida Counties

County	1994	1995	2000	2005	2010	2015	2020
Broward	1,340.2	1,362.9	1,471.1	1,569.8	1,665	1,760.2	1,854.2
Colllier	180.5	187.8	224.0	256.6	288.6	321.0	353.5
Miami-Dade	1,990.4	2,016.3	2,140.8	2,254.3	2,363.8	2,473.2	2,581.2
Monroe	82.3	83.5	89.2	94.4	99.5	104.5	109.5
Palm Beach	937.2	960.8	1,074.4	1,177.8	1,277.9	1,378.7	1,478.7

Florida Statistical Abstract 1995: Bureau of Economic and Business Research, College of Business Administration) (in thousands rounded to hundreds)

The characteristics of this population and of the population growth rate, have changed over the years. The South Florida Regional Planning Council reports in its Regional Profile (SFRPC, 1996) that the composition of in-migration to the region has changed. Migration, through the end of the 1950’s, consisted primarily of people from the northern United States; beginning in the 1960’s south Florida began to see a shift to immigration from Latin America. This immigration was first characterized by hundreds of thousands of Cuban refugees in the period from the 1960’s to the 1980’s and then in the 1970’s and 1980’s by immigrants form other Central and South American countries and from the Caribbean. The volume of this new inflow of population has also increased relative to migration from the northern United States. The Treasure Coast Regional Planning Council also notes a significant increase in the Hispanic population reflecting these shifted demographics.

In addition to the ethnic changes there is also a change in the age of the population and the immigrants (domestic and international). Traditionally the south Florida area has been a mecca for retirees, in part due to the lack of a state income tax and to the balmy climate. In 1990, the counties of the SFRPC were home to 544,000 people 65 years old or older, representing 17 percent of the region’s population. Increased population density and resulting congestion are thought to be part in part responsible for the declining proportion of the elderly immigrants drawn to the region covered by the SFRPC. The SFRPC notes that the previous generations of elderly immigrants are not being replaced by new ones (SFRPC Regional Profile 1996).

Collier County shows similar changes in the age composition of its population; historically a resort and retirement community, the recent rapid population growth has brought younger, permanent households to the county (Collier County, 1997). ***Table J-8.6.1-3*** shows the median age and percentage of population over 65 years old for the decades between 1970 and 1990 for the 5 counties. The projected population by age group and County is shown in ***Table J-8.6.1-4***. The new character of the current south Florida population results in altered demands on the ecosystem, increased urban development pressures and altered resource management problems.

Table J-8.6.1-3
Age Characteristics Of Population
Median Age

County	**Census**			**Projections**		
	1970	1980	1990	2000	2005	2010

Florida Statistical Abstract 1995: Bureau of Economic and Business Research, College of Business Administration

J.8.6.2 Park Contributions to Economics and Recreation

Everglades National Park is contained within Collier, Miami-Dade, and Monroe counties. The cities of Homestead and Florida City serve as the gateway communities to the eastern portion of Everglades National Park, while Everglades

City is the gateway to the Ten Thousand Islands section of the western portions of Everglades National Park. The Park's extensive fresh and salt water areas, open Everglades prairies, mangrove forests, and Florida Bay provide a home for abundant wildlife including many endangered and threatened species of flora and fauna. The Park has over 150 miles of walking and canoe trails, including 2 miles of elevated boardwalk trails. There are three campgrounds with over 420 campsites with another 48 backcountry campsites available to boaters and canoeists. The Park has a national and international reputation as a tourist destination and is an important part of the south Florida tourism industry. The park is the largest remaining sub-tropical wilderness in the continental United States, 1,296,500 acres of Everglades National Park are protected as designated wilderness. In 1997, this wilderness was re-dedicated as the Marjory Stoneman Douglas Wilderness. The Park is also home to the Miccosukee Tribe of Indians of Florida who use and occupy 333.3 acres on the northern boundary. It is designated as a World Heritage Site, an International Biosphere Reserve, and a Wetland of International Significance.

The diverse and unique beauty and character of Everglades National Park draw visitors from all over the world: in the spring of 1996 international visitors accounted for 21 percent of Park visitation. Of these international visitors, over half are from Germany, 13 percent from the United Kingdom, and 10 percent from Canada. Thirty six percent of domestic visitation is from Florida, while Illinois and Michigan are the next most represented states with 6 percent each of the domestic total. Visitors come to Everglades National Park to view wildlife, for the solitude and wilderness experience, for birdwatching and to visit a wetland. They also come specifically to visit the International Biosphere Reserve and World Heritage Site.

An understanding of the economic value of National Park Service lands on the local economies in south Florida is outlined in the recent draft of a study entitled "Compilation of Available Data on Economic Impacts of Federal Interest Lands in south Florida" which reports the following combined benefits to Miami-Dade County attributable to Everglades National Park in FY94. Combined Sales Benefits: $119,165,051; Combined Increased Tax Revenue Benefits $7,745,728; and Combined New Jobs Created 4,930. An update completed for Everglades National Park for FY 97 calculated Combined Sales Benefits of $128,186,563; Combined Increased Tax Revenue Benefits of $8,332,127; and Combined New Jobs Created 5307.

Everglades National Park has three major concession operations. AMFAC is located at Flamingo, at the end of the main park road, 38 miles from the main entrance. They employ about 150 people and operate a restaurant, lodge, bar, gift shop, marina store (including equipment rentals), boat tours and boat rentals. Shark Valley Tram Tours operates tram tours, vending machines and bicycle rentals within the Shark Valley area. They are located off the Tamiami Trail near the Shark Valley Visitor Center and employ 12 people. Everglades National Park

Boat Tours Inc. is located at Everglades City and offers boat tours of the 10,000 islands area, equipment rentals, snacks, books, etc. This firm employs 20 people. Gross receipts for the concessions in FY 96 were approximately $ 6.7 million dollars. An additional component employment and income is the Incidental Business Permit (IBS) program under which boat tour operations, canoe outfitters and fishing guides operate. Visitors can use these services for sightseeing, photography, fishing and canoeing. In FY 96, the IBS gross receipts came to $3.4 million dollars and IBS permit holders employed 300 people.

J.8.7 Land Use

As the region has grown its land use patterns have dramatically changed. In south Florida the character of the land has acted as one of the constraints dictating early settlement patterns. Topography, soils, and aquifer maps illustrate the vulnerability of south Florida to inundation. On the east coast, the Atlantic Coastal Ridge (coastal ridge) and associated pine rocklands, due to its higher elevation and more stable soils, were the first to develop. As the coastal ridge developed and available lands were depleted, particularly over the last few decades, other, less suitable lands were developed in the sprawl pattern characteristic of current day south Florida.

J.8.7.1 East Coast Land Use

Miami-Dade and Broward Counties have the most pronounced sprawl patterns. The SFRPC describes the change:

> "Essentially rural areas in the western extremes of Broward and Miami-Dade Counties have given way to sprawling suburban residential development and shopping centers. Indeed, these have been an important component of the economic growth that has taken place in the Region. During the process, the once significant rural population has virtually disappeared, resulting in the emergence of a distinctly urban character to the Region. Miami-Dade County was already 94 percent urban in 1950, and 77 percent of Broward County's population lived in urban areas. By 1980, both counties were 99 percent urban. Only in Monroe County did a significant portion of the population still live outside of urban areas in 1990 (27 percent), consistent with the special characteristics of that county's political geography." (SFRPC, 1996).

Palm Beach County is experiencing a similar change. The Treasure Coast Regional Planning Council reports that while the coastal area of Palm Beach County from Riveria Beach to Boca Raton, is heavily urbanized, much of the recent population growth has occurred in the western unincorporated areas (TCRPC, 1996). This sprawling urbanization tended to push agricultural land uses off of prime farmlands into the less suitable wetlands fringing the coastal ridge. As the development continues to expand it is expected that it will consume the remaining agricultural lands (both historic and recent) and eventually make its way into the remaining unprotected wetlands of the counties. The SFRPC explains that the region, in the response to the pressure of continued population growth, is likely to yield to the pressure to continue to urbanize.

J.8.7.2 Southwest Coast Land Use

Collier's population is currently heavily concentrated on the northwestern coastline (Continental Shelf Associates, Inc, 1990) within the communities of Naples, Marco Island, Golden Gate, and Everglades City. Of the 1,994 square miles of land within the county 780 are in conservation and another 528 are currently proposed for public acquisition and preservation.

J.8.7.3 Increased Pressure on Open Land

As this trend continues the availability of developable land decreases putting pressure on the unprotected wetlands and agricultural lands. There is a fear that agriculture lands will come under increased pressure as lands are converted into subdivisions or set aside for environmental protection. South Miami-Dade County typifies this trend. As people continue to move into the county pushing the north and central regions to capacity, the remaining undeveloped areas in south Miami-Dade County become the easiest option for future growth. The 80,000 acres of agricultural lands in the Redland region and other parts of unincorporated Miami-Dade County are increasingly under development pressure. In the 1995 Evaluation and Appraisal Report Miami-Dade included a recommendation that a Farmland Retention Study be conducted, noting that: "By [the Evaluation and Appraisal Report for 2000], the currently planned Urban Development Boundary will be substantially built out and the County will be facing the prospect of having to plan for the urbanization of an additional 20 square miles of land, if we continue the past trend of low-density development."

There are several other efforts to halt these land conversion and development trends including the following: Eastward Ho!, Brownfields, and the South Miami-Dade U.S. 1 Corridor Project.

J.8.8 Recreation Resources

Everglades National Park and Florida Bay offer unique and diverse opportunities for a variety of natural resource and wilderness based recreational activities. Day use and camping (front and backcountry) facilities are available throughout the Park. There are over 150 miles of walking and canoe trails, including 2 miles of elevated boardwalk trails and three campgrounds with over 420 campsites and an additional 48 backcountry campsites in the Park. Recreation activities include: hiking, boating and canoeing, fishing, bird and wildlife viewing, and going on guided interpretive tours. The C&SF Restudy regional boundaries include the authorized boundary of the park although not all lands within the East Everglades Expansion Area have been acquired by the federal government.

Everglades National Park has been designated a World Heritage Site, and International Biosphere Reserve, and a Wetland of International Significance. In addition, 86% of the Park is designated Wilderness under the Wilderness Act of 1964. The state of Florida has designated the Park an Outstanding Florida Water. The Park has also been listed as one of the nation's top ten most endangered parks (USACE, 1994).

Diverse ecosystems from sawgrass prairie to pinelands and hammocks to the estuarine environment of Florida Bay area easily accessible from the main park road or the Shark Valley tram road. The main park road ends at Flamingo, a former fishing village, and a main port of entry to Florida Bay, where a variety of self-guided, concession or ranger led walks and boat tours are available. Anhinga Trail, at the U.S. 29 leads to Everglades City and the Gulf Coast Visitor Center where the island-bay-mangrove ecosystems of the 99 mile Wilderness Waterway and Chokoloskee Bay, Turner River, and the Ten Thousand Islands area can be accessed. At Shark Valley, within the Shark River Slough, there are opportunities for biking, a guided interpretive tram tour, guided interpretive walks, as well as the climb to the top of the observation tower for a spectacular view of the sawgrass prairie. Chekika, (a former state park within the East Everglades Acquisition Area and donated by the state to the Park in 1991) offers a slightly different experience with opportunities for a soak in a sulfur pool as well as for picnicking and hiking.

Recreation resources within Florida and Whitewater Bays, the Ten Thousand Islands, the Wilderness Waterway, West Lake and Nine Mile Pond are characterized primarily by water-based resources and include boating, fishing, bird and wildlife observation, and interpretive programs. The opportunity to enjoy the sounds of nature, solitude, tranquility and wilderness are also part of the recreational aspect of these areas. The Wilderness Waterway and Florida Bay are dotted with backcountry camp sites (by permit only). There are three kinds of backcountry campsites: chickees, ground sites, and beach sites. All offer opportunities for wildlife viewing and experiencing the sounds of nature, solitude, tranquility, and wilderness.

J.8.9 Aesthetic Resources

The Everglades National Park regional aesthetic overview is comprised of historical landscape communities that create a mosaic of textures, colors, and viewsheds. The Shark River Slough community is characterized the wet prairie-slough-sawgrass-tree island mosaic (D&O, 1994). The views of this vegetative community are panoramic and of interest. The Shark River slough is bordered on its east and west by fresh water marl prairie. The dominant vegetative community is sawgrass with few spotted tree hammocks. This area is characterized by broad, panoramic views of good aesthetic quality.

In the southeast portion of the Everglades National Park region are cypress stands and pinelands. These areas possess good quality aesthetics but are viewed from the entrance road that provides a vehicle corridor of limited access and perspective. Taylor Slough is located to the southeast of the pinelands and is a much smaller version of the Shark River Slough with very similar aesthetics. South of these areas the marl prairie begins and provides expansive scenic views above the Florida Bay and its diverse viewshed. Few roads and canals cross the Everglades National Park Region, which helps to maintain the aesthetic resource. Air traffic noise is an increasing adverse aesthetic impact. The Everglades National Park has been designated as one of the nation's top ten most endangered parks (USACE, 1994). Development and its water terms are an increasing threat to the park natural and aesthetic resources.

Marine and estuarine open and closed viewsheds of good quality aesthetics and panoramic coastal prairie views of expanse characterize the Florida Bay regional aesthetic overview. Wildlife is an integral aspect of the aesthetic quality of the region and adds interest and spur reactions. The open prairie viewsheds extend into the waters and islands of Florida Bay on the very southern portion of the Florida Bay region. To the northwest are more coastal prairies and islands amongst the marine and estuarine communities. These communities provide waterways and trails that have varying corridor widths, environmental interest and unique aesthetic resource characteristics. The trade winds ameliorate the temperatures in the region like nowhere else and provide a comfortable climate year round.

Development and its water requirements are an increasing threat to the park's natural and aesthetic resources. Reduced water deliveries to the wetland areas has allowed saltwater concentrations to adversely affect the natural and aesthetic resources of the region.

J.9 FLORIDA KEYS

The Florida Keys (***Figure J.9-1***) are a limestone island archipelago extending southwest over 200 miles from the southern tip of the Florida mainland to the Dry Tortugas, 60 miles west of Key West. The relatively shallow waters of Biscayne Bay, Barnes and Blackwater Sounds, Florida Bay, and the Gulf of Mexico, bound them on the north and west. Hawk Channel lies to the southeast, between the mainland Keys and the extensive reef tract 5 mi offshore. The Keys are made up of over 1,700 islands encompassing approximately 100 square miles. They have little relief (generally less than one meter), have a shoreline length of 1,870 miles,

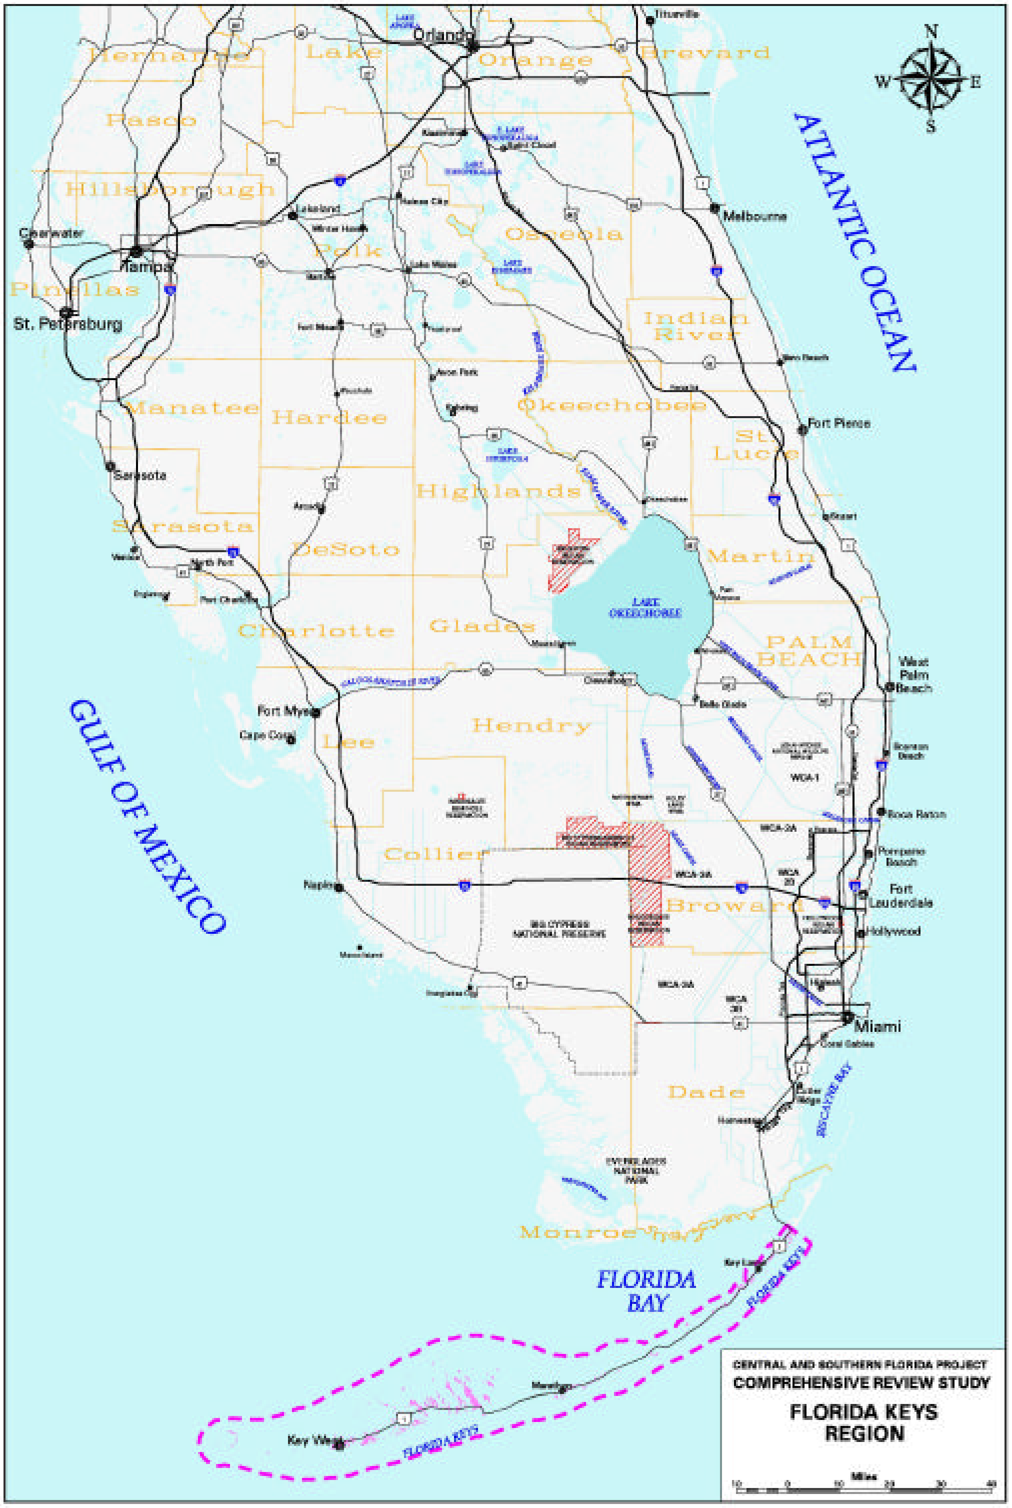

Figure J.9-1 Florida Keys Region

and are inhabited from Soldier Key to Key West. Key Largo (25 mi^2) and Big Pine Key (10 mi^2) are the largest individual islands in the archipelago (Monroe County, 1992).

This region also encompasses the Florida Keys National Marine Sanctuary, an area of approximately 3,700 mi^2 of submerged lands and waters between the southern tip of Key Biscayne and the Dry Tortugas Bank. The Sanctuary contains partof Florida Bay and the entire Florida Reef Tract, the largest reef system in the continental United States. Approximately 2,150 mi^2 (58 percent) of Sanctuary waters are under State jurisdiction. Numerous State and Federal parks and reserves are located within the Sanctuary's boundaries.

J.9.1 Vegetation

Plant Communities found on the Keys include seagrass beds, algal flats, mangroves, salt marsh, pine rocklands, tropical hardwood hammocks, coastal berm, open beach / dune strand and coastal rock barrens. Seagrass beds are described in the Florida Bay chapter.

Algal flats are communities that occur in lagoons and shallows adjacent to the Keys, especially in high-salinity areas. Algal species, including the calcareous agal species *Halimeda spp., Acetabularia crenulata, Caulerpa verticillata,* and *Udotea wilsoni*, dominate low energy, shallow, open-water flats, especially on the Bay side of the Keys. These algae are resistant to elevated water temperatures and salinity. The red algae *Dasya pedicellata* and *Gracilaria confervoides* are observed when salinities are greater than 20-25 ppt (Tabb *et al.*, 1962). Calcareous algal communities are often found interspersed in finger coral (*Porites)* rubble of the shallowest waters on the Atlantic side. Wherever they are predominant calcareous algal assemblages generate large quantities of carbonate sediments. Off the Upper Keys Ginsburg (1956) found that more than 80 percent of the sediment was derived from the calcareous alga *Halimeda*. Shinn *et al.* (1990) reported that an average of 48 percent of the sands in an area 35 miles west of Key West (the Quicksands) was derived from *Halimeda*.

Seagrass beds occur on both the Florida Bay and Atlantic sides of the Keys, in low energy areas where the water is clear and there is sufficient soft bottom sediment that they can root. In many areas where a shallow lagoon is found on the protected side of the offshore reef tract, this area is also covered with mixed seagrasses. Grassy bottoms are also found bordering inlet channels between the Keys, and generally in low energy, protected areas that are deep enough that they are never exposed to the air at low tide. Turtlegrass (*Thalassia testudinum)* is the predominant species in waters deeper than 1-2 feet. Associated with the turtlegrass is manatee grass (*Cymodocea manatorum*). Shallower areas may have a thin cover of shoal grass (*Halodule wrightii*). Seagrass beds are essential habitat for juvenile fish and invertebrates. Calcareous algae often occur interspersed with seagrasses in mixed assemblages.

Mangrove forests are the most extensive habitat type in the Lower Everglades and Florida Keys areas (Schomer and Drew, 1982; Minerals Management Service, 1990). In 1974 Florida's Coastal Coordinating Council (CCC) estimated that there were 235,000 acres of mangroves in Monroe County. Mangrove communities are composed of an association of unrelated tropical hardwood tree species adapted to grow in saline soils under conditions of intermittent flooding. Mangrove species are not generally frost hardy, and are found throughout the tropical world along low energy coasts. In the Keys and coastal Florida the red mangrove (*Rhizophora mangle*) dominates the intertidal zone of outer fringes and mangrove cays, while black mangrove (*Avicennia germinans*) occupies the inner side of fringing stands, as well as lower-energy hypersaline flats and deeply flooding basins. White mangrove (*Laguncularia racemosa*) is found in lower salinity areas, as well as forming extensive “dwarfed” stands over rocky flat areas of the lower Keys. Mangrove stands and cays are important wildlife habitat. Most mangrove stands export particulate and dissolved organic matter to surrounding waters, supporting a diverse food web (Odum, 1982). Red mangrove prop roots provide vital nursery and grow-out habitat for many species of commercial fish and such invertebrates as lobsters and crabs, and many species of wading birds utilize mangrove canopies and islets for roosting and nesting.

Salt marsh formations are nearly absent in the Keys proper, except in recently disturbed areas, where cordgrass (*Spartina)* may act as a pioneer species in the intertidal zone, eventually being replaced in succession by slower-growing red mangrove trees.

Upland terrestrial habitats within the Keys may be grouped into five major ecosystem types, based on their geographic location and dominant plant species. These habitats include: pine rockland, tropical hardwood (rockland) hammocks, coastal berm, open beach dune/strand, and coastal rock barren.

Pine rockland communities occur mainly in inland areas and are associated with fresh (or low-salinity) groundwater. While there were once pine forests in the Upper Keys, the habitat is now found only in the Lower Keys. On Key Largo, only charred pine logs, stumps, and some persistent species typical of the understory remain. Approximately 2,200 acres of undisturbed pinelands remain in the Keys (Monroe County, 1986). These communities are most common in the lower Keys, with the greatest acreage occurring on Big Pine, Little Pine, No Name, Sugarloaf, and Cudjoe keys (Schomer and Drew, 1982). Pine stands generally contain three layers of vegetation. The most visible species is the south Florida slash pine or

Caribbean pine (*Pinus elliottii* var. *densa*), a distinct variety found only in south Florida (Hardin, 1991). The understory may be tall, dense, or nearly absent, and is composed of trees, shrubs, palms, and young pines. The ground layer is composed of numerous wildflowers and grasses (Hardin, 1991). Some pinelands appear prairie-like, with wildflowers and grasses (including *Cassia* and *Ruellia*) on the ground layer more conspicuous than the few scattered pines. Pine rockland is the habitat of the endangered Key deer and of several endemic plant species.

Tropical hardwood hammocks are the most extensive upland plant community in the Keys. Monroe County has estimated that there are about 7,000 acres of hardwood hammock between North Key Largo and Lower Sugarloaf Key, with over 3,600 acres in the Upper Keys (to Marathon) and over 3,200 acres between Big Pine Key and Lower Sugarloaf Key. Hammocks in the Keys consist of closed, broadleaf forests containing a large number of evergreen and semievergreen trees. They develop on elevated, rocky, rarely flooded and fire-free sites. More than 150 species of trees and shrubs are found in this habitat within south Florida and the Keys. Tropical species are found in the Keys more often than in south Florida. Keys vegetation is similar to that of the Bahamas and Greater Antilles, with many of the plants at the northern limits of their range.

Common tree species found in both the Upper and Lower Keys include poisonwood (*Metopium toxiferum*), Spanish stopper (*Eugenia foetida*), saffron plum (*Bumelia celastrina*), black bead (*Pithecellobium keyensis*), pigeon plum (*Coccoloba diversifolia*), Jamaican dogwood (*Piscidia piscipula*), gumbo limbo (*Bursera simaruba*), white stopper (*Eugenia axillaris*), white indigo berry (*Randia aculeata*), blolly (*Pisonia discolor*), torchwood (Am*yris elemifera*), and yellowroot (*Morinda royoc*). Many other species of trees, shrubs, and cacti are present, including live oak, mahogany, mastic, wild coffee, lancewood, wild tamarind and strongbark.

Over 4,000 acres of excellent quality hammock remain in the Upper Keys due to a lack of recent disturbances, with 89 percent in eight publicly owned sites, mostly in Biscayne National Park and on North Key Largo (Kruer, 1992). Of almost 3,000 acres of hammocks reported in the Lower Keys, 54 percent are publicly owned, 44 percent are private, and two percent remain in nonprofit ownership.

The term coastal berm is used to describe the mostly wooded upland plant community that develops on high ridges of storm-deposited sand, shell, and marine debris. It includes forested sections of large dunes. There are only 159 acres of this cover type in the Keys. Kruer (1992) reported 84 plant species as occasional to abundant in the coastal berm habitat. Of the 10 most frequent, black bead, Spanish stopper, poisonwood, buttonwood, seagrape, blolly, and gumbo limbo were also reported as dominant in the Lower Keys hardwood hammock habitat. Seven-year apple, bay cedar (*Suriana maritima*), wild sage, silver palm, Bahama nightshade (*Solanum bahamense*), broadleafed spider lily, Australian pine, and green knickerbean were also reported as common. Australian pine is an undesirable exotic tree that invades this community.

Dune strand habitats are similar to the dune environments of Florida's southeast coast. Dunes are typically located in open areas, with pioneering vegetation occurring on coarse carbonate sand, shell, and marine debris of biogenic origin. The upper beach is vegetated with pioneer species, especially sea oats. Kruer (1992) reported sea purslane (*Sesuvium portulacastrum*), sea lavender (*Limonium* spp.), sea oats, picnic grass, broadleafed spiderlily (*Hymenocallis lafifolia*), bay cedar (*Suriana maritima*), wild sage (*Lantana involucrata*), sea blight, yellowtop (*Flaveria linearis*), coastal dropseed, and spurge from this habitat. Seven of the 11 genera found on Florida's southeast coast also dominate the habitat in the Keys. Sea lavender sites are of particular significance, as the species is seriously threatened in other parts of the state.

Coastal rock barren habitats are unusual upland communities, vegetated by sparse drought tolerant plants and cacti on flat rocklands with considerable exposed limestone. Most sites contain several species of cactus,. The rare three-spined prickly pear *(Opuntia priacantha*) occurrs in this cover type. Plants frequently found include the endemic *Indigofera keyensis, Evolvulus convolvuloides, Cienfugosia yucatensis, Sida cilans, Jacquemontia penthantha,* false sisal, prickly pear, and shrubby hardwoods.

J.9.2 Fish and Wildlife

The limited land area and relative isolation of the individual islands making up the Keys have limited the species-richness of its land animal fauna. In contrast, the surrounding waters support a great variety of fish and invertebrate species. On land, the mangroves, rocky pinelands and tropical hardwood hammocks all provide important wildlife habitat.

J.9.2.1 Fish

Warm temperate zone fish species arrive in the Keys as larvae from the Gulf of Mexico circulation, while tropical forms arrive on the Florida Current from the Caribbean. The Keys serve as a partial barrier between the two regions, with numerous major tidal passes separating the islands of the Lower to Middle Keys. Water exchange through these passes allows for a mixing of biota in the area's nearshore transitional habitats. The following discussion is organized by habitat type, beginning with hardbottoms, through seagrass beds, mangrove roots and coral reefs.

Hardbottoms in shallow Bay waters provide habitat for many species of invertebrates, including molluscs, crustaceans, and echinoderms, including species of sea urchins, sea stars, sea cucumbers, many shrimp species, lobsters, portunid and calappid crabs, conchs, bivalves, nudibranchs, and annelids (Minerals Management Service, 1987). Hardbottom habitats with high-relief ledges or solution holes often support commercially important species such as lobsters (*Panulirus argus*, *P. guttatus, Scyllarides* spp., and *Scyllarus* spp.). Stone crabs are often found in burrows or solution holes.

Diverse and abundant fish assemblages are found within the Keys seagrass habitats. These areas are important nursery and feeding grounds for many species that will ultimately have commercial or sportfishing value (Zieman, 1982). Fish populations are a mix of temperate and tropical species, and seagrasses serve as nursery grounds for seasonal residents (i.e., those fishes that spend only part of their life cycle in these areas). Examples include drums (*ciaenids*), porgies (*sparids*), grunts (*haemulids*), snappers (*lutjanids*), cobia (*rachycentrids*), and mojarras (*gerrids*) (Zieman, 1982).

The seagrass community is vital habitat for a variety of commercially important fish species. Snapper, an important species to the seafood industry, spends much of its life cycle in the seagrass habitat. Examples include the mangrove (gray) snapper (*Lutjanus griseus*), lane snapper (*L. synagris*), schoolmaster (*L. apodus*), and mutton snapper (*L. analis*). Recreationally important species utilizing the seagrass community include spotted seatrout (*Cynoscion nebulosus*), red drum (*Sciaenops ocellatus*), bonefish (*Albula vulpes*), permit (*Trachinotus falcatus*), tarpon *(Megalops atlanticus*), great barracuda (*Sphyraena barracuda*), and various sharks. These species are sought by professional fishing guides and sportfishermen from all over the world, and form the basis of an important recreational industry. Although these species are found in the Gulf region and throughout the Keys region, they are most common in the Keys' nearshore habitats and tidal channels.

The seagrass beds also support commercially important invertebrate species such as shrimp and lobster. South Florida's commercial shrimp fishery is based on the region's pink shrimp population (Saloman, 1968). Although the brown shrimp (*Penaeus aztecus aztecus*) and the pinkspotted shrimp (*Penaeus brasiliensis*) are also present, they are not as important (Saloman, 1968).

Pink shrimp are historically common in the estuaries and shallow marine waters surrounding southern Florida and in the deep waters (approximately 100 m) southeast of the Keys, and are the dominant species within the Dry Tortugas shrimping grounds and Florida Bay (Saloman et al., 1968).

The commercially important spiny lobster begins their existence in the Keys as larvae arriving by oceanic currents. They then metamorphose into a transitional swimming stage, travel through channels between the Keys, and enter nursery areas in the seagrass beds in Florida Bay and the Gulf. They then metamorphose into juveniles and take up solitary residence in the Bay. They remain in these nurseries for 18 months to two years (Hunt et al., 1991).

Adult lobsters move to deeper waters and the coral reef environment, where they occupy dens or holes during daylight hours. They are nocturnal feeders and predominantly prey on molluscs and crustacea, including hermit crabs and conch.

Stone crabs are distributed in various habitats throughout the Keys regions. They inhabit warm-temperate, subtropical, and tropical waters, and although found in harvestable quantities along parts of Florida's west coast from Cedar Key to the Ten Thousand Islands, the greatest concentrations occur in the coastal waters adjacent to Collier County and throughout Florida Bay (Bert et al., 1978). They occur, but are less abundant, in nearshore habitats and tidal passes with suitable substrate. Although stone crab fishermen set traps on the Atlantic side of the Keys, the majority of the fishery is within Gulf waters.

Mangrove-related fish communities can be organized along various environmental gradients including salinity, mangrove detritus dependence, and substrate (Odum *et al*., 1982). The sheltered backwater pools of the black mangrove basin forest community are harsh environments inhabited by killifishes (*Cyprinodonts*) and live bearers (*Poeciliids*) (McPherson, 1971; Odum et al., 1982). However, it is the shaded, sheltered community of the red mangrove prop roots and the surrounding shallow waters that provide the most significant juvenile fish habitat in the Keys mangrove community. Among fish species associated with the mangrove habitat as juveniles or adults, mullet (*Mugil curema*), tarpon (*Megalops atlanticus*), and, as juveniles, several species of snappers (lutjanids), grunds (haemulids) and groupers (serranids). Many of these fish exploit the detritus-based mangrove food chain, feeding on forage fish supported by the mangrove detritus.

Coral reefs attract a diverse assemblage of fish. Resident and transient species include wrasses, angelfish, tangs, parrotfish, surgeonfish, porkfish, cardinals, blennies, damselfish, grunts, and hogfish. Commercially important species such as grouper and snapper are seasonally abundant, and migrate shoreward and seaward between spawning events. Examples of tropical fish include the blue chromis (*Chromis cyanea*), redspotted hawkfish (*Ambiycirrhitus pinos*), and Spanish hogfish (*Bodianus rufus*).

J.9.2.2 Wildlife

The native vertebrate (mammal, bird, reptile and amphibian) fauna of south Florida rockland ecosystems is primarily derived from southeastern temperate North American fauna (Robertson, 1955; Duellman and Schwartz, 1958; Robertson and Kushlan, 1984; Layne, 1984; Snyder *et al*., 1990). Invertebrate groups show both southeastern and West Indian relationships. A large number of resident butterflies and skippers are primarily West Indian in origin (Snyder *et al*., 1990). Included in this group is the endangered Schaus swallowtail butterfly (*Heraclides aristodemus ponceanus*) (Loftus and Kushland, 1984; Snyder *et al*., 1990). The Florida tree snail (*Liguus fasciatus*) is native to hammocks of the Florida Keys. Mangrove forests have a rich invertebrate fauna that includes insects, molluscs and crustaceans. The mangrove tree crab (*Aratus pisonii*) is an important ecological component (Schomer & Drew 1982).

Twenty-four species of amphibians and reptiles have been identified in mangrove and upland habitats (Odum *et al*., 1982). The Florida Keys are habitat to a variety of amphibians and reptiles including: various species of frogs, the Diamondbacked terrapin (*Malaclemys terrapin*), the endangered Eastern indigo snake (*Drymarchon corais couperi*), the Miami black-headed snake (*Tantilla oolitica*), and the mangrove water snake (*Nerodia fasciata compressicauda*) (SFWMD, 1992; Snyder *et al*., 1990). Although not terrestrial, all species of sea turtle found in the U.S. are sighted in waters around the Keys. Hawksbill (*Eretmochelys imbricata)* and occasionally, loggerhead (*Caretta caretta*) females nest on Keys beaches, and subadult turtles are observed over reef and seagrass habitats. The endangered American Crocodile inhabits Florida Bay and the bayside of Key Largo.

Birds in the Florida Keys area come from both the southeastern temperate fauna and the West Indian fauna. Typical West Indian species include the black-whiskered vireo (*Vireo altiloquus*), the Cuban yellow warbler (*Dendroica petechia gundlachi*), the antillean nighthawk (*Chordeiles gundlachii*) the white crowned pigeon (*Columba leucocephla*), the smooth-billed ani (*Crotophaga ani*), the grey kingbird (*Tyrannus dominicensis*), and the mangrove cuckoo (*Coccyzus minor*) (Snyder *et al*., 1990).

There is extensive use of the Keys by southeastern birds and migrants from northern continental areas. The Keys are particularly important for raptors migrating along the Central and East Coast flyways. Mangroves are significant bird habitat. The tricolor heron (*Egretta tricolor*) and snowy egret (*Egretta thula*) are the most abundant wading birds, while the white ibis (*Eudocimus albus*) and wood stork are less common (Kushlan 1979; Schomer & Drew, 1982). The commonest diving bird is the double-crested cormorant. The Wilson's plover and willet are present all year.

Odum et al. (1982) listed 181 birds that utilize the south Florida mangrove zone, and classified them into six categories based on feeding habits: wading birds, probing shorebirds, floating and diving water birds, aerially searching birds, birds of prey, and arboreal birds. Wading, aerially searching, and floating and diving birds are the most prominent. Eighteen species of birds of prey are found in the mangrove and upland habitats.

Typical land mammals include such small rodents such as the Key Largo woodrat, and the Keys' best recognized endangered species, the Key deer (*Odocoileus virginianus clavium*). Twenty species of mammals have been identified in the mangrove zone (Odum et al., 1982). Of these, the mangrove fox squirrel (*Sciurus niger avicennia*) is also Federally endangered.

J.9.3 Water Management

There is no overall surface water management canal infrastructure in the Florida Keys. The C&SF canal system has very little influence on the Florida Keys except in the estuarine areas of Florida Bay, where it controls the amount and timing of freshwater releases into the estuaries.

J.9.4 Water Supply

Keys water is supplied almost entirely by a pipeline from the mainland that draws water from the West Miami Wellfield. This water supply is near capacity.

J.9.4.1 Groundwater

Because of the slight geographic relief and pervious nature of the Key Largo Limestone and Miami Oolite rock formations, most rainfall in the Keys infiltrates the surficial aquifer and forms shallow freshwater lenses. Groundwater in south Florida and the Keys is restricted to these shallow lenses and the deeper waters of the Floridan Aquifer (Schomer and Drew, 1982). The size of a freshwater lens is controlled by several factors, with the lens generally becoming thicker during the rainy season and thinner during the dry season. Permeability of the subsurface sediments, proximity to seawater and tidal fluctuations, and the rate of freshwater pumpage or seepage from these lenses are also significant (Schomer and Drew, 1982).

J.9.4.2 Floridan Aquifer

At the latitude of the Keys the Upper Floridan aquifer contains brackish groundwater, while the lower Floridan aquifer contains seawater. Groundwater movement in the upper aquifer is generally toward the Keys, from the area of highest head in central Florida, southward to the Straits of Florida, and westward to the Gulf of Mexico. Studies suggest saltwater upwelling occurs from the lower to upper aquifer (Meyer, 1989).

The aquifer system in the Keys is used by the public mainly for subsurface storage of liquid wastes, primarily injected treated municipal wastewater (Meyer, 1989).

J.9.4.3 Potable Water

South Florida's Biscayne Aquifer provides the Keys with its primary source of public potable water. Through this aquifer, the county extracts water from well fields in the Homestead area south of Miami. Ocean Reef Club, in North Key Largo, is the only area in the Keys that uses an alternative source of water (the Floridan Aquifer and a reverse-osmosis plant).

The Florida Keys Aqueduct Authority (FKAA) manages the distribution of potable water within the Keys. It is permitted by the South Florida Water Management District to withdraw up to 19.77 million gallons per day (mgd). About 15 mgd is currently being used. The total permitted yearly withdrawal is 5.56 billion gallons. The FKAA is currently operating at approximately 90 percent of capacity.

J.9.5 Socio-Economics

The Keys' economy is unique because of the area's location and geography. Monroe County's economy is dominated by the tourism industry, and the Keys attract both seasonal residents and short-term visitors because of their abundant recreational resources. The military and the commercial fishing industry are also important sectors of the region's economy. The Monroe County economic base expanded during the 1980s, with income and employment increasing at a faster rate than those of Florida or the nation did. In 1980, per capita income in Monroe County was $8,917, nearly nine percent below that of Florida and 10 percent below that of the nation for that year. By 1989, however, per capita income had increased to $17,896, higher than that of both the state and the nation.

J.9.5.1 Public Sector Employment

Public-sector employment makes up approximately 23 percent of the total work force in the Keys. About nine percent of these workers are State and county employees, seven percent are employed by the military, and seven percent are Federal employees. The number of State and local government employees increased substantially during the 1970s, but grew at a slower rate during the 1980s. The public-sector component of the work force has increased at a significant rate in recent years, but has yet to reach its previous level. There was a large decline in the number of military personnel employed in the Keys during the 1970s, but it appears that the military's strategy has been to hire additional civilian employees when possible.

J.9.5.2 Recreation/Tourism

In 1990, 16,691 jobs in Monroe County were dependent on the tourism/recreation industry. Recreation activities also had an indirect or induced effect, creating over 2,500 jobs (Kearny/Centaur, 1990). Consequently, outdoor recreation and tourism supported about half of all employment in the county, and half of all personal income by place of work came from these activities. Recreational activities include boating, camping, tourism, ecotourism, sport fishing, sport diving, and other activities associated with "vacationing."

J.9.5.3 Commercial Fishing

Commercial fisheries are among the Keys' most valuable natural resources. The area is one of the richest fishing grounds in the Gulf of Mexico (Phillips, 1990) and commercial fishing is the fourth-largest industry in the region, representing nine percent of Monroe County's private-sector employment (White, 1991).

The diversity of the Keys' aquatic habitats and communities (including coral reefs, seagrass beds, and softbottom and hardbottom areas) provides food and shelter for these invertebrates and fishes (Environmental Science and Engineering, Inc. et al., 1987; Comp and Seaman, 1985). Ninety percent of the region's commercially important species use these habitats for shelter, food, or nurseries during at least one stage of their life history (Comp and Seaman, 1985).

Population growth in Monroe County has raised management concerns about potential overfishing (Bohnsack, 1991). Commercial harvest is regulated by measures including annual catch quotas, closed seasons, gear restrictions, and guidelines setting minimum catch sizes. These regulations have been developed for most commercially important invertebrates, finfish, and corals through management plans written by the South Atlantic and Gulf of Mexico fishery management councils, the Florida Marine Fisheries Commission, and the Florida Cabinet (Bohnsack, 1991).

The State collects landings information on approximately 400 kinds of fish, invertebrates, and plants harvested in Monroe County. Information is collected from every commercial fishing trip (including those involving marine-life collecting). In 1990 commercial landings of food and bait species were 19.7 million pounds (approximately 10 percent of Florida’s total landings) (FDEP, unpublished data). Landings are impacted by the cyclical and migratory patterns of various species and quotas that have been imposed on certain commercial seafood.

Spiny lobster has recently surpassed pink shrimp, and leads the county in both landings and value. In 1990 spiny lobster landings totaled 5.3 million pounds, followed by pink shrimp (3.7 million pounds) and stone crab (2.6 million pounds). Of the finfish, yellowtail snapper accounted for the greatest landings (1.6 million pounds), followed by Spanish mackerel (1.1 million pounds).

Fishermen typically participate in a variety of fisheries during the year. A cycle may begin in August by fishing for spiny lobsters, adding or switching to stone crabs in mid- to late October, briefly switching to king and Spanish mackerel in January and February, and shifting to snapper, grouper, and dolphin in early summer (Muller, pers. comm.).

In 1989 over 1,700 fishermen regularly operated in association with wholesale fish houses, not including part-time or independent fishermen (White, 1991). In 1989 there were over 1,600 registered commercial fishing vessels in the county (White, 1991). Between 1980 and 1990, however, the number of commercial vessels declined by six percent, contributing to a 22 percent decline in total commercial landings during the period. Factors influencing the declining number of vessels included the high cost of living in the Key West (Stock Island) area, increased dock fees, a reduction in available dock space, the retirement of older fishermen, and a declining shrimp industry (Monroe County, 1992; Bohnsack, pers. comm.).

J.9.5.4 Marine Life Collecting

In addition to the commercial food and bait fish industries, a poorly documented fishery has recently been recognized as economically important. This "marine-life" fishery supplies small fishes, invertebrates, algae, and live rock to wholesalers, retailers, hobbyists, and public aquaria throughout the world (Feddern, pers. comm.).

Although the actual economic value of the marine-life fishery has not been determined due to its recently recognized significance, the wide variety of species involved, and the reluctance of fishermen to release financial data, it is estimated to be $30 million annually. About 260 species are harvested, including the juveniles of a small number of species managed in other fisheries (Feddern, pers. comm.). Overall harvest totals are not applicable because market categories are given as colonies, individuals, and pounds of material (e.g., live rock). Live rock is an important resource in the Key's coastal areas serving as a refuge and food source to many juvenile and cryptic species and serving as a substrate to filter feeders. However, rock beauty was the most frequently reported species collected in 1990 (on 1,913 trips). Angelfish and butterflyfish are the most frequently collected fish species in the county (Muller, pers. comm.).

J.9.5.5 Aquaculture

Aquaculture operations makeup a relatively minor portion of the Keys' commercial fisheries, and although various aquaculture attempts have been made, most have failed. There are currently several projects operating in the Keys involving shrimp, finfish, and conch (Little, pers. comm).

J.9.6 Land Use

In 1975 Florida designated Monroe County an Area of Critical State Concern under the authority of Chapter 380, F.S. This legislation was designed to preserve and protect the county's unique natural resources, which were being degraded by large development projects. It gave the State Department of Community Affairs (DCA) the responsibility of overseeing all development activities within the designated area. The legislation required both the drafting of a comprehensive plan and development regulations designed to set the county's growth-management standards, over which the State has final review and approval.

Significant features of the plan include the "down-zoning" of large natural areas (excluding Key West, Key Colony Beach, and Layton), and the establishment of the Monroe County Land Authority, which is responsible for purchasing these down-zoned areas. The plan was also designed to preserve the contiguous areas of habitat as biologically functional units, specifying that required open-space areas may not be altered. It also contained the rudiments of the concept of "concurrency," which requires that a project cannot be completed without the public infrastructure necessary to support it.

Monroe County and its sister municipalities are currently revising their comprehensive plans under Chapter 163, F.S. In general, Chapter 163 legislates more specific standards, significantly expands the concept of concurrency, and allows the local government to set a "level of service" for hurricane evacuation that cannot be exceeded as a result of new development. However, because the county is an Area of Critical State Concern, the County must still meet the standards of Chapter 380, F.S.

J.9.6.1 Existing Land Use

The inhabited Keys make up only five percent of Monroe County's total land area (65,500 of 1.2 million acres). The county also contains over 99,000 acres of the Everglades, but this area is almost entirely within Everglades National Park and Big Cypress National Preserve. The majority of the county, consequently, is classified as "conservation land."

Within the county, the unincorporated area is distinguished from the four incorporated areas of Key West, Key Colony Beach, Layton and Islamorada. Within the unincorporated area, land use is also apportioned differently between the Upper, Middle, and Lower Keys. The types of land use can be defined as residential, commercial, industrial, or public facilities and buildings; historical buildings and districts; military facilities; and recreation, conservation, and vacant land.

Residential Land

The portion of land used for residential purposes ranges from 12 percent in the Lower Keys to 58 percent in Key Colony Beach. The small percentage of residential use in the Lower Keys is due to the high proportion of conservation land, primarily in the National Key Deer Refuge. The relatively high proportion of residential development in Key Colony Beach reflects the city's reliance on Marathon for commercial and other use categories. Within the unincorporated area, the majority of residential development (78 percent) consists of single-family units. The unincorporated area also has the majority of the county's mobile homes, although the total area is relatively small. The cities of Key West and Key Colony Beach have substantial duplex development. In the City of Key West, the single-family/duplex zoning category accounts for 62 percent of all residential area. Key Colony Beach has similar percentages.

Commercial Land

The proportion of commercial land in each area is similar, although there are significant differences between the Upper, Middle, and Lower Keys. In general, commercially zoned land accounts for about four percent of land-use acreage within the Keys. The Middle Keys contain significantly higher proportions because of the large amount of commercial land in Marathon. The lower levels in the Lower Keys reflect the large amount of refuge conservation land.

Industrial Land

The cities of Key West, Key Colony Beach, and Layton contain no significant industrial development, and rely on the adjacent unincorporated areas for their industrial needs. Two industries, rock mining and marine repair and salvage define industrial use in the Keys. The majority of rock mining operations are in Stock Island and Marathon. Other small-scale industrial businesses are located in Stock Island, Big Pine Key, Marathon, and Key Largo.

Public Facilities and Buildings

As much as eight percent of Key West is allocated to public buildings and facilities (excluding recreational uses), while the unincorporated area, Key Colony Beach, and Layton provide one percent or less.

Historic Buildings and Districts

Within the cities of Key Colony Beach and Layton, and in the unincorporated areas of the Keys, virtually no acreage is allocated for historical lands. There are, however, historic structures and buildings outside Key West, including those on Pigeon Key and the Carysfort Light off North Key Largo, both of which are listed, in the National Register of Historic Places. The City of Key West also considers large areas of "old town" historic and, as a result, requires additional permits before allowing development. In addition, the City has established a Historic Architectural Review Commission to ensure that the traditional character and appearance of the area is maintained.

Military Facilities

Military facilities are located exclusively in Key West and the Lower Keys. About 25 percent of Key West’s land is used for military purposes. In the Lower Keys there are three military facilities that make up five percent of all land in the unincorporated area.

Recreational Facilities

The City of Key West provides about seven percent of its land area for recreational purposes, while the Lower and Upper Keys provide less than two percent each. The Middle Keys provide 11 percent, Key Colony Beach nine percent, and Layton none. These numbers may be somewhat misleading, however, as they are derived primarily from a list of publicly and privately owned lands that provide recreational activities. Many private owners of resort areas provide recreational facilities geared toward water activities that include swimming pools and/or tennis courts.

Conservation Land

Conservation land makes up about 34 percent of all unincorporated land use within the Keys. The largest proportion is in the Lower Keys, and is associated with the National Key Deer and Great White Heron refuges (28 percent). In the Upper Keys (51 percent), conservation land is located primarily in North Key Largo. The cities of Layton and Key Colony Beach have no conservation land. Within the City of Key West, conservation land is undeveloped and categorized as open water, freshwater islands, tidal wetlands, mangrove, and hammock. Some of the land is in private ownership and, therefore, could be subject to future development. However, substantial areas around the “Salt Ponds” area of Key West have been (and are currently being) acquired by the Monroe County Land Authority. A total of 550 acres remains undeveloped in Key West.

Vacant Land

About 210,000 acres of land are potentially available for development, representing just over 34 percent of the Keys' total land area. In the unincorporated area of the county, vacant land is the largest land-use category. Ten percent of the county's vacant land is divided into nearly 15,000 vacant lots. These lots represent the only reasonably buildable property remaining in the Keys, and make up a substantial proportion of the total potential single-family development area.

J.9.7 Recreation Resources

Recreation resources in the Florida Keys region are mostly water-based, with some upland shoreline activities. Boating, fishing, diving, and nature interpretation are some of the many recreation opportunities in the region. Five wildlife refuges and one of the busiest State Parks (Pennekamp) are located in the Keys. Several other state parks are also present (SCORP, 1994). Key Largo National Marine Sanctuary designates protection for the delicate reefs outside of Pennekamp. Divers and snorklers heavily visit these reefs. Fort Jefferson National Monument is the most southern point of the continental United States and is one of the most unique monuments in the world because of its setting. Recreation resources depend on the very fragile Florida Keys regional ecosystems. Diving is the most popular recreation activity followed by fishing, bird watching, etc. The overall region is a delicate natural resource that provides visitors with excellent recreation resources. Development pressures could adversely affect the regional water quality and recreation resources.

J.9.8 Aesthetic Resources

The Florida Keys visual landscape can be described in terms of expansive open water views, West Indian-style ("conch") architecture, coastal island beaches and small roadside developments. The Florida Keys and the offshore coral reefs and sea grasses are a threatened resource of international significance (DCA, 1996). The underwater aesthetics of the region are as significant as those above water. Many varieties of coral provide a seemingly limitless palette of textures, color, relief, and contrast beneath the sea. Reefs in the Gulf of Mexico and the Atlantic Ocean have been awarded preserve, refuge and sanctuary status due to their unique character and appearance. The trade winds ameliorate the temperatures in the region and provide a comfortable climate year round.

J.10 BIG CYPRESS REGION

The Big Cypress physiographic region is defined as that region bordered on the south by Everglades National Park, along the east by WCA-3A, the L-1, L-2, and L-3 levees, the northern boundary is State Road 832, and the west is bounded by the Gulf of Mexico. It includes all of the Big Cypress National Preserve (BCNP), including the Addition lands to the north (***Figure J.10-1***). Due to the nature and scope of the alternative plans for the Restudy, it is this area which has been identified as being the affected environment, and is primarily described below. The Big Cypress Swamp spans approximately 1,568,000 acres (Duever et al. 1986) from southwest of Lake Okeechobee to the Ten Thousand Islands in the Gulf of Mexico.

The 729,000 -acre BCNP was established by Public Law 93-440 in 1974 to protect natural and recreational values of the Big Cypress watershed and to allow for continued traditional uses such as hunting, fishing, and oil and gas production. It was also established to provide an ecological buffer zone and protect the Everglades National Park's water supply. The original designation of the Preserve encompassed a total of 582,000 acres. In 1988, Congress passed the Big Cypress National Preserve Addition Act which will add 147,000 acres to the BCNP.

J.10.1 Vegetation

The Big Cypress region is characterized by a variety of upland and wetland plant communities, including hardwood hammock, pine forests, low density pine woodlands, hardwood scrub, herbaceous prairie, cypress prairie, mixed-hardwood cypress strand, graminoid marsh, exotic vegetation assemblages, and others. Fire, as it modifies ecological succession and water as it affects hydroperiod, and seed germination, are major influences in determining the predominant vegetative community. Below are described the predominant upland and wetland vegetative community types.

J.10.1.1 Hardwood Hamock

Hardwood hammocks are climax communities found on rock outcrops at elevations between 10 and 12 feet above mean sea level (MSL). Inundation may occur only during extremely high water periods (Duever et al., 1986; Gunderson et al., 1982; Olmstead et al., 1980), although forests have been observed with hydroperiods of 10 to 45 days (Duever et al., 1986). Major canopy species include live oak (*Quercus virginiana*), wild tamarind (*Lysiloma latisliquum*) and gumbo limbo (*Bursea simaruba*) which are typically the largest and tallest trees in the hardwood hammocks (Gunderson and Loope, 1982c). A variety of understory vegetation is also present including several species of shrubs, vines, orchids, bromeliads, and other epiphytes. Hardwood hammocks support a great number of rare and threatened plants. The majority of these are epiphytes from the bromeliad, orchid, and fern families. Solution holes support some of the rare plant associations. Tropical hardwood hammocks have a high diversity of plant species, yet are one of the least frequently used of all the habitats by wildlife. Wildlife that are known to frequent this environment include wading birds, Florida tree snails, owls, lizards, skinks, and raccoons.

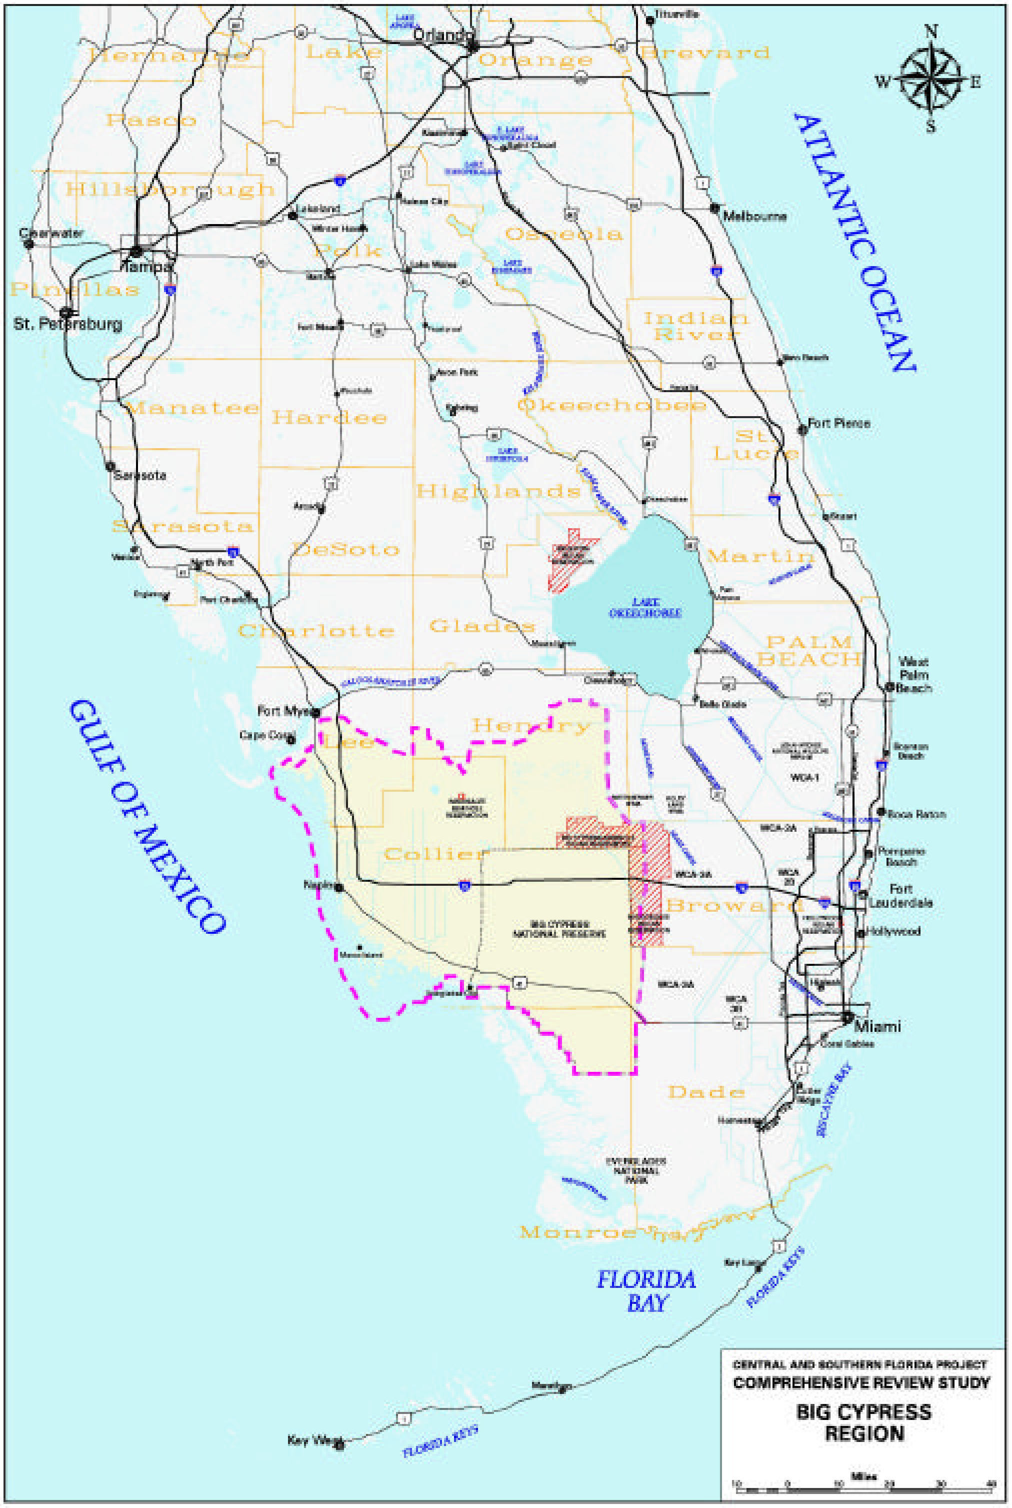

Figure J.10-1 Big Cypress Region

J.10.1.2 Pine Forest

The hydroperiod for the pine forest is 0 to 60 days (Duever et al., 1986; USACE, 1990). Pine forests are subclimax communities preceding the development of hardwood hammock. As such, fire is a major determinant of species composition. In the absence of fire for two or three decades, a pineland will take on the characteristics of a hammock in the process of succession (Lodge, 1994).

South Florida slash pine (*Pinus elliottii* var. *densa*) is the only species found in the canopy. Species found throughout the shrub layer include saw palmetto (*Serenoa repens*), cabbage palm (*Sabal palmetto*), varnish leaf (*Dodonaea viscosa*), wax myrtle (*Myrica cerifera),* bitter gallberry (*Chiococca alba*), and velvet seed (*Guettarda scabra*).

The pine rocklands of southern Florida are home to many endemic species, including several of the endangered plant species identified by the USFWS as likely to be effected by the Restudy. Examples include crenulate lead-plant (*Amorpha crenulata*), deltoid spurge (*Chamaesyce deltoidea*), and Small's milkpea (*Galactia smallii*).

J.10.1.3 Low Density Pine Woodland

Low density pine woodlands form in areas having longer hydroperiods, approximately 60 days, more than pine forests (Duever et al., 1986; Gunderson et al., 1982; USACE, 1990). Low density pine woodlands are successional communities maintained by water levels and periodic fires, and are among the most diverse plant associations in the Big Cypress region. South Florida slash pine is the dominant canopy species. The vegetation found in the understory contains many of the same species found in the herbaceous prairie, including maidencane (*Panicum hemitomon*), sand cordgrass (*Spartina bakeri*), beakrush (*Rhynchospora spp*.), muhly grass (*Muhlenbergia spp*.), spikerush (*Eleocharis spp*.), and sawgrass (*Cladium jamaicense*) (Duever et al. 1986; Olmstead et al., 1980)

J.10.1.4 Hardwood Scrub

This community is thought to be an early successional stage of the hardwood hammocks. The only common feature is that the vegetation is composed of hardwood species less than 5 meters tall. Some scrub areas can be recognized as disturbed oak/palm-Serenoa hammocks. Others, with saplings of gumbo limbo, and *Bumelia spp*., appear to be disturbed hardwood hammocks.

Common species observed in these scrub areas include cabbage palm, saw palmetto, Florida trema (*Trema micrantha*), false willow (*Baccharis glomeruliflora*), sweet bay, pond apple, red bay, cocoplum, dahoon, and poisonwood (Gunderson and Loope, 1982d).

J.10.1.5 Herbaceous Prairie

Herbaceous prairie is typically found on thin marl over limestone. Herbaceous prairies are one of the driest grass dominated communities with hydroperiods of 60 to 130 days (Gunderson et al., 1982; Gunderson and Loope 1982a; Olmstead et al., 1980; USACE, 1990). Herbaceous prairies have the most diverse flora of all the graminoid communities (Olmstead et al., 1980).

Muhly grass (*Muhlenbergia capillaris*) is typically the dominant species found in this community, and in pure stands may contribute 90-95 percent of the biomass. Sawgrass is always an associate of muhly grass and is favored at the wetter end of the hydrological gradient.

J.10.1.6 Cypress Prairie

Cypress prairie communities typically have a hydroperiod ranging from 90 to 270 days (Duever et al., 1978; Duever, 1980, Weakley et al., 1996), and are characterized by low densities of stunted cypress under 30 feet tall, interspersed in wet prairie. There are extensive areas within the BCNP which contain cypress prairie, throughout the BCNP north of Hwy 41, within the Loop Rd. area, and immediately south and west of Loop Road, west of Pinecrest.

J.10.1.7 Exotic Trees

Exotic trees found within the Big Cypress Region, include Melaleuca (*Melaleuca quinquenervia*), two species of Australian pine, (*Causuarina cunninghamia* and *C. glauca*), and Brazilian pepper (*Schinus terebinthifolius*). Exotic trees usually occur as individuals within natural communities and do not typically occur in large monotypic stands, exclusive of highly disturbed areas.

J.10.1.8 Mixed-Hardwood Cypress Strand

The hydroperiod of the mixed-hardwood cypress strand is 125 to 365 days (Gunderson and Loope, 1982a; USDI, 1991). The dominant species within this community type are pond cypress (*T. ascendens*), red maple (*Acer rubrum*), laurel oak and live oak.

J.10.1.9 Cypress Strand/Cypress Dome

Cypress strands and domes surround water filled centers. Strands are elongated depressions filled with deep peat, whereas domes are circular in shape, with similar peat deposits. Taller trees are found near the center with tree height decreasing toward the edge (Olmstead et al., 1980). Natural hydroperiods in cypress strands and domes are thought to be between 240 and 340 days (Duever et al., 1986; Olmstead et al., 1980; USDI, 1991). Pond cypress is the dominant species and often forms the entire canopy. Cypress strands and cypress domes are found in abundance within the BCNP, particularly north of Hwy 41 and west of the L-28 levee.

J.10.1.10 Graminoid Marsh

Graminoid marshes have a hydroperiod of 220 to 365 days (Gunderson and Loope, 1982b; Olmstead et al., 1980; Weakley et al., 1996; USACE, 1990). Species composition varies throughout the graminoid marsh and is strongly influenced by substrate. In areas with deep peat, sawgrass is the dominant species (Olmstead et al., 1980; USACE, 1990). In areas with shallow marl and sand, spikerush (*Eleocharis cellulosa*) is the dominant species (Gunderson and Loope, 1982b; USACE, 1990).

J.10.1.11 Inland Sloughs

Sloughs occur throughout the BCNP and are typically the deepest wetland community, with hydroperiods of about 11 months (Lodge 1994). Important sloughs which drain the Big Cypress region include the Okaloacoochee Slough in the extreme northwest BCNP, Mullet Slough in northeast BCNP, East Slough, and Lostmans Slough in southeast BCNP. The dominant vegetation occurring within the sloughs include submerged and floating aquatic plants such as water lily, pond lily, spatterdock, bladerwort, and maidencane. As sloughs may be continuously inundated for several years at a time, they provide valuable habitat for fishes, aquatic invertebrates, and as refugia for other animals during drought.

J.10.2 Fish and Wildlife

The following descriptions of wildlife habitats found in the project area have been adapted from the accounts of Duever et al., (1986). The pine forests and inland marshes, ponds and sloughs are heavily used by a large number of species. Some of the richest wildlife habitats in the project area are found in pine woodlands. These predominantly dry pine communities provide optimal conditions for burrowing, litter-dwelling, and ground-nesting species. In addition, the open nature of pine woodlands and the abundance of grassy forage are favorable to a diversity of wildlife. Frequent inhabitants of these habitats include the white-tail deer, gray fox, the Eastern meadowlark, and the Chuck-will's widow. In addition, the endangered Florida panther ranges extensively in pine woodland areas.

Inland ponds, marshes, and sloughs also support a multitude of wildlife species, and are particularly valuable to water-dependent species such as the gallinule, the snowy egret, and the American alligator. The endangered wood stork uses these ponded areas as foraging grounds, as does the endangered snail kite in the eastern BCNP.

Mixed swamp forests are used by substantially fewer wildlife species than the pine woodlands and the inland ponds, marshes, and sloughs. However, the lengthy hydroperiods often associated with these wet habitats are favorable to reptilian species such as the Florida cottonmouth, various turtles, and the alligator.

Wet prairies are not suitable as breeding grounds for most fauna due to the lack of adequate cover. However, several species such as the turkey vulture, snail kite, caracara, white ibis, and arctic falcon use these open expanses as foraging grounds. Muhly grass is often found in herbaceous prairies with shorter hydroperiods, and provides critical nesting habitat for the endangered Cape sable seaside sparrow.

Cypress dominated forests are often characterized by a sparsely vegetated understory, infertile soils, and fluctuating water levels. Few vertebrates in southwest Florida can tolerate such unfavorable conditions for extended periods, however the tall trees and surrounding water provide good nesting sites for wood storks, bald eagles, white ibis, snowy egrets, and little blue herons. The Florida Black bear, alligator, Everglades mink, and Florida panther may also use these habitats.

Hammock communities within wetland or water-dependent expanses, support a diversity of floral species, although wildlife sightings in such habitats are surprisingly scarce. The absence of wildlife in hammock areas may be due to the generally small size and isolation of the habitats. Hammock communities are extensively utilized by the Florida panther, most likely because they provide dense areas of dry cover. Important game species in these areas include white-tailed deer, hog, turkey, quail, gray squirrel and snipe.

Major freshwater fish species present within sloughs, canals, ephemeral and permanent ponds, and borrow pits, are listed below in table ***J-10.2-1***.

The Cyprinodontids such as the golden topminnow (*Fundulus chrysotus*), the least killifish (*Heterandria formosa*), and the Florida flagfish (*Jordanella floridae*) have been sampled and are known to be important food resources for wading birds, amphibians, and reptiles.

Table J-10.2-1 Common Freshwater Fish Species Found Within the Big Cypress Region	
Florida Gar	*Lepisosteus platyrhincus*
Bowfin	*Amia calva*
Gizzard Shad	*Dorosoma cepedianum*
Threadfin Shad	*D. petenense*
Yellow Bullhead Catfish	*Ictalurus natalis*
Channel Catfish	*I. punctatus*
Everglades Pygmy Sunfish	*Elassoma Evergladei*
Bluespotted Sunfish	*Enneacanthus gloriosus*
Largemouth Bass	*Micropterus salmoides*
Dollar Sunfish	*Lepomis marginatus*
Bluegill Sunfish	*L. macrochirus*
Spotted Sunfish	*L. punctatus*
Striped Mojarra	*Diapterus plumieri*
Mosquito fish	*Gambusia spp.*
least kilifish	*Heterandria formosa*
flagfish	*Jordanella floridae*
golden topminnow	*Fundulus chrysotus*

The USFWS has identified eighteen Federally listed plant and animal species as being present in the study area and likely to be affected by alternatives under the C&SF Restudy. Of these eighteen, seven animal species are known to occur or likely to occur within the area of the Big Cypress. These include the Florida panther, snail kite, wood stork, Cape Sable seaside sparrow, Red-cockaded woodpecker, bald eagle, and Eastern indigo snake. No Federally listed plant species within this region are expected to be affected by Restudy alternatives.

J.10.3 Water Management

The Big Cypress swamp is a recognized physiographic province in southwestern Florida. It is a source of recharge for the shallow aquifers of south Florida and is important to the integrity of the water resources in the western part of Everglades National Park. The hydrological features of the swamp were recognized by Congress when it established BCNP.

The water regimen of the area largely determines the patterns in which temperate and tropical vegetative communities and their related wildlife species occur. During the wet season (summer and fall) when heavy rains lead to widespread surface inundation, the almost imperceptible slope of the land creates an overland sheet flow. During the dry season (winter and spring) natural surface water flows are confined to the lower elevations of strands, swamps, and sloughs.

The BCNP has been mapped by the USFWS as part of the national wetlands inventory. The majority of BCNP lands are classified as wetlands; exceptions are scattered hardwood hammocks, some pinelands, and artificially filled areas.

The Big Cypress region is essentially a rain-driven hydrologic unit, and for the most part it is not dependent on adjacent land for water flow. Only three small areas (approximately 5 percent of the BCNP) receive flows from external drainages. These areas include less than 5 square miles in the Okaloacoochee Slough, about 30 square miles in the Mullet Slough component of the Everglades drainage, and approximately 40 square miles in the southeastern corner of the BCNP along the western boundary of the Shark River Slough.

J.10.3.1 Water Flows

Much of the BCNP is flooded during the rainy season, generally May through October, when nearly 80 percent of the rain falls. Rainfall averages 54 inches per year, but it has ranged from 35 inches to 80 inches per year. Summer rains are usually short, intense, and frequent. Winter rains are a result of frontal systems, and they last longer and have less intensity. Hurricanes occur most frequently in September and October and usually bring torrential rainfall.

During the rainy season shallow depressions fill with water. Because of the poor drainage, water stands on the land until it evaporates, infiltrates to the underlying aquifer, or slowly drains off through sloughs or strands. Thus, at the peak of the rainy season as much as 90 percent of the BCNP is inundated to depths ranging from a few inches to more than 3 feet. When the dry season begins, the water level starts to recede. The recession normally continues into May, when perhaps only 10 percent of the BCNP is covered by water in ponds, cypress domes, and sloughs.

Flows generally follow bedrock undulations, which run mostly to the northeast and range in relief from approximately 1 foot to as much as 10 feet. Marshy sloughs occupy the shallower undulations, and cypress stands and mixed hardwood swamps grow in the deeper ones. These relatively low channels control surface water flows because the water table is below the crests of the undulations most of the time; even during high water, the bedrock channels still carry a relatively large volume of water.

The BCNP is underlain by a shallow aquifer extending from the vicinity of Forty Mile Bend to the west coast of Florida and covering almost all of Collier County and the upper part of Monroe County. The aquifer is the prime source of freshwater for human use in Collier County and adjoining parts of Lee and Hendry counties. It is about 130 feet thick in western Collier County and becomes progressively thinner to the east, where it eventually disappears in the vicinity of

Forty Mile Bend. Throughout much of the BCNP, the limestone of this shallow aquifer is within 10 feet of the surface. The aquifer is replenished primarily by the infiltration of rainfall. During the rainy season groundwater levels are high. By April, the usual end of the dry season, water levels normally reach their annual lows.

J.10.4 Water Supply

The BCNP is considered wilderness and is primarily undeveloped. Throughout the BCNP are numerous inclusions of private properties and Native American lands that require potable water for consumption. Water supply needs in the area are minimal and are only related to these individually-owned lands. The need for additional water supply is not expected to significantly increase in the future. The source of the potable water are wells that extend into the surficial and Floridan aquifers. The interaction of the surface water with the surficial aquifer and the Floridan aquifer is a concern. The BCNP is not considered a water supply area although groundwater and surface water is critical in the operation of its existing ecosystem.

The area immediately east of the L-28 levee and the BCNP is WCA-3A, an important component of the water supply system for southern Florida. Any alterations to this area could impact the existing delivery of flows through the existing gaps and structures in the L-28 system. Conversely, any modifications to the gaps in the levee or the operation of the existing structures will need to be considered in terms of its potential impact on the water levels in WCA-3A.

J.10.5 Socio-Economics

South Florida has experienced tremendous growth since the end of World War II, particularly during the late 1950s and into the 1960s. Collier County, being one of the fastest growing counties in Florida, has seen its population increase by 126 percent from 1970 to 1980 (see table ***J-10.5-1***). The population of Miami-Dade County increased by 78 percent during this same decade, and Monroe County by 20 percent. The population increases suggest a growing potential visitor base for the Big Cypress region, as well as other parks in the south Florida region.

Population growth is primarily due to the rapid in-migration of retirees and people from the Caribbean and Latin America, not a high birthrate. One effect of this in-migration has been a disproportionate number of senior citizens. The median ages in the three counties increased from 1970 to 1980 in Collier from 35.2 to 38.2, in Miami-Dade from 34.2 to 34.8, and in Monroe from 27.3 to 35.5. These patterns are indicative of age changes occurring all across the Sunbelt, and they may represent a need for more programs aimed at senior citizens.

Table J-10.5-1
Area Population Statistics
Tri-County Area

	Miami-Dade County*	Monroe County	Collier County
Total Population			
1970	1,267,792	52,586	38,040
1980	1,625,781	63,180	85,971
% Change	+ 78	+ 20	+126
Total Minority Population			
1970	196,130	4,896	6,979
1980	363,506	5,254	11,310
% Change	+ 85	+ 7	+ 62
Median Age			
1970	34.2	27.3	35.2
1980	34.8	35.5	38.2

* only a minor portion of Miami-Dade Co. is within the Big Cypress Region

Another effect of this in-migration is the high percentage of minorities, particularly Spanish-speaking residents. Between 1970 and 1980 Miami-Dade County experienced an 85 percent increase in the number of minority residents, Collier County a 62 percent increase, and Monroe County a 7 percent increase. The growth in minority residents indicates a potential need for bilingual interpretive programs.

The median family income for Collier and Monroe counties for 1980 was slightly below the national average of $19,917, but higher than the state average of $17,280. The median family income in Collier County was $18,700 and in Monroe County $18,050. The Miami-Dade County median family income was $20,176, ahead of both the state and national averages.

The socio-economic data below were obtained from the 1990 Census of Population and Housing for Florida (U.S. Department of Commerce, 1992).

The region's employment consists of retail industry (19 percent), agriculture, forestry and fishery industries (13 percent) and construction (9 percent). Other industry includes finance, insurance, and real estate (7 percent), personal services (7 percent), business, repair services, other professional services, and public administration (6 percent each).

Fourteen percent of the labor force described themselves as administrative support. Another fourteen percent described themselves as service providers (excluding protective and household) and yet another fourteen percent described themselves as precision production, craft, and repair specialists. The overall unemployment rate for eligible workers in the vicinity of the project area was 4.5 percent.

About 12 percent of the families in the vicinity of the project area were classified as living below the poverty level. Although the definition of poverty varies depending upon the size of the size of the family, the number of children, and the age of the family householder, it is defined as $12,674 for a family of four in 1989.

The Census defines housing units as houses, apartments, mobile homes or trailers, or a group of rooms or a single room occupied as separate living quarters. There are 3,968 housing units in the vicinity of the project area. Of these units, four percent of the housing units lacked complete kitchens and three percent lacked indoor plumbing. Fifty-two percent of the units are part of public or private water systems. Forty-two percent have a drilled well. Sixty-eight percent of the housing units dispose of their waste in a septic tank or cess pool while thirty percent are hooked to a public sewer.

J.10.6 Land Use

Land use is organized into major public and private lands and their principal uses, including preservation, recreation, urban, agriculture and water supply.

J.10.6.1 Big Cypress National Preserve

Roadways in south Florida often obtain necessary roadfill from excavation of a parallel canal, resulting in both an elevated obstruction to natural drainage patterns and rerouting of flow in open canals. Such drainage alterations in the BCNP include the Tamiami Trail (U.S. Highway 41), Interstate 75 (Alligator Alley), County Route 839 (Turner River Road), County Route 841 (Birdon Road), County Route 94 (Loop Road) and numerous smaller roads. State Route 29, a north-south road, parallels the western boundary just outside of the BCNP, although its borrow canal is just within the boundary of the BCNP. Extending northward from the Tamiami Trail along the eastern boundary of the BCNP, the L-28 levee forms the boundary between the Everglades and Big Cypress drainage. Although the levee is located immediately outside of the BCNP boundary, it is significant to the hydrology of the BCNP. The L-28 Interceptor canal cuts through the extreme northeastern corner of the BCNP. This canal rapidly drains the agriculturally active lands north of the BCNP.

Oil and gas are currently produced from two active fields in the BCNP. A portion of the Bear Island field lies within the Okaloacoochee Slough in the northwestern corner of the BCNP. The Raccoon Point field is located in the northeastern corner of the original BCNP and north of the Jetport site.

The Miami-Dade-Collier Transition and Training Airport, popularly known as the Jetport, occupies a 32-square- mile site just north of the Tamiami Trail and adjacent to the eastern boundary of the BCNP. Although originally intended as an international airport, it is currently used only for limited training activities. Since all structures must be elevated above the seasonal high water levels, fill material must be excavated from borrow pits. Numerous such pits exist within the BCNP, ranging in size and depth, depending upon the extent of the development. One of the most significant borrow areas is associated with the construction of the Miami-Dade-Collier Training and Transition Airport just north of the Tamiami Trail and west of the eastern boundary of the BCNP. The Miami-Dade-Collier Transition and Training Airport, popularly known as the Jetport, occupies a 32-square-mile area. Construction required 3 million cubic yards of fill excavated from 7 pits, ranging from 30 to 40 feet deep and covering 65 acres of surface area just west and south of the Jetport runways.

Off-road vehicle (ORV) usage in the BCNP is regulated by the National Park Service and is permitted by the enabling legislation to the extent that it does not significantly harm the environment. About two-thirds of the original Preserve is currently open for ORV use. Permits are required, a maximum of 2,500 per year have been established, and areas open to use are designated. The Bear Island Unit, located in the northwestern corner of the BCNP, is restricted to designated trails. Other areas are open to either full or limited use, and two are closed to all ORV use. Airboat and swamp buggy use is mostly during October through March. There has been a general trend toward an increased number of permits annually since 1987.

Some 38,700 acres, totaling 6 percent of the BCNP's original boundary, are non-Federal lands. These non-Federal lands consist of 12,236 acres of School Board lands consisting of one section in each township set aside for schools, 23,488 acres of Jetport Authority lands, 1,514 acres of county roads, and 1,271 acres of private lands. Non-Federal lands within the Additions have not yet been completely defined.

Agriculture within the original boundary of the BCNP is minimal. Farming is known to be more extensive within the Additions, but until the lands are formally transferred to the Federal government, these agriculturally-impacted areas will not be completely defined.

Five active "life" leases, cover grazing rights on approximately 29,000 acres in the northwestern corner of the original Preserve. All leases are located north of

Alligator Alley. The leases can only be renewed by the permittee or spouse and are not transferable. These are gradually being phased out as lessees curtail operations or leases are relinquished.

Public Law 93-440 provides that members of the Miccosukee Tribe of Indians of Florida and members of the Seminole Tribe of Florida shall be permitted, subject to reasonable regulations established by the Secretary, to continue their usual and customary use and occupancy of Federal or Federally acquired lands and waters within the BCNP, including hunting, fishing, trapping on a subsistence basis and traditional tribal ceremonies.

J.10.6.2 Urban Areas

Naples, Marco Island, and Everglades City comprise the three largest urban areas within the Big Cypress region. All three cities are on the west coast, and Naples is among the fastest growing urban areas in the United States. It has developed into a significant retirement destination with extensive residential and business center construction. Water supply demands to meet this fast growing and developing urban area are rapidly increasing.

J.10.6.3 Fakahatchee Strand State Preserve

The Fakahatchee Strand, located just west of the BCNP, is included in the area designated by the State of Florida as an Area of Critical State Concern. It is the recipient of the flow of the Okaloacoochee Slough which cuts across the extreme northwestern corner of the BCNP and crosses under State Route 29 into the strand.

J.10.6.4 Southern Golden Gate Estates

West of the Fakahatchee Strand State Preserve and south of Interstate 75 is the Southern Golden Gate Estates. The area was planned as a large residential sub-division and construction began in the 1960's. The building of roads and several drainage canals in this 94 square-mile area has affected the areas environmental quality, by over-draining the watershed, sending harmful freshwater discharges to the estuaries, increasing frequency of forest fires, and reducing aquifer storage (SFWMD 1996).

J.10.6.5 Water Conservation Areas

The BCNP is bounded on the east by WCA-3A which, is managed by the South Florida Water Management District. Water is impounded in the Conservation Area and released to Everglades National Park and BCNP on predetermined schedules. The L-28 levee forms the boundary between WCA-3A and the BCNP.

J.10.6.6 Everglades National Park

The southern and portions of the eastern boundary of the BCNP abut Everglades National Park. The BCNP's southern boundary forms a "stair-step" pattern that distinguishes the wetland environment of the BCNP and the estuarine environment of the Everglades National Park. The Stair-Step area receives flows from the BCNP enroute to the estuarine environment of the Everglades National Park.

J.10.6.7 American Indian Reservations

Two American Indian reservations abut the BCNP. The Seminole Tribe along the eastern part of the BCNP's northern boundary, and the Miccosukee Tribe along the eastern boundary of the BCNP.

J.10.6.8 Agriculture

A persistent southward progression of agricultural development presents an external threat to the water quality and quantity of the Okaloacoochee Slough and Mullet Slough drainages. Expanding agricultural development is now located along the BCNP's northern boundary.

Hendry and Collier Counties are included in this region. More than 800,000 acres are farmed in the Big Cypress Region, and almost half of that area is pastureland. The region is characterized by moderate to large farms producing more than $600 per acre in market value (UFBEBR, 1995). Hendry County ranks third in the state of Florida for cattle production (FASS, 1996a). Approximately 70,000 acres of sugar were harvested in 1996 (FASS, 1996d). Hendry County ranks third in the state for acres of citrus with over 100,000 acres, while Collier County is ninth with over 36,000 acres (FASS, 1996b). Citrus production in the Big Cypress Region is currently increasing. The Big Cypress Seminole Indian Reservation is located in this region along the northern boundary of the BCNP. The reservation includes some citrus groves and row crops as well as pastureland.

More than 17,000 people are employed in agricultural production and services, and the payroll totals approximately $16 million. Agricultural products in this region have a total market value of more than $525 million. Hendry and Collier Counties rank third and fourth in Florida for market value of agricultural products (UFBEBR, 1995).

J.10.7 Recreation Resources

Recreation resources in the Big Cypress region are primarily wetland based with some upland access and facility use. Air boating, fishing, hunting, and nature interpretation are all very popular recreation activities in the region. Camping facilities are also found within the region. In the heart of the region, the BCNP and Wildlife Management Area is rivaled in size statewide only by the Everglades WMA. Five state parks and recreation areas are located in the region as is a state preserve. The Panther National Wildlife Refuge is also within the region. Artificial reefs are located in the region's coastal area (SCORP, 1994).

Major roadways in the region include Alligator Alley (I-75) and S.R. 41, which transect the region west to east. Several canals range north to south for many miles. Tamiami Canal runs east and west for many miles also. These represent pending concerns due to water quality issues and exotic species transport that could adversely affect recreation resources in the near future. Surrounding development pressures could also be critical to the natural and recreation resources. Substantially altered water deliveries to the Big Cypress Region could have a detrimental affect on many recreation resources in the region.

J.10.8 Aesthetic Resources

This region provides large expanses of undeveloped lands, expansive freshwater prairies and marshes, with cypress forest interspersed that create a patchwork of vertical elements that contrast with the flat panoramic views. The Big Cypress Region coastline contains a mosaic of vegetative communities that are diverse in their natural and aesthetic resources. These vegetative communities provide environmental interest, are a wildlife haven, and showcase unique aesthetic resource attributes. Contained within the Big Cypress Region are six national or state parks, sanctuaries, preserves, and refuges. It is a region of scenic and panoramic aesthetic resources.

Major infrastructures (I-75, S.R. 41, and miles of canals) have minimal background visual impact but act as corridors for the transport of exotic species. Development pressures are a growing factor in maintaining the aesthetic quality of the region.

J.10.9 Hazardous, Toxic, and Radioactive Wastes

The U.S. Army Corps of Engineers conducted an HTRW investigation of the Big Cypress Region in 1996 to facilitate early identification and appropriate consideration of HTRW problems. Due to the extensive size of the study area, the primarily undeveloped wilderness and budgetary limitations, a radial regulatory data base search was not conducted. The study area was investigated for possible HTRW contamination through the following means:

Visual inspection of the accessible regions of the study area

Interviews with personnel from the Florida Department of Environmental Protection, Collier and Miami-Dade Counties, and the BCNP.

Review of the history of the property from aerial photographs and available state, county and park records.

Review of other public documents.

The study area is primarily undeveloped, wetland wilderness with no grazing or agricultural uses. Several small areas of human habitation exist primarily along Tamiami Trail and the Loop Road in the form of permanent private residences, camps and Native American dwellings. A few other camps and less substantial dwellings exist in outlying areas away from the main roads that are only accessible by off-road vehicles or helicopter. Other than these features, the only other alteration in the study area is the Miami-Dade-Collier training and transition airport. This airport is managed by the Miami-Dade County Aviation Department as a training facility with no regular fleet maintained at the airport.

The findings from the review of the aerial photographs from the 1950's and the 1990's indicate that some changes in vegetation have occurred either from fires or timbering and does not appear to be the result of dumping or discharge of hazardous material on or adjacent to the study area.

The result of the personal interviews to collect information on possible HTRW issues revealed that only the Jetport is a possible point of concern. Although records for the Jetport are vague, they do indicate that two underground storage tanks (USTs) are located at the facility. These USTs were installed during the construction of the Jetport in the late 1960's and early 1970's and have a capacity of 4,000 and 5,000 gallons each. The USTs contain diesel fuel for generators and ground vehicles. Records show that they are past due for replacement and/or removal. Miami-Dade County Aviation Department indicated that the tanks would be removed during the early part of 1997. It is not now known whether or not these tanks have been removed/replaced. Since no groundwater monitoring is being performed in this area, it is unknown if leaking or soil/groundwater contamination exists. During replacement of the tanks, soil and groundwater conditions will be assessed and remediated if needed.

Visual inspection of the property was limited to areas accessible by Loop Road and the Tamiami Trail. This inspection indicated no signs of wastewater sources, hazardous waste, pits, solid waste disposal, chemical storage areas, storm drains, catch regions, fill pipes, pesticide storage areas, PCB-containing equipment or asbestos except as noted below:

The area known as the Corn Dance Ritual Site south of the airport has a large dumpster containing and surrounded by household trash, and other related debris.

Abandoned fuel pumps and an above ground storage tank (AST) are located on the south side of the Loop Road near parcel 72-36m Section 21, T54S, R34E.

Maintenance operations for equipment is performed at the Tamiami Range Station and Wildlife Check Station south of the eastern intersection of Loop Road and Tamiami Trail.

Fueling and storage of swamp buggy vehicles occurs at the Oasis Station along Tamiami Trail.

Storage of swamp buggy vehicles occurs at the Miami-Dade-Collier training and transition airport.

Maintenance operations are occurring at a private residence at or near parcel 508-45, Section 36, T53S, R34E.

Airport operations which may include refueling, vehicle maintenance and storage at the airport training facility.

Creosote Contamination at Jerome. Local contamination of the ground water, prior to 1956, by polynuclear aromatic hydrocarbons from a wood-treating facility at Jerome is currently undergoing remediation. The site is located on State Route 29, three miles north of the Tamiami Trail. The site is located within the western Additions and will be acquired under Public Law 100-301.

During the inspection, no evidence of soil staining or underground fuel tank vent pipes were observed at the AST fuel pump location, the Tamiami Range and Wildlife Check Stations or the private residence noted above to suggest possible leaks or contamination. No other records exist for these observed facilities in public records. Since access to the airport was not possible, a detailed inspection of the facility was not performed. The records noted above indicate the possibility of contamination in this area.

J.11 CALOOSAHATCHEE RIVER REGION

The Caloosahatchee River physiographic region extends approximately 70 miles from Lake Okeechobee to the lower Charlotte Harbor Basin at San Carlos Bay. The Caloosahatchee River Region is the northern portion of the South Florida Water Management District's Lower West Coast (LWC) Planning Area. This region primarily covers parts of Charlotte, Glades, Hendry, and Lee counties and dips slightly into Collier County (***Figure J.11-1***).

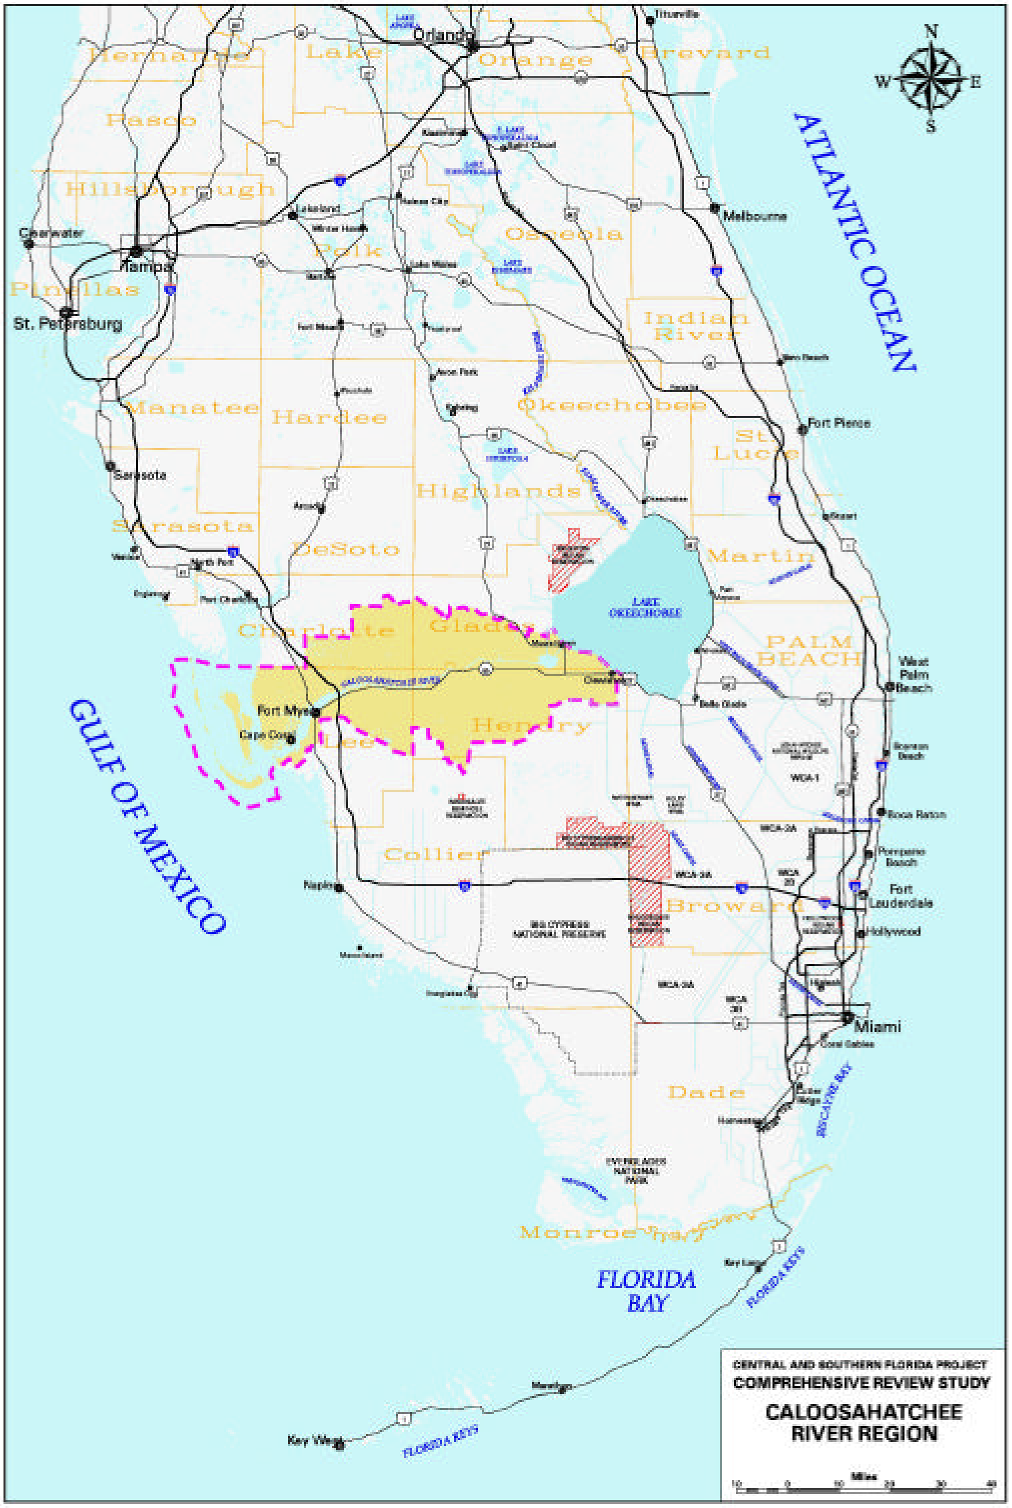

Figure J.11-1 Caloosahatchee River Region Map

The Caloosahatchee River, originally a blackwater river that drained low, flat mucklands located west of Lake Okeechobee, is now also a major navigation canal and flood control channel. It is the only flood-control outlet leading west from Lake Okeechobee, part of the Okeechobee Waterway, and the only navigable passage between the Gulf of Mexico and the Atlantic Ocean. From Olga to the Gulf, roughly 30 miles, the river broadens into a tidally influenced estuarine system. The river has a long history of human use. It flows past some of southern Florida's oldest settlements. The Indians used the river as a trade route before the Seminole Wars in the early 1800s. It later became more important as a steamboat waterway, especially after dredging and channeling in the early to mid-1900s (FDEP, 1996).

The Caloosahatchee River region is divided into major drainage basins according to their respective hydrologic characteristics. These basins are the North Coastal Basin, Tidal Caloosahatchee Basin, Telegraph Swamp Basin, the West and East Caloosahatchee basins, and the S-236 Basin (SFWMD, 1995).

J.11.1 Vegetation

The region contains a wide variety of cover types, ranging from coastal barrier islands, mangrove forests, bays, beaches, dunes and estuaries to an inland mosaic of forested uplands and forested, scrub/shrub and herbaceous wetlands. Many of these areas are public and private preserves, aquatic preserves, and lands proposed for public acquisition. The inland resources include lakes, rivers, canals, freshwater wetlands, and uplands. The coastal resources include estuaries, tidal wetlands, beaches, sand dunes, and barrier islands (SFWMD, 1994).

Vegetation in the Caloosahatchee River Region includes 174,850 acres of upland forest, largely pine flatwoods (107,633 acres). Wetlands total 173,159 acres including 50,102 acres of freshwater marshes, 30,261 acres of mangrove swamps, over 17,000 acres of wet prairie, and 23,513 acres of cypress/cypress mixed. There are 140,039 acres of water including streams, lakes, reservoirs, embayments, and slough waters.

Natural resources protected by public ownership within the Caloosahatchee River region include: J.N. Ding Darling National Wildlife Refuge, Matlacha Pass Aquatic Preserve, Matlacha Pass National Wildlife Refuge, Pine Island Sound Aquatic Preserve, Little Pine Island, Caloosahatchee National Wildlife Refuge, Caloosahatchee River State Park, Fred C. Babcock/Cecil M. Webb Wildlife ManagementArea, Nicodemus Slough, Charlotte Harbor State Aquatic Preserve, Pine Island Sound Aquatic Preserve, Matlacha Pass State Aquatic Preserve, Cayo Costa State Park.

The western portion of the region is dominated by large estuarine systems where the waters of the Gulf of Mexico mix with the freshwater inflow from numerous river systems, sloughs and overland sheetflow. These estuarine areas are characterized by low relief shorelines and islands separated by wide, shallow bays, extensive seagrass beds, and sand flats. To the north is the southern half of Charlotte Harbor, which is a large open water bay bounded on the east by the mainland, and on the west by barrier islands. Charlotte Harbor, Shell and Prairie creeks are considered important aquatic resources in the north. Pine Island Sound, San Carlos Bay, and Estero Bay comprise the southern element of this large estuarine network. Most of the uplands within or surrounding this area are buffered by extensive mangrove habitats that protect against erosion from storms and high tides, and also act as nursery and feeding grounds for Gulf of Mexico fisheries. Many of these estuaries are now designated as State Aquatic Preserves. Other associated habitats are high salt marshes and riparian fringing marshes. The Caloosahatchee River discharges into the estuarine system at Ft Myers. The river maintains an estuarine character up to the Franklin Lock and Dam (S-79) at Olga.

Over the past 50 years, the natural systems of the coastal sector have changed dramatically. Growth has altered the nature of these habitats, mainly through drainage, fragmentation, and conversion to residential and agricultural uses. In the west, the large peninsula now occupied by the City of Cape Coral was originally characterized by high marshes, seasonal ponds and sloughs, pine flatwoods, coastal scrub, and oak/cabbage palm hammocks. Most of these systems have now been lost to residential development. Lehigh Acres, a large-scale residential development project in the extreme eastern part of Lee County, south of the Caloosahatchee River, has also resulted in the ditching and draining of thousands of acres of the original wetland/upland mosaic.

Pine flatwoods or interior wetlands (including fresh marshes and ponds, wet flatwoods, wet prairies, swamps, sloughs and open water) dominate inland areas not converted to agriculture. In addition to major surface water features (Lake Okeechobee, the Caloosahatchee River and Lake Hicpochee) there are also numerous small tributary creeks, sloughs, marshes, and wet prairies. Isolated marshes and ponds are scattered throughout with higher concentrations in the north central parts of the region. Before the excavation of the C-43 canal, the area west and south of Moore Haven was a complex of emergent marshes and pond apple swamps. In this area today, only a remnant of Lake Hicpochee remains. It is a shallow open water body, covered by aquatic vegetation, bisected by the navigational channel for the Caloosahatchee River. Surrounding Lake Hicpochee is a large area of emergent marsh vegetation.

In addition to natural plant associations, large portions of the interior lands west of Lake Okeechobee are agricultural. Important uses include pasture (cattle ranching) and citrus.

J.11.2 Fish and Wildlife

The Caloosahatchee River region includes many outstanding wildlife and fish habitat areas. These include state and county parks, state Aquatic Preserves, several National Wildlife Refuges, and many sites on private lands. Wildlife species regularly sighted include most of the high-priority (threatened, endangered and State Special Concern) species. For example, manatees use the Okeechobee waterway and estuaries. Florida Panther habitat includes inland pine flatwoods, hardwood hammocks and swampy forest west of Lake Okeechobee. The American crocodile's range apparently extends up the cost as far north as Sanibel Island, where it is occasionally spotted. Inland species include the bobcat, river otter, gopher tortoise, eastern indigo snake, water birds such as the wood stork, and white ibis; and raptors including the snail kite (freshwater sloughs and wet prairies), bald eagle, and Audubon's crested caracara. Migratory seabirds and shorebirds frequent the coastal shorelands and beaches, along with waders such as the wood stork and roseate spoonbill. Pine flatwoods provide habitat for red-cockaded woodpecker. At least one nesting colony of this species occurs in the Cecil M. Webb Water Management Area. Upland game and non-game wildlife includes white-tailed deer, racoon, rabbit, gray squirrel, doves and pigeons, and migratory woodcock and snipe. J.N. 'Ding' Darling NWR, Charlotte Harbor State Aquatic Preserve, Cayo Costa State Park, and Fred C. Babcock/Cecil M. Webb Wildlife Management Area provide some of the most outstanding natural habitat for the above species. Addionally, the Orange River, a tributary entering the Caloosahatchee River estuary below the locks, is a favored wintering place for manatees, because a nearby power plant discharges warm water (FDEP, 1996).

Threatened and endangered species found in the Caloosahatchee region include the eastern indigo snake, bald eagle, red-cockaded woodpecker, Audubon's caracara, wood stork, snail kite, West Indian manatee and Florida panther.

The freshwater fishes of the Caloosahatchee River watershed are a mix of northern freshwater species, marine species, and exotics. Some principally marine species such as the tarpon, American eel, and mullet occasionally move far inland via canals and rivers. The freshwater fauna of south Florida consists of 108 species of fishes from 34 families. Small fish, including the golden topminnow, least killifish and Florida flagfish, inhabit the shallow emergent wetlands and sloughs, providing essential forage for wading birds. Freshwater game fish include largemouth bass, black crappie, sunfish and catfish. Significant freshwater invertebrates include the crayfish and apple snail.

Marine and estuarine fishes of southwest Florida are grouped by habitat into four types based on salinity, detritus, and substrate. These are a) black mangrove basin forest: *Rivulus*, mosquito fish, and marsh killifish; b) riverine fringing community: juvenile sheepshead, tidewater silverside, and sheepshead minnow; c) estuarine bay fringing community: silver perch, pig fish, and black cheek tonguefish; d) oceanic bay fringing community: lemon shark, gold spotted killifish, and southern stingray (Drew and Schomer, 1984). Many of the estuarine channels and open sounds are seasonal habitat for such inshore game fish as tarpon, redfish, and snook.

J.11.3 Water Management

Inflows from Lake Okeechobee and runoff from within its own basin supply the Caloosahatchee River. The freshwater portion of the river (C-43 Canal) extends westward from Moore Haven, on Lake Okeechobee, through La Belle, to the Franklin Lock and Dam (S-79). The C-43 Canal is part of the Lake Okeechobee Waterway, providing navigation between the east and west coasts of Florida. West of S-79, the river mixes freely with estuarine water as it empties into the Gulf of Mexico (SFWMD, 1995; SFWMD, 1997). C-43 is 45 miles long, averages 20 to 30 feet deep and ranges from 150 to 450 feet wide. The Ortona Lock and Dam (S-78), located approximately 27 miles upstream of S-79, separates the freshwater portion of the river into the east and west Caloosahatchee basins. Roughly 40 percent of the drainage area is in the east basin, and the remaining 60 percent is in the west basin. The total drainage area to the river between S-77 and S-79 is about 880 square miles (Camp, Dresser and Mckee, 1991).

The Caloosahatchee River region is part of the Lake Okeechobee Service Area. The Lake Okeechobee Service Area sub-basins lie at critical intermediary points in the water management system of south Florida. The needs of the Okeechobee sub-basin for flood protection and drainage services affect inflows to the Caloosahatchee Estuary. Excessive discharges of fresh water to the Caloosahatchee Estuary are caused by regulatory releases from Lake Okeechobee and runoff from each local watershed (SFWMD, 1997).

The Lake Okeechobee regulation schedule determines the timing and quantity of water that is released from the lake into the Caloosahatchee river, depending on lake water surface elevation and season. The current lake regulation schedule allows the lake to peak at 16.75 ft. on September 30th. The stored water is intended for water supply during the dry season. The lake regulation schedule is often called a 15.65 to 16.75 ft. regulation schedule because of these key low and high lake stages. When lake levels exceed the highest allowable elevation (generally during flooding rainfall events), rapid releases of large volumes of water occur down both the Caloosahatchee and St. Lucie canals. At intermediate elevations, lower continuous releases of water occur. Timing and duration of releases are set by a targeted discharge volume from Lake Okeechobee, which in turn is set according to the lake level. Maximum water releases through the Caloosahatchee may be up to 9,300 cfs. Lake Okeechobee regulatory releases are made after the peak of the local inflow has passed. Lower, but continuous flows occur under "Zone B" or "Zone C" conditions. Minor rainfall events lead to smaller, pulsed discharges, intended to mimic natural rainfall events.

Continuous discharges to the Caloosahatchee and St. Lucie estuaries have caused documented negative effects on estuarine ecology (Chamberlain et al. 1995, Haunert and Startzman 1985, Chamberlain and Hayward 1996). Research has shown that prolonged releases, even at the modest Zone C rates, transform the estuarine systems into freshwater habitats within three to four weeks. The dramatic and rapid changes in salinity, and associated siltation caused by the release of suspended solids and precipitation of dissolved organic matter at the fresh/salt interface, can produce long-term negative effects on these estuaries. In addition, continuous flow releases at these levels tend to create critically low benthic oxygen concentrations at the transitional zone between fresh water and the Ocean or Gulf. High, continuous releases generate even more problems, because of greater potential for environmental disruption and associated public concern. Even with a thorough understanding of these major environmental concerns, flood control remains a major purpose of the man-made structures, and regulatory discharges are sometimes necessary because of the high risk of loss of life and property associated with high lake stages and hurricane generated waves and tides.

J.11.3.1 Problems related to Water Management

During the annual November to April dry season, little water is released into the river from the lake, resulting in low flows and low water levels in the upper Caloosahatchee. Two problems may develop as a consequence: First, low flow may lead to development of an occasional severe algal bloom in the river above Franklin Lock (S-79) and Dam. The City of Ft. Myers and Lee County both have municipal water intakes in this area. Short term high rates of discharge from Lake Okeechobee are used to break up the blooms by the U.S Army Corps of Engineers whenever requested by the South Florida Water Management District (SFWMD) (USACE, 1991). During the extreme driest months (April-May) river flow may drop to near zero. When this occurs, navigation lockages through the W. P. Franklin Lock (S-79) allow a salt-water wedge to move upstream. If salt intrusion is too severe, South Florida Water Management District requests the Corps of Engineers to flush out the salt water with a short-term high rate of discharge from Lake Okeechobee. During a declared water shortage period, the South Florida Water Management District requests the U.S. Army Corps of Engineers to go to reduced hours of lockages (USACE, 1991).

J.11.4 Water Supply

The Lower West Coast is one of the fastest growing regions in the state. Rapid population growth is projected to continue, accompanied by an increase in water demand. In addition, the area is experiencing growing and changing agricultural activity. Citrus has begun moving into this area following a series of freezes in central Florida, and it is displacing more traditional agricultural activities, including cattle ranching. This trend will increase agricultural water demands (SFWMD, 1995).

The major issues influencing water availability in the lower west coast include: dependency upon rainfall, limited and regulated surface water sources, protection of water resources and associated natural systems, and pressure on these resources from increasing urban and agricultural demands.

J.11.4.1 Surface Water Resources

Two utilities, Ft. Myers and Lee County (Olga) take surface water from the Caloosahatchee River to meet some or all of their water demands. Other utilities in the basin use ground water as their source (SFWMD, 1997). The river (C-43) is the only major surface water body used for water supply. It is maintained by releases from Lake Okeechobee. Lake Hicpochee, in the East Caloosahatchee Basin, is not considered a good source of water supply (SFWMD, 1994). Three structures (S-77, S-78 and S-79) provide navigation and water control in the C-43 Canal. The S-79 structure also serves as a saltwater barrier. The operation schedule for these structures is dependent on rainfall conditions, agricultural practices, the need for regulatory releases from Lake Okeechobee, and the need to provide water quality control for the public water supply facilities (SFWMD, 1987; SFWMD, 1992).

J.11.4.2 Ground Water Resources

Three major aquifer systems have been recognized within the region: the Floridan Aquifer System (FAS), Intermediate Aquifer System (IAS), and Surficial Aquifer System (SAS). Ground water is the predominant source of supply to public utilities and agricultural users not adjacent to the Caloosahatchee River. Although the deep Floridan Aquifer System is capable of high yields, it produces poor quality to nonpotable water throughout this region, except for the northern part of Glades County. Salinity also increases as a function of depth, making the deeper producing zones less suitable for development than those zones near the top of the system. Nearer the coast (Charlotte and Lee Counties) Floridan water requires desalination treatment to be acceptable for potable uses and some other uses. Currently, only four utilities (the City of Cape Coral, Florida Cities, Greater Pine Island, and Sanibel Island Water Association) obtain water from the FAS. In Glades County, the Floridan aquifer is a major source of irrigation and potable water. Elsewhere it supplies only a few agricultural irrigation wells.

The IAS yields moderate quantities of water in certain parts of the region. The sandstone aquifer sub-unit provides large quantities of water for both potable and irrigation uses in the south central portion of Lee County. The aquifer provides all of the water withdrawn by the Lehigh Acres public water supply wellfield and a portion of the water withdrawn by the Corkscrew and Green Meadows wellfields. Other communities and areas using the IAS include domestic self-supply in Cape Coral, and small water utilities north of the Caloosahatchee River. It is also a major potable and irrigation water source in southern Charlotte County.

The surficial aquifer is used for potable supply and irrigation in many areas, although it may suffer from salt intrusion near the coast. Five major public water suppliers, Lee County Utilities (Corkscrew wellfield), Gulf Utilities, Florida Cities (Green Meadows wellfield), the City of Fort Myers, and Bonita Springs, all pump water from the Surficial Aquifer System. The system also furnishes irrigation water for many uses, including vegetables, nurseries, and landscaping (SFWMD, 1998). It is also a significant water source in inland southern Charlotte County. In Hendry County, most users depend primarily on water from the surficial and intermediate aquifer systems as a primary water source for domestic and agricultural use. The water table aquifer and the sandstone aquifer (part of the IAS) supply most potable water demands.

J.11.5 Socio-Economics

The human population in the Caloosahatchee River region is concentrated along the coast, as in most of Florida. The coast is rapidly becoming highly urbanized. The southwest subregion has the highest growth rate in Florida over the past ten years, and the highest projected growth rate from now to 2010. The Cape Coral, Ft. Myers and Naples metropolitan areas are among the seven fastest growing in the United States. In the 1980s, Lee County population grew by 63 percent (SFWMD 1992). Projected population increases for Lee county from 1990 to 2010 is 90 percent (SFWMD 1992).

A somewhat unique aspect of this subregion is large scale "planned" residential development projects, which date from the late 1950s to the early 1970s. Cape Coral, Lehigh Acres, and Golden Gates are the largest of these developments. Cape Coral is the second largest Florida city in area (285 km2). The natural habitats in over 90 percent of this area were destroyed. Wetlands were filled; terrestrial forests were cleared of vegetation. Over 2000 km of roads and 650 km of freshwater and estuarine residential canals were constructed. During this process most of the land was platted and sold as residential home sites. The projected build out population of Cape Coral is 400,000 people. Population today is 80,000-100,000. Many areas of the city are sparsely populated, however Cape Coral is one of the five fastest growing cities in the country.

Agriculture is a major activity in the interior of this region. It probably has the highest rate of land conversion to agriculture, primarily citrus. In the 1980's, irrigated agricultural acreage in Lee County grew by 35 percent. Recently, land conversion to citrus has increased substantially. From 1985 to 1990, citrus acreage in Hendry and Lee counties increased 83 percent and 46 percent, respectively (SFWMD 1992). This boom in acreage is the result of interregional movement of citrus from central to southwest Florida following several severe freezes in the mid-1980's. The projected increases in citrus acreage for Hendry, Glades, and Lee counties from 1990 to 2010 are 100 percent, 90 percent, and 50 percent (SFWMD 1992).

Through 1988, industrial earnings were concentrated in services (30 percent, retail trade (19 percent) and government(14 percent). In Charlotte and Lee counties, the service industry provided the main economic activity, while agriculture and associated products are the dominant industrial activities. In Glades and Hendry counties, agriculture and service industries represent 72.5 and 54.7 percent of total earnings, respectively (SFWMD, 1992).

J.11.6 Land Use

The Caloosahatchee River Region has 169,660 acres of urban land, largely fixed single family units (69,172 acres) and an almost equal number of acres in some stage of construction. There are 355,125 acres of agriculture with improved and unimproved pastures (163,348 acres), citrus groves (92,410 acres) and sugar cane (67,628 acres) predominant. Various types of rangeland make up 51,663 acres of land use. The category of barren land has 10,000 acres. This includes spoil and borrow areas (7,090 acres) and rural land in transition (2,377 acres). Transportation, communication and utilities comprise 16,280 acres.

Rangeland and agriculture dominate land use in the basin, particularly the upper portion (FDEP, 1996). The freshwater portion of the Caloosahatchee River Region is mostly agricultural in nature. The only urban areas are the cities of LaBelle, Alva, and Moore Haven (Camp, Dresser and Mckee, 1991).

Land use adjacent to the Caloosahatchee River Estuary is largely residential and urban with the city of Cape Coral on its northern bank and the highly urbanized city of Fort Myers on its south bank. Both of these communities have experienced rapid growth with even more growth anticipated in the near future (SFWMD, 1997).

J.11.6.1 Agriculture

Glades and Lee Counties are included in this region. Almost one half million acres are farmed in the Caloosahatchee River Basin, and approximately three-fourths of that area is pastureland (UFBEBR, 1995). The region is characterized by large farms averaging 1800 acres, with relatively low productivity per acre (UFBEBR, 1995). Glades County ranks eighth in the state of Florida for cattle production (FASS, 1996a). Citrus production in the Caloosahatchee River Basin covers more than 20,000 acres (FASS, 1996b) and is currently increasing. Much of this acreage is likely categorized as unique farmland based upon its location, growing season, and high value citrus crops.

Almost 5,000 people are employed in agricultural production and services, and the payroll totals approximately $5 million (UFBEBR, 1995). Agricultural products in this region have a total market value of more than $135 million (UFBEBR, 1995).

More than 77,000 acres of farmland are irrigated in the Caloosahatchee River Basin (UFBEBR, 1995). Reliable water supply is a big concern in this region which has traditionally relied upon water deliveries through the Caloosahatchee River from Lake Okeechobee. Irrigation demands can be expected to increase as additional land is used for citrus production.

J.11.7 Recreation Resources

Recreation resources in the Caloosahatchee Basin and West Coast Region are diverse, consist of good quality and include coastal, inland water and land based resources. The Caloosahatchee River provides approximately 67 miles of navigable waterway with ten U.S. Army Corps of Engineers recreation facilities that include boating, fishing, picnicking, and camping. Several other river bodies also offer recreational opportunities in the region.

The Caloosahatchee River provides approximately 67 miles of navigable waterway with ten Corps recreation facilities that include boating, fishing, picnicking, and camping. The J.N.”Ding” Darling NWR, a popular birding area, administers Caloosahatchee, Matlacha Pass, Island Bay National Wilderness area and Pine Island National Wildlife Refuge, all located near the region’s western edge. Boca Grande Pass is world renowned for record tarpon, Sanibel Island is reported among the top shelling destinations in the Western Hemisphere. The Fred C. Babcock/Cecil M. Webb Wildlife Management Area and CREW Wildlife and Environmental Area also provide recreational ammenities in this region.

Caloosahatchee State Park and Recreation Area is located near Alva on the Caloosahatchee River. Estero River and Hickory Creek State Canoe Trails are within the region and provide excellent recreation resources. Cayo Costa State Park, Sanibel Island State Park, and State Aquatic Preserves are located in the Lower West Coast region. The region’s boating, diving and fishing are very popular recreational activities. Surrounding development pressures could adversely affect the region’s natural and recreational resources. Substantially altered water deliveries to this region have had detrimental affect on natural and recreation resources in the region. The region's recreation resource use is substantial and anticipated to increase.

J.11.8 Aesthetic Resources

The Caloosahatchee Basin and Lower West Coast regional aesthetic overview is characterized by the Caloosahatchee River corridor, the Gulf of Mexico coastal plain, and surrounding uplands. The Caloosahatchee River is a linear body of water whose width allows observation of shoreline vegetation that includes texture, color, and wildlife varieties of interest and beauty. Minor urban impacts exist along the Caloosahatchee until the Fort Myers area where impacts increase noticeably.

The coastal segments of the region possess a higher degree of aesthetic quality within the visual environment. State Parks, Wildlife Management Areas, and Wilderness Areas secure natural resources of prominent aesthetics.

Much of the region's interior aesthetics are comprised of forested wetlands and irrigated pasturelands of moderate aesthetic quality. Many of the regional rural areas possess scenic quality on a small scale. Rural areas are largely pine forested with some oak, hickory and gum associations. Air traffic noise is an increasing adverse aesthetic impact. Development pressures are an increasing concern to natural and aesthetic resources.

APPENDIX K
ENVIRONMENTAL EFFECTS
OF THE
INITIAL DRAFT PLAN

K.1 INTRODUCTION

The following describes the expected beneficial and adverse physical, ecological, and socio-economic affects to resources of regional concern within the study area. In all instances the assessment of effects in this appendix is based on a comparison between Alternative D-13R (henceforth called the "Initial Draft Plan") and the Without Plan Condition (2050 base). In a few instances a comparison to the 1995 base (existing conditions) was also documented, as it may have lent additional relevant evidence to the impact analysis. This appendix is organized to discuss impacts to the regional system first on a comprehensive basis. A finer resolution of environmental effects, based on the ten physiographic regions (described in ***Appendix J***), which comprise the entire study area, is presented afterwards.

Detailed analyses of affects to water quality are available in ***Appendix H***, to air quality in ***Appendix I***, and to Socio-economics in ***Appendix E***. Summary discussions of these effects only are included in this appendix. This analysis includes the approximately fifty project features included in the Initial Draft Plan. It does not attempt to assess impacts associated with the Other Project Elements (OPEs) as the OPEs included in the recommended Comprehensive Plan had not yet been decided on until late in the preparation of the draft document and several others were being re-organized under the Restudy during preparation of the final Programmatic EIS. More detailed analysis of environmental impacts, including the full range of OPEs, will be conducted in future National Environmental Policy Act documents which will be "tiered" from this Programmatic EIS as per guidance in 40 CFR, Parts 1502.2 and 1508.8. Supporting information, including Fish and Wildlife Coordination Act Reports, supplied by Department of Interior and the Florida Game and Fresh Water Fish Commission (GFC), and a final programmatic biological opinion on affects to threatened and endangered species, supplied by the U.S. Fish and Wildlife Service, are provided in Annexes A and B, respectively.

K.2 REGIONAL SYSTEM

While this section's organization is similar to traditional National Environmental Policy Act documentation of environmental effects, it includes a preliminary discussion of the overall changes thought necessary to restore the C&SF Project area to a more natural and sustainable ecological system. These remarks include brief summaries on key Everglades (for the purposes of this report defined as the Water Conservation Area and Everglades National Park regions) essential characteristics that have helped shape the Restudy planning efforts to date.

This report reviews the impacts of the Initial Draft Plan on the essential characteristics of the south Florida ecosystem that operate on a landscape scale. These characteristics include spatial extent, heterogeneity of habitat, and sheet flow. Because they affect both the abundance and distribution of wide-ranging fish and wildlife species and the success of more localized species at an ecosystem scale (See Chapter 2), the extent to which these essential characteristics will be recovered has bearing on the ecological sustainability of the future, restored system.

This section also discusses trade-offs that involve the region-wide balance of benefits and the sharing of adversity. Because different alternatives tend to favor different parts of the system at the expense of others, one strength of the Initial Draft Plan is that it tends to balance benefits and impacts across the south Florida ecosystem.

Spatial extent of the interior marshes has been reduced by nearly half in comparison to their original size. This reduced the storage and affected the timing of water delivered through the central Everglades marshes. Recent studies suggest that the deepest marshes were once located east of the Miami-Dade-Broward levee in areas now developed. To restore historic flows and depths to the southern Everglades and Florida Bay, alternatives either needed to pass more water through the small, remaining Everglades, which would continue the flooding of tree islands, or find other ways to move water.

The alternative plans contained four strategies to store and transport water around and through the Everglades in a timely manner. First, extensive storage facilities substitute for the lost marsh area. Second, interior levees that impeded flow were removed. Third, remaining levees and canals were used to direct and speed flow south. Fourth, a Central Lake Belt conveyance system was designed to route water around the WCAs to compensate somewhat for the lost eastern portion of deeper Everglades that once fed Shark River Slough and Everglades National Park. Only the Initial Draft Plan, using all four strategies, came close to replicating natural flows throughout the northern, central, and southern Everglades. The alternative also meets or comes close to meeting the goals for reducing dependence on Lake Okeechobee for storage, and provides appropriate fresh water flows to the St. Lucie and Caloosahatchee estuaries, Florida Bay, and Biscayne Bay to maintain proper salinities.

Natural patterns of habitat heterogeneity in the interior Everglades marshes have been compromised by the network of canals and levees that deeply pond water upstream and overly dry areas downstream of man-made barriers. The hydrologically disjunct areas these features create disrupt the natural continuity of the landscape. When the differences in water surface elevations across existing levees were compared with the differences predicted by the Natural Systems Model (NSM), the Initial Draft Plan greatly improved connectivity over the 2050 base. Removing levees and canals or installing weirs will eliminate abrupt differences in water depths on either side of a given levee and restore hydrologic connectivity within interior Everglades marshes. As a result, free movement of fish and smaller animals can occur. Foraging habitat for wading birds will be more consistent over the landscape as drydown patterns that concentrate fish for them to harvest become reestablished. The natural heterogeneity of the marsh will replace the pattern of discrete pools the current system supports.

Canals and levees physically fragment habitat by interjecting strands of deep water and dry land where they should not occur. The Initial Draft Plan reduces the number of miles of interior canals, within the natural system by 40 percent and levees by 20 percent, compared to the 2050 base. Removing levees reduces the ability of land-based predators and exotic plants to spread to the interior of the marsh. Similarly, removing the canals adjacent to levees is expected to benefit smaller native fishes, by removing habitat for larger-bodied predators, exotic fishes, and invasive waterborne plants.

A relative value for improvement in sheetflow in the Everglades marshes was obtained by comparing flow volumes across a number of transects in the north, central and southern Everglades and Big Cypress National Preserve with NSM and 2050 base flow volumes. Sheetflow throughout the system in the Initial Draft Plan closely resembled NSM flows and was a vast improvement over the 2050 base condition. Restoring sheetflow to large areas of the freshwater marshes will allow the system to naturally shape tree islands, take up nutrients, precipitate phosphorus and calcium carbonate into the substrate, and retain water into the dry season. The implications for fish and wildlife are implicit and deserve additional study.

In the natural system, 62 percent of the water that crossed from WCA-3 into Everglades National Park flowed east of the L-67 levee, while 38 percent flowed to the west of it. That pattern of flow, coupled with sufficient volumes, ensured that northeast Shark River Slough received a majority of the water flowing into Everglades National Park. Only 11 percent of the reduced flows in the 2050 base condition crossed the eastern portion of the Tamiami Trail. In the Initial Draft Plan, 110 percent of the predicted NSM volume crosses from WCA-3 to the Park and 55 percent of that water flows east of L-67. Only this alternative came close to recapturing the natural pattern, which would ensure that a most of the water crossing into the Park supplies Shark River Slough, and, by implication, Taylor

Slough. With sufficient water in Shark River Slough, the Marl Prairies and Florida Bay are highly likely to receive the water they require for restoration.

Trade-offs at the regional scale cannot be avoided. In theory, no portion of the system should bear a disproportionate share of the cost of ecosystem restoration. Careful evaluation of negative impacts to local areas must be balanced against the benefits gained by the system as a whole. Three issues that have already emerged are: 1) the trade-offs inherent in creating vast storage areas, 2) the trade off between further decompartmentalizing the system and keeping structures that allow flexible water management, and 3) the potential trade-off of increasing hydroperiods in portions of the WCAs in order to restore Shark River Slough.

System-wide, the most important feature of all of the alternatives has been the vast amount of water storage that has been created in the system. Storage facilities, including aquifer storage and recovery, reduce the dependence of the urban areas on Lake Okeechobee for water supply, allowing Lake Okeechobee to fluctuate more naturally for its own benefit. Protecting the littoral zone of Lake Okeechobee from damaging high lake stages will support healthy emergent aquatic vegetation and its function as a reliable nursery for the fish populations. Capturing flood waters in storage areas will diminish the need for damaging regulatory releases to the St. Lucie and Caloosahatchee estuaries, benefiting seagrass beds and oysters, among other species. Water from the storage areas will become available during dry seasons to support minimum flows to the estuaries, to enhance dry season flows to the central and southern Everglades, and to supplement water supply in developed areas.

The problem with creating vast storage areas is that the land on which they are built will be permanently altered. None of these storage areas has been located yet, so impacts are conceptual at this time. Whether they are eventually built on uplands or wetlands, they must be carefully located and designed to minimize potential impacts to threatened or endangered species and to avoid environmentally sensitive areas. Care must be take to ensure that the regional benefits gained will exceed the local habitat values lost. In addition, because these storage areas are of considerable size, care should be taken in their design and operation to take advantage of any opportunity to benefit fish and wildlife.

The second tradeoff is that despite the ecological values of decompartmentalizing the system, some canals and levees will be needed to perform the functions once performed by the missing parts of the system. WCA-3B, for example, is one of the healthier parts of the current Everglades system and biologists want to avoid degrading it if possible. However, in an effort to increase flows to Shark River Slough, it has been nearly impossible to do so without increasing high water events and lengthened hydroperiods in WCA-3B. Since the former deep marshes east of the WCAs have been developed, WCA-3B has become the new headwaters of the Shark River Slough. In the Initial Draft Plan, instead of removing the L-67 levee and the adjacent canal, which would increase sheetflow, increase connectivity, and reduce fragmentation, a modified L-67 was kept in place to protect WCA-3B from excessive flooding seen in earlier scenarios. This tradeoff appears to be entirely justified, given the many obvious benefits of protecting a pristine portion of the Everglades. Using the levee and canal to route flows around this valuable area justifies their existence and modeling results appear to prove the effort was successful.

The Initial Draft Plan succeeds in moving large volumes of water through the northern and central Everglades to the southern Everglades without causing as many extreme high and low water events as earlier plans. Unfortunately, increased hydroperiods are still a potential problem in parts of the WCAs. In some places, WCA-3B for example, hydroperiods are longer than the NSM predicts for Shark River Slough. Although ecologists are fairly open to allowing portions of the Everglades to transform from one healthy freshwater marsh type to another, it is unknown whether a pristine area like WCA-3B will become a more slough-like system or simply become degraded. As more detailed studies continue, there needs to be a duel path of seeking ways to reduce excessive hydroperiod lengths and to reach a better understanding of what is likely to occur in WCA-3B if it is subjected to lengthened hydroperiods.

K.2.1 Geology and Soils

Implementing the Initial Draft Plan will not affect regional geology. Soil effects should be largely beneficial, and lead to a reversal or retarding of peat soil subsidence. Extensive monitoring should assist in more accurately assessing beneficial or other impacts to relatively long-term processes such as soil formation and subsidence.

K.2.1.1 Soils

The peat soils of the Everglades were formed under anaerobic conditions when, due to insufficient oxygen because of flooding, microorganisms were unable to completely decompose plant remains to carbon dioxide, water and mineral constituents. Therefore, partially decomposed organic matter accumulated, forming peat soils, which in some places were 12 feet thick. When the soils were drained, the land surface began falling (subsiding) for a number of reasons: (1) loss of buoyancy; (2) peat shrinkage; (3) fires; (4) wind erosion; and, most importantly, (5) aerobic microbiological decomposition (oxidation). This is not a condition unique to the Everglades; all organic soils subside when drained. In the Everglades, the rate of subsidence averages about 1 inch per year, the exact rate being directly related to the depth of the water table. The lower the water table, the more rapid the rate of subsidence (Snyder and Davidson, 1994).

For any area within the limits of the Restudy that contains peat soils, an increase in hydroperiod will help retard subsidence. For areas that contain peat soils, a decrease in hydroperiod will increase the magnitude of oxidation, rate of subsidence and frequency of peat fires. Immediate effects of this decrease in hydroperiod will result in decreased volume of peat that can be exploited as a resource, alteration of vegetation types, and reduction in productivity of current agriculture. On a regional scale, the Initial Draft Plan results in generally longer hydroperiods throughout the affected area of the natural system relative to both base conditions. The long-term average rate of peat deposition was estimated by McDowell et al. (1969) at 8.4 centimeters per century, with a maximum rate of 16 centimeters of peat deposited per 100 years. Therefore it is reasonable to conclude that the rate of soil subsidence and the frequency of peat fires will be reduced and peat may begin to accrue again. Protecting peat soils will improve the sustainability of natural vegetative cover and agriculture.

K.2.1.2 Geology

For any area within the limits of the Restudy that is underlain by limestone, an increase or decrease in hydroperiod should not result in subsidence. For any area underlain by quartz sands of the Pamlico Sand, a decrease in hydroperiod could produce relatively very minor subsidence and increase susceptibility to erosion as the sands are drained. Increase in hydroperiod should not effect elevation of the upper bounding surface of the Pamlico Sand. No significant effect is anticipated to the geology of the project area as a result of implementation of the Initial Draft Plan.

K.2.2 Climate

Overall, climate is not expected to be directly or indirectly affected, in the short or long-term, by implementation of the Initial Draft Plan. Air circulation patterns (wind, storms), evapotranspiration, and rainfall patterns, distribution and abundance (all factors of climate) should not be affected. Local microclimates may be affected on a modest scale, and to a moderate extent, in the vicinity of particularly large (>5,000 acres) storm water treatment areas, and above ground reservoirs, where uplands have been converted to open water systems with differential effects on local air circulation patterns, ET, and humidification.

K.2.3 Air Quality

The implementation of the Initial Draft Plan is not expected to have an impact on existing air quality. Overall, the air quality for the region is considered good, or to be in attainment with all National Ambient Air Quality Standards (NAAQS), as established by the Clean Air Act (CAA). Air quality is expected to remain the same as under the 2050 base, and will not affect the region's attainment status as described above. Limited, minor, and localized impacts may occur within construction zones due to earth moving equipment and transportation of fill and materials. Fugitive dust and hydrocarbon emissions from heavy equipment and construction vehicles may have moderate, temporary impacts on air quality, but this should be restricted to those areas currently under construction. There will be no effect on air quality due to the operation and maintenance of the project, once construction is completed. For further information on air quality impacts, reference ***Appendix I***.

K.2.4 Noise

Overall implementation, operation and maintenance of the proposed project, will cause little effect on ambient noise levels. Within the natural areas, the site will retain its wilderness characteristics, and noise emissions will be limited in source and of low occurrence. No new transportation corridors, which are significant noise emission sources, are proposed under the Initial Draft Plan. Urban and agricultural areas will retain their land use functions and will not be significantly affected by the Initial Draft Plan.

Noise levels due to construction of the proposed project will be moderate in both scope and scale and limited to areas where construction activities are currently ongoing. Construction equipment would be expected to include bulldozers, backhoes, tractors, graders, front-end loaders, trucks, and other heavy equipment. This earth-moving equipment has noise levels at 50 feet in the range of 70 decibels to about 95 decibels. Continuous exposure above about 86 decibels is likely to degrade the hearing of most people (U.S. Environmental Protection Agency 1972). At these times, noise effects may be locally bothersome, but will likely affect few individuals as most project features are planned to take place in natural or rural areas, and away from areas normally frequented by people. These localized impacts would likely occur for relatively brief periods at any one location. On a regional basis however, impacts may occur for an extended period of time, as the schedule for construction activities may last up to 20-30 years prior to project completion.

K.2.5 Vegetation

The Initial Draft Plan reduces dependence on Lake Okeechobee for storage by increasing artificial water storage in the system. The consistent need for extreme high lake water levels that damage the littoral zone is reduced, maintaining a more healthy plant community around the lake margin. Alternative storage areas also improve the timing of water releases to the Caloosahatchee estuary, the St. Lucie estuary, and into the Everglades Protection Area. Regulatory releases will no longer be a constant threat to seagrass beds in the estuaries, and extreme high and low water events in the central Everglades will no longer be as pervasive or as damaging to freshwater marsh vegetation. Although lengthy hydroperiods and extreme low and high water events still remain a concern in portions of the central

Everglades, their impact is less understood, and the problems are more likely to be solved by improved operations during detailed studies.

The northern and central Everglades (Holey Land and Rotenberger Wildlife Management Areas, A.R.M. Loxahatchee National Wildlife Refuge (WCA-1), and the Everglades and Francis S. Taylor Water Management Area) constitute roughly 900,000 acres of Everglades landscape. The managed system caused widespread loss of peat soils from over-drainage, followed by microbial oxidation and muck fires. Tree island vegetation was lost due to muck fires in over-drained regions and prolonged high water in deeply ponded areas. The Initial Draft Plan appears to make major steps toward solving these two critical problems. Although all of the final alternatives developed by the Restudy team help relieve drought conditions that damage peat soils, the Initial Draft Plan provides the best reduction in extreme high-water conditions that would flood tree island vegetation communities.

K.2.6 Fish and Wildlife

Allowing Lake Okeechobee to function more as a natural lake, rather than as a reservoir should enhance fish populations. Juvenile fish and other small aquatic species depend on a healthy, vegetated littoral zone for food and cover. If the Initial Draft Plan is implemented and Lake Okeechobee's stages act more normally, the littoral zone would be less subject to excessive flooding and drying.

Increasing the geographical extent of the Everglades marshes is unlikely, given the extensive urban and agricultural development in south Florida. None of the alternatives addressed this issue directly except to attempt to increase the acres of wetlands restored. However, operations within the planned storage areas and the water preserve areas may be able to serve as fish and wildlife habitat to some degree.

Many of the effects of compartmentalization and fragmentation on fish and wildlife are hypothetical and need further study. Water appears to flow more evenly through the system in the Initial Draft Plan than the 2050 base. As pooling effects disappear and as physical barriers to native fish and other aquatic species are removed, the flow of genetic material may be enhanced and the ability of aquatic species to repopulate the WCAs following dryouts may be improved. Unnaturally deep areas within canals and upstream of levees should no longer favor large predatory fish, allowing smaller native species to increase in abundance. Removal of canals may also slow the spread of exotic fish into the interior of the Everglades. Removal of levees is expected to slow the spread of exotic plants and reduce easy access to the marshes by predatory mammals.

In the Water Conservation Areas the Initial Draft Plan tends to reduce extreme high and low water events at the expense of increasing inundation period in several areas. Compared to the 2050 base, the plan improves conditions in southern WCA-3A by reducing high water and in northern WCA-3A by reducing drydowns, but worsens conditions in northeastern WCA-3A and WCA-3B by increasing high water. The potential long-term biological effect of longer inundation periods and greater depths than NSM predicts are unknown. While peat soils may be better protected by reducing the number of drydown events, wading birds depend on the seasonal drying pattern to concentrate their prey in shallow pools, and the depth at which they can fish is limited by their leg length. A system that is deeply flooded year after year may increase fish populations, yet the water may be too deep or the fish too dispersed to be harvested by wading birds.

Localized and short-term impacts on wading bird nesting and foraging within eastern WCA-3A are likely to occur, but they are expected to be offset at the regional scale if the plan is implemented with an adaptive management strategy and regional monitoring programs. It will be necessary, for example, to develop sufficient breeding and foraging sites in other areas before existing sites are impacted. Specifically, the Initial Draft Plan predicts increased hydroperiods and a 2-foot increase in depths in northeastern WCA-3A. On the other hand, the area south of the 3A-3 gage and east of the Miami Canal will remain deeper than NSM values, but have far fewer high-water events. Both of these areas support important wading bird rookeries. The Initial Draft Plan, therefore, is likely to improve breeding habitat in eastern WCA-3A, possibly damage it in northeastern WCA-3A, and alter the distribution of suitable foraging areas as well. Although restoration of the Everglades watershed is expected to improve habitat for nesting wading birds at a system-wide scale, significant short-term and/or localized effects on particularly rookeries are probably unavoidable. Suitable breeding and foraging sites must exist and be reliably in use to offset any expected negative impacts to current sites. Careful system-wide research, development of better performance measures, additional modeling, careful monitoring of wading bird responses to changes in hydrologic conditions, and a flexible implementation plan will be critical to protecting the remaining wading bird populations in the Everglades.

Higher average fish abundances than the 2050 base should be produced by the hydrologic conditions created by the Initial Draft Plan. In particular, increased hydroperiods in northeast Shark River Slough, Taylor Slough, WCA-3B, northeast WCA-3A, and Loxahatchee NWR should increase fish abundance. Increased abundance of prey-sized fish will enhance wading bird survival if seasonal drydown patterns can be optimized to concentrate them.

For white-tailed deer, the reduction of excessive high water conditions in many portions of the WCAs should provide slightly better foraging conditions and reduced drowning losses. Overall, however, increased hydroperiods in most of the WCAs and northeastern Big Cypress compared to the 2050 base are likely to decrease the quality of these marginal deer habitats slightly except for small areas of northeastern and southern WCA-3A and the Big Cypress-Everglades National Park border. In Everglades National Park where deer habitat is already poor, the NSM-like conditions in the plan would reduce quality further. For those few areas with high deer breeding potential (Long Pine Key and surrounding short hydroperiod marsh and northwest Big Cypress), there will be no impact.

For the southern Everglades and for Florida Bay, the Initial Draft Plan greatly improves hydropatterns. Improved timing and duration of freshwater flows to Florida Bay estuaries and improved timing of fish-concentrating drydowns should lead to better wading bird foraging and breeding conditions in the southern Everglades than both base cases. Greater fish abundances suggest improved foraging conditions for wading birds and fish-eating raptors.

K.2.7 Threatened and Endangered Species

Within the regional system, improved habitat conditions and benefits for overall populations are anticipated for the West Indian manatee, American crocodile, snail kite, wood stork, Cape Sable seaside sparrow, and the Okeechobee gourd. In the case of the manatee and crocodile, this is due to substantially enhanced freshwater flows to Florida Bay, and decreased salinities in the Florida Bay and Shark River Slough estuarine habitats relative to the 2050 base. For the snail kite, wood stork, and Cape Sable seaside sparrow, restoring hydroperiod to NSM like conditions throughout much of their habitat, leads to an overall regional improvement in their populations. In some instances there may be local, minor negative impacts to habitat, by vegetation shifts over time, or increased ponding depths in relatively small areas currently serving as functional foraging or breeding grounds.

The endangered Okeechobee gourd is also expected to benefit due to a reduced occurrence of high water events and flooding of its habitat on the south shore of Lake Okeechobee.

The development of new water storage reservoirs on the scale proposed under the Initial Draft Plan is a concern in that they may create "attractive nuisance" conditions for wading birds, or nesting raptors such as the wood stork, bald eagle and caracara. These reservoirs are expected to operate primarily for flood water retention, storage and later release. Therefore, should birds and other wildlife become attracted to them, possibly becoming dependent upon them for foraging during a breeding cycle, significant mortality or breeding collapse may result should operational criteria demand a significant release of floodwaters downstream.

As a whole, the scrub jay, bald eagle, caracara and eastern indigo snake may be negatively impacted by the Initial Draft Plan, primarily through the construction and operation of water storage and treatment areas, mostly within the Kissimmee

River and Caloosahatchee River regions. Filling in of canals is also likely to negatively impact some eastern indigo snake habitat, and may cause direct mortality of snakes. The impacts to these animals are not likely to jeopardize their continued existence.

According to the United States Fish and Wildlife Service, Preliminary Programmatic biological opinion, received by the Corps on August 7, 1998 and later certified as the final biological opinion (Annex B) implementation of the Initial Draft Plan is not likely to affect the following species found within the project area: 1) Florida panther, 2) Florida grasshopper sparrow, 3) red-cockaded woodpecker, 4) crenulate lead-plant, 5) deltoid spurge, 6) Small's milkpea, 7) tiny polygala and, 8) Garber's spurge. Moreover the Initial Draft Plan is not expected to adversely modify Critical Habitat for the American crocodile, West Indian manatee, snail kite, and Cape Sable seaside sparrow.

Comments received from the Florida Game and Fresh Water Fish Commission in a letter dated December 14, 1998 state that the following state listed species may also be affected (positively or negatively) by the Comprehensive Plan. Specific impacts to these species will be discussed in future National Environmental Policy Act documents resulting from detailed planning. Miami black-headed snake, southeastern snowy plover, white-crowned pigeon, resident subspecies of the southeastern American kestrel, Florida sandhill crane, Everglades mink, Big Cypress fox squirrel, and Florida black bear (all threatened); common snook, gopher frog, gopher tortoise, Florida pine snake, roseate spoonbill, limpkin, little blue heron, reddish egret, snowy egret, tricolored heron, white ibis, American oystercatcher, brown pelican, black skimmer, whooping crane, burrowing owl, Sherman’s short-tailed shrew, Sherman’s fox squirrel, and Florida tree snail (all species of special concern).

K.2.8 Water Management

The Lower East Coast Regional Water Supply planning process demonstrated that, by taking advantage of the seasonal availability of surplus water throughout the regional system, a major portion of future needs can be met with increased storage. Modeling results show that increasing storage capabilities within the system will enable users to be less affected by dry seasons and droughts and at the same time save excess freshwater that would otherwise be discharged to tide and lost. Increasing the storage capabilities throughout the system will help the regional system meet increasing agricultural, environmental, and urban demands. The regional system will continue to experience significant fluctuations in water availability depending on the natural cycles of flood and drought. Alternative sources can help provide stable supplies during dry cycles.

One method of storing surplus water in the system is through the use of Aquifer Storage and Recovery wells. These Aquifer Storage and Recovery wells are associated with some type of reservoir to store water to feed the wells. These Aquifer Storage and Recovery wells make the reservoir more effective by steadily drawing it down and creating storage, enabling the next rainfall event to be captured within the reservoir.

For the Kissimmee Basin, water managers will use a climate based inflow forecasting model, in conjunction with operational rules, which will help them in deciding when to pump water to the storage facilities outside Lake Okeechobee. Climate based inflow forecasting, reservoir storage north of Lake Okeechobee, lakeside Aquifer Storage and Recovery wells, and other project features located in the C-43 and C-44 basins are expected to reduce the occurrence of peak lake stage events and harmful flood control discharges to the estuaries. Under the Initial Draft Plan, most of the water previously stored in the lake at prolonged and even extreme lake stages and/or sent to tide via the estuaries, is pumped to storage north of the lake (127,000 acre-feet on a mean annual basis) or to other storage facilities in the Everglades Agricultural Area, Caloosahatchee River (C-43) Basin or the St. Lucie (C-44) Basin.

Changes to the existing Lake Okeechobee operation schedule (Run-25) include operational changes only, except for the project features designed to enhance water storage outside of the lake. All flood releases to the St. Lucie and Caloosahatchee River estuaries are expected to be eliminated except pulse releases in Zone A of the regulation schedule. These water storage facilities will reduce the frequency and duration of flood control releases to the estuaries. Water from Lake Okeechobee will be pumped into Aquifer Storage and Recovery wells when the climate-based inflow forecasting model projects that the lake water level will rise significantly above those levels that are desirable for the littoral zone. Water management of the lake will rely on existing structures that will not require structural modification. In order to meet capacity requirements for water conveyance to Aquifer Storage and Recovery facilities, stormwater treatment area's and storage reservoirs, additional canals, resizing existing canals, pumps and conveyance structures will be constructed outside of the immediate lake area.

Lake Okeechobee operators have traditionally considered input from meteorologists, biologists, hydrologists, and engineers in making real-time release decisions. Modifying discharges based on weather and/or climate forecasts is not a new concept and was specifically stated as part of the operational rules on many of the historical regulation schedules. The new schedules are designed to increase operational flexibility. It appears desirable to design flexible operating rules that give water managers some latitude to utilize best available multi-disciplinary information, and adjust operations as necessary to achieve a better balance of the competing objectives. Considering the potential benefits from recent lake inflow forecasting tools, and the rapid increase in the state-of-the-art in forecasting technology, it makes good sense to establish more flexible rules which allow lake managers to utilize supplementary information and apply their sound judgement in making operational decisions.

The Caloosahatchee Basin storage reservoir and Aquifer Storage and Recovery system will capture local basin runoff and releases from Lake Okeechobee. Water from the reservoir will be used to provide environmental deliveries to the Caloosahatchee estuary, to meet demands in the Caloosahatchee Basin, and to inject water into the Aquifer Storage and Recovery wellfield for long-term (multi-seasonal) storage. Water from the Aquifer Storage and Recovery facilities will be used to meet the environmental demands of the estuary and local basin demands. Any estuarine demands not met by basin runoff, the reservoir and the Aquifer Storage and Recovery system, will be met by Lake Okeechobee, as long as lake stages are above 11.5 feet NGVD. Lake Okeechobee water will also be used to meet any remaining local basin demands subject to supply-side management. The Caloosahatchee Basin storage reservoir and Aquifer Storage and Recovery system will be operated in conjunction with the Caloosahatchee backpumping facilities, which include a stormwater treatment area for water quality treatment. This component operates after estuary and agricultural/urban demands have been met in the basin and when the level of water in the storage reservoir exceeds 6.5 feet and Lake Okeechobee is below the pulse release zone. When this situation occurs, water is released from the reservoir and delivered to the stormwater treatment area at the capacity of the backpumping/treatment system of 2000 cfs. The stormwater treatment area water is then backpumped to Lake Okeechobee. The operation of project components in the Caloosahatchee Basin will significantly improve regional water managers' abilities to meet local basin agricultural/urban demands as well as the environmental needs of the downstream estuary.

The Initial Draft Plan introduced operational changes in Water Conservation Area 2A that improved inundation patterns in the north, but in so doing increased the frequency of extreme drought conditions in the south. It appears that water management in Water Conservation Area 2A imposes tradeoffs between providing improved marsh conditions in some areas but worse conditions in others. It is also possible that restoration of a more natural hydropattern to this portion of the Everglades is hampered by constraints imposed by water management elsewhere, notably the fixed regulation schedule in Water Conservation Area 1 that may be amplifying high and low water conditions in Water Conservation Area 2A. If rainfall based operational rules are adopted for Water Conservation Area 1 in the future, such unnatural fluctuations in depth in Water Conservation Area 2A may be alleviated. Overall, the most significant component affecting performance in Water Conservation Areas 2A and 2B is the Central Lake Belt storage facility, which takes water from southern Water Conservation Area 2B (as well as from eastern Water Conservation Area 3A and 3B) and routes it to the Central Lake Belt reservoir for later delivery to Everglades National Park or other areas. Rather than exhibiting high water in the south combined with over-drainage in the north, as is currently the case in all of the Water Conservation Areas, the Initial Draft Plan predicts longer hydroperiods near Stormwater Treatment Area-2 input in the north, increased drying in the south, and accumulation of water at the “bottom” in Water Conservation Area 2B. As a result, those areas that most closely match hydrologic performance targets are those nearest to the location of gages that trigger inflow/outflow operations. A more detailed study of the effects of different operational rules will be needed in order to identify the most ecologically beneficial method of water management for this region.

A number of components in the Initial Draft Plan lead to significant predicted changes in hydrologic conditions in Water Conservation Area 3A. Those components having the most direct effects on the Water Conservation Area are (1) the changes in the location and magnitude of water deliveries along the northern and western boundaries; (2) the Central Lake Belt reservoir and its operation; (3) the L-67A canal and levee changes; and (4) the removal of the L-28, L-28 tieback, and L-29 levees.

The Initial Draft Plan succeeded in holding the frequency of extreme high water events within the overall bounds defined for the natural system by the NSM. This performance can clearly be credited to the barrier provided by the L-67 levee, which prevents excess build up of water within the northern and central sections of the Water Conservation Areas. The Initial Draft Plan avoided excessive flooding in Water Conservation Area 3B. In addition, the Initial Draft Plan predicts a lower frequency of extreme high water events than that predicted for the 2050 base, although 2050 base conditions in Northeast Shark River Slough are drier than their ideal restoration targets.

The proposed storage areas under the Initial Draft Plan will significantly improve water management on the Upper East Coast relative to the 2050 base. Water storage sites will allow localized rainfall runoff to be captured and used for flow augmentation to the St. Lucie estuary when needed during the dry season. The greatest benefit will come from storage of peak rainfall inside the basins, and reduced loss of this turbid, nutrient-laden water to tide. The Initial Draft Plan reduced the frequency of high-flow discharges to the estuary by nearly 80 percent.

The principal changes in water management will be an increase of structures (levees, pumps, weirs, and canals) associated with the storage areas and their operation. A fairly complex operation schedule will have to be designed and implemented to maximize the benefits of these storage sites. Water will be pumped into and out of the storage areas, requiring fuel and causing additional noise to nearby areas.

Under the Initial Draft Plan, all flood control releases to the St. Lucie and Caloosahatchee River estuaries are expected to be eliminated except pulse releases in Zone A of the regulation schedule. The Indian River Lagoon Issue Paper (1999) stated that the Indian River Lagoon feasibility study will review this problem in much greater detail. Water managers will use a climate based inflow forecasting model, in conjunction with operational rules, which will help them decide when to pump water to the storage facilities outside the lake. When the model shows that lake water levels may rise above desirable levels for the littoral zone, water will be pumped to the storage facilities in the Everglades Agriculture Area with increased conveyance from Lake Okeechobee to the reservoir. The purposes are to improve timing of environmental deliveries to the Water Conservation Areas, including reducing damaging flood releases from the Everglades Agriculture Area to the Water Conservation Areas, reduce Lake Okeechobee regulatory releases to estuaries, meet supplemental agricultural irrigation demands, and increase flood protection within the Everglades Agriculture Area. Conveyance capacity of the Miami, North New River, Bolles, and Cross Canals between Lake Okeechobee and the storage reservoirs would be increased to convey additional Lake Okeechobee regulatory releases that would have otherwise been discharged to the Caloosahatchee and St. Lucie Estuaries.

The proposed structural changes in water management associated with Biscayne Bay will be due to structures associated with the water reuse plants and transport of recycled water to the Bay. Any reuse water going to Biscayne Bay will be treated with superior technology and will meet the stringent low nutrient levels of the main bay and the coral communities of the National Park. No adverse impacts on flood protection are expected as a result of any of the seepage barrier or seepage control methods employed. Components will be designed to function so that the rise in groundwater elevation will not cause a loss of storage in the affected area. Alternatively, seepage impacts will be mitigated through the addition of seepage pumps and improved or new secondary collection systems. Excess water, when available, will be sent to the South Miami-Dade Conveyance System, Northeast Shark River Slough and deep injection wells. Saltwater intrusion benefits to the southern part of Miami-Dade County are anticipated under the Initial Draft Plan. The effects of above ground storage on flood protection will be positive. The western C-4, C-9, and Hillsboro basins are currently flood prone basins. Available above ground storage areas should greatly reduce flooding in those areas during storm events.

Further evaluation of large scale regional Aquifer Storage and Recovery facilities utilizing surficial aquifer ground water in association with C&SF Project canals and proposed storage facilities are recommended. Computer simulations of certain regional groundwater Aquifer Storage and Recovery facilities indicate the potential for using large scale Aquifer Storage and Recovery as a regional storage mechanism. Regional groundwater Aquifer Storage and Recovery systems have great potential to be highly effective in meeting local demands during the dry season and reducing excessive discharges of freshwater to tide during the rainy periods.

Overall, the remaining Everglades should be managed as a whole, not as individual subcomponents of the regional system. A number of hydrologic benefits will be gained by construction of the Everglades Construction Project and implementation of rainfall-driven hydropattern targets within the Everglades. Rainfall-based delivery plans for Water Conservation Areas 2A and 3A based on antecedent rainfall and natural system hydropatterns should be developed. In addition, modifications should be made to the Everglades National Park's current rainfall-based delivery plans in a manner that replicates natural system-like conditions. Model results showed that using the rainfall-driven targets significantly improve the quantity, timing, and distribution of water delivered to Water Conservation Area 2A, Water Conservation Area 3A, and Everglades National Park to more closely resemble natural, pre-drainage patterns.

A recommendation for future water management of the C&SF Project is that the application of recent advances in the field of climatology be applied for increasing the flexibility and efficiency of managing the C&SF Project water control system. The ability to forecast changes in water availability associated with climate fluctuations would be a valuable asset to regional water management authorities. These forecasts may provide advanced warnings of extended periods of deficits or surpluses of water availability, allowing better regional water management for flood protection, water supply, and environmental enhancement.

K.2.9 Water Quality

Viewed from a regional perspective, the Initial Draft Plan is expected to greatly improve water quality conditions in the Restudy area. The Initial Draft Plan creates approximately 181,270 acres of surface water storage area, totaling approximately 1.5 million-acre feet of additional storage volume compared to existing and future base conditions (***Table K.2-1***). Minimally, this proposed tremendous increase in surface water storage volume is expected to result in a reduction in pollution loading into downstream receiving water bodies, simply through the attenuation of surface flows and settling of attendant pollution loads prior to discharge. Aquifer storage and recovery components in the Initial Draft Plan provide additional deep aquifer storage capacity totaling approximately 1,665 MGD (***Table K.2-2***). This additional storage capacity will also improve regional water quality conditions through aquifer storage of existing flood discharges.

Table K.2-1 **Storage Areas/Volume in the Initial Draft Plan**	
Name of Component	**Storage Area/Volume**
North of Lake Okeechobee	20,000 acres @ 10 feet (200,000 AF)
Upper East Coast C-23	8,400 acres @ 8 feet (67,200 AF)
Upper East Coast C-24	6,000 acres @ 8 feet (48,000 AF)
Upper East Coast C-25	12,800 acres @ 8 feet (102,400 AF)
Upper East Coast St. Lucie River, N. Fork	11,800 acres @ 8 feet (94,400 AF)
Upper East Coast St. Lucie River, S. Fork	9,350 acres @ 4 feet (37,400 AF)
St Lucie (C-44)	10,000 acres @ 4 feet (40,000 AF)
Caloosahatchee (C-43)	20,000 acres @ 8 feet (160,000 AF)
EAA	60,000 acres @ 6 feet (360,000 AF)
Taylor Creek/Nubbin Slough	5,000 acres @ 10 feet (50,000 AF)
Southern L-8	1,200 acres @ 40 foot depth (48,000 AF)
Central Palm Beach (Ag Reserve)	1,660 acres @ 12 feet (19,920 AF)
Site 1	2,460 acres @ 6 feet (14,760 AF)
C-9	2,500 acres @ 4 feet (10,000 AF)
North Lake Belt	4,500 acres @ 20 foot depth (90,000 AF)
Central Lake Belt	5,200 acres @ 36 foot depth (187,200 AF)
Bird Drive Basin	2,900 acres @ 4 feet (11,600 AF)
TOTAL	***181,270 acres (1,530,870 AF)***

Table K.2-2 **Aquifer Storage And Recovery Facilities in the Initial Draft Plan**	
Name of Component	**Storage Capacity**
Caloosahatchee Storage Reservoir	220 MGD (44 @ 5MGD)
Site 1 Impoundment	150 MGD (30 @ 5MGD
Lake Okeechobee	1,000 MGD (200 @ 5MGD)
C-51	170 MGD (34 @ 5MGD)
Palm Beach County Ag Reserve	75 MGD (15@5MGD)
L-8	50 MGD (10 @ 5 MGD)
TOTAL CAPACITY	***1,665 MGD***

Additionally, several components of the Initial Draft Plan include treatment features to assure that water quality conditions are improved or not degraded as a result of the operation of those components. Specifically, the Initial Draft Plan includes nineteen stormwater treatment areas totaling approximately 35,550 acres, providing approximately 126,370 acre feet of treatment volume (including other project elements; see ***Table K.2-3***). These stormwater treatment areas represent additional storage volume beyond that provided by the storage areas. Furthermore, those components of the Initial Draft Plan involving aquifer storage and recovery and wastewater reuse include treatment facilities to meet applicable State of Florida water quality standards.

For further information and details on the anticipated effects of the Initial Draft Plan on regional water quality as well as water quality within the ten physiographic regions, refer to ***Appendix H*** and this Appendix.

Table K.2-3
Stormwater Treatment Areas/Volume in the Initial Draft Plan

Name of Component	Storage Area/Volume
Caloosahatchee River (C-43)	5,000 acres @ 4 feet (20,000 AF)
North of Lake Okeechobee	2,500 acres @ 4 feet (10,000 AF)
Taylor Creek/Nubbin Slough	5,000 acres @ 4 feet (20,000 AF)
Western C-11	1,600 acres @ 4 feet (6,400 AF)
C-9	2,500 acres @ 4 feet (10,000 AF)
Central Lake Belt	640 acres @ 4 feet (2,560 AF)
L-28I	1,100 acres @ 4 feet (4,400 AF)
L-28I	800 acres @ 4 feet (3,200 AF)
C-17 Backpumping	550 acres @ 4 feet (2,200 AF)
C-111 North	3,200 acres @ 4 feet (12,800 AF)
L-8 Project	Undetermined acreage
North Lake Belt	1,200 acres @ 4 feet (4,800 AF)
C-51 Backpumping	600 acres @ 4 feet (2,400 AF)
Miccosukee Tribe Water Management Plan (OPE)	900 acres @ 4 feet (3,600 AF)
Acme Basin B (OPE)	310 acres @ 4 feet (1,240 AF)
Seminole Tribe Big Cypress (OPE)	5,270 acres @ 1 foot (5,270 AF)3,835 AF)
South Biscayne Bay Coastal Wetlands (OPE)	Undetermined acreage
S-154 Basin (OPE)	1,775 acres @ 4 feet (7,100 AF)
S65-D Basin (OPE)	2,600 acres @ 4 feet (10,400 AF)
TOTAL	35,550 + acres; 126,370 + AF

K.2.10 Water Supply

The Initial Draft Plan substantially improves water supplies for the Lower East Coast Service Area (LECSA) compared to the 2050 base. The Initial Draft Plan meets public water demands, minimizes the duration of cutbacks, and maintains saltwater intrusion stages in the primary coastal canals. Compared to the 2050 base, it greatly improves the ability to meet public water supply demands and prevent saltwater intrusion. All of the alternative plans reduce the dependence of users on Lake Okeechobee and the Water Conservation Areas. In the Initial Draft Plan, there is 23 percent less water delivered from Lake Okeechobee and the Water Conservation Areas through the structures to the Lower East Coast than in the 2050 base case. The future for urban water supply looks significantly worse in the 2050 base without the C&SF Restudy, even if the health of the environment were not a consideration. The urban areas are expected to benefit from a sustainable system that supports their future water supply demands and restores the Everglades ecosystem. In addition, as expensive as these projects are, they are likely to be even more expensive if delayed farther into the future.

In its effort to control flood waters and provide water supply, the C&SF Project created miles of canals, levees, and water control structures with associated deep pools. In the Initial Draft Plan, the miles of canals and levees fragmenting the remaining natural system was reduced. In the natural area, the number of miles of canals was reduced by 40 percent and levees by 20 percent from the 2050 base. In the Initial Draft Plan, flows across the Tamiami Trail not only increased 92 percent over 2050 base but the proportion flowing east of the L-67 vs. west of L-67 improved from only 11 percent in 2050 base to 55 percent in the Initial Draft Plan. Flows through southern WCA-3A increased from only 62 percent of NSM volumes in the 2050 base to 110 percent of NSM in the Initial Draft Plan without causing excessive high water events. Flows in western WCA-3A were spread more evenly into the dry season in the Initial Draft Plan, preventing the premature dry season drydowns seen in the 2050 base.

In the Lake Okeechobee Service Area (Everglades Agricultural Area, Caloosahatchee and St. Lucie basins, S-4 and L-8 basins, and Seminole Indian reservations), the performance measures are based on frequency, duration and severity of water supply cutback events. Water restriction events vary according to how often they occur (frequency), how long an event lasts (duration), and how much of the water that would normally be demanded is not delivered (severity). Scores were developed for each of these characteristics. The principal goal for the alternatives was that they should be able to meet all demands in a 1-in-10 year drought. The best indicator for this goal is the number of years with water shortage restrictions that does not exceed three in the 31-year simulation period. The Initial Draft Plan comes closest to the goal, with just 5 events. By comparison, the 2050 base has 16 events.

Low ground water levels near the coast increase the vulnerability of the Biscayne Aquifer to saltwater intrusion. Continuing to meet urban water demands may exacerbate lowering of ground water levels and therefore cutbacks are necessary when there is a threat to the resource. Low storage levels in Lake

Okeechobee at the beginning of the dry season are indicative of a prolonged storage problem that dictates when the cutbacks can be removed, while low ground water levels indicate immediate problems within the LECSA. Either of these triggers, Lake Okeechobee or local ground water levels can initiate a water supply cutback and are reflected in the ability to meet the 1-in-10 level of service water supply goal. Although regional water supplies or local ground water levels may rebound during the dry season, cutbacks are continued through the end of the dry season, May, to ensure protection of the Biscayne Aquifer.

K.2.11 Socio-Economics

The economic impact evaluation of the alternative restoration plans includes four principal elements.

1. Anticipated Effects of Alternative Plans on the National Economic Development (NED) Account: Alternative plans could result in positive or negative effects on net national economic efficiency due to project-induced impacts on the following economic activities in south Florida:

- Agricultural water supply,
- Municipal and industrial (M&I) water supply,
- Flooding potential,
- Commercial navigation,
- Recreation (Everglades-related), and
- Commercial and recreational fishing.

2. Evaluation of Project Costs: Project costs include all expenditures required to implement the alternative plans. These costs would be shared by the Federal government and the State of Florida. Project costs include initial construction costs; lands; relocations; rights of way; rehabilitation, replacement, and repair costs; and operations and maintenance (O&M) costs (including the costs of post-construction monitoring and adaptive management).

3. Regional Economic Development (RED) Effects: The potential RED effects of the alternative plans include changes in income, employment, or economic output of the region.

4. Other Social Effects (OSE): The potential social effects of the alternative restoration plans include effects on minority, elderly, and disadvantaged groups, population displacement, and community cohesion.

The economic analysis for the C&SF Restudy was conducted consistent with Federal statutes and Corps policy. Procedures for estimating NED and RED effects are specified in the <u>Economic and Environmental Principles and Guidelines for</u>

Water and Related Land Resources Implementation Studies (U.S. Water Resources Council, 10 May 1983), Engineering Regulation (ER) 1105-2-100, and other Corps guidance.

The South Florida Water Management Model (SFWMM), the principal analytical tool used in this study, was not designed to conduct economic analysis, but does include many indicators of hydrologic change, which can have economic consequences. To assist in estimating the economic effects of water management decisions, the South Florida Water Management District developed the Economic Post-Processor (EPP) to estimate the economic effects of cutbacks in agricultural and urban water supply during drought periods. The EPP was used in the Restudy economic analysis to estimate the impacts of alternative restoration plans on the frequency and duration of drought-induced changes in agricultural and urban water supply. Other categories of economic effects were estimated by conducting “outside-the-model” analyses of various SFWMM-generated hydrologic performance indicators.

Using SFWMM as the principal tool for evaluating the economic effects of alternative restoration plans requires some practical modifications to the traditional with and without-project analysis procedures typically used in Corps of Engineers water resource planning studies. In a traditional feasibility investigation, a probabilistic analysis is conducted to project conditions expected to occur throughout the planning period (typically 50 years), both with and without implementation of a project. Average annual expected value of economic impacts are estimated by evaluating a range of possible future conditions, weighting the likelihood (i.e., probability) of these conditions by their economic effects, and then statistically combining them. The difference between this average annual value under with vs. without-project conditions constitutes the net annual economic impacts (positive or negative) of the alternative plans.

This type of with and without-project analysis had to be modified during the C&SF Restudy to account for the limitations imposed by SFWMM. As stated previously, the SFWMM is a simulation model, which equally weighs each of the days in the 31-year simulation period. As a result, it is not possible to use SFWMM to determine the likelihood of occurrence of any given hydrologic event. While the 31 years of past climate data are considered representative of future climatic conditions, they are of insufficient duration to assign frequencies of occurrence to specific simulated hydrologic events (e.g., 25-, 50-, or 100-year return period events). Therefore, the economic effects of the alternative restoration plans were estimated by comparing two “snapshots” of study area conditions that are expected to exist in the future, with and without each alternative plan.

The potential economic impacts of the alternative restoration plans are a secondary consequence of the hydrologic changes, which are expected to result from the proposed structural and operational modifications to the C&SF system. The figure on the following page traces the causal linkages between the structural and operational modifications to the C&SF system and the different categories of economic effects.

Some categories of economic impact, such as urban and agricultural water supply effects, can be estimated directly from SFWMM-simulated hydrologic changes associated with each alternative restoration plan. Other economic effects, such as commercial and recreational fishing impacts in the St. Lucie and Caloosahatchee estuaries and in Biscayne and Florida bays, are less directly linked to the hydrologic changes resulting from the alternative restoration plans. In this latter case, the chain of cause and effect includes: the impacts of project-induced changes in water release rates, the impacts of changes in release rates on the productivity of the fisheries, and the impacts of changes in the fisheries on the net income of commercial fishing operations and the quality of recreational fishing experiences. These chains of cause and effect have important consequences for our ability to quantify the economic effects of the alternative plans. Economic analyses cannot be applied to estimate the value of physical or ecological impacts of the alternative plans if those impacts cannot first be defined and quantified.

The principal challenge of ecosystem restoration economics is estimating the value of restoration benefits. The benefits of ecosystem restoration are usually expressed by ecologists in non-monetary units, such as acres of specific habitat created or enhanced, indices of biological productivity associated with habitat improvement, or increased abundance and/or diversity of particular species of plants or animals. Environmental amenities are public goods that are generally not exchanged in the marketplace. For marketable commodities (i.e., items that people buy and sell), the demand, and prices paid, for these goods can be used as “proxies” for determining their value to consumers. In the absence of data on consumers’ expenditures for environmental amenities, resource economists have attempted to develop techniques that can be used to estimate their value using indirect indicators of consumers’ “willingness to pay” for ecosystem restoration. There are a number of surrogate-market techniques, such as contingent value methodology (CVM), which can be used to estimate these willingness to pay values.

Unfortunately, these methods, including CVM, have significant shortcomings that lead to concerns about their reliability and validity. Therefore, Corps of Engineers ecosystem restoration policy has been formulated in recognition of the practical limits of available economic tools to value environmental resources. Corps of Engineers ecosystem restoration policy is such that ecosystem restoration projects are not subject to traditional benefit-cost analyses. Economic justification of ecosystem restoration is not required in the traditional sense of ensuring that the monetary benefits of the alternative plans exceed their monetary costs

The focus of the economic impact evaluation studies has been on: (1) the NED costs (in monetary terms), (2) the positive and adverse NED effects expected to occur in the following economic impact categories: agricultural water supply, municipal and industrial water supply, commercial navigation, recreation, and commercial fishing (in monetary and non-monetary terms) and (3) the positive and adverse regional economic effects (RED) resulting from project implementation. The development of this information can be found in ***Appendix E*** of this report.

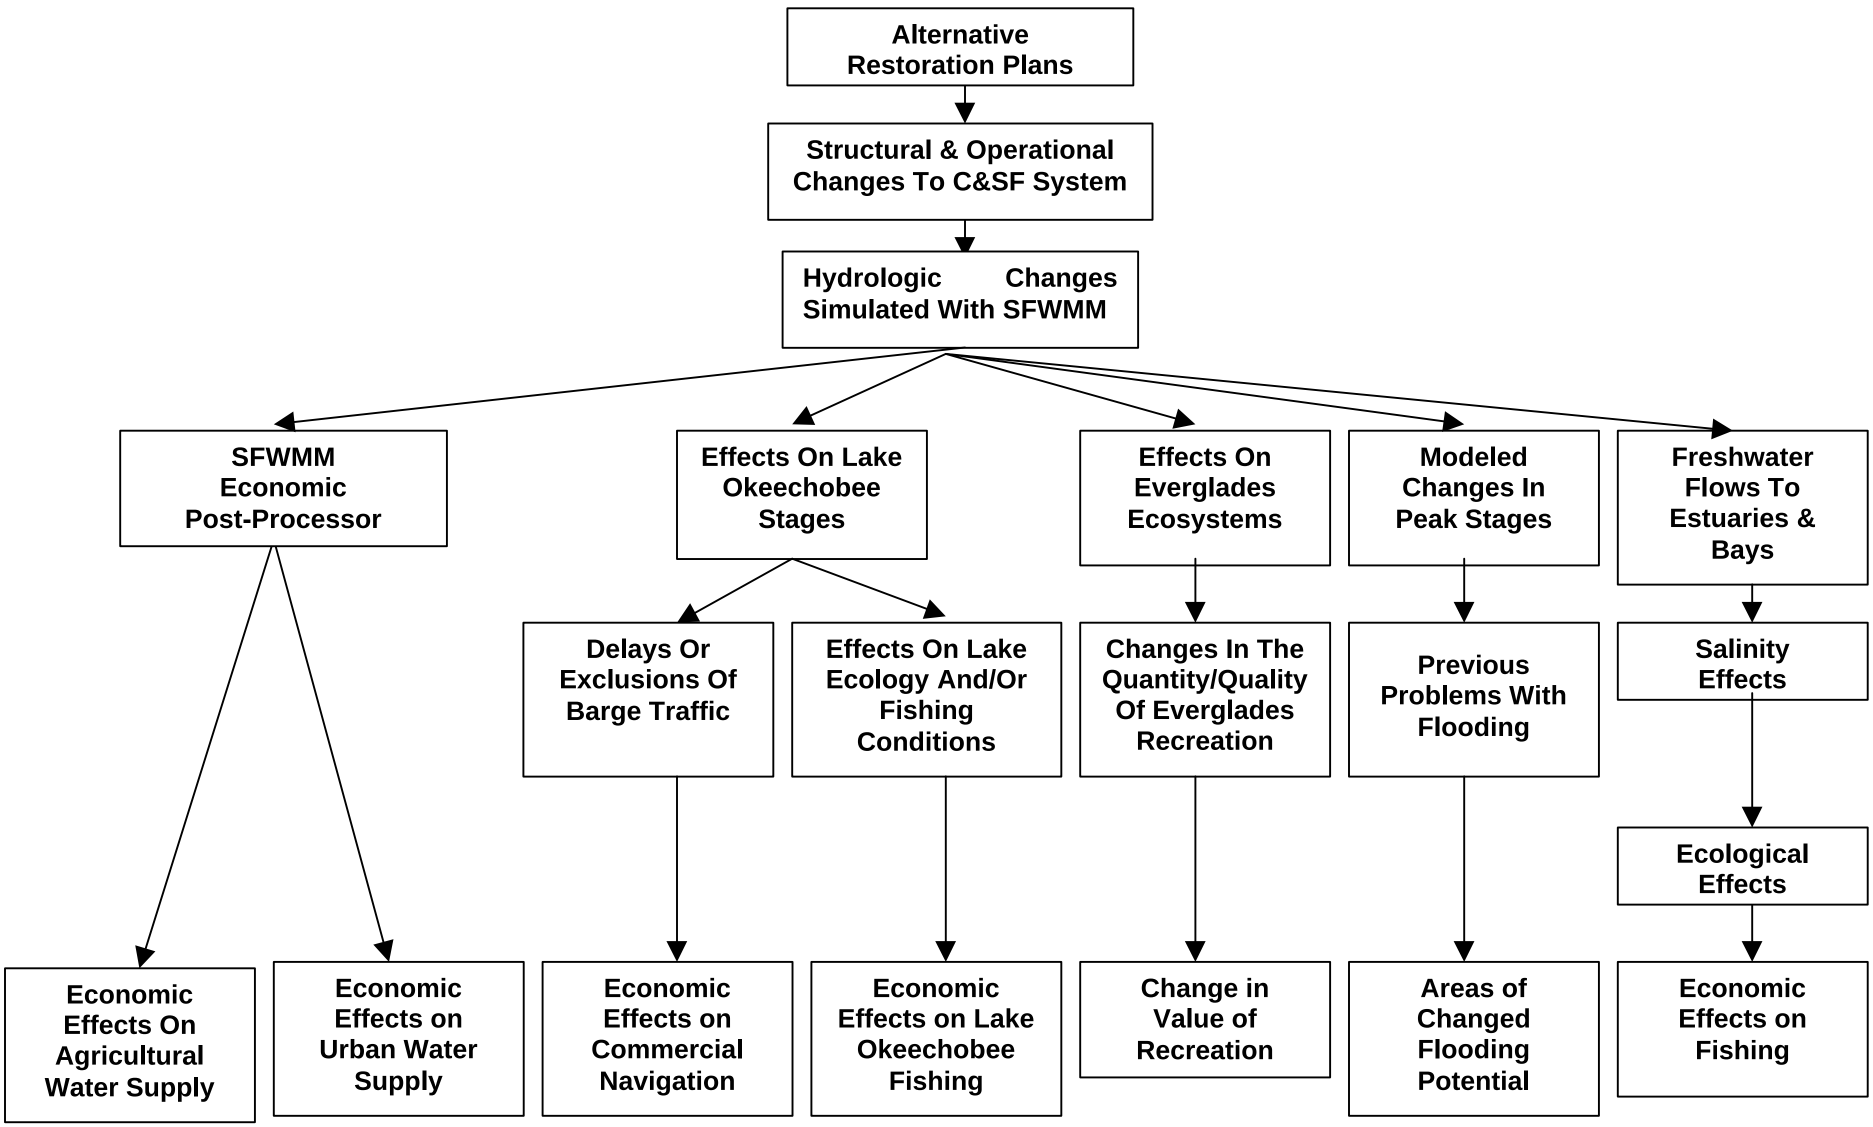
SOURCES OF ECONOMIC EFFECTS



This page is intentionally left blank.

K.2.11.1 NED Effects

The NED effects are the changes in the economic value of the National output of goods and services from a plan. The following discussion outlines the NED effects estimated to result from the alternatives.

K.2.11.1.1 Agricultural Water Supply

Effects on agricultural water supply are based on simulated water shortages under the different alternatives compared against the without-project condition. Water shortages are translated into plant growth and crop harvest effects, which are in turn translated into estimated net farm income differences between alternative plans and the without-project condition. Water shortage reductions are reduced with all of the plans, with estimated average annual positive NED effects ranging from about $1.7 million to $2.0 million. The effect for the Initial Draft Plan is $1.9 million per year.

K.2.11.1.2 Municipal And Industrial Water Supply

Effects on M&I water supply are based on consumers' willingness to pay to avoid water shortages. This represents the economic value to consumers of water not received during shortages. The difference between the without-project condition and the alternatives ranges from an average annual positive effect of $21.5 million to $27.2 million (for the Initial Draft Plan).

K.2.11.1.3 Flood Control

Studies to estimate the flooding implications of the alternative plans were limited by the spatial resolution of the SFWMM. This model was not designed for flood studies, and the relatively coarse spatial resolution of this regional model limits its utility in assessing the flood impacts of the alternative restoration plans. Recognizing these limitations, the flooding studies conducted for the Restudy employed a four-part methodology. First, using secondary information and professional judgement, flood problem areas in the region were identified. Second, the SFWMM was used to assess whether these areas would be expected to have higher or lower peak stages as a result of the implementation of the alternative plans. Third, other areas with potential adverse and beneficial effects from the alternative plans were identified. Finally, for those existing problem areas that are expected to be adversely affected, further studies were recommended.

K.2.11.1.4 Commercial Navigation

As discussed in Chapter 7, the alternative regulation schedules are expected to alter average lake stages on Lake Okeechobee, which is a critical link in the Lake Okeechobee Waterway connecting the Atlantic Ocean with the Gulf of Mexico via the Caloosahatchee River and the St. Lucie Canal. There has been a small but relatively stable level of commercial navigation on this waterway over the past ten years. The Lake Okeechobee Waterway was used to transport 430,000 tons of freight in 1995. Based upon field research and database searches regarding commercial navigation on the Lake Okeechobee Waterway, it can be concluded that the effects of the alternative restoration plans on the NED account would be very small. All of the alternative restoration plans are expected to lead to significant reductions in the frequency of low lake stages. However, the economic effects of these improvements for commercial navigation are expected to be minimal to negligible.

K.2.11.1.5 Recreation

Tourism is Florida's largest industry. Many Florida residents and visitors recreate in the Everglades-related recreation resources of south Florida. The economic value of resource-based recreation is determined by the users' willingness to pay for a recreation occasion. The interaction of demand with the quantity and quality of recreation resources available determines the recreation use or "participation" levels for that resource-based activity. When the quantity or quality of recreation resources is modified by a project, such as the alternative restoration plans, the change in value of resource-based recreation is based on the difference in the willingness of users to pay under the with- and without-project conditions. The restoration of the Everglades ecosystems could potentially have significant impacts on the value of outdoor recreation in south Florida. If the alternative restoration plans improve the ecology of the Everglades, the quality of the Everglades-related recreation and/or the number of people who participate in Everglades-related recreation could increase significantly. Consequently, the value of outdoor recreation in south Florida could increase as well. Estimating the future value of Everglades-related recreation in south Florida is problematic, and anticipating the incremental changes in value associated with Everglades restoration is even more challenging. There are three principal uncertainties, which limit the ability to anticipate the future quantity and quality of outdoor recreation under with- and without project conditions:

- <u>Timing and character of the ecological changes from restoration</u>: If the results of the restoration effort can not be predicted, secondary effects on recreation are even more uncertain.

- <u>Marketing of tourism and Everglades-related recreation</u>: Tourism is particularly sensitive to marketing efforts. Restoration may or may not be accompanied by promotion of the enhanced recreation opportunities.

- <u>Development of recreational facilities and recreational access</u>: Facilities and access are critical determinants of recreation participation. Restoration may or may not be accompanied by development of additional recreation facilities and access.

Given these uncertainties, it is beyond the scope of this analysis to quantify the value of Everglades-related recreation under the with- and without-project future conditions through the 50-year planning period. However, the alternative plan that is expected to be most effective in terms of restoration can be expected to also be most effective in terms of positive recreation effects.

Although recreation benefits have not been estimated, current expenditures have been estimated for Everglades-related recreation in order to help frame the issues surrounding the recreation effects of the alternative restoration plans. There are approximately 6.3 million visitors annually to the principal Everglades parks and preserves. At the regional scale, there are approximately 16.6 million wildlife watching participants in south Florida. It is estimated that the current annual expenditures associated with visitation to the Everglades parks and preserves is approximately $404 million, and expenditures for wildlife watching in south Florida are approximately $598 million. These provide insight into the value of the Everglades-related recreation resources, and the potential for increases brought about by improved conditions with implementation of a plan.

K.2.11.1.6 Commercial and Recreational Fishing

The alternative plans have the potential to affect recreational and commercial fishing throughout south Florida by modifying the hydrologic regime in the region's waterways and estuaries. There are five principal fishing impact zones that would experience the majority of the potential economic effects on fishing in the region: Lake Okeechobee, the Caloosahatchee and St. Lucie estuaries, and Biscayne and Florida bays. Total annual revenues associated with recreational sportfishing, guided sportfishing, and commercial fishing are significant.

The hydrologic changes that are expected to result from the alternative restoration plans may have economic implications for commercial and recreational fishing in the study area. Estimating the actual extent of such effects has been beyond the scope of this study. Economic effects on commercial fishing would be based on changes in net income for commercial fishing, and changes in the quality and quantity of recreational fishing experiences. Not enough is known about the linkages between hydrological changes which would be brought about by plan implementation, nor is enough known about the timing of the linkages between these changes, the resulting ecological changes, and ultimately the changes in the value of fishing, to estimate the economic effects on fishing in this study.

Appendix E discusses the economic fishing activity in the major five impact zones of Lake Okeechobee, St. Lucie and Caloosahatchee estuaries, Biscayne Bay, and Florida Bay. All of the plans are expected to positively impact fishing, with the exception of Biscayne Bay, whose fishery would likely be slightly positively affected only with Alternative D and the Initial Draft Plan.

K.2.11.1.7 NED Costs

The initial costs for construction and real estate range from $5.2 billion to $7.8 billion for the Comprehensive Plan. Recurring annual costs for operation and maintenance, and monitoring, ranges from $70 million to $165 million per year. These costs translate into a uniform annual equivalent cost alternatives ranging from $254 million to $402 million for the Comprehensive Plan.

K.2.11.2 Regional Economic Effects

The effects of the alternative plans on the regional economy include such primary effects as the economic activities stimulated by the purchases of materials and services required in the construction of the project, the purchases of real estate, operation and maintenance of the system, and monitoring costs. They also include secondary consequences, such as changes in agricultural land use and changes in agricultural water supply. The types of regional economic impacts that a new project can have on output, earnings, and jobs in a region are known as “direct,” “indirect,” and “induced.” Direct impacts are caused by first round of expenditures associated with the project. The indirect impacts count only the inputs that are purchased as a result of the first round expenditures. The importance of these “indirect” effects will vary with the complexity of production in the study area and the degree to which required materials are supplied by local producers. Induced effects are the multiplier effects of the project expenditures as that spending circulates in the regional economy.

Total regional impacts are a net positive for all alternatives, and though large in absolute terms, they are small relative to the study area’s regional economy. Average annual effects on total sales are estimated to range from +$173 million to +$307 million, close to 1/10th of one percent of the study area’s total output of over $220 billion per year. Employment effects range from about +1,700 to +3,165 jobs; the regional economy’s total employment exceeds 2.9 million. Impacts on earnings ranges from $59 million per year to $108 million per year; annual earnings for the regional economy exceed $78 billion.

K.2.11.3 Other Social Effects

The categories of potential effects include:

- Urban and community impacts,
- Life, health, and safety factors,
- Displacement,

- Long-term productivity, and
- Energy requirements and energy conservation.

The most potentially significant OSE consideration for the alternative restoration plans concerns the development of new storage reservoirs in the rural areas surrounding Lake Okeechobee, and the consequences for urban and community impacts and displacement of people. These project features would convert farmland to reservoirs. Their development could eliminate the jobs of the individuals who depend on those lands for their employment and have adverse effects on local communities and economies. The potential locations of the new reservoirs are not known at this time. However, the resilience of local economies and the cohesion of local communities to agricultural land conversion depend on a variety of factors, including the age, ethnic, and racial composition of the community and income, unemployment, and poverty levels. A social vulnerability index was developed using county-scale socioeconomic characteristics, and this type of analysis could be replicated in more detail when and if new reservoir sites are proposed.

K.2.12 Land Use

The following section discusses the effects of the Initial Draft Plan on land use within the region. The most significant effect upon land use will be the proposed construction of approximately 171,000 acres of above ground water storage. It is anticipated that the majority of the water storage areas will be located over land that is currently in some form of agricultural production.

In the immediate vicinity of Lake Okeechobee, agricultural lands are not expected to be affected by implementation of the lake regulation schedule proposed under the Initial Draft Plan. Storage reservoirs designed to augment Lake Okeechobee will occupy 30,000 acres in the Kissimmee River region and 60,000 acres in the Everglades Agricultural Area. Proposed aquifer storage and recovery facilities include 200 wells located near the Lake Okeechobee levee. These wells will require some land for construction, operation, and maintenance. Agricultural production may be compatible with aquifer storage and recovery wells, as the structures are expected to take up minimal land above ground. It appears likely, however, that more than 90,000 acres of land in the regions surrounding Lake Okeechobee will be taken out of agricultural production. Conversion of 60,000 acres of agricultural land in the Everglades Agricultural Area to reservoirs would be an approximate 9 percent reduction of the area farmed in this region. Everglades Agricultural Area lands are designated as unique farmland. Implementation of the Initial Draft Plan should have no negative effect on future urban land use around Lake Okeechobee. Urban lands surrounding the lake should benefit through a greater, more consistent source of water for urban and industrial use, including continued flood protection, beyond that projected in the 2050 base.

This page is intentionally left blank.

SUMMARY OF ECONOMIC EFFECTS OF ALTERNATIVE RESTORATION PLANS
(all dollar values in $ millions)

IMPACT CATEGORY	WITH- AND WITHOUT-PROJECT CONDITIONS					
	2050 Base Condition	**Alternative A**	**Alternative B**	**Alternative C**	**Alternative D**	**Comprehensive Plan**
NED EFFECTS						
Agricultural Water Supply: Avg. annual value of unmet demand*	$2.6	$0.6 (+$2.0)	$0.9 (+$1.7)	$0.7 (+$1.9)	$0.8 (+$1.8)	$0.7 (+$1.9)
M&I Water Supply: Avg. annual value of unmet demand*	$31.8	$10.2 (+$21.7)	$10.3 (+$21.5)	$6.4 (+$25.4)	$4.6 (+$27.2)	$4.6 (+$27.2)
Flood Control	• Limited evaluation of impacts, since SFWMM not designed for flood studies.					
Commercial Navigation	• No significant difference expected between with- and without-project conditions.					
Recreation	• Problematic to quantify effects of alternative plans. • Current Expenditures: $404 million (parks/preserves); $598 million (region). • Current Consumer Surplus: $290 million (parks/preserves); $764 million (region).					
Commercial/Recreational Fishing	• Annual revenues estimated for commercial and guided & recreational sportfishing in five areas: Lake Okeechobee, St. Lucie & Caloosahatchee estuaries, and Biscayne & Florida bays. • Significant positive economic impacts are expected to result from hydrologic modifications and consequent ecological impacts to all five areas with the exception of Biscayne Bay.					
NED COSTS						
Total Construction & Real Estate Costs		$5,229	$6,023	$6,725	$7,335	$7,789
Total Operations & Maintenance Costs		$70	$72	$126	$162	$165
Total Monitoring Costs		$10	$10	$10	$10	$10
Annualized Costs		$254	$286	$341	$383	$402
REGIONAL EFFECTS						
Average annual effects (% of regional economy)						
Output		$173 (.08%)	$195 (.09%)	$192 (.09%)	$277 (.12%)	$307 (.14%)
Employment (jobs)		1,707 (.06%)	1,934 (.07%)	2,057 (.07%)	2,903 (.10%)	3,165 (.11%)
Earnings		$59 (.08%)	$65 (.08%)	$78 (.10%)	$103 (.13%)	$108 (.14%)
OTHER SOCIAL EFFECTS	• Potential community disruption from conversion of agricultural land to reservoirs.					

* A "+" indicates a reduction in unmet water demand.

This page is intentionally left blank.

Implementation of storage sites in the upper East Coast will cause land use changes in the area. About 46,000 acres of mostly agricultural lands are being targeted for siting surface water storage areas. Some of the agricultural activity in the area, especially citrus, has been on the decline and the land use could possibly have changed with or without the Restudy. However, lands acquired for surface water storage will be removed from the agricultural land base of St. Lucie and Martin Counties.

The Initial Draft Plan would alter agricultural land use within the Caloosahatchee River region. A 20,000 acre storage reservoir is proposed for the C-43 Basin to capture basin runoff and water releases from Lake Okeechobee for eventual use for water supply and environmental demands. Conversion of 20,000 acres from agriculture to reservoir would be an approximately 4 percent reduction of agricultural acreage, in a region that has experienced recent expansion of agricultural production.

Several thousand acres of land will be needed for above ground storage facilities in the lower East Coast region. The lands proposed for the Water Preserve Areas in the lower East Coast are generally vacant or are in agricultural production. It is assumed that the majority of these lands would eventually be designated urban land, especially low density residential. These urban land uses can in general be accommodated on other vacant lands or by increases in density of development. The lake belt reservoirs, which are in-ground facilities, are not expected to diminish the land use of rock mining or impinge on productive agricultural land. Seepage management should not cause changes to existing land use; minimal land is required for the wells and physical barrier methods. Seepage control components along eastern Water Conservation Areas 3A and B are located on wetlands; these components will lengthen the hydroperiods of the wetlands involved.

Land use within the Big Cypress basin will not likely be significantly affected by implementation of the Initial Draft Plan. Residential development and future Miccosukee Indian residences along Loop Road will not be affected by flow modifications to southeast Big Cypress. Traditional use of lands within the preserve, guaranteed to the Miccosukee Tribe of Indians of Florida and members of the Seminole Tribe of Florida under Public Law 93-440, would not be affected by implementation of the Initial Draft Plan. The urban areas along the coast, including the municipalities of Naples, Everglades City, and Marco Island are outside the area of hydrologic influence of the plan and land use will be unaffected by the project.

No land use changes in the Florida Keys are contemplated by the Initial Draft Plan, as no construction is proposed for this region.

K.2.13 Recreation Resources

Overall, hydroperiods resulting from implementation of the Initial Draft Plan within the Kissimmee River region will not be substantially affected by or adversely affect recreation resources in the region. The proposed construction of above ground water storage reservoirs north of Lake Okeechobee, in the Caloosahatchee and St. Lucie basins, within the Everglades Agricultural Area, and along the eastern perimeter levees (Water Preserve Areas) could provide important recreation benefits depending on specific resource function and future design. These reservoirs could provide opportunities for fishing, bike riding, bird watching, hunting, and environmental interpretive recreation activities. Reservoirs sited near urban areas such as the Water Preserve Areas would probably have a greater beneficial impact on the area recreation resource potential, due to the larger potential user community located close by.

The Initial Draft Plan will modify the existing hydrologic cycle of Lake Okeechobee, producing more natural lake level fluctuations. This should improve the general health of the lake's recreational fishing resources. A reduction in the frequency of extreme and prolonged low water events should further provide a benefit both for fish habitat and access for recreational fisherman to backwater and littoral zone areas.

The following discussion on impacts to recreation resources within the Water Conservation Area and Big Cypress regions is excerpted in part from the Florida Game and Fresh Water Fish Commission Fish and Wildlife Coordination Act Report, Attachment B, dated August 6, 1998. This report is available in entirety in Annex A.

Under the Initial Draft Plan, WCA-3B and northern WCA-3A will be wet for a greater proportion of the year; thus airboat access would probably be increased in these areas. The increased accessibility of tree islands in this area may lead to an increase in privately constructed camps, which function primarily as a base for recreational pursuits.

Although airboat activity may increase as a result of the longer hydroperiods predicted by the Initial Draft Plan, the use of vehicles that require relatively little or no surface water for operation (tracks, swamp buggies, ATVs, etc) would be expected to decline. Although tracked vehicle use may continue to decline, hydrological conditions in Holey Land Wildlife Management Area and perhaps the northern portion of WCA-3A in drier years would probably still be suitable for tracked vehicle operation. Rehydration of Rotenberger Wildlife Management Area will probably result in a decrease in use by tracked vehicles and walk hunting. The use of swamp buggies is currently minimal on Everglades mucky soils, and would likely disappear altogether under the elevated water table proposed under the 2050 base. Thus, the use of swamp buggies is not expected to be affected under the Initial Draft Plan. In the Everglades Wildlife Management Area increased water levels will likely reduce opportunities for hunting deer.

The adoption of the Initial Draft Plan may result in an initial, localized decline in the mileage of canals available to fishermen. According to Corps design and costs estimates for the Initial Draft Plan, approximately 72 miles of canals are scheduled to be filled, while 74 miles of new canals will be constructed, and 100 miles of existing canals will be widened. The planned addition of 6,977 acres of water preserve areas with maximum water depths of 4 feet; 9,700 acres of water-storage areas with variable depths in the Lakebelt region; and 1,600-acres of stormwater treatment areas of an unspecified depth in Broward and Miami-Dade counties offer an important potential for new water based recreational areas.

Of particular concern to the GFC is the L-67A canal. The Initial Draft Plan proposes to backfill approximately six miles of the southern end of this canal. The “three pines” area, located near the proposed end of the canal, has been a particularly productive fishing spot, and may be eliminated if this portion of the canal is backfilled. In general, the southern half of the L-67A canal receives the most fishing pressure, probably due in part to the prolonged hydroperiod that normally exists in the southern portion of WCA-3A (Jon Fury, pers. com.) Fisherman would still be able to access the remaining L-67A from the Holiday Park area. GFC records indicate that over 75 percent of fisherman currently launch their boats from this boat landing as opposed to the boat landing at Tamiami Trail. Regardless of what access problems may exist, modeled hydrological conditions for the WCA-3A marsh adjacent to the L-67A canal predict somewhat lower mean water depths than would exist under the 2050 base, and considerably lower mean depths (> 1 ft.) than would occur under the 1995 base. With implementation of Modified Water Deliveries in the 2050 base, the size of the flooded area, with flooding duration in WCA-3A sufficient to maintain a productive marsh/canal bass fishery, is expected to decline dramatically. The reduction in flooding depth and duration would be even greater under the Initial Draft Plan. At this time, it is not clear how the weir design and operations across the L-67A levee will affect the fishery of the L-67A canal.

The L-67C canal, although not as popular a fishing area as the L-67A canal, also receives fishing pressure, especially when marsh water levels recede during the dry season. A count of the boat trailers parked at the L-67C boat ramp during the 6-month period extending from December 1996 through May 1997 yielded a total count of 2,900 boats using this canal, with an average of two persons per boat (Jon Fury, GFC, pers. com.). This canal would be backfilled entirely in the Initial Draft Plan, and this fishery would be lost as well.

Under the Initial Draft Plan, the area of upland refugia in the form of tree islands and levees is expected to decline in WCA-3B. The removal of the entire length of the L-67C levee and portions of the L-67A levee would significantly reduce the area of upland habitats in this portion of the Everglades.

Due to increased water levels in WCA-3B, deer hunting opportunities and huntable deer populations may decline in this area, where tree islands occur at lower densities and many are at relatively low elevations. Conversely, the area and duration of emergence of tree islands above ambient water levels is expected to increase in the southern portion of WCA-3A after removal of the impounding effects of the L-28, L-29, and partial removal of the L-67 levees. This would allow a relatively large number of tree islands to remain above ambient water levels for much longer periods of time. The greater density of tree islands in southern WCA-3A and a considerable reduction in the length of time that slough water levels remain above 30 inches deep in the Initial Draft Plan may provide a more stable environment for upland game animals. Hence, deer hunting opportunities should improve in the southern portion of WCA-3A. Although the removal of the L-28 levee would result in the loss of dry habitat that has served as relief for deer and other upland dependent wildlife in the past, lower water levels and reduction in prolonged high water events predicted by the Initial Draft Plan would make this levee less critical as an upland refugium.

The removal of the L-29 levee and canal by the Initial Draft Plan could have negative impacts on recreational access into WCA-3A and WCA-3B from U.S. 41, since the roadway would have to be elevated in some way. There are three public boat ramps providing airboat access into WCA-3B and three public boat ramps providing airboat and jon boat access into the L-29 canal and marsh of WCA-3A. One of the boat ramps for WCA-3B also provides jon boat access into the L-67C canal, which would be backfilled in the Initial Draft Plan. Therefore, it will be necessary to construct on and off ramps to these recreational areas and provide ample parking space for vehicles and boat trailers.

Within the Big Cypress region, the Stairsteps and Loop Road units of BCNP would most closely approach NSM conditions under the Initial Draft Plan. Under the ATLSS Cape Sable Seaside Sparrow Model and Index output for the Initial Draft Plan versus the 2050 base, the hydroperiod length was shown to decrease somewhat in the Stairsteps and Loop Road units. Ponding depths in the eastern portion of the Stairsteps unit also appeared to be slightly less in the Initial Draft Plan than under the 2050 base. Although no ATLSS output for the White-tailed Deer Breeding Potential Index was generated for the Initial Draft Plan, output was available for Alternative B, which was structurally similar to the Initial Draft Plan in that both the L-28 and L-29 levees were removed. Under this modeled output, the overall deer breeding potential mean was slightly higher in the Stairsteps and Loop Road units than under the 2050 base, but remained relatively unchanged in the Corn Dance unit. In conclusion, these evaluations suggest that more favorable hydrological conditions will exist for deer and upland game animals in the Stairsteps and Loop Road units of the Big Cypress Water Management Area with the adoption of the Initial Draft Plan than would occur in the 2050 base. Deer populations in the Corn Dance unit will probably remain relatively stable.

The proposed improved water deliveries to Northeast Shark River Slough in Everglades National Park, based on seepage control and redirecting outfall from L-31, will provide water for environmental purposes. Water structures will be removed and others will be added, L-31N will be rerouted and L-31N borrow canal will be backfilled. A five-foot high levee will be constructed along the west side of the existing lake. Bank fishing along L-31N borrow canal could be adversely affected. An associated action (L-31N Levee improvements for seepage management) will reduce groundflows to Everglades National Park 100 percent during the wet season and will help to restore hydropatterns in Everglades National Park. These proposals could produce temporary interruption of recreation resources that would cease once construction had been completed. The 2050 base plan would propose no such component.

The economy of the Florida Keys is very water resources oriented and depends upon healthy water-based ecosystems. Over 36 percent of Monroe County's annual gross earnings are generated from tourism and recreation activities (USDC, 1995). Proposed C&SF Restudy Components do not directly affect the Keys, but are expected to improve water quality in Florida Bay that could improve shrimp and fishery habitats, which would enhance the sustainability of the recreation and tourism industry in the Keys.

K.2.14 Aesthetic Resources

Restoration of the south Florida ecosystem is expected to result in a healthy ecosystem that will support vigorous plant communities, large fish and aquatic animal populations, large numbers of wading birds, alligators, and sustainable populations of wide-ranging mammals in a natural setting, in perpetuity. Viewing wildlife, wetlands and open, relatively pristine spaces is important to people. Recent studies are discovering that recognizing our connection with nature brings peace of mind and respect for life.

Reducing high stages in Lake Okeechobee will improve water clarity and fish production in the littoral zone. Reducing damaging freshwater releases into the Caloosahatchee and St. Lucie estuaries will improve water clarity, restore seagrass beds, oyster beds, attract more wading birds and increase densities of fish, shrimp and crabs among other species.

Decompartmentalization of the Everglades, which removes many miles of structures, improves the wilderness character of the Everglades by removing some of the human ability to control it. While levees provide human access to the Everglades interior, the exotic vegetation that covers them is visible at a distance, marring the view of the landscape. Levee removal, therefore, will restore the visual impact of the Everglades as well as remove a source of invasive exotic species.

K.2.15 Cultural Resources

Component features at this stage of planning are conceptual and feature locations are not precisely determined. Under the tiering concept of the National Environmental Policy Act, specific effects to historic properties will be addressed and coordinated with the State Historic Preservation Officer under Section 106 of the National Historic Preservation Act. A separate Environmental Assessment or supplemental EIS will be prepared for each project feature, and cultural resources assessments will be conducted in support of those documents, when necessary. Specific effects to historic period and pre-Columbian period archeological sites and standing structures, engineering structures and architectural features will be evaluated after individual project feature sites are determined. Effects from the proposed project are anticipated to come from project feature construction, operational changes, erosion, human disturbance, and changes in the hydrologic regime of the flood plain.

Early in the planning stage of each project feature, appropriate cultural resources investigations will be conducted to locate and identify potentially significant historic properties that will be affected by the project. Initially, a comprehensive archival and background review will be completed, and an historical overview will be compiled. Archival research should culminate in the formulation of specific research question that will direct future field studies, guide analysis of collected data, and most importantly, give the resource managers a basis against which to measure site significance and National Register eligibility.

An architectural assessment will be made of structures and architectural features that may be affected. An archeological sample survey, stratified by culturally meaningful environmental variables, will be undertaken. A geomorphologic investigation designed to identify landforms that could contain significant resources may be completed.

Based on the results of the archival and background review, the archeological sample survey and the geomorphologic investigation, a predictive model will be developed to identify areas with a high probability to contain significant resources. Additional archeological investigations are expected to be necessary, in order to adequately assess the National Register of Historic Places eligibility of all potentially significant historic properties.

In consultation with the State Historic Preservation Officer, the Corps will apply the criteria of effect and adverse effect (36 CFR 800.9) for historic properties that meet the criteria of eligibility to the National Register of Historic Places. For those historic properties that will be adversely affected, mitigation plans will be developed by the Corps, in consultation with the State Historic Preservation Officer and the Advisory Council on Historic Preservation. The Corps will implement the mitigation plans prior to any ground disturbing activities or reinundation being initiated. Collections from cultural resources investigations will be curated in repositories meeting the standards established by the Corps and the National Park Service.

Water control structures that will be removed or altered will be assessed to determine if they meet the criteria for eligibility to the National Register. Assessments will consider the age, integrity and design of the structures, and evaluate if they contribute to the history of the C&SF project. Based on a preliminary assessment, the proposed project is expected to have no adverse effect on standing structures, engineering structures or architectural features that are National Register eligible.

Construction of water storage areas, stormwater treatment areas and aquifer storage and recovery wells may affect significant archeological sites. The footprints of constructed portions of these features will be surveyed for archeological sites. If significant archeological sites are found to be affected by construction of these features, efforts will be made to modify the construction footprint to reduce or eliminate those effects. If effects can not be avoided, a mitigation plan will be developed and implemented, in consultation with the Florida State Historic Preservation Officer, to mitigate those effects.

Storage of water within the water storage areas and stormwater treatment areas will not in itself create an effect on archeological sites within the basins of the storage areas or stormwater treatment areas. Efforts will be made to identify archeological sites within the storage and stormwater treatment area basins for future historic resource management needs, but no mitigation will be necessary if water is stored on lands containing archeological sites.

Operational changes to water regulation schedules may also effect historic properties through erosion and changes in the hydrology of the sites. These effects will be considered during cultural resources investigations in support of operational changes.

The State Historic Preservation Officer, in a letter dated August 14, 1998, reaffirmed the archeological and historical potential of the C&SF project area. They also acknowledged our commitment to adhere to the procedures outlined in 36 CFR

Part 800, and concurred that, at this stage of project planning, the Restudy will have no adverse effect on historic properties listed or eligible for listing on the National Register.

K.2.16 Hazardous, Toxic, and Radioactive Wastes

Phase I Hazardous, Toxic and Radioactive Waste (HTRW) Site Assessments were conducted in all subregions in conformance with the scope and limitations of ASTM Practice E 1527 and Engineer Regulation ER-1165-2-132 The findings and conclusions provided below reflect existing HTRW conditions based on database searches, aerial photography, review of available records, site inspections and interviews. These findings and conclusions are of existing conditions at this time. The project conditions assume that any HTRW found during any phase of the project would be remediated in accordance with local, state and federal laws. Therefore, it can be assumed that conditions at future construction sites will be contamination free or of low levels, which would include de minimis conditions that generally do not present a material risk of harm to public health or the environment. This assessment of environmental effects is not intended to be site specific in that definitive sites for the placement of most project features have not been decided. In some instances, tasking involved assessment of a certain area, or areas which were identified as possible conceptual locations for a project feature, subject to change, pending future detailed planning.

The assessment covered all Restudy regions, within the general vicinity of proposed project features or existing features proposed for significant modification. Several site visits were conducted over the past few years, with the most recent survey having been performed during the week of 12 August 1998. The HTRW database search was performed on the entire area and it indicated that overall, the majority of the selected sites investigated are free of hazardous and toxic waste. Most of these general features are proposed for remote and rural areas, and were farms, vacant land, or wildlife management areas. The most common type of HTRW, hydrocarbons, was found along state highways in which the majority of the gasoline stations had leaking underground storage tanks.

Databases also revealed that several locations are National Priority Listed (NPL). Most of these NPL sites are due to past landfill operations. These sites are located in Palm Beach County, the Lower East Coast Lakebelt area in the vicinity of the S-9 Structures and in Broward County south of Alligator Alley. Contaminated sites located on the perimeter of any proposed water storage area may have migrating or expanding pollution plumes into the project area. Any such sites would require further survey and specific evaluation prior to detailed design for Restudy features. Another feature of concern is the numerous landfills and waste handling facilities existing in the Lower East Coast sub-region. To the extent feasible, water storage areas should not be sited immediately adjacent to these known sites.

There are, in addition to identified sites, numerous undocumented tanks and landfills that may be present in future project areas that were not included in the database. These HTRW locations may be due to undocumented dumping or other HTRW operations. Within the agricultural areas there are numerous temporary pump sites and fuel storage areas. These makeshift portable tanks are not reported, and therefore are not presented in the HTRW database. In addition, pesticide/chemical-mixing areas may also exist. Project implementation requires that any HTRW problems revealed during the real estate acquisition or actual project construction require full remediation.

The database and Phase-1 assessment results are maintained at the U.S. Army Corps of Engineers, Planning Division, as a series of maps and GIS overlays. It is not appropriate to include detailed information in this Programmatic report and EIS. However, the data will be available to planners for consultation during development of specific project features, and is expected to aid in avoiding sites with major remediation needs.

K.2.17 Unavoidable Adverse Environmental Effects

Land Use (Agriculture). A significant number of acres within a given hydrologic basin and cumulatively throughout the project area, and an even larger number of acres of agricultural lands will be permanently removed from production due to the construction of large above ground storage reservoirs, and stormwater treatment areas north of Lake Okeechobee, in the Caloosahatchee River and St. Lucie basins, and within the Everglades Agricultural Area. Further agricultural land use will be permanently removed from Palm Beach, Broward and Miami-Dade Counties due to the construction of the Water Preserve Areas.

Wetlands. A limited number of acres of wetlands will be permanently altered within the boundaries of the large above ground storage reservoirs and stormwater treatment areas, and within the Water Preserve Areas.

Water quality. Temporary increases in turbidity of local waters are expected from the removal of canals and levees and by the construction of raised roadways and other structures.

Air quality. Fugitive dust from vehicular traffic and earth moving will be unavoidable but insignificant.

Wildlife. Significant short-term disruption of wading bird colonies is expected from altering hydroperiods in the WCAs. Localized disturbances to fish and wildlife are expected from removal of canals and levees and from the elevation of roadways and construction of other structures.

Recreation. Increased depths in WCA-3B will increase airboat access, encouraging illegal camping on tree islands. Campers often use trees for firewood and occasionally allow campfires to get out of control. Alteration of the L-67 canal will reduce access to important and popular fishing areas.

Cultural Resources. An unknown number of historic and archeological sites may be affected. Studies will identify significant sites and necessary mitigation will be implemented.

K.2.18 Relationship Between Short Term Uses and Long Term Productivity

In the process of improving conditions regionally, short-term or localized problems will undoubtedly occur. For example, in the process of improving wading bird nesting and foraging areas regionally, current rookeries may be affected. The changed conditions may improve breeding habitat in the Andytown rookery, on one hand, but possibly damage the Rescue Strand rookery on the other. Although overall restoration of the Everglades watershed is expected to improve habitat for nesting wading birds regionally over time, the transition period could have significant effects on regional wading bird populations. Further study and close monitoring will be critical to maintaining viable wading bird populations in the Everglades as the system transforms.

K.2.19 Irreversible and Irretrievable Commitments of Resources

Construction of the proposed project will include many features considered permanent, or modifications to existing C&SF Project features that may be deemed irreversible. This would include, among others, such things as construction of a large reservoir, degradation of levees and filling in of canals. Funding, labor, equipment, and supplies necessary for these features, as well as building regional aquifer storage and recovery facilities, large storage reservoirs, stormwater treatment area, water preserve area's, and waste water reuse facilities, all necessary for the restoration of the natural ecosystem and maintenance of the urban and agricultural system, on the scale proposed in the Restudy, are probably of such a magnitude that this would represent an irreversible and irretrievable commitment of resources. These resources would include state and Federal funding to purchase lands and labor, energy and project materials to build, operate, and maintain the project.

Fish and wildlife habitat, located within the project footprint, particularly in the case of storage reservoirs, and stormwater treatment area facilities which would likely be inundated for much of the year, may be permanently altered and could represent a irreversible commitment of land and/or wetland resources.

K.2.20 Cumulative Effects

Important areas north of Lake Okeechobee, within the Everglades Agricultural Area, around the lake, in the Caloosahatchee River basin, and the upper east coast will be committed to providing storage for the overall gain and long-term benefit of the regional system. These project features, by providing important storage functions, are intrinsic to the overall restoration of the study area downstream and in the east-west estuaries. Project features may cause some adverse consequences locally, however the overall benefit to the regional system will be far greater than the localized adverse effects. As these features occur disparately across the landscape, within different hydrologic basins, and as distinct units rather than multiple features within a single watershed, they likely will not result in a detrimental cumulative effect.

Overall, the Restudy project elements in the Water Preserve Areas may cumulatively slow or stop expansion of lower east coast cities toward the west, and may make other residential or potentially residential lands more valuable. Restudy project components are not expected to result in a cumulative negative effect to the environment of the Lower East Coast. Project components in the area, especially storage, seepage control, and water reuse plants, will act to restore more natural freshwater flows to Biscayne Bay, and should result in other beneficial environmental effects. The Florida Keys are the subject of a separately funded, cooperative carrying capacity study. All identified indirect effects of the Initial Draft Plan recommended by the Restudy on the Keys would be positive (i.e., increased freshwater flows to Florida Bay).

K.3 KISSIMMEE RIVER REGION

This assessment will cover only those consequences realized within the Kissimmee River geographic planning region, which includes the Taylor Creek and Nubbin Slough drainage. The primary project features of the Initial Draft Plan in the Kissimmee River region are large scale above ground storage reservoirs in two locations north of Lake Okeechobee. These changes will provide a substantial net increase in regional storage capacity, which Lake Okeechobee has provided in the past. Features include: 1) an approximately 20,000 acre above ground storage reservoir, located north of the lake at a location to be determined, with a maximum design depth of 10 feet, inflow pump capacity of 4,800 cfs, and outflow structure sized at 4,800 cfs; 2) an approximately 5,000 acre above ground storage reservoir, 10 feet deep, with an inflow pump capacity of 2,500 cfs, and outflow structure sized at 1,000 cfs, linked to a 5,000 acre stormwater treatment area, at 4 foot depth, with inflow pump capacity of 1,000 cfs, and outflow structure sized at 1,000 cfs located in the Taylor Creek / Nubbin Slough drainage basin at a location to be determined. In aggregate, these features will provide 250,000 acre-feet of storage.

Taylor Creek and Nubbin Slough were identified as a priority location for these project features, as they are two of the largest sources of phosphorous loading to the Lake Okeechobee (SWIM Plan 1997). The reservoir and stormwater treatment area are designed for 10 feet and 4 feet maximum depth respectively. They will be operated with inflow and outflow pumps, and are expected to reduce phosphorous concentrations in the basin runoff from about 528 ppb to 107 ppb.

The report below will address potential effects (beneficial or harmful) of the Initial Draft Plan compared to the 2050 base, on several key physical, ecological and socio-economic resources of the Kissimmee River region.

K.3.1 Vegetation

The above ground storage reservoirs and stormwater treatment area located north of Lake Okeechobee and in the Taylor Creek / Nubbin Slough area will cover approximately 30,000 acres total. The existing plant cover is predominantly agricultural in nature, i.e., row crops, rangeland, upland forest, and barren lands. Isolated emergent wetlands are scattered throughout this area, representing approximately 5 percent of land cover. Converting 30,000 acres of lands into reservoirs and a stormwater treatment area could potentially impact approximately 1,500 acres of emergent freshwater wetlands. These wetlands and the adjoining uplands, i.e., agricultural lands, would be directly converted to an open water system. The 4-foot deep areas will function as emergent marsh and probably will become dominated by cattails. The deep reservoirs will become colonized by floating and rooted aquatic vegetation. During detailed planning of these components, every effort will be made to minimize impacts to wetlands or habitats determined to be critical to threatened or endangered species.

K.3.2 Fish and Wildlife

The wildlife now occupying the lands that would become water storage areas would be completely displaced to adjacent sites and face an increased risk of mortality. No adverse effects on endangered, threatened or state special concern species are anticipated. It is expected that unknown numbers of common wildlife species will be displaced into adjoining areas when wetlands or uplands are flooded to provide surface water storage. This will unavoidably cause some mortality. Affected species likely would include white-tailed deer, opossum, raccoon, native mice, rats and rabbits, as well as many species of songbirds. This fauna would be replaced by fish, reptiles (alligator, turtles) and water birds. Siting of water storage areas over altered or agricultural lands will minimize adverse impacts on native wildlife. However, even agricultural lands provide some minimal terrestrial wildlife habitat, habitat that will be irretrievably converted to marsh or open water habitat. Foraging habitat will be created for some fish-eating birds in the shallow (4' deep) storage areas, including osprey, snail kite, and kingfisher.

K.3.3 Threatened and Endangered Species

Of the eighteen listed plant and animal species submitted by the USFWS as likely to be affected by the C&SF Restudy, seven are thought to occur within the affected area of the Kissimmee River region. A brief description of effects to these state and federally listed threatened and endangered species follows.

K.3.3.1 Florida Scrub-jay

The Florida scrub-jay (*Aphelocoma coerulescens*) is known to inhabit well drained, sandy uplands, typical of a xeric oak scrub habitat. A "core population" of scrub-jays is also located within the Lake Wales Ridge sub-region, northwest of Lake Okeechobee. An essential feature of the Initial Draft Plan is the construction of a 20,000-acre above ground storage reservoir and a 5,000 acre storage reservoir and 5,000-acre stormwater treatment area. All are to be built at sites to be determined, north of Lake Okeechobee. Although no definitive site has been selected for these project features, preliminary sites identified are outside of the Lake Wales Ridge sub-region. No effect on the scrub-jay is anticipated at this conceptual level of planning, until definitive sites are identified and selected for the project features it is impossible to determine precise impacts to scrub-jays or scrub-jay habitat. The scrub-jay is listed by both the USFWS and GFC as a threatened species.

K.3.3.2 Eastern Indigo Snake

The eastern indigo snake (*Drymarchon corais couperi*) could potentially be affected by construction of storage reservoirs, the stormwater treatment areas and their associated facilities. No effect is anticipated at this conceptual level of planning. When definitive sites are identified and selected, it will be possible to determine precise impacts. The USFWS and the GFC classify the eastern indigo snake as a threatened species.

K.3.3.3 Snail Kite

The snail kite (*Rostrhamus sociabilis plumbeus*) is wide ranging raptor, listed as endangered by the USFWS and GFC. Within the study area, critical habitat includes the WCA's, portions of Everglades National Park and western portions of Lake Okeechobee. Lake Okeechobee and surrounding wetlands are major nesting and foraging habitats, particularly the large marsh in the southwestern portion of the lake. No adverse effect on the snail kite is anticipated due to construction of water storage facilities in this region. Under some conditions the water storage areas may provide suitable habitat for foraging snail kites. However, the USFWS is concerned that these areas would become "attractive nuisances" when temporarily favorable conditions are created, drawing in opportunistic wildlife species.

Temporary favorable conditions could induce species such as wood storks, snail kites, bald eagles and others to nest nearby; but nesting success would depend on continued favorable foraging conditions. Short term success could produce artificially inflated populations of some species. When reservoir operations then cause a rapid change in conditions, widespread nesting failures and direct mortality of adult individuals could result due to loss of foraging resources.

K.3.3.4 Bald Eagle

The bald eagle (*Haliaeetus leucocephalus*) should benefit by implementation of the Initial Draft Plan water storage components north of Lake Okeechobee due to the reduction of lake level fluctuations. Lake Okeechobee levels, with fewer occurrences of lake stages in the vicinity of 11-12 feet NGVD and below should benefit the bald eagle by providing for a more sustainable and reliable foraging ground within the shallow littoral areas. The regular occurrence of lake level recessions would concentrate prey fish over an extended period of time, which may further benefit the eagle. Both the USFWS and GFC currently list the bald eagle as a threatened species.

K.3.3.5 Wood Stork

The wood stork (*Mycteria americana*) is listed as an endangered species by the USFWS and the GFC. Wood storks forage in freshwater marshes, seasonally flooded roadside or agricultural ditches, narrow tidal creeks, shallow tidal pools, managed impoundments, and depressions in cypress heads and swamp sloughs. No adverse effect on the wood stork is anticipated due to construction of water storage facilities in this region. Under some conditions the water storage areas may provide suitable habitat for foraging wood storks. However, the USFWS is concerned that these areas would become “attractive nuisances” when temporarily favorable conditions are created, drawing in opportunistic wildlife species. Temporary favorable conditions could induce species such as wood storks, snail kites, bald eagles and others to nest nearby; but nesting success would depend on continued favorable foraging conditions. Short term success could produce artificially inflated populations of some species. When reservoir operations then cause a rapid change in conditions, widespread nesting failures and direct mortality of adult individuals could result due to loss of foraging resources.

K.3.3.6 Audubon’s Crested Caracara

The Florida population of this resident, non-migratory raptor is listed as threatened by the USFWS and GFC. The caracara (*Polyborus plancus*) commonly occurs in dry or wet prairie areas, as well as improved or semi-improved pasture. The region of greatest abundance is a five county area north and west of Lake Okeechobee, including Glades, DeSoto, Highlands, Okeechobee, and Osceola counties (Kissimmee River and Caloosahatchee River regions). Their numbers continue to decline throughout their range due largely to loss of habitat. Implementation of the Initial Draft Plan components in this region could impact this species through loss of habitat. No effect on the caracara is anticipated at this conceptual level of planning, until definitive sites are identified and selected for the project features it is impossible to determine precise impacts to caracara or caracara habitat.

K.3.3.7 Florida Grasshopper Sparrow

The Florida grasshopper sparrow (*Ammodramus savannarum floridanus*) was listed by the USFWS as endangered in 1986 because of habitat loss and degradation resulting from conversion of native vegetation to improved pasture (USFWS 1998). It is also listed as endangered by the GFC. No critical habitat has been designated for this sub-species. The Florida grasshopper sparrow is non-migratory, and is limited to the prairie region of south-central Florida. Within the study area, it is known to inhabit Glades, Highlands, Okeechobee, Osceola, and Polk Counties, in habitat consisting primarily of tree-less, relatively poorly drained grasslands that have a history of frequent fires. Implementation of the Initial Draft Plan components in this region could impact this species through loss of habitat. No effect on the Florida grasshopper sparrow is anticipated at this conceptual level of planning, until definitive sites are identified and selected for the project features it is impossible to determine precise impacts to Florida grasshopper sparrow or Florida grasshopper sparrow habitat.

K.3.4 Water Management

Under the Initial Draft Plan all flood control releases to the St. Lucie and Caloosahatchee River estuaries are expected to be eliminated except pulse releases in zone A of the regulation schedule. Water managers will use a climate based in-flow forecasting model, in conjunction with operational rules, which will help them in deciding when to pump water to the storage facilities outside the lake. Use of climate based in-flow forecasting, reservoir storage north of Lake Okeechobee, lakeside aquifer storage and recovery's, and other project features located in the C-43 and C-44 basins, is expected to reduce the occurrence of peak lake stage events and harmful flood control discharges to the estuaries. When the model shows that Lake Okeechobee water may rise above desirable levels for the littoral zone (14.35 feet to 14.75 feet,), water will be pumped to the storage facilities in the Everglades Agricultural Area, and north of the lake. In the dry season, flows will be allowed back to the lake, when the lake is predicted to fall back to within 0.75 feet of the supply side management line within the same dry season or below 11.75 feet NGVD in the upcoming wet season. During the wet season, flow is allowed from the storage facilities to Lake Okeechobee when the model projects less than 1.5 million acre-feet of inflow during the next 6 months and the lake water level is either below 11.75 feet or projected to be in supply side management during the upcoming dry season. Most of the water previously stored in the lake, at prolonged and even extreme lake stages and/or sent to tide via the estuaries, under the Initial Draft Plan, is pumped to storage north of Lake Okeechobee (127,000 acre-feet on a mean annual basis) or other storage facilities in the Everglades Agricultural Area, Caloosahatchee River (C-43) Basin or the St. Lucie (C-44) Basin.

K.3.5 Water Quality

Water quality conditions in the Kissimmee River region are expected to improve compared to both the 1995 and 2050 base conditions through implementation of the Initial Draft Plan. The Initial Draft Plan calls for two water storage/treatment components in the Kissimmee River region: one 20,000 acre, 10 foot deep storage reservoir (200,000 acre-feet of storage) and one, 5,000 acre, 10 foot deep storage area connected to a shallow stormwater treatment area. The larger, deeper storage reservoir would be at an unspecified site north of Lake Okeechobee, and the two smaller areas would be sited in the Taylor Creek and Nubbin Slough drainage.

Construction and operation of water storage areas north of Lake Okeechobee would result in an aggregate 30,000 acres and 250,000 acre-feet of off-Lake Okeechobee storage in the subregion. The north of Lake Okeechobee components would be operated to receive backpumped water from Lake Okeechobee, or receive high drainage flows from Kissimmee and Taylor/Nubbin Slough sub-basins and retain them for later release downstream, depending on lake stage and predicted weather conditions. Under the first scenario, the water storage areas would serve to prevent overly high stages in Lake Okeechobee. Under the second scenario the storage areas would retain a portion of flood flows and reduce pollutant loading from the Kissimmee and Taylor/Nubbin sub-basins to Lake Okeechobee. From a water quality enhancement perspective, the second operation scenario would be preferred over the first, since the second operating scenario would maximize reduction in pollutant loading from the Kissimmee River to Lake Okeechobee. Total phosphorus (TP) loading data provided in the Lake Okeechobee SWIM Plan (SFWMD, 1997) indicates that average TP concentrations in the lower Kissimmee River, i.e., Pools S-65D and S-65E, during 1990-94, were 0.77mg/l and 0.36 mg/l respectively.

These average TP concentrations in the lower Kissimmee River are some of the highest TP average concentrations in the entire Kissimmee River drainage basin. The associated average TP loading from Pools S-65 D&E, during 1990-94, were 29.1 and 43.0 tons/year, respectively. These TP loading rates were some of the highest in the entire Kissimmee River basin with the exception of the TP loading to Lake Okeechobee coming from the Taylor Creek/Nubbin Slough area (91.4 tons/year).

The South Florida Water Management District 1997 Lake Okeechobee SWIM Plan identifies four critical upstream drainage basins where TP loading to Lake Okeechobee must be significantly reduced to enable long-term recovery and restoration of Lake Okeechobee water quality conditions and ecological health.

Those four critical basins which produce high TP loads to the downstream Lake Okeechobee are: the S-65 D basin, the S-65-E basin, the TCNS basin and the S-154 basin. Water quality degradation in the lower Kissimmee River region south of Lake Kissimmee is mainly attributable to agricultural non-point pollution consisting primarily of elevated nutrients and bacteriological contamination and increased turbidity and sedimentation in watercourses of the region.

Construction of one or more water storage areas in the Kissimmee River region consistent with north of Lake Okeechobee storage would result in removal of particulate and dissolved nutrients and other pollutants in the water storage area through sedimentation and biological uptake processes. Maximizing the retention time of surface runoff waters captured in the water storage area would increase the pollutant reduction benefits provided by the water storage area.

In addition to phosphorus loading, other key water quality parameters of concern in the Kissimmee River region are dissolved oxygen (DO) and nitrogen compounds (NOx). Construction of water storage areas north of Lake Okeechobee would result in reduction of NOx loading to the surface water bodies in the basin as well as to Lake Okeechobee.

In terms of maximizing future water quality benefits provided by water storage area construction and operation in the lower Kissimmee River area, it is likely that water quality benefits could be increased by siting multiple water storage areas totaling 20,000 acres at strategic locations, optimized for reducing nutrient loading to downstream surface water bodies, as opposed to the construction of one large contiguous 20,000 acre water storage area in the basin. Existing and ongoing water quality monitoring in the Kissimmee river region being conducted by the South Florida Water Management District could be used to optimally site several water storage areas totaling 20,000 acres while realizing the primary hydrologic water storage purpose of the Kissimmee River basin water storage areas.

Construction and operation of the recommended plan features in the Taylor Creek/Nubbin Slough area includes a combined 5,000 acre water storage area coupled with a 5,000 acre stormwater treatment area. This component will result in substantial reduction of nutrient loads entering the Taylor Creek/Nubbin Slough watercourses and Lake Okeechobee. The purpose of this component is to provide flood protection, water quality treatment, water supply benefits and enhancement of the St. Lucie and Caloosahatchee River estuaries. This water storage area combination is sized to capture and treat stormwater runoff from the Taylor Creek /

Nubbin Slough basin, the highest nutrient loading basin flowing to the eutrophic Lake Okeechobee. The design of the combination water storage area/stormwater treatment area is intended to reduce TP concentrations in TCNS runoff to Lake Okeechobee by 80 percent from 0.528 mg/l down to 0.107 mg/l. This reduction in nutrient loading to Lake Okeechobee would contribute toward the Lake Okeechobee SWIM Plan target for reducing TP loading to Lake Okeechobee and ultimately restoring its ecological health.

Another water quality related Initial Draft Plan component that will improve water quality conditions in tributary basins flowing to Lake Okeechobee is the Other Project Element (OPE) entitled "Water Treatment Facilities for Pollutant Load Reduction: Lake Okeechobee". This project is a logical extension of the WRDA '96 Critical Project entitled Lake Okeechobee Water Retention/Phosphorus Removal" that is not associated with the Initial Draft Plan. The OPE Lake Okeechobee watershed water quality treatment facilities project would entail re-isolation of previously drained wetlands (ditch plugging) in the four previously identified critical phosphorus loading basins north of Lake Okeechobee, (S-65 D&E, S-154 and TCNS) as well as construction of stormwater treatment areas at key locations within the four drainage basins. The main purpose of this OPE would be nutrient load reduction within the basins and to Lake Okeechobee downstream.

K.3.6 Water Supply

Utilization of the revised Lake Okeechobee operation schedule, coupled with the climate based in-flow forecasting model, and in conjunction with the reservoir storage features described above, will allow greater retention and storage of regional water, greater flexibility in operations, and more opportunities to store water during wet periods for use in dry periods. This new regional water supply system, proposed under the Initial Draft Plan, will markedly enhance water supply to all water users in the Lake Okeechobee Service Area (LOSA), and the Everglades Agricultural Area, as well as the Service Areas of the lower east coast, above and beyond that provided by the 2050 base.

K.3.7 Land Use

The C&SF Comprehensive Restudy recommends land use changes within the Kissimmee River region, north of Lake Okeechobee, by construction and operation of water storage areas and a stormwater treatment area. Existing land uses include agriculture, ranching, and forestry. The below discussion of impacts to agriculture will include all existing land uses except urban.

The two proposed above ground storage reservoirs and stormwater treatment area would have a combined surface area of 30,000 acres. The proposed action would convert the existing land uses into open water (water storage areas) or emergent marsh (stormwater treatment area).

K.3.7.1 Agriculture

A 20,000 acre storage reservoir is proposed in the Initial Draft Plan for this region to help shorten the duration and frequency of high water levels in Lake Okeechobee, as well as reduce discharges from the lake to downstream estuaries. An additional 5,000 acres of storage and 5,000 acres for stormwater treatment area is planned in the Taylor Creek/Nubbin Slough area for flood protection, estuary protection, water quality treatment, and water supply benefits. It is likely that these reservoirs will be located in an area currently being used for agricultural production and designated as unique farmland. Conversion of 30,000 acres from agriculture to storage reservoirs would represent a 1.5 percent reduction in total farm acreage in this four county area.

K.3.8 Recreation Resources

The proposed components (water storage areas and stormwater treatment areas recommended under the Initial Draft Plan in the Kissimmee River region are not anticipated to impact any existing recreational facilities. Due to their large size every effort will be made during the detail design phase of the project to minimize any future impacts. The reservoirs and stormwater treatment area may provide future recreational opportunities compatible with their primary restoration purpose.

K.3.9 Aesthetic Resources

The main visual components of the Initial Draft Plan features in the Kissimmee River region are the low levees of the reservoirs and stormwater treatment area, water control structures, and pump stations. These features are not unlike existing features in the region. The stormwater treatment area would appear from a distance as areas similar to agricultural fields or marsh. The project components do not include any tall structures that would interrupt the existing landscape profile.

K.3.10 Unavoidable Adverse Environmental Effects

The following unavoidable adverse effects are expected to occur with implementation of the project features described above, which are expected to have an affect on the Kissimmee River physiographic region.

Construction of above ground storage reservoirs, and stormwater treatment areas, will take large tracts of agricultural lands out of production, and possibly remove the functional values of lesser amounts of wetlands, prairie, forested lands, or other natural areas. There will be a change in the dominant plant cover (from emergent or crop to floating aquatic) and dominant animal groups (common terrestrial wildlife to aquatic birds, reptiles, amphibians, fish and invertebrates).

K.3.11 Relationship Between Short Term Uses and Long Term Productivity

Construction of the reservoir storage and stormwater treatment area facilities represents a significant short-term disruption to the environment, and possible unintentional direct and indirect environmental consequences. Short-term effects due to construction activities (clearing, grubbing, levee building, installation of structures, equipment noise, etc.) may be visually unpleasant and annoying to adjacent landowners. However, the storage areas will be sited in rural zones. Grading and restoration will improve the visual quality of the landscape when construction is finished, and adverse effects will be minimized wherever possible.

Once completed, vegetation would be expected to recolonize the levee slopes and crest and the reservoirs. In addition, these modifications to the water management system will have a beneficial long-term and permanent effect on the Lake Okeechobee and ultimately downstream throughout the Everglades Protection Area

K.3.12 Irreversible and Irretrievable Commitments of Resources

The proposed construction of reservoir storage sites and stormwater treatment area, represents, in all likelihood, an irreversible and irretrievable commitment of land and monetary resources. These resources would include, in addition to the lands themselves, state and Federal funding, labor, energy and project materials and equipment to build the storage sites and the structures associated with the operation of these storage sites. Fish and wildlife habitat, located within the proposed component footprint, particularly in the case of storage reservoirs and stormwater treatment areas, which would likely be inundated for much of the year, may be permanently altered and could represent a irreversible commitment of land and/or wetland resources.

K.3.13 Cumulative Effects

Restudy project components are not expected to result in a cumulative negative effect on the environment of the Kissimmee River region. Project components in the Kissimmee River region, especially reservoir storage and stormwater treatment area water quality treatment, will act cumulatively to restore more natural freshwater flows to Lake Okeechobee. The restoration of Lake Okeechobee will lead to the restoration of the estuaries and eventually downstream to the Everglades. To achieve restoration will require substantially more storage in the headwaters of the system in order to provide for the correct quantity, quality, timing, and duration of flows. The land spatially occupying these headwater areas once provided these important functions to the regional system. Today, they are largely developed, drained, and ditched. The restoration of these important natural functions will require some reversal of the current trend in order to provide the retention area for holding, storing and treating water prior to being discharged downstream. The proposed project features, along with a restored Lake Okeechobee, able to provide important storage functions, is intrinsic to the overall restoration of the study area downstream. The commitment of tens of thousands of acres of land represents a huge investment in funding and land resources. It may also cause some adverse consequences locally, however the overall benefit to the regional system will be far greater than the localized adverse effects. The localized adverse effects will not result in a detrimental cumulative effect within the region.

K.4 LAKE OKEECHOBEE

This assessment will cover only those consequences realized within Lake Okeechobee proper and those communities immediately surrounding Lake Okeechobee. Effects incurred downstream in the WCA's, estuaries or within the Everglades Agricultural Area, as a result of flood control discharges or water supply issues, will be addressed in sections of the report dealing with those physiographic regions. The primary project features of the Initial Draft Plan affecting the hydrology and ecological sustainability of Lake Okeechobee are the introduction of large scale above ground storage reservoirs and a belt of aquifer storage and recovery wells. These changes will provide a substantial net increase in regional storage capacity, which the lake heretofore has provided. Features include: 1) an approximate 20,000 acre above ground storage reservoir, located north of the lake at a location to be determined, with a maximum design depth of 10 feet, inflow pump capacity of 4800 cfs, and outflow structure sized at 4800 cfs; 2) an approximate 60,000 acre above ground storage reservoir (comprised of 3 separate 20,000 acre cells), located within the Everglades Agricultural Area, at a location to be determined (conceptually between the Miami and North New River canals), and with a maximum design depth of 6 feet for all 3 cells. This reservoir would be operated by inflow and outflow pumps and structures of various capacity.

Another feature that will affect Lake Okeechobee is the construction of a 5,000 acre above ground storage reservoir and 5,000 acre stormwater treatment area to control and treat runoff from the Taylor Creek and Nubbin Slough area north of Lake Okeechobee. Taylor Creek and Nubbin Slough were identified as a priority location for these project features as they remain two of the largest sources of phosphorous loading to Lake Okeechobee (SWIM Plan 1997). The reservoir and stormwater treatment area are designed for 10 feet and 4 feet maximum depths respectively, will be operated with inflow and outflow pumps, and are expected to reduce phosphorous concentrations in the basin runoff from about 528 ppb to 107 ppb.

Lake Okeechobee aquifer storage and recovery is being proposed under the Initial Draft Plan, to provide additional storage while reducing ET loss, and to reduce the amount of land removed from current land use compared to an above ground reservoir. Two hundred 5-MGD (million gallons per day) aquifer storage and recovery wells and associated infrastructure are proposed outside Lake Okeechobee, near the Herbert Hoover Dike, at a location(s) to be determined. Water from Lake Okeechobee to be injected into the aquifer storage and recovery wells will need to meet coliform standards as specified by the U.S. Environmental Protection Agency, before injection. Efficiency of aquifer storage and recovery is estimated for planning purposes to be about 70 percent, although there is considerable uncertainty associated with this estimate, and recovery rates may vary depending on area geology and other factors. More detailed information on design and operation of reservoirs, stormwater treatment areas, and Lake Okeechobee aquifer storage and recovery is included in Section 9.

The report below will address potential effects (beneficial or harmful) of the Initial Draft Plan compared to the 2050 base, on several key physical, ecological and socio-economic resources of the Lake Okeechobee ecosystem. Ecological evaluations will consider first, a suite of priority performance measures as discussed in Havens et al. (1998). They include: 1) frequency of extreme low lake stage events <11 feet NGVD; 2) frequency of prolonged low lake stage events <12 feet NGVD for >12 continuous months; 3) frequency of extreme high lake stage events >17 feet NGVD; 4) frequency of prolonged high lake stage events >15 feet NGVD for >12 continuous months; and 5) number of years in which spring lake level recessions occur (defined as a lake level decline from near 15 feet to 12 feet NGVD without reversals greater than 0.5 feet from January to May). These performance measures were developed through scientific research and interagency consensus over a period of several years. Other hydrologic performance measures and model output from the SFWMM posted on the Restudy web site at http://www.sfwmd.gov/org/pld/restudy/hpm/index.html was considered as well. This information was used primarily to supplement conclusions based on the priority performance measures, or to evaluate non-ecological resources such as socio-economics, water supply etc.

K.4.1 Vegetation

Modeling results indicate that hydrologic conditions within Lake Okeechobee under the Initial Draft Plan are substantially improved relative to both 1995 base conditions and the 2050 base. The changes in hydroperiod observed under the Initial Draft Plan, are considered by experts to be more conducive to a healthy littoral plant community (Havens et al. 1998). Under the Initial Draft Plan, occurrence of extreme low lake stage events (<11 feet) are reduced relative to both base conditions, which should enhance conditions within the littoral zone and marsh for natural vegetation assemblages, and reduce the spread of exotics, and suppress less desirable cattail. Richardson and Harris (1995) showed that melaleuca and cattail, both problematic species, were increasing in abundance in the marsh. Panicum (torpedograss) is also commonly thought to be expanding within the marsh (Hanlon, pers. comm.). Richardson et al. (1995) found that vegetation distribution in Lake Okeechobee is largely controlled by hydroperiod. For example, the hydroperiods of melaleuca and torpedo grass are 78 and 81 percent, respectively, while the hydroperiod of spike rush (the native plant that dominates Moonshine Bay) is 96 percent. Richardson et al. concluded "higher elevation areas of the marsh which now have melaleuca and torpedo grass on them may expand if hydroperiods are shortened." Lockhart (1995) showed that Melaleuca seedlings could not germinate effectively under water, and D. Thayer (pers. comm.) observed a dramatic increase in the areal extent of Melaleuca seedlings in the marsh following the 1989 drought, when lake stage fell below 11 feet NGVD and over 95 percent of the marsh was exposed.

The performance of the Initial Draft Plan, with fewer extreme and prolonged (<12 feet >1 year) low lake stage events, should indirectly inhibit the expansion of these exotic and less desirable species relative to conditions under the 2050 base. These effects, which may require a few to several years to fully manifest themselves, will lead to more sustainable populations of native vegetation, and heterogeneous communities, as they affect the ability of exotic plant seeds and cattail to germinate, or spread through the extension of rhizomes. Evaluations done by the Alternative Evaluation Team (Havens et.al. 1998) showed the 2050 base experienced 13 events in which lake levels fell below 11 feet over the 31 year simulation period, while the 1995 base showed nine events, and the Initial Draft Plan, three events. This represents a marked improvement by the Initial Draft Plan over the 2050 base, and should lead to hydrologic conditions considered by experts to be more favorable for supporting native plant communities than conditions under the 1995 and 2050 base (Havens et al. 1998).

Occurrence of extreme high lake stages (>17 feet) and prolonged high lake stages (>15 feet >1 year) are about the same under the Initial Draft Plan as in the 2050 base. Both the Initial Draft Plan and the 2050 base represent a moderate improvement over the existing 1995 base in reducing prolonged high lake stage events. Prolonged high stages can cause wind and wave damage to near shore plant communities, and facilitate the resuspension and transport of phosphorous laden waters into the lake water column, which facilitate algae blooms. Conditions under both the 2050 base and the Initial Draft Plan may help to protect and reinvigorate willow trees, whose loss has been documented to be connected to higher lake levels (Aumen, 1995; Richardson and Harris, 1995). Prolonged moderately high lake levels (> 15 ft NGVD) also can be harmful because they bring about changes in the extent of nutrient transport within the lake, as well as losses of benthic plants due to light limitation. A Lake Okeechobee hydrodynamic model indicated that at high lake levels, P-rich pelagic water is mixed into the littoral zone (Sheng and Lee 1991), where it may impact the pristine, nutrient-poor littoral communities. If such events persist over a long period of time, there may be eutrophication trends in the littoral zone similar to those observed in the Everglades Water Conservation Areas

(Koch and Reddy 1992, McCormick et al. 1996), and in recent experimental studies in Lake Okeechobee (Havens et al. 1997). It is possible that the dense growth of cattails at the pelagic / littoral interface in Lake Okeechobee is attributable to advection of nutrient-rich water from the pelagic zone. During periods of extreme high lake levels (>17 ft NGVD), wind and erosion cause emergent and submerged plants to be torn loose from their substrates, resulting in a loss of important fish and wildlife habitat. When lake levels exceeded 17 ft NGVD in 1995, large sections of bulrush (*Scirpus californicus* and *S. validus*) were lost. These plants, which occur at the interface between the pelagic and littoral zone, where they are exposed to wave action, are a prime habitat for largemouth bass and black crappie, two of the most important recreational fishes in the lake (Furse and Fox 1996).

Conditions under the Initial Draft Plan also show the greatest number of spring lake level recessions (January to May lake level declines from near 15 feet to 12 feet, without any reversals greater than 0.5 feet), which may prove favorable in reinvigorating willow habitat and in reducing cattail thatch through a more natural fire periodicity (Smith et al. 1995).

K.4.2 Fish and Wildlife

There has not been research to explicitly link water level variations in Lake Okeechobee with fisheries status. However, a general understanding of how fisheries respond to changes in habitat structure and resource availability leads to a consensus among experts that Lake Okeechobee's fishery may be harmed by extreme high and low lake stage events (Havens et al. 1998). When lake stage declines below 11 ft NGVD for instance, the stage considered to be extreme, 95 percent of the littoral zone is exposed land without standing water. In that condition, it no longer can function as a habitat for fish or wildlife that depend on local fish populations as a food resource. Spike rush and bulrush are almost completely dry at this lake level, and can no longer support the fish and bird communities that depend on them for foraging and nesting (Havens et al. 1998). Fish stocks may improve, under conditions brought about by the Initial Draft Plan, in terms of reproductive success and overall production, both directly, through the initiation of more natural hydrologic conditions. Particularly a marked reduction in the occurrence of extreme and prolonged low lake stage events, and indirectly through the promotion of native submergent vegetation, which provides quality fish habitat. Given the critical importance of the littoral zone to the reproductive success of native fish species. Maintaining minimum water level conditions necessary for optimum reproduction, as well as improving the overall nesting and foraging habitat for fishes within the littoral zone, conditions under the Initial Draft Plan should lead to an improvement in the fishery resource over conditions predicted under the 2050 base.

Both the Initial Draft Plan, and the 2050 base, show a slight improvement over existing conditions in reducing prolonged high lake stages which has been shown to limit light penetration to bottom dwelling benthic plants, algae and invertebrates (Havens et al. 1998). These resources provide habitat and food for fry and fingerling populations in the first weeks of their existence. Actually, extreme and prolonged high lake stage events occur infrequently under the 2050 base, due to the high demands put on Lake Okeechobee in future, so the Initial Draft Plan and the 2050 base represent a substantial improvement over the 1995 base. Although there is a perception among many resource users that high lake stages negatively affect the fishery, there is little hard data to substantiate this. A key benefit of the Initial Draft Plan is to protect the existing fishery resource from the harm that may be caused by 2050 demands on Lake Okeechobee (K. Havens pers. comm.). During a Corps study on Lake Okeechobee (1998), coincident with high lake stages (16 to 18 feet NGVD), reptiles and amphibians were not captured at several littoral sites where previously they had been sampled in high numbers. There are several possible explanations for this: 1) high water levels caused animals to seek out more favorable habitat; 2) traps may have failed in deep water; and 3) seasonal effects such as cold water effects on animal movement. With additional data collected over another hydro-cycle, relationships between lake stage and animal densities may become clearer.

Spring lake level recessions appear to be an important dynamic in providing optimal foraging conditions for wading birds during critical nesting periods. Smith et. al. (1995) observed that most wading birds were attracted to the lake during periods of protracted surface water recession, when the lake stage was below about 15.4 feet NGVD (4.7 m). This may mean that Lake Okeechobee functions as a regional habitat of "last resort" when all the other aquatic habitats are dry (K. Havens, pers. comm.). Smith et al. (1995) also noted that birds enjoyed particularly good nesting success in years when a regular and pronounced spring recession occurred. Under the Initial Draft Plan, performance measure results, as modeled by the SFWMM, indicate a distinct improvement in the occurrence of these events (once in three years) over the 2050 base, or the 1995 base (once in five years for 2050 and 1995). Lake Okeechobee stages under the Initial Draft Plan are also more representative of the historical target than are the 2050 base. Assuming that spring lake level recessions were a part of a more historical condition, then this result, would tend to support the implication that the Initial Draft Plan will produce more conditions indicative of a springtime water level recession and support and sustain a more productive foraging habitat for wading birds.

It is less clear what, if any, benefits may be accrued under the Initial Draft Plan in terms of macroinvertebrate abundance, species composition, and/or diversity. Warren et. al. (1995) documented a shift towards macroinvertebrate dominance in the sub-littoral sediments by species known to be tolerant of organically enriched sediments and highly eutrophic waters. Oligochaeta (segmented worms), larval Chironimidae (true midges), and Nematodes (roundworms) dominated samples where caddisfly (Trichoptera) and mayfly

(Ephemeroptera) had once been abundant. Conditions under the Initial Draft Plan are not likely to affect the hyper-eutrophic status of the sub-littoral sediments, or reverse, in a meaningful way, the current species composition. Benthic invertebrate fauna, within the littoral zone, dominated by fairly intolerant species (Warren et. al. 1995), and high quality as fish prey, will likely be maintained and protected as a critical element in the food chain due to the improved conditions under the Initial Draft Plan.

Apple snail populations, which are the primary food source of the endangered snail kite, may improve due to less prolonged low and extreme low lake stage events. Any improvement in their food source, coupled with optimum water depths, a healthy spike rush community, and suitable perches for surveying prey, may lead to locally improved foraging conditions for the snail kite as well.

It is uncertain what, if any, benefits or effects may be felt by resident mammal populations. Water levels in rim canals are not expected to recede to the point of affecting the habitat for manatees, river otters, bobcat or other mammals that feed or hunt along the canals or within the marsh. These populations may, in fact, benefit indirectly, over the long term, by improved habitat conditions under the Initial Draft Plan, relative to the 2050 base. Creating conditions less favorable for dense monotypic stands of melaleuca, cattail and torpedograss, and more favorable for a heterogeneous habitat with a multitude of niche space for both predator and prey. Conditions for alligators, who use the interior marsh canals, airboat trails, and rim canal may improve slightly under the Initial Draft Plan relative to the 2050 base, given a reduction in prolonged low and extreme low lake stage events, which could impede their mobility, reduce availability of quality nesting areas, and reduce spatial habitat. The alligator may further benefit from a more abundant food base made available by improved conditions for spawning fish, and other animals linked to improved conditions for primary and secondary productivity through predator/prey relationships.

K.4.3 Threatened and Endangered Species

Of the eighteen listed plant and animal species submitted by the USFWS as likely to be affected by the C&SF Restudy, seven are thought to occur within the affected area of Lake Okeechobee. A brief description of effects to these state and federally listed threatened and endangered species follows.

K.4.3.1 American Alligator

The american alligator (*Alligator mississippiensis*), although not identified as a species likely to be affected by Restudy alternatives by USFWS, is a keystone species, and an important component in the ecology of Lake Okeechobee. The american alligator is currently listed as threatened by the USFWS, due to its similarity to the american crocodile (*Crocodylus acutus*). It is currently listed as a species of special concern by the GFC. Hydrologic conditions for the american alligator may improve slightly from an improved hydroperiod for Lake Okeechobee due to the Initial Draft Plan. A reduction in the frequency of occurrence of prolonged low and extreme low lake stage events, and associated enhancements to the fishery resource and overall quality of habitat for wildlife in the littoral zone of Lake Okeechobee, may prove moderately beneficial to the alligator population. The alligator may also benefit by expanding its range into newly created habitat, made available by thousands of new acres of wetlands (reservoirs) proposed under the Initial Draft Plan.

K.4.3.2 Eastern Indigo Snake

The eastern indigo snake (*Drymarchon corais couperi*) would not likely be affected, as lake stages will not be sufficiently altered in depth or duration such that they would impact adjacent uplands where Indigo snakes are known to exist. The USFWS and the GFC classify the eastern indigo snake as a threatened species.

K.4.3.3 Bald Eagle

Lake Okeechobee levels, with fewer occurrences of lake stages in the vicinity of 11-12 feet NGVD and below should benefit the bald eagle (*Haliaeetus leucocephalus*) by providing for a more sustainable and reliable foraging ground within the shallow littoral areas. The regular occurrence of lake level recessions, would concentrate prey fish over an extended period of time, which may further benefit the eagle. Both the USFWS and GFC currently list the bald eagle as a threatened species.

K.4.3.4 Wood Stork

Impacts to the wood stork (*Mycteria americana*) would be moderately beneficial due primarily to the greater frequency of occurrence of spring Lake Okeechobee level recessions under the Initial Draft Plan. The wood stork is a long-legged wading bird which fishes with tactile probing of its beak and attains greatest success when water levels are receding, which concentrates prey species (Smith et al. 1995). More dynamic Lake Okeechobee level fluctuations, with minimal occurrence of extremely low lake levels, which may be harmful to stork prey species such as fish, may result in greater foraging habitat, and nesting success around Lake Okeechobee. Both the USFWS and GFC currently list wood storks as an endangered species.

K.4.3.5 Snail Kite

The hydrologic conditions expected to occur long term as a result of the Initial Draft Plan may be moderately beneficial for the snail kite (*Rosthrhamus sociabilis* *plumbeus*) on a local, and possibly regional scale. Water levels, with fewer dry downs, are expected to benefit the apple snail, long term. The apple snail is the primary food source of the snail kite. Water levels must be sufficiently stable to prevent loss of the apple snail through drying out of the surface. Dr. Robert Bennetts (pers. comm.) expressed the opinion that impacts to snail kites due to the Restudy would be moderated due to the kites' relatively high mobility, and critically important habitat, outside of the sphere of Restudy influence, within the Kissimmee River and St. Johns River watersheds. The Initial Draft Plan, which nearly succeeds in preventing the occurrence of lake stage events <11 feet NGVD, will be able to provide habitat within the Moonshine Bay area to kites from other areas when those areas are dry. The 2050 and 1995 bases will be able to provide this habitat of last resort much less frequently, as these dry out events occur much more frequently (four out of ten years for 2050 base and three out of ten years for 1995 base). Both the USFWS and GFC currently list the snail kite as an endangered species.

K.4.3.6 Audubon's Crested Caracara

The Florida population of this resident, non-migratory raptor is listed as threatened by the USFWS and GFC. The caracara (*Polyborus plancus*) commonly occurs in dry or wet prairie areas, as well as improved or semi-improved pasture. The region of greatest abundance is a five county area north and west of Lake Okeechobee, including Glades, DeSoto, Highlands, Okeechobee, and Osceola counties (Kissimmee River and Caloosahatchee River regions). Their numbers continue to decline throughout their range due largely to loss of habitat. Implementation of the Initial Draft Plan components in this region could impact this species through loss of habitat. No effect on the caracara is anticipated at this conceptual level of planning, until definitive sites are identified and selected for the project features it is impossible to determine precise impacts to caracara or caracara habitat.

K.4.3.7 West Indian Manatee

No appreciable impact would be expected to occur to the West Indian manatee (*Trichechus manatus*) as a result of the Initial Draft Plan. No effects on water levels within boat canals, the rim canal, at structures or navigation locks would expose this animal to boat traffic or result in a die-off of food supplies. Both the USFWS and GFC currently list the West Indian manatee as an endangered species.

K.4.3.8 Okeechobee Gourd

Okeechobee gourd (*Curbita okeechobeensis okeechobeensis*) sites currently known to exist in the Lake Okeechobee region are limited to the shores of Lake Okeechobee inside of the Herbert Hoover Dike. Given its limited range and habitat requirements, any alteration in the hydrology where this plant currently exists could potentially damage the population. Since lake levels under the Initial Draft Plan will not result in a greater occurrence of prolonged high or extreme high lake stage events compared to the 2050 base conditions, the gourd is not flooded and, therefore, it is reasonable to conclude that no appreciable effects are anticipated to the Okeechobee Gourd. Both the USFWS and the Florida Department of Agriculture and Consumer Services currently list the Okeechobee gourd as an endangered species.

K.4.4 Water Management

Under the Initial Draft Plan, Lake Okeechobee will retain all of its authorized project purposes, including the ability to provide flood control, water supply to the urban areas, agriculture, and the natural system, navigation, protection of estuarine resources, and recreation. Changes to the existing lake operation schedule (Run 25-3) include operational changes only, except for the project features designed to enhance water storage outside of the lake. This includes the storage reservoirs north of Lake Okeechobee, the storage and stormwater treatment area facilities in Taylor Creek and Nubbin Slough, the storage facilities in the Everglades Agricultural Area, and the aquifer storage and recovery facilities outside of the Herbert Hoover Dike. All flood control releases to the St. Lucie and Caloosahatchee River estuaries are expected to be eliminated except pulse releases in zone A of the regulation schedule. These water retention facilities are expected to provide an overall net environmental benefit to the lake by increasing storage capacity, and reducing both the duration and frequency of high lake stage events, which are documented to be stressful to the littoral zone. Furthermore, these water storage facilities will reduce the frequency and duration of flood control releases to the estuaries from about a mean annual 206,000 acre-feet to the Caloosahatchee River under 2050 base conditions to 15,000 acre-feet under the Initial Draft Plan and from a mean annual 88,000 acre-feet (2050 base) to 13,000 acre-feet (the Initial Draft Plan) in the St. Lucie estuary. Most of the water previously stored in the lake, at prolonged and even extreme lake stages and/or sent to tide via the estuaries, under the Initial Draft Plan, is pumped to storage north of Lake Okeechobee (127,000 acre-feet on a mean annual basis), to the Everglades Agricultural Area storage facilities (mean annual 278,000 acre-feet), sent to aquifer storage and recovery injection wells outside Lake Okeechobee (mean annual 264,000 acre-feet), or discharged to the WCA's (mean annual 102,000 acre-feet).

Water managers will use a climate based in-flow forecasting model, in conjunction with operational rules, which will help them in deciding when to pump water to the storage facilities outside the lake. Use of this system, along with other project features in the C-43 and C-44 basins, is expected to reduce the occurrence of peak lake stage events and harmful flood control discharges to the estuaries. When the model shows that lake water levels may rise above desirable levels for the littoral zone (14.35 feet to 14.75 feet), water will be pumped to the storage facilities in the Everglades Agricultural Area, and north of the lake (***Figure 4.4-1***). In the dry season, flows will be allowed back to the lake, when the lake is predicted to fall back to within 0.75 feet of the supply side management line within the same dry season or below 11.75 feet NGVD in the upcoming wet season. During the wet season, flow is allowed from the storage facilities to Lake Okeechobee when the model projects less than 1.5 million acre-feet of inflow during the next 6 months and Lake Okeechobee water level is either below 11.75 feet or projected to be in supply side management during the upcoming dry season.

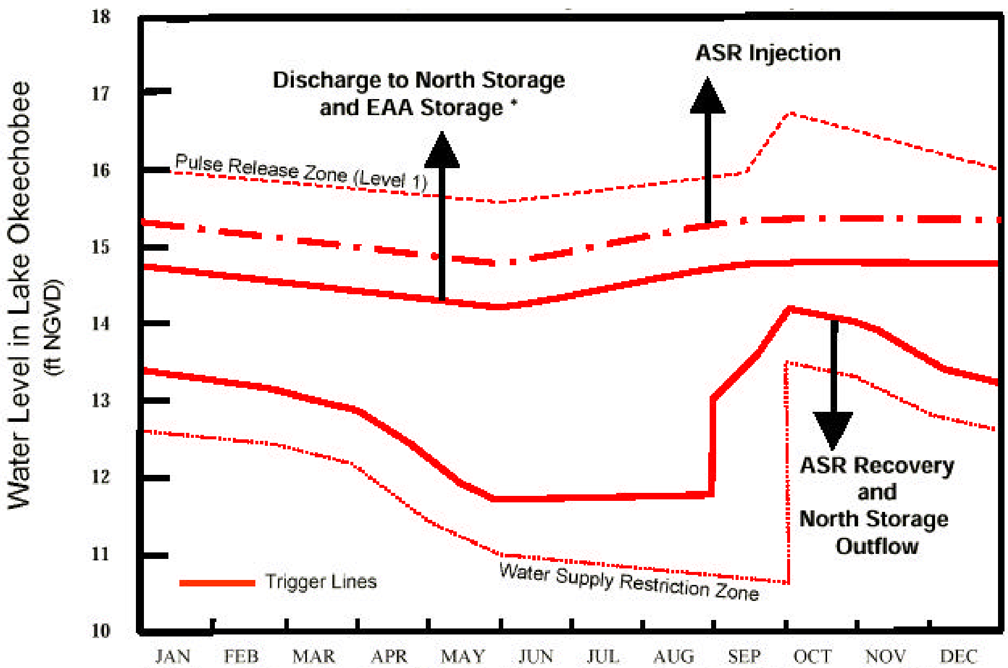
Water from Lake Okeechobee will be pumped into aquifer storage and recovery wells when the climate-based inflow forecast projects that Lake Okeechobee water level will rise significantly above those levels that are desirable for the Lake Okeechobee littoral zone (14.5 - 15.0 feet NGVD; Figure 4.4-1). During the dry season, flow may be moved back to Lake Okeechobee from the aquifer storage and recovery wells either when Lake Okeechobee water level is projected to fall to within three-quarters of a foot of the supply side management line during the same dry season, or below 11.75 feet NGVD during the upcoming wet season. During the wet season, flow is allowed from the aquifer storage and recovery wells to Lake Okeechobee when climate-based inflow forecast projects less than 1.5 million acre-feet of inflow during the next 6 months, and Lake Okeechobee water level is either below 11.75 feet NGVD during the current wet season, or is projected to be in supply side management during the upcoming dry season.

Water management will rely on existing structures, which will not require structural modification. In order to meet capacity requirements for water conveyance to aquifer storage and recovery facilities, stormwater treatment area and storage reservoirs, additional canals, resizing existing canals, pumps and conveyance structures will be constructed outside of the immediate Lake Okeechobee area. Potential effects associated with construction and operation of these project features are discussed under their respective physiographic sections.

K.4.5 Water Quality

Water quality conditions in Lake Okeechobee are expected to be slightly improved relative to the 1995 base and the 2050 base conditions as a result of implementation of several components of the Initial Draft Plan. Water quality improvements in water inflows to Lake Okeechobee will be more marked then in-lake water quality improvements. The discussed Initial Draft Plan related water quality improvements in watersheds north of Lake Okeechobee will result in reduction of agricultural non-point source pollutants (nutrients, bacteriological contamination, turbidity/sedimentation) entering Lake Okeechobee relative to the 1995 and 2050 base conditions.

Figure 4.4-1: Trigger Lines for Storage Reservoirs and Aquifer Storage and Recovery Water Management.



* Discharge to North and EAA Storage if Lake Okeechobee stage is forecasted to be above "Discharge to …Storage" line, or if stage is above Pulse Release Zone (level 1) line.

The key water quality parameters of concern in Lake Okeechobee waters are TP, NOX, chlorophyll a and turbidity. Currently, water quality can be characterized as eutrophic, with in-lake TP concentrations averaging 90-100 ppb TP. Pollutant loading, primarily nutrients, over the past several decades has significantly degraded Lake Okeechobee water quality and resulted in massive loading of nutrients to Lake Okeechobee sediments. Average TP concentrations have increased from 40 to 100 ppb TP since the early 1970s. Resuspension of nutrient laden lake sediments during strong wind events dominate pollutant loading in the lake (Reddy et al., 1995).

Initial Draft Plan components in the Lake Okeechobee area are expected to result in incremental improvement for in-lake water quality conditions. The Lake Okeechobee aquifer storage and recovery project component would result in the construction and operation of 200 aquifer storage and recovery wells located on Lake Okeechobee's peripheral levee (Herbert Hoover Dike) with each aquifer storage and recovery pump having a maximum capacity of 5 million gallons per day (MGD), for a total Lake Okeechobee aquifer storage and recovery, maximum capacity of 1 billion gallons per day. The multiple purposes of Lake Okeechobee aquifer storage and recovery include: providing additional regional water storage while reducing evapotranspiration losses and minimizing the acreage of regional above ground storage reservoirs; improving the Lake Okeechobee's water supply capacity for downstream environmental/urban/ agricultural users; and, reducing harmful regulatory discharges to the St. Lucie and Caloosahatchee estuaries and maintaining existing flood protection.

Although implementation of aquifer storage and recovery facilities on the scale is unprecedented, preliminary data (Pyne, personal communication) indicates that nutrient levels in aquifer storage and recovery waters stored and recovered from the upper Floridan aquifer may be significantly decreased from concentrations in well injectate. If future pilot project associated with this component prove this nutrient reduction feature of aquifer storage and recovery to be present in large scale aquifer storage and recovery projects, then some water quality benefits may be realized in Lake Okeechobee waters (at least localized) as a result of large scale aquifer storage and recovery implementation. The aquifer storage and recovery will be designed and operated to meet the requirements of regulating agencies (U.S. Environmental Protection Agency and Florida Department of Environmental Protection) that all recovered aquifer storage and recovery waters will be treated to meet the Class I Water Quality Standards applicable to Lake Okeechobee waters.

The Initial Draft Plan calls for the construction and operation of a 5,000 acre stormwater treatment area in the vicinity of structure S-77, where the Caloosahatchee River flows from Lake Okeechobee. The stormwater treatment area would be coupled with a backpumping facility to backpump excess Caloosahatchee basin water to Lake Okeechobee. Backpumping would only occur when Lake Okeechobee water levels and storage capacity was appropriate. Based on the design of the 5,000 acre stormwater treatment area and the performance of the Everglades Nutrient Removal (ENR) Project, it is anticipated that backpumped water from the stormwater treatment area to the lake would be below 50 ppb TP. Since average TP concentrations in Lake Okeechobee are 100 ppb TP, it is anticipated that the backpumped waters would reduce in-lake nutrient conditions.

Although implementation of Lake Okeechobee watershed Initial Draft Plan components along with the Lake Okeechobee Aquifer Storage and Recovery system, and the Caloosahatchee Backpumping with stormwater treatment area facilities are anticipated to reduce nutrient and pollutant loading to Lake Okeechobee, the Restudy Water Quality Team's analysis of the overall effect of the Initial Draft Plan on Lake Okeechobee waters concluded that only minor improvements would result to Lake Okeechobee water quality. This conclusion was based on several analyses, including extensive water quality modeling of the 1995 and 2050 base conditions and all evaluated Restudy alternatives using the Lake Okeechobee Water Quality Model (LOWQM) (James et al., 1997). The LOWQM analysis concluded that when comparing the Initial Draft Plan to the 1995 and 2050 base conditions using six Lake Okeechobee water quality performance indicators: TP Inload; TP Outload;

Median Lake Okeechobee TP; Median Lake Okeechobee chlorophyll; Maximum Lake Okeechobee TP and Maximum Lake Okeechobee chlorophyll A, that the Initial Draft Plan would result in slightly better cumulative water quality conditions then either the 1995 or the 2050 base conditions. However, the slight water quality benefits of Initial Draft Plan components, the Lake Okeechobee Aquifer Storage and Recovery system, and the Caloosahatchee Backpumping with stormwater treatment area facilities, on in-lake water quality conditions are overwhelmed by the effects of lake resuspension of nutrient rich sediments as well as by nutrient enriched inflows from the watersheds flowing into Lake Okeechobee.

Supporting this general conclusion is recent work (Havens and James, 1998) indicating that due to the dominant effect of Lake Okeechobee sediment resuspension with the associated release of nutrients into the lake water column, even if all nutrient inflows to the lake were eliminated, it would be several decades before lake-wide TP concentrations and other associated lake water column parameters would show significant improvement.

K.4.6 Water Supply

Lake Okeechobee will continue to function as a multipurpose regional reservoir. The prolonged staging of relatively high lake levels as is the case under the 1995 base, will largely be replaced, under the Initial Draft Plan, with more hydrologically dynamic lake stage fluctuations, including fewer prolonged low and extreme low lake level events and greater spring recession events as was believed to be the case historically. Utilization of the revised lake operation schedule, coupled with the climate based in-flow forecasting model, and in conjunction with the other project features described above, will allow greater retention and storage of regional water, greater flexibility in operations, and more opportunities to store water during wet periods for use in dry periods. This new regional water supply system, proposed under the Initial Draft Plan, will markedly enhance water supply to all water users in the Lake Okeechobee Service Area (LOSA), and the Everglades Agricultural Area, as well as the Service Areas of the lower east coast, above and beyond that provided by the 2050 base.

While water supply targets are largely met in these areas, and a distinct improvement is demonstrated by modeling results over the 2050 base, there is a marked improvement to the lake and the littoral zone as well. As discussed above, the lake receives adequate amounts of water to prevent prolonged low, and extreme low lake stage events under the Initial Draft Plan, relative to both the 1995 and 2050 base. For example, model results predict that the Lake Okeechobee stage will fall below 12 feet NGVD 30 percent of the time (during the 31 year simulation period) under the 2050 base, and 18 percent of the time under the existing conditions (1995 base). This is harmful to the lake littoral zone as over 90 percent of the littoral zone is dry under these conditions, removing spawning habitat, available wildlife habitat, and encouraging the spread of exotic plants such as melaleuca and possibly torpedograss. Under the Initial Draft Plan, lake stages fall below 12 feet NGVD only 9 percent of the time, and below 12 feet for a year or more only once in 30 years.

The Initial Draft Plan and the 2050 base both predict similar positive results for reducing the frequency of prolonged high and extreme high lake stage events which can be harmful to Lake Okeechobee, particularly in allowing the transport of nutrient rich limnetic waters into the relatively pristine littoral zone. Both the Initial Draft Plan and 2050 base model results forecast a one in ten year return frequency of extreme high lake stage events (>17 feet), which is an improvement over the one in five year return frequency predicted by the 1995 base. The Initial Draft Plan performs slightly better than the 2050 base in reducing the frequency of prolonged high lake stage events (>15 feet >1 year), which occur about 18 percent of the time over the simulation period, 7 percent less than the 2050 base, and 14 percent less than the 1995 base. It is reasonable to conclude that implementation of a new regional water supply system within and around the Lake Okeechobee basin, including the use of additional water storage reservoirs, stormwater treatment area, and lake aquifer storage and recovery, will result in noticeable hydrologic changes, and indirectly, in long-term ecological benefits to Lake Okeechobee beyond those demonstrated by both the 2050 and 1995 base conditions.

K.4.7 Socio-Economics

The following discussion will address affects on commercial navigation, agriculture production, urban areas around Lake Okeechobee, recreation and sport fishing, and commercial fishing. These are the principal socio-economic activities on and around Lake Okeechobee that may be affected by the project.

K.4.7.1 Commercial Navigation

According to a U.S. Army Corps of Engineers socio-economics report (1998), the Lake Okeechobee Waterway has an authorized project depth of eight feet based upon a lake stage of 12.56 feet NGVD. Lake Okeechobee levels above (or below) 12.56 feet NGVD will result in a corresponding increase (or decrease) in channel depths. Daily stage hydrographs for Lake Okeechobee indicate that lake stages, under the Initial Draft Plan, are usually higher than the 2050 base and with fewer extreme low lake stages, at or below the 12 foot and 11 foot thresholds, relative to the 2050 base, where one may begin to observe moderate effects to commercial navigation. In this sense then, the Initial Draft Plan is an improvement over the 2050 base, in reducing the occurrence of reduced waterway stages which could prevent ship passage, delay passage or induce reductions in average loads.

Stage duration curves for Lake Okeechobee support the premise that lake stages under the Initial Draft Plan are actually higher than under the 2050 base nearly 75 percent of the time, and higher than existing lake stage conditions about half the time. Moreover, when model results predict that lake stages, under the Initial Draft Plan, will be lower than the 2050 base, it occurs at high lake stages, generally at 14.75 feet NGVD and above, which would not affect commercial navigation. It is therefore reasonable to conclude that the Initial Draft Plan will not result in any negative effects to commercial navigation, and may result in intermittent benefits to navigation through a dampened frequency of extremely low lake stages where effects to navigation may be realized.

K.4.7.2 Agriculture Production

The agriculture community immediately surrounding Lake Okeechobee is a critical industry to the local and regional economy. Agriculture is dependent on Lake Okeechobee for irrigation water, particularly during dry periods and during drought. Farmers also back pump excess waters to Lake Okeechobee in order to maintain canals at adequate levels for flood protection and to provide drainage for their fields. Under the Restudy Initial Draft Plan, the new regional water supply system proposed under the Initial Draft Plan demonstrates a much improved ability to meet the agricultural community's needs in terms of water supply. Under the 2050 base case, model results predict 16 years, over the 31-year simulation, in which the LOSA will experience water restrictions of some magnitude. Usually this is defined as being under supply side management with cutbacks of at least 10 percent for a minimum of 7 days. The Initial Draft Plan improves this scenario substantially to just 5 years, over the 31-year simulation period, with the above described water restrictions. This is just 2 years over the target.

The use of 200 5-MGD aquifer storage and recovery facilities outside Lake Okeechobee is expected to provide a substantial amount of additional storage for lake water for use by the regional system. These facilities present several possible benefits in that they can store considerable amounts of water without taking large contiguous areas of valuable and expensive land out of production. Storage of water in a deep aquifer is not subject to evapotranspiration losses, although only a percentage of the stored water may be recoverable (estimated to be approximately 70 percent). Depending on the ultimate location and design of the proposed aquifer storage and recovery field, an unknown quantity of land would need to be purchased and committed to the building, operation and maintenance of these facilities. This is expected to permanently remove some land from agricultural production. However the benefits accrued by agriculture in terms of meeting future and increasing water supply needs, with a minimum of agricultural lands being directly effected, probably far outweigh the costs of permanently losing these lands from cultivation or other agricultural purposes.

Agriculture will also benefit from the enhanced flexibility in being able to draw supplemental irrigation water from the Everglades Agricultural Area storage facilities. No water supply shortage effects on agriculture are expected. The ability of the proposed regional water supply system to meet the water supply demand of agriculture, now and in the future, is nearly assured under the Initial Draft Plan, assuming all project features prove to be technically feasible and permittable by state and Federal agencies. The agricultural community perceives the conversion of existing water supply from Lake Okeechobee, to a combination of Lake Okeechobee, aquifer storage and recovery, and above ground storage reservoirs, as uncertain. It is reasonable to conclude, however, that no detrimental short or long term effect will be incurred by the agriculture community as a result of the inability of the project to function as a water supply and flood control facility.

K.4.7.3 Urban

The residential and commercial water users of the urban areas around Lake Okeechobee depend on lake water for wellfield recharge, drinking water, and industrial processes. As was discussed above, the Initial Draft Plan model results predict that Lake Okeechobee will far exceed the 2050 base (with its increased population and associated demand), in meeting water supply demands around Lake Okeechobee and among the service areas. This includes demands of the urbanized and municipal areas for drinking water, commercial, private and industrial uses. Flood protection is also maintained around Lake Okeechobee under the Initial Draft Plan. Flood protection criteria, described as the number of days, over the entire simulation period, the lake stage exceeds 16.5 feet during the August 1 to September 15 time period, is improved under the Initial Draft Plan (19 days), compared to the 2050 base (32 days) or the 1995 base (47 days). Also, the structural integrity of the Herbert Hoover Dike should not be compromised under the lake stages proposed in the Initial Draft Plan (as assessed from Lake Okeechobee stage duration curves). The residence time of high Lake Okeechobee levels (about 15 feet NGVD and above) predicted under the Initial Draft Plan, will actually be less as a percent of time equaled or exceeded at a given lake stage, than the 2050 and 1995 base conditions. The urban landscape surrounding Lake Okeechobee should therefore not be appreciably affected by either reduced water supply or a reduced level of flood protection as a result of the Initial Draft Plan.

K.4.7.4 Recreation and Sport Fishing

Recreation and sport fishing may indirectly benefit as a result of implementation of the Initial Draft Plan. Under the 2050 base, increased development pressure, and an increasing demand on the water supply, would have affected Lake Okeechobee by increasing the frequency of prolonged low and extreme low lake stage events. This alone would effect the recreation potential of Lake Okeechobee in the short term by reducing access to many areas of Lake Okeechobee, which are normally available by boat, air boat, canoe etc. In the long term, extreme low lake levels, and related ecological stress imposed on Lake Okeechobee by 2050 base demands, may have reduced available fish spawning habitat, spatially available wildlife habitat, as well as habitat quality due to encroachment by exotic plant species.

As discussed above, the Initial Draft Plan, substantially reduces the frequency of both prolonged low, and extreme low lake stages that cause the kinds of ecological stress described above. Furthermore, the Initial Draft Plan predicts a greater frequency of occurrence, relative to the 2050 base, of spring lake level recessions which have been documented to be productive for wading birds, and the overall quality, health and vigor of the native vegetation communities in the littoral zone. Thus, the ecosystem upon which much of the recreation and sport fishing is dependent, should be substantially restored under the Initial Draft Plan, as well as maintaining lake level conditions conducive to user access by recreation enthusiasts.

K.4.7.5 Commercial Fishing

No negative effects on the commercial fishing industry are expected as a result of the Initial Draft Plan. Lake Okeechobee levels predicted under the Initial Draft Plan, as described above, will not impede navigation of fishing boats, trawls, use of seines, or placement of traps. It is probable that the commercial fishing industry on the whole, and over the long term, are expected to benefit through a healthier, more sustainable commercial fishery as a result of improved fish spawning and reproductive success, greater available littoral habitat for forage production, and possibly enhanced food resources for commercial species.

K.4.8 Land Use

Up to three-quarters of the land area immediately around Lake Okeechobee, is used for agricultural production. In the immediate vicinity of Lake Okeechobee, agricultural lands are not expected to be negatively effected by implementation of the lake regulation schedule implemented under the Initial Draft Plan. Development and operation of 200 5-MGD aquifer storage and recovery facilities will remove some amount of land from future agricultural production purposes. No precise acreage figure is known at this time, as a location, or locations for the project, design features and specifications are not addressed under this conceptual comprehensive plan. Some agricultural production may be compatible with aquifer storage and recovery wells, as the structural components of the aquifer storage and recovery wells are expected to take up minimal lands above ground. Additional facilities required such as holding reservoirs, inflow-outflow conduits, and associated plumbing infrastructure etc. are not known at this time. Specific impacts relative to aquifer storage and recovery and its effects on agricultural land use will be addressed in future; tiered National Environmental Policy Act documents will be prepared specifically for this project feature. Above ground storage reservoirs to be located north of Lake Okeechobee and in the Everglades Agricultural Area, and their effects on agricultural land use, will be discussed in their respective physiographic regions (Kissimmee River and Everglades Agricultural Area regions).

K.4.8.1 Agricultural Land Use

There is no agricultural production in Lake Okeechobee. However, Lake Okeechobee has traditionally been the water supply source for surrounding agricultural areas including the Everglades Agricultural Area, Caloosahatchee Basin, St. Lucie Basin, and Big Cypress Reservation. Changes in the distribution of Lake Okeechobee water to supply the storage reservoirs and aquifer storage and recovery facilities will reduce the volume of lake water delivered directly to agricultural areas for supplemental irrigation by approximately 50 percent. Although the total supplemental irrigation supply for the agricultural areas will be increased through deliveries from storage reservoirs and aquifer storage and recovery facilities, this represents a major shift in water supply source.

Improvements to the ecology of Lake Okeechobee are achieved in the Initial Draft Plan by preventing extremely low lake levels. Storage reservoirs and aquifer storage and recovery wells proposed for locations near the lake provide the capacity to store excess water when it is available. These facilities then provide a water source to be pumped into Lake Okeechobee when the lake stage falls below a minimum level. Specific locations for the storage reservoirs and aquifer storage and recovery wells have not been determined, but they will most likely be placed on land now used for agricultural production. The storage reservoirs designed to supply Lake Okeechobee will occupy 30,000 acres in the Kissimmee River region and 60,000 acres in the Everglades Agricultural Area. The proposed aquifer storage and recovery facilities include 200 wells located near the Lake Okeechobee levee. These wells will require some land for construction, operation, and maintenance. It appears likely that more than 90,000 acres of land in the regions surrounding Lake Okeechobee will be taken out of agricultural production to improve conditions in Lake Okeechobee. In addition, the majority of this acreage will likely come from lands designated as unique farmland based upon their location, growing season, high value crops, and other factors (UFIFAS, 1982).

K.4.8.2 Urban Land

Implementation of the Initial Draft Plan should have no negative affect on the existing or future urban land use around Lake Okeechobee. As noted earlier, water supply to the LOSA is substantially improved over and above the 2050 base with its associated increased urban population, and user demand. Flood protection for the urban areas is also maintained into the future. It is reasonable to conclude, that urban lands surrounding Lake Okeechobee, including their future use, will benefit as a result of the Initial Draft Plan through a greater, more consistent source of water for urban and industrial use, including continued flood protection, beyond that projected in the 2050 base.

K.4.9 Recreation Resources

Lake Okeechobee hydroperiods under the Initial Draft Plan will modify the existing lake levels towards a more natural water level cycle as depicted by the daily stage hydrographs for Lake Okeechobee. The more natural and seasonal fluctuations, generally forecasted, should improve conditions for the lake's recreational fishing resources. The proposed construction of 200, 5-MGD aquifer storage and recovery wells and associated infrastructure will be located adjacent to the outside levee toe. The proposal will not affect recreation resources within the Lake Okeechobee region. Construction impacts would most likely be temporary and are not anticipated to adversely affect recreation resources in the region.

K.4.10 Aesthetic Resources

General forecasts of increasing public water supply demands under the 2050 base result in lower lake levels for longer duration throughout the year (K. Havens, 1998). These developments could expose more of the lake shoreline and result in the growth of successional or exotic species, nearshore erosion, and exposed mud and nearshore banks. Accessible, nearshore aesthetic resources could be negatively affected while panoramic aesthetics would remain largely unaffected. Water levels predicted under the Initial Draft Plan would maintain more natural lake levels most of the time, decrease prolonged low and extreme low lake stage events, and maintain the existing visual appeal of Lake Okeechobee.

The proposed construction of 200, 5-MGD aquifer storage and recovery wells and associated infrastructure located on the peripheral levee could affect aesthetic resources locally, depending on well and infrastructure siting. Local residents and visitors to the area could experience some temporary adverse aesthetic impacts during construction of aquifer storage and recovery wells. Long term, the aquifer storage and recovery facilities may pose a moderate detrimental effect on the overall aesthetics of the surrounding remnant natural areas behind the levee.

K.4.11 Unavoidable Adverse Environmental Effects

The following unavoidable adverse effects are expected to occur with implementation of the project features described above, which are expected to have an effect on the Lake Okeechobee physiographic region.

Land Use - The construction, operation and maintenance of 200 5-MGD Lake Okeechobee aquifer storage and recovery facilities will likely remove significant acreage of existing land from agriculture production, and possibly convert remnant wetlands around the outside of the Herbert Hoover Dike. While the exact extent, and nature of this land use impact is unknown, and some level of agricultural production may be compatible with aquifer storage and recovery facilities, some lands are expected to be permanently removed from their existing land use in order to accommodate these facilities. Likewise, with the construction of above ground storage reservoirs, and stormwater treatment areas, these facilities will take large tracts of agricultural lands out of production, and possibly remove the functional values of lesser amounts of wetlands, prairie, forested lands, or other natural areas.

K.4.12 Relationship Between Short Term Uses and Long Term Productivity

There is no project construction planned to take place within Lake Okeechobee proper, atop the Herbert Hoover Dike, or at any of the associated water control structures along the Herbert Hoover Dike. Construction of all 200 5-MGD aquifer storage and recovery well facilities may require several years to complete. This construction would involve a comparatively short-term use of resources within the project area, which has, as yet, not been sited. Several unavoidable effects such as disruption and dislocation of agricultural lands, wildlife habitat, wetlands and other resources are likely. Such adverse effects associated with these storage facilities will be minimized wherever possible, and aquifer storage and recovery facilities will be located and sited so as to cause the least adverse effect to the natural and social environment. Placement of the aquifer storage and recovery facilities near to the back toe of the Herbert Hoover Dike should minimize effects to agricultural lands as well as socio-economic impacts to urban areas and infrastructure. Above ground reservoirs will remove large areas of land from their current land use. Factors such as location of urban areas, regional and local infrastructure, wetlands, critical habitat for threatened and endangered species, and other unique or pristine natural areas will be avoided to the maximum extent possible. In the longer term, restoration of the dynamic water storage capacity of the region, without adversely affecting Lake Okeechobee's natural characteristics, are expected to enable the regional water supply system to restore and sustain the ecological values of Lake Okeechobee, and estuaries, including valuable commercial and sport fisheries, and wetlands resources critical to native fish and wildlife.

K.4.13 Irreversible and Irretrievable Commitment of Resources

Construction of the Lake Okeechobee aquifer storage and recovery facilities, and above ground storage reservoirs, necessary for the restoration of Lake Okeechobee and downstream estuaries, is such an expensive undertaking that full implementation of these project features would represent an irreversible and irretrievable commitment of resources. These resources would include state and Federal funding to purchase lands and labor, energy and project materials to build, operate, and maintain the project. Fish and wildlife habitat, located within the project footprint, particularly in the case of storage reservoirs, which would likely be inundated for much of the year, may be permanently altered and could represent a irreversible commitment of land and/or wetland resources.

K.4.14 Cumulative Effects

The restoration of Lake Okeechobee, the estuaries, the Everglades and the developed lands downstream, require substantially more storage in the headwaters of the system in order to provide for the correct quantity, quality, timing, and duration of flows. The land spatially occupying these headwater areas once provided these important functions to the regional system. Today, they are largely developed, drained, and ditched. The restoration of these important natural functions will require some reversal of the current trend in order to provide the retention area for holding, storing and treating water prior to being discharged downstream. Important areas north of Lake Okeechobee, within the Everglades Agricultural Area, within and around Lake Okeechobee will be committed to providing this lost storage for the overall gain and long-term benefit of the regional system. These project features, along with a restored Lake Okeechobee, able to provide important storage functions, is intrinsic to the overall restoration of the study area downstream. The commitment of tens of thousands of acres of land represents a huge investment in funding and land resources. It may also cause some adverse consequences locally, however the overall benefit to the regional system will be far greater than the localized adverse effects. As these features occur disparately across the landscape, within different hydrologic basins, and as distinct units rather than multiple features within a single watershed, they likely will not result in a detrimental cumulative effect.

K.5 UPPER EAST COAST AND INDIAN RIVER LAGOON

The Initial Draft Plan would add six surface water storage areas to the Upper East Coast subregion. Individual areas would range from 8,000-12,000 acres in size. These storage areas are conceptually planned for siting in the western parts of St. Lucie and Martin Counties, over mostly agricultural lands. The storage areas would capture local runoff from C-25, North Fork (St. Lucie River), C-24, C-23, C-44 and South Fork (St. Lucie River) catchment basins. The C-44 storage basin would capture local runoff and store it in a reservoir of about 10,000 acres, at 4 feet maximum depth. It would be operated to reduce flood flow to the estuary from this basin and provide fresh water during the dry season. The C25, North Fork, C-24, and C-23 storage areas would be located in each sub-basin. Storage requirements were 39,000 acres (total) at 8 foot depth. Water storage areas should improve water quality by inducing sedimentation and deposition of phosphorus out of the water column. The South Fork storage area would be about 10,000 acres at 4 foot depth. The exact location of these features is not known; however, they would be most beneficial if sited in the western part of Martin and St. Lucie counties (one in each drainage).

K.5.1 Vegetation

Nearly 50,000 acres of agricultural lands, with included wetlands and upland, would be converted to water storage areas under the Initial Draft Plan. Small amounts of upland forest (pine flatwoods) and wetlands might be included in the total acreage. These lands will be permanently removed from agricultural production, and are expected to develop emergent or floating vegetation, depending on depth. The 4 foot deep areas will function as emergent marsh and probably become dominated by cattails. The deep (8') reservoirs will become colonized by floating and rooted aquatic vegetation. Many of these sites are located near marginal wetlands that could be enhanced through active management or passively through seepage from the storage facility. The storage sites will remove sediments and some nutrients, particularly phosphorus. The shallower areas are expected to provide additional wildlife habitat and recreational values, as do the created marshes and water management areas in the headwaters of the adjoining St. John's River drainage (Indian River and Brevard Counties).

The Initial Draft Plan is expected to benefit the St. Lucie estuary and the southern Indian River Lagoon. It will nearly eliminate excessive and prolonged freshwater releases to the estuary that now occur after regionally heavy rainfall. It will increase desirable fresh water deliveries during the dry season. Reduction of sediment-laden, freshwater runoff will decrease the turbidity of estuarine water during the rainy season. In contrast, increased freshwater deliveries during the dry season will reduce the wide annual swings in water salinity that are believed responsible for sea grass die-offs. Clearer water and more stable salinity is expected to foster re-colonization of the bottom by benthic plants, especially shoal grass. In the southern Indian River lagoon (IRL), submerged aquatic vegetation (SAV) is also expected to benefit. The St. Lucie estuary is the most important source of fresh water into the IRL. Less frequent and extreme salinity fluctuations and a potential decrease in flocculent material should cause an increase in the cover and health of SAV in the area.

K.5.2 Fish and Wildlife

The wildlife now occupying the lands that would become water storage areas would be completely displaced to adjacent sites. No adverse effects on endangered, threatened or state special concern species are anticipated. It is expected that unknown numbers of common wildlife species will be displaced into adjoining areas when wetlands or uplands are flooded to provide surface water storage. This will unavoidably cause some mortality. Affected species likely would include white-tailed deer, opossum, raccoon, native mice, rats and rabbits, as well as many species of songbirds. This fauna would be replaced by fish, reptiles (alligator, turtles) and water birds. Siting of inland water storage areas over altered or agricultural lands will minimize adverse impacts on native wildlife. However, even agricultural lands provide some minimal wildlife habitat, which will be irretrievably converted to marsh or open water habitat. Foraging habitat will be created for some fish-eating birds in the shallow (4' deep) storage areas, including osprey, snail kite, and kingfisher.

If, as expected, the Initial Draft Plan restores estuarine conditions and permits the return of oysters and seagrass, substantial fish and wildlife benefits will occur. Both oysters and seagrass have a number of invertebrate and fish species associated with them that are either absent from the estuary or present in very low numbers. Once the habitats are restored fish and invertebrates that depend on these substrates should recolonize the area quickly. Past high discharge events have caused fish kills, fish lesions, invertebrate kills, and probably impacted spawning of a number of species. By reducing freshwater flow events outside the natural salinity envelope, the Initial Draft Plan should reduce stress on fish and wildlife of the estuary. A number of species utilize the area as a spawning, nursery, or juvenile area. Restoring the St. Lucie to estuarine conditions should re-create favorable spawning and nursery grounds for a number of important commercial and recreational species, including snook, red drum, spotted seatrout, tarpon, mangrove snapper and mullet.

As the health of the St. Lucie estuary increases as a result of plan implementation, a number of endangered species may benefit. Restored seagrasses will provide additional forage area for the manatee. Improved fisheries will be particularly beneficial to the wood stork and bald eagle.

K.5.3 Threatened and Endangered Species

Of the eighteen listed plant and animal species submitted by letter from the USFWS as likely to be affected by the C&SF Restudy, five are thought to occur within the affected area of the Upper East Coast and Indian River Lagoon. A brief description of affects to these Federally listed threatened and endangered species follows.

K.5.3.1 West Indian Manatee

Manatees, an endangered species, are known to frequent the Indian River Lagoon and migrate up major tributaries such as the St. Lucie canal. Within the Indian River Lagoon, they are highly dependent on seagrass beds for foraging. Implementations of the Initial Draft Plan will likely benefit seagrasses through improved overall water quality conditions, improved timing of deliveries and fewer high volume discharges, as is the case under the existing conditions. Under the 2050 base regulatory discharges from Lake Okeechobee and the Upper East Coast basin carry high loads of sediment and nutrients, producing turbid conditions within the lagoon, colors the water column, limiting light penetration to benthic biota, physically smothers some benthic organisms and seagrasses, and renders the estuarine waters fresh. Model results show that the frequency of regulatory discharges is drastically reduced under the Initial Draft Plan, and no discharges are made from Lake Okeechobee. Benefits to seagrass, coupled with the above hydrologic and biological improvements to water deliveries to the Indian River Lagoon and throughout the St. Lucie estuary is expected to benefit manatees.

K.5.3.2 Sea Turtles

Although not identified by the USFWS as likely to be affected by the Restudy, sea turtles, including the green turtle (*Chelonia mydas*) and the loggerhead turtle (*Caretta caretta*) may also be present along the Atlantic coast and near the mouth of the Indian River Lagoon. The green turtle is listed as endangered and the loggerhead as threatened by the USFWS. Both species are known to nest along Florida beaches, with highest nesting densities for green turtles occurring at Melbourne Beach, Hutchinson Island, and Jupiter Island, and for loggerheads between Brevard and Broward Counties (Moler 1992). It is doubtful that the Initial Draft Plan will have any real affect on foraging or nesting sea turtles which rarely frequent the inner lagoon waters and no effect on sea turtles or their habitat is anticipated.

K.5.3.3 Florida Scrub-jay

The Florida scrub jay is known to inhabit coastal upland areas with well-drained soils within the Upper East Coast. Their range extends inland from the coast to include about on quarter of the two county area. This area consists of the Atlantic Coast sub-region, an area of particular importance to scrub jays due to the presence of major sand deposits, which is an important habitat requirement. Since final siting of storage reservoirs has not yet been decided for the 10,000 acres of proposed storage under the Initial Draft Plan there is no definitive means of assessing impacts to this species at this time. It is anticipated however, that most of the reservoirs sites will be on agricultural lands, already developed for citrus groves and other crops which in all likelihood would have removed the necessary scrub jay habitat from these areas. No negative impact to this species is anticipated at this time. In any event, final siting of storage reservoirs within the Upper East Coast will need to consider potential impacts to this threatened species.

K.5.3.4 Eastern Indigo Snake

Indigo snakes, a threatened species are known to inhabit this region and often reside within burrows of gopher tortoises, which also inhabit sandy uplands within the region. Indigo snakes are also known to inhabit canal banks where they use crab holes as refuge. Some negative impacts to indigo snakes is probable due to the construction of storage reservoirs but the total impact will probably not be a significant.

K.5.3.5 Bald Eagle

The threatened southern bald eagle is known to inhabit and breeds within large areas of the Upper East Coast, particularly along the Indian River Lagoon. No negative affects to bald eagles or their habitat is expected at this time. However, final siting of storage reservoirs within the Upper East Coast will need to consider nest locations and possible affects to bald eagles due to the possible creation of "nuisance habitats". That is, the creation of open water habitat, which may attract foraging and/or nesting eagles, and due to water management priorities and downstream discharges, not be able to sustain them throughout the year.

K.5.3.6 Wood Stork

Endangered wood storks are also known to frequent and breed throughout the Upper East Coast. Two breeding sites are known in western St. Lucie County and one in western Martin County (Moler 1992). Some limited and localized negative affects to wood storks may occur (such as construction activities, blasting, earth moving equipment, noise etc.), but overall, significant improvements to wood stork habitat should result under the Initial Draft Plan. As with bald eagles, final siting of storage reservoirs within the Upper East Coast will need to consider wood stork rookery locations and possible affects to storks due to the possible creation of "nuisance habitats". That is, the creation of open water habitat, which may attract foraging and/or nesting storks, and due to water management priorities and downstream discharges, not be able to sustain them throughout the year.

K.5.4 Water Management

The proposed storage areas will significantly improve water management on the Upper East Coast. Water storage sites will allow localized rainfall runoff to be captured and used for flow augmentation to the St. Lucie estuary when needed during the dry season. The greatest benefit will come from storage of peak rainfall inside the basins, and reduced loss of this turbid, nutrient-laden water to tide. The Initial Draft Plan model output predicted that this alternative could significantly reduce basin high flow events (>1600 cfs over a 14-day period) as compared with the 2050 base. In fact, while the Initial Draft Plan did not completely meet the performance target, it reduced the frequency of high-flow discharges to the estuary by nearly 80 percent.

The principal changes in water management will be an increase of structures (levees, pumps, weirs and canals) associated with the storage areas and their operation. A fairly complex operation schedule will have to be designed and implemented to maximize the benefits of these storage sites. Movement of water into and out of the storage areas will be by pumps, which will require fuel to run and will be an additional source of noise to nearby areas.

K.5.5 Water Quality

The Initial Draft Plan includes several components specifically addressing ecological conditions in the Upper East Coast/Indian River Lagoon sub-region, including the St. Lucie River estuary. Furthermore, other regional storage features (e.g., North of Lake Okeechobee Storage reservoir, Caloosahatchee Basin Storage reservoir(s) with Aquifer Storage and Recovery System, Everglades Agricultural Area Storage Reservoir, Taylor Creek/Nubbin Slough Storage and Treatment Area, and Lake Okeechobee Aquifer Storage and Recovery System, see below) are expected to improve water quality conditions in the sub-region by contributing to the attenuation of flood discharges via the C & SF Project. Additionally, an “Other Project Element” (OPE) involves attenuation of C-25 Canal flows to improve water quality in the Indian River Lagoon.

Water quality conditions in the St. Lucie River and Indian River Lagoon estuaries are expected to be significantly improved as a result of the implementation of the following components:

North Storage reservoir, Kissimmee River watershed; regional system storage reduces flood discharges from Lake Okeechobee into St. Lucie (C-44) Canal;

C-44 (St. Lucie) Canal reservoir; attenuates C-44 basin runoff, reduces flood discharges into C-44 Canal;

Environmental water supplies to St. Lucie River estuary to achieve optimal salinity;

Caloosahatchee (C-43) Canal regional system storage reduces flood discharges into St. Lucie and Caloosahatchee Canals;

modified regulation schedule for Lake Okeechobee to provide increased environmental deliveries to the WCAs/Everglades National Park and reduce flood discharges to St. Lucie and Caloosahatchee estuaries;

Everglades Agricultural Area reservoir; regional system storage reduces Lake Okeechobee flood discharges into C-44 Canal;

Taylor Creek/Nubbins Slough storage and treatment; regional system storage reduces flood discharges from Lake Okeechobee into C-44 Canal; long-term net improvement of Lake Okeechobee water quality discharged into C-44 Canal;

Regional-scale aquifer storage of Lake Okeechobee water reduces flood discharges into C-44 Canal; water supply to St. Lucie River estuary upon recovery;

Surface water storage reservoirs totaling 27,200 acres in C-23, C-24 and C-25 Canal basins and 21,150 acres of storage in North Fork and South Fork basins of the St. Lucie River. The reservoirs provide regional storage volume totaling 349,400 acre-feet and are designed to prevent undesirable flood discharges to the St. Lucie River estuary.

Key water quality parameters of concern in this sub-region include nutrients, mercury, dissolved oxygen, pesticides, salinity, turbidity, coliform bacteria, and heavy metals. A substantial amount of the surface water storage area in the Initial Draft Plan (St. Lucie/C-44 Basin Storage Reservoir and C-23, C-24, C-25, North and Southfork Basins Storage Reservoirs, was developed specifically to prevent fresh water inundation of the St. Lucie River estuary consistent with salinity targets. It is expected that these surface water storage areas can be optimized to reduce nutrient and heavy metals concentrations and turbidity levels in inflows to the estuary. Nutrient reductions may also improve dissolved oxygen conditions by reducing biochemical oxygen demand (BOD). Attenuation of runoff should also reduce coliform bacteria concentrations in the estuary. Certain pesticide concentrations may also be reduced, depending upon pesticide forms (dissolved or particulate) and pesticide application practices in the watershed. It is not expected that increased surface water storage will affect mercury concentrations.

K.5.6 Water Supply

Of all the alternatives evaluated, the Initial Draft Plan came closest to attaining performance targets. The Initial Draft Plan components greatly decrease the amount of agricultural irrigation demands not met when compared with the 2050 base condition. The storage reservoir in the C44 basin accounts for a portion percentage of the decrease in the demand not met. The project elements will have no effect on urban demands.

K.5.7 Socio-Economics

Implementation of the Initial Draft Plan could provide minor economic benefits related to the boating and fishing industry. The restored St. Lucie Estuarine System should bring in an increase in recreation, thus causing an increase in revenue for the area, through increased use of boat ramps, bait and tackle sales, guide services and rentals.

K.5.8 Land Use

Implementation of the storage sites will cause direct land use changes in the Upper East Coast. About 60,000 acres of mostly agricultural lands, whose specific location is not known yet, are being targeted for siting surface water storage areas. Some of the agricultural activity in the area, especially citrus, has been on the decline and the land use could possibly have changed with or without the Restudy. However, lands acquired for surface water storage will be removed from the agricultural land base of St. Lucie and Martin Counties.

K.5.8.1 Agriculture

A 10,000 acre storage reservoir is proposed in this region to capture local runoff from the C-44 basin. An additional 48,350 acres of storage are proposed for the C-23, C-24, C-25, North Fork, and South Fork basins. These reservoirs are designed to attenuate flood flows to the St. Lucie estuary and provide water supply and water quality benefits. This represents a potential conversion of almost 60,000 acres from productive agriculture to storage reservoirs in an area designated as unique farmland. This total is approximately 12 percent of the area currently used for agriculture in the Upper East Coast region.

These reservoirs should, however, offer water supply benefits for agriculture in this region. Results of the South Florida Water Management Model indicate that irrigation demands not met would be reduced from 31.6 percent in the future without-project condition to 6.7 percent in the Initial Draft Plan. This would be a substantial improvement in water supply.

K.5.9 Recreational Resources

The proposed elimination of fresh water discharges to the St. Lucie and the Caloosahatchee Estuary except for emergencies would more closely resemble "natural conditions" prior to the existence of the canal system. The 2050 base would propose no such component. This component could improve seagrass cover and fisheries in estuarine areas, ultimately improving recreational fishing, boating, diving and bird watching.

The proposed construction of water storage reservoirs could potentially improve recreation resources in those locations, depending on several factors. The construction of gentle sideslopes could produce high quality fish and wildlife habitat. Water depths potentially occurring in some of these water storage reservoirs are known to sustain breeding, feeding, and growth for various fish. The stockpiling of some excavated material adjacent to the WSRs could provide access for bank fishing, bike riding, bird watching, and hunting or environmental interpretive recreation opportunities. The 2050 base plan would propose no such component.

K.5.10 Aesthetic Resources

The proposed construction of Water Storage Reservoirs in Martin and St. Lucie Counties could have an adverse affect on aesthetic resources depending on WSR design, location, construction and proximity to visual corridors and populated areas. Local residents and visitors could experience some temporary adverse aesthetic impacts during construction of the reservoirs. Temporary construction impacts would most likely return to pre construction conditions upon construction completion. The stockpiling of excavated material adjacent to the reservoirs could adversely affect visual resources within the component area. However, the reservoirs themselves would resemble natural marsh and lake areas, as observed from boundary levees. The marshy areas (4' deep) will undoubtedly attract waterfowl and provide many visual benefits. The deeper areas may develop game fisheries (bass and crappie) as other such water management areas have done. The 2050 base plan would propose no such benefit.

The proposed operational water delivery change to the St. Lucie Estuary via S-80 and C-44 could potentially improve aesthetic resources in the estuarine area by more closely duplicating historical salinity levels. This plan could improve underwater views of seagrass beds and associated wildlife for improved aesthetics.

K.5.11 Unavoidable Adverse Environmental Effects

The Initial Draft Plan, the Initial Draft Plan, has not quite reached the proposed salinity envelope targets for reduction of high flow, either from regulatory releases from Lake Okeechobee or from high flow basin runoff. These flows above the salinity envelope targets could have potential unavoidable adverse impacts to the St. Lucie and Indian River Lagoon estuaries, but these are reduced in comparison to existing (base 1995) or future (base 2050) conditions.

Storage areas will modify land use by converting land (agricultural land, wetland or upland forest) to open water. There will be a change in the dominant plant cover (from emergent or crop to floating aquatic) and dominant animal groups (common terrestrial wildlife to aquatic birds, reptiles, amphibians, fish and invertebrates).

K.5.12 Relationship Between Short Term Uses and Long Term Productivity

Construction of the storage facilities represents a significant short-term disruption to the environment, and possible unintentional direct and indirect environmental consequences. Short-term effects due to construction activities (clearing, grubbing, levee building, installation of structures, equipment noise, etc.) may be visually unpleasant and annoying to adjacent landowners. However, the storage areas will be sited in rural zones. Grading and restoration will improve the visual quality of the landscape when construction is finished, and adverse effects will be minimized wherever possible.

Once completed, vegetation would be expected to colonize over the levees and in the reservoirs. In addition, these modifications to the water management system will have a beneficial long-term and permanent effect on the St. Lucie Estuary and some of the wetlands in the associated watersheds.

K.5.13 Irreversible and Irretrievable Commitments of Resources

The proposed construction of storage sites, as described above, represents, in all likelihood, an irreversible and irretrievable commitment of land and monetary resources. These resources would include, in addition to the lands themselves, state and Federal funding, labor, energy and project materials and equipment to build the storage sites and the structures associated with the operation of these storage sites.

K.5.14 Cumulative Effects

Restudy project components are not expected to result in a cumulative negative effect on the environment of the Upper East Coast. Project components in the Upper East Coast, especially storage and on-site retention/detention, will act cumulatively to restore more natural freshwater flows to the St. Lucie Estuary, but should not result in negative environmental effects or effects unfavorable to the restoration of the natural environment.

K.6 EVERGLADES AGRICULTURAL AREA

This assessment will cover only those consequences realized within the Everglades Agricultural Area geographic planning region. The primary project feature of the Initial Draft Plan that would affect the hydrology and ecological sustainability of the Everglades Agricultural Area region is the introduction of a large above ground storage reservoir. This change will provide a substantial net increase in regional storage capacity, and reduce demands on Lake Okeechobee water. Features include an approximately 60,000-acre above ground storage reservoir, at a location to be determined. The reservoir will be divided into three compartments. Compartment 1 will cover 20,000 acres, with inlet capacities for excess runoff of 2,700 and 2,300 cfs, for the Miami Canal Basin and the North New River Basin, respectively. It will have outlet capacities of 3000 and 4400 cfs, for the Miami Canal Basin and the North New River Basin, respectively, to meet Everglades Agricultural Area water demands. Compartment 2A covers 20,000 acres and will be operated as a dry storage reservoir. Compartment 2B, also covering 20,000 acres, will be operated as a dry storage reservoir. Both compartments 2A & B will have inlet and outlet facilities.

K.6.1 Vegetation

Approximately 60,000 acres of agricultural lands would be converted to a water storage reservoir under the Initial Draft Plan. These lands will be permanently removed from agricultural production. It is difficult to predict what vegetative communities will be present in the individual cells of the new water storage areas, due to the unusual hydrologic patterns they will experience. These areas will act primarily as “surge tanks”, storing large amounts of excess water during wet periods and drying out completely during dry times. Alternating wet and dry conditions may last only a few days or may last for many months to more than a year, and water depth will vary widely, from 6 feet to only a few inches, depending on rainfall conditions and operational demands. These irregular hydrological patterns will certainly cause profound and widespread changes in wildlife habitats existing in these areas at the time of construction. Long periods of flooding would be expected to kill trees used as nesting sites by bald eagles, caracara and many other species, eventually destroying the nests and reducing available nesting substrates.

Under some conditions, large areas of habitat suitable for foraging wood storks, snail kites, bald eagles, and Audubon’s crested caracaras may be created. However, the USFWS is concerned that these areas would become “attractive nuisances” when temporarily favorable conditions are created, drawing in opportunistic wildlife species. Temporary favorable conditions could induce species such as wood storks, snail kites, bald eagles and others to nest nearby; but nesting success would depend on continued favorable foraging conditions. Short term success could produce artificially inflated populations of some species. When reservoir operations then cause a rapid change in conditions, widespread nesting failures and direct mortality of adult individuals could result due to loss of foraging resources. In addition, the rapid filling of storage areas that have been dry for extended periods would likely result in direct mortality due to drowning of less mobile species such as the eastern indigo snake.

K.6.2 Fish and Wildlife

Fish and wildlife resources inside the 60,000 acres water storage area would be directly affected by construction of the features recommended by the Initial Draft Plan. The wildlife now occupying the lands that would become a water storage reservoir would be completely displaced, exposing them to increased risk of mortality. No adverse effects on endangered, threatened or state special concern species are anticipated. It is expected that unknown numbers of common wildlife species will be displaced when wetlands or uplands are flooded to provide surface water storage. This will unavoidably cause some mortality. Affected species likely would include opossum, raccoon, native mice, rats and rabbits, as well as many species of songbirds. This fauna would be replaced by fish, reptiles (alligator, turtles) and water birds. Siting of the Everglades Agricultural Area water storage reservoir over altered or agricultural lands will minimize adverse impacts on native wildlife. However, even agricultural lands provide some minimal wildlife cover, which will be irretrievably converted to marsh or open water habitat. Foraging habitat will be created for some fish-eating birds in the reservoir cells as water levels recede to shallow (<4' deep) stages, including osprey, snail kite, and kingfisher.

K.6.3 Threatened and Endangered Species

Of the eighteen listed plant and animal species submitted by the USFWS as likely to be affected by the C&SF Restudy, two are thought to occur within the affected area of the Everglades Agricultural Area region. A brief description of effects to these state and federally listed threatened and endangered species follows.

K.6.3.1 Eastern Indigo Snake

The eastern indigo snake (*Drymarchon corais couperi*) could potentially be affected by construction of storage reservoirs and their associated facilities. No effect is anticipated at this conceptual level of planning. When definitive sites are identified and selected, it will be possible to determine precise impacts. The USFWS and the GFC classify the eastern indigo snake as a threatened species.

K.6.3.2 Wood Stork

The wood stork (*Mycteria americana*) is listed as an endangered species by the USFWS and the GFC. Wood storks forage in freshwater marshes, seasonally flooded roadside or agricultural ditches, narrow tidal creeks, shallow tidal pools, managed impoundments, and depressions in cypress heads and swamp sloughs. No adverse effect on the wood stork is anticipated due to construction of water storage facilities in this region. Under some conditions the water storage areas may provide suitable habitat for foraging wood stork. However, the USFWS is concerned that these areas would become “attractive nuisances” when temporarily favorable conditions are created, drawing in opportunistic wildlife species. Temporary favorable conditions could induce species such as wood storks, snail kites, bald eagles and others to nest nearby; but nesting success would depend on continued favorable foraging conditions. Short term success could produce artificially inflated populations of some species. When reservoir operations then cause a rapid change in conditions, widespread nesting failures and direct mortality of adult individuals could result due to loss of foraging resources.

K.6.4 Water Management

Under the Initial Draft Plan, all flood control releases to the St. Lucie and Caloosahatchee River estuaries are expected to be eliminated except pulse releases in zone A of the regulation schedule. Water managers will use a climate based inflow forecasting model, in conjunction with operational rules, which will help them decide when to pump water to the storage facilities outside the lake. When the model shows that lake water levels may rise above desirable levels for the littoral zone (14.35 feet to 14.75 feet), water will be pumped to the storage facilities in the Everglades Agricultural Area (one 20,000 acre compartment at 6 ft. maximum depth for supplying Everglades Agricultural Area irrigation demands and two 20,000 acre compartments at 6 ft. maximum depth for supplying environmental demands) with increased conveyance from Lake Okeechobee to the reservoir. The purposes are to improve timing of environmental deliveries to the Water Conservation Areas, including reducing damaging flood releases from the Everglades Agricultural Area to the Water Conservation Areas, reduce Lake Okeechobee regulatory releases to estuaries, meet supplemental agricultural irrigation demands, and increase flood protection within the Everglades Agricultural Area. Conveyance capacity of the Miami, North New River, Bolles and Cross Canals between Lake Okeechobee and the Storage Reservoirs would be increased to convey additional Lake Okeechobee regulatory releases that would have otherwise been discharged to the Caloosahatchee and St. Lucie Estuaries. The two compartments (2A&B) are to be operated as dry storage areas with withdrawals being made down to 18" below ground level. They were also subdivided to allow for more efficient use of the reservoir and to facilitate alternative uses of the compartments during dry times (i.e., agriculture).

K.6.5 Water Quality

The Initial Draft Plan is expected to improve water quality conditions in the Everglades Agricultural Area. This conclusion is based on the premise that the existing Everglades Agricultural Area regulatory program (Florida Administrative Code Rule 40E-63), which has resulted in significant phosphorus load reductions in runoff from Everglades Agricultural Area farmland, will continue to be effectively implemented.

Phosphorus is the primary pollutant of concern in the Everglades Agricultural Area, especially as it affects ecological conditions in the downstream WCAs. The phosphorus load reduction target for the regulatory program is 25 percent. The three-year trend (for the period ending April 30, 1997) in total phosphorus loads originating from Everglades Agricultural Area farms indicates a 51 percent reduction compared to the 1979–1988 baseline period (SFWMD, 1998). Other pollutants of concern in the Everglades Agricultural Area include mercury, nitrogen compounds (NOx), dissolved oxygen, and pesticides.

The principal water quality benefit to the Everglades Agricultural Area resulting from the Initial Draft Plan is the conversion of approximately 60,000 acres of farmland, and concomitant elimination of attendant non-point source pollution loads to surface water storage. Water column mercury concentrations in the Everglades Agricultural Area are not expected to be affected by construction and operation of storage reservoirs.

Combined with the existing Everglades Agricultural Area regulatory program, the increase in storage volume on former farmland in the Everglades Agricultural Area will result in a net reduction of phosphorus and other non-point source pollutants in surface waters of the Everglades Agricultural Area compared to existing and future base conditions.

K.6.5.1 Effects of Initial Draft Plan on the Everglades Construction Project

Increasing hydraulic and phosphorus loads are predicted to affect the performance efficacy of the Everglades Construction Project. The Everglades Construction Project and Best Management Practices (BMPs) in the Everglades Agricultural Area comprise the primary water quality improvement strategy for the downstream WCAs.

For purposes of evaluating the future (2050) base condition and alternative plans, “Phase 2” treatment technologies necessary to meet water quality criteria adopted pursuant to the Everglades Forever Act, were assumed to be implemented. However, since the numeric treatment targets are not yet known, nor has the most appropriate supplemental treatment technology been selected, the potential impact of the future base and restudy alternatives on the design and operation of the Everglades Construction Project was evaluated in the context of the interim treatment targets defined in the conceptual plan for the Everglades Construction Project (Burns & McDonnell, 1994) and current design criteria for the Everglades Construction Project.

An evaluation of the effect of the future base condition and Restudy alternatives on the Everglades Construction Project was conducted by William W. Walker, Jr. (Walker, 1998). Walker’s evaluation indicates that, utilizing existing water quality data and the phosphorus settling rate constant and Everglades Agricultural Area BMP phosphorus load reduction assumptions used in the conceptual design for the Everglades Construction Project (Burns & McDonnell, 1994), the 31-year average hydraulic and phosphorus loads in the Initial Draft Plan cause the interim phosphorus concentration target (50 ppb) to not be met at Stormwater Treatment Areas 1W, 2, 5, and 6. This potential problem also exists for all of the stormwater treatment areas except Stormwater Treatment Area 1E in the 2050 base condition.

On the other hand, using the 51% observed average phosphorus reduction rate from 1995 to 1997 for the EAA BMP significantly changes the outcome. Walker observes that all STAs with the exception of STA 5, meet or exceed the interim phosphorus concentration target. STA 5 is the sole exception due to the hydrologic model not including the nearly 2,000 acre treatment area of STA 6 Section 2. Design of STA 6 Section 2 was not completed at the time this analysis was done. Changing other criteria such as the settling rate constant or the target outflow phosphorus concentration to that observed in the Everglades Nutrient Removal project over the 1995 to 1997 period would also significantly improve the STA performance models.

When compared to projected 2050 base conditions, the Initial Draft Plan is not predicted to worsen performance deficiencies predicted for the Everglades Construction Project. Significantly, the Initial Draft Plan improves the predicted performance at Stormwater Treatment Area 3\4. Stormwater Treatment Area 3\4 benefits from the proposed 60,000 acre Everglades Agricultural Area reservoir, acting as a net sink for phosphorus. Stormwater Treatment Area 1E is not predicted to be adversely affected by the future base or Initial Draft Plan flows.

The predicted performance deficiency at Stormwater Treatment Area 5 is caused by not including Stormwater Treatment Area 6, Section 2 as a future base condition or in any of the Restudy alternatives. Excluding Stormwater Treatment Area 6 Section 2 requires all of the C-139 basin runoff to be routed through Stormwater Treatment Area 5, thereby increasing the average hydraulic and phosphorus loads above the amounts for which it was designed.

The Everglades Construction Project is designed to treat one hundred percent of the runoff originating within the Everglades Agricultural Area for the 1979-1988 baseline period to an interim phosphorus concentration target of 50 ppb. The conceptual design for the Everglades Construction Project does not provide for any bypasses of 1979-1988 flows. The period of record utilized for evaluating alternatives during the Restudy was 1965-1995, a much longer and, on average, wetter period than the baseline period utilized to design the Everglades Construction Project. In addition, different operational rules (Rain-Driven Operational Rules,) were used to evaluate the effects of Restudy alternatives, including the Initial Draft Plan, on the Everglades Construction Project.

Nevertheless, using 1979-1988 hydrologic conditions, Walker's evaluation indicates that bypasses of the stormwater treatment areas are predicted to occur in the 2050 base condition. Furthermore, the amount of bypassing is predicted to increase over the 2050 base with implementation of the Initial Draft Plan. Bypass phosphorus loads to the WCAs are further increased when considering 1965-1995 average hydrologic conditions.

One preliminary conclusion is that if the Everglades Agricultural Area reservoir is constructed and operated as modeled in the Initial Draft Plan, the size of Stormwater Treatment Area 3\4 (the costs for construction and operation of that would be fully paid for by the state funding as provided for in the Everglades Forever Act) could be reduced. The interim phosphorus concentration target could still be achieved.

Furthermore, the beneficial effect of reservoir storage on stormwater treatment area function illustrated by Walker's evaluation suggests that splitting the 60,000 acres of storage area into other basins or delivering water from other basins would similarly benefit other stormwater treatment areas.

Third, supplemental treatment technologies designed to achieve low phosphorus concentrations (Phase 2) in discharges from the stormwater treatment areas consistent with the requirements of the Everglades Forever Act should be designed consistent with the average hydraulic and phosphorus loads inherent in the Initial Draft Plan. It should be noted that this conclusion is based on Walker's modeling results utilizing existing water quality data, operational rules (lake regulation schedule, etc.) for the 2050 base condition and the Initial Draft Plan, and the phosphorus settling rate (10.2 m/yr.) and the BMP load reduction (25 percent) assumptions used to develop the conceptual plan for the Everglades Construction Project (Burns & McDonnell, 1994).

However, the observed three-year trend in actual phosphorus load reduction resulting from implementation of Best Management Practices in the Everglades Agricultural Area is 51 percent (SFWMD, 1997), not the 25 percent assumed for the conceptual design of the Everglades Construction Project. Walker's evaluation further indicates that a 51 percent load reduction resulting from Best Management Practices enhances the performance of the stormwater treatment areas. Furthermore, observed performance at the Everglades Nutrient Removal stormwater treatment area demonstration project indicates that under certain conditions, vegetated stormwater treatment areas can be operated to achieve a higher settling rate and lower concentrations of phosphorus than the interim concentration target of 50 ppb (SFWMD, 1998). Increased phosphorus load reduction and an increased settling rate consistent with that observed at the ENR Project may negate the need to modify the size and/or operation of the stormwater treatment areas.

There are many uncertainties to be evaluated before more reliable predictions can be made about the impact of the recommended plan on phosphorus loading. They include the following: (1) how great a reduction in phosphorus loading will result from adoption of Best Management Practices in the Everglades Agricultural Area; (2) future Lake Okeechobee phosphorus concentrations; (3) net phosphorus settling rates in stormwater treatment areas; the effects of supplemental (Phase 2) stormwater treatment technologies; (4) the effects of bypasses of the stormwater treatment areas, and (5) the effects of operation schedules on the distribution of phosphorus loads. These issues will need further evaluation as the appropriate components of the Initial Draft Plan progress toward detailed design.

K.6.6 Water Supply

Under the Initial Draft Plan, large-scale storage would augment the regional water supply budget. The storage reservoir would improve the timing of environmental deliveries to the Water Conservation Areas. It would reduce damaging flood releases from the Everglades Agricultural Area, with their high nutrient loads, to the WCA's. The reservoirs would be used to meet supplemental agricultural irrigation demands within the Everglades Agricultural Area. Modifications to flow volume, timing and duration due to implementation of the Initial Draft Plan with its storage reservoirs in the Everglades Agricultural Area, will have significant positive benefits downstream through the Everglades Protection Area by contributing to a healthier Everglades system.

Water supply for supplemental irrigation to the Everglades Agricultural Area is substantially improved in the Initial Draft Plan over both the future without-project condition and the existing condition. The demands not met are reduced from 24 percent in the future without-project condition and 12 percent in the existing condition to 5 percent in the Initial Draft Plan. State of Florida House bill 715 specifies that the planning goal for water supply needs shall be based upon meeting the needs for a 1-in-10 year drought event. The South Florida Water Management Model shows the frequency of water restrictions would be cut from 16 years (restricted) out of 31, under the 2050 base (future without-project) condition to 5 years out of 31 in the Initial Draft Plan. Five years with restrictions is closer to the 1-in-10 year goal of 3 years of water restrictions over the 31-year model simulation period.

The change in water supply source, however, is a concern. This region has historically relied upon Lake Okeechobee for its supplemental irrigation water. Approximately 25 percent of the Everglades Agricultural Area irrigation supply will come from storage reservoirs in the Initial Draft Plan. The agricultural community is reluctant to rely upon reservoir technology that is new to this region for their water supply. The reservoirs will have to be completed and functioning before the Everglades Agricultural Area water supply from Lake Okeechobee is reduced, in order to prevent a potential water shortage.

The Initial Draft Plan does not address the soil subsidence issue in the Everglades Agricultural Area. Research is currently underway to develop sugarcane varieties and management practices to control subsidence (Glaz, 1995).

Higher water tables are a key factor in controlling subsidence. When more water-tolerant sugarcane varieties become available, the water supply needs within the Everglades Agricultural Area will increase, in an effort to maintain higher water tables. Adaptive management should enable modifications to the Initial Draft Plan to raise Everglades Agricultural Area water tables in order to preserve the valuable soil resource.

K.6.7 Land Use

Under the Initial Draft Plan the main existing land use to be impacted would be agriculture. The proposed above ground storage reservoirs would have a combined surface area of 60,000 acres. The proposed action would convert an undetermined, but significant amount of land currently in agricultural acreage or vacant, into open water.

K.6.7.1 Agriculture

Conversion of 60,000 acres of agricultural land to reservoirs would be an approximate 9 percent reduction of the area farmed in this region, which is designated as unique farmland. The first two 20,000 acre components are filled approximately 20 percent and 35 percent of the time, respectively; and they hold at least four feet of water approximately 50 percent and 40 percent of the time, respectively. The third compartment, however, is full only about 8 percent of the time, and holds at least four feet of water approximately 10 percent of the time. This is rather limited use to justify conversion of 20,000 acres of farmland. Options for continued agricultural production during dry periods in these reservoir compartments, particularly the third, should be pursued.

K.6.8 Recreation Resources

Overall, existing recreation resources in the Everglades Agricultural Area region would not be significantly adversely affected under the Initial Draft Plan. The proposed construction of 60,000 acre reservoirs to the depth of six feet should not adversely affect either existing or future recreation resources forecast under the 2050 base conditions in the Everglades Agricultural Area Region. The three-compartment reservoir, depending on the reservoir construction and placement of the excavated material, could enhance fishery resources in the region. If public access is permitted, recreational fishing, bird watching, and environmental interpretation could be developed. The 2050 base plan proposed no such component.

The proposed reduction of dryout periods in the northwest corner of the WCA 3A by increasing the capacity of pump station G-404 in the Everglades Agricultural Area Region should not adversely affect recreational resources in the region. The proposal should enhance water-dependent recreation resources in the WCA 3A area.

K.6.9 Aesthetic Resources

The main visual components of the C&SF Restudy in the Everglades Agricultural Area region are the low levees of the reservoirs, water control structures, and pump stations. These features are not unlike existing features in the region. The storage reservoirs would appear from a distance as areas similar to flooded agricultural fields or marsh. The project components do not include any tall structures that would interrupt the existing landscape profile. The Initial Draft Plan would not significantly affect aesthetic resources within the Everglades Agricultural Area.

K.6.10 Unavoidable Adverse Environmental Effects

The following unavoidable adverse effects are expected to occur with implementation of the project features described above, which are expected to have an affect within the Everglades Agricultural Area physiographic region.

Construction of a 60,000 acre above ground storage reservoir will take large tracts of agricultural lands out of production, and possibly remove the functional values of lesser amounts of wetlands, prairie, or other natural areas. There will be a change in the dominant plant cover (from emergent or crop to floating aquatic) and dominant animal groups (common terrestrial wildlife to aquatic birds, reptiles, amphibians, fish and invertebrates).

K.6.11 Relationship Between Short Term Uses and Long Term Productivity

Construction of the reservoir storage facilities represents a significant short-term disruption to the environment, and possible unintentional direct and indirect environmental consequences. Short-term effects due to construction activities (clearing, grubbing, levee building, installation of structures, equipment noise, etc.) may be visually unpleasant and annoying to adjacent landowners. However, the storage areas will be sited in rural zones. Grading and restoration will improve the visual quality of the landscape when construction is finished, and adverse effects will be minimized wherever possible.

Once completed, vegetation would be expected to colonize over the levees and in the reservoirs. In addition, these modifications to the water management system will have a beneficial long-term and permanent effect downstream throughout the Everglades Protection Area.

K.6.12 Irreversible and Irretrievable Commitments of Resources

The proposed construction of a 60,000 acre reservoir storage site represents, in all likelihood, an irreversible and irretrievable commitment of land and monetary resources. These resources would include, in addition to the lands themselves, state and Federal funding, labor, energy and project materials and equipment to build the storage site and the structures associated with the operation of these facilities. Fish and wildlife habitat, located within the proposed component footprint, would likely be inundated for much of the year, would be permanently altered and could represent a irreversible commitment of land and/or wetland resources.

K.6.13 Cumulative Effects

Restudy project components are not expected to result in a cumulative negative effect on the environment of the Everglades Agricultural Area physiographic region. Project components in the Everglades Agricultural Area region, especially reservoir storage, will act cumulatively to restore more natural freshwater flows to the Water Conservation Areas, Everglades National Park and ultimately to Florida Bay. To achieve restoration will require substantially more storage in the Everglades Agricultural Area region of the system, in order to provide for the correct quantity, quality, timing, and duration of flows. The land spatially occupying these Everglades Agricultural Area areas once provided these important functions to the regional system. Today, they are largely developed, drained, and ditched agricultural lands. The restoration of these important natural functions will require some reversal of the current trend in order to provide the retention area for holding, storing and treating water prior to its discharge downstream. The proposed project features, along with a restored Lake Okeechobee, able to provide important storage functions, are necessary to the overall restoration of the study area downstream. The commitment of 60,000 acres of land represents a huge investment in funding and land resources. It may also cause some adverse consequences locally, however the overall benefit to the regional system will be far greater than the localized adverse effects. The localized adverse effects will not result in a detrimental cumulative effect within the region.

K.7 WATER CONSERVATION AREAS

Within this physiographic region are contained the Arthur R. Marshall Loxahatchee National Wildlife Refuge (WCA 1), Water Conservation Areas 2 A, 2B, 3A, and 3B (collectively managed by the Florida Game and Fresh Water Fish Commission as the Everglades Wildlife Management Area), as well as the Holey Land Wildlife Management Area and Rotenberger Wildlife Management Area. Although the latter two areas are not, strictly speaking, a part of the Water Conservation Area system, for the purposes of organization of this report only, they have been included within the overall Water Conservation Area region.

The following is a discussion of affects to the largest contiguous area of historic Everglades outside Everglades National Park. The C&SF Project has compartmentalized the WCA's into several water conservation areas and water management areas through a large system of levees and canals. The assessment of effects to this region, presented below, is drawn largely from the Florida Game and Fresh Water Fish Commission, Fish and Wildlife Coordination Act Report, Part I, submitted to the Corps on August 6, 1998. This Coordination Act Report, and two additional Coordination Act Reports (Parts II-III) dated January 19, 1999 and February 19, 1999 respectively, are available in their entirety in Annex A.

K.7.1 Vegetation

The discussion of affects to existing vegetation is organized by the several different Water Conservation Areas, beginning with Water Conservation Area 1 in Palm Beach County, and proceeding southwards. Holey Land and Rotenberger Wildlife Management Areas are discussed last.

K.7.1.1 Water Conservation Area 1 (Arthur R. Marshall Loxahatchee NWR)

Current refuge management goals are to maintain present conditions, comparable to the 1995 base. Therefore, the Initial Draft Plan was formulated with the current water regulation schedule. Overall, Water Conservation Area 1 would be expected under the Initial Draft Plan to maintain marsh conditions favoring deeper water species such as snail kites and waterfowl, as well as substantial populations of marsh fishes. However, it is possible that a continuation of the existing schedule, which maintains deeper water in the southern part of the refuge, could lead to adverse effects on tree island communities and the wildlife that depend on them.

In Water Conservation Area 1 the number and duration of extreme low water conditions is reduced in the Initial Draft Plan, an improvement over the drier conditions predicted for the 2050 base. The number and duration of high water events are also reduced compared to the 2050 base, and meet the performance targets for extreme high water. There is some uncertainty about the effect of high water on tree islands in southern Water Conservation Area 1, however, overall, the proposed alternative conforms to current hydrologic management objectives for the refuge.

K.7.1.2 Water Conservation Area 2A

The marsh ecosystem in Water Conservation Area 2A has suffered substantial damage as a result of past water management. In the south, most of its tree islands have been lost to prolonged high waters (Dineen 1974), while many acres of northeastern Water Conservation Area 2A have been overtaken by cattails. The highest quality marsh occurs in central Water Conservation Area 2A in the vicinity of the 2-17 gage and to the northwest of the gage, where a small number of intact tree islands persist. Principal hydrological restoration needs are a reduction in over-drainage in the north and in extreme high-water events that have drowned tree islands in the south.

The Initial Draft Plan introduced operational changes that improved inundation patterns in the north, but in so doing increased the frequency of extreme drought conditions in the south. It appears that water management in Water Conservation Area 2A imposes tradeoffs between providing improved marsh conditions in some areas, but worse conditions in others. It is also possible that restoration of a more natural hydropattern in this portion of the Everglades is hampered by constraints imposed by water management elsewhere, notably the fixed regulation schedule in Water Conservation Area 1, that may be amplifying high and low water conditions in Water Conservation Area 2A. If Water Conservation Area 1 adopts rainfall based operational rules in the future, such unnatural fluctuations in depth may be alleviated.

In general, the Initial Draft Plan exhibited problematic performance in Water Conservation Area 2A compared to the 2050 base and it is uncertain whether these conditions would lead to a sustainable healthy marsh in the future. Generally, model results are poor in northern Water Conservation Area 2A and mixed in southern Water Conservation Area 2A. Inundation patterns in northern Water Conservation Area 2A were much longer. NSM predicts that northern Water Conservation Area 2A dried out approximately every year, yet the Initial Draft Plan predicted dry-outs to occur less than once every three years on average. In southern Water Conservation Area 2A, conditions were similar to NSM. Both southern and northern Water Conservation Area 2A failed to meet target values for extreme high water conditions. High water conditions in the north were similar to the 2050 base, but in the south, conditions were slightly worse. Although extreme high water events occurred only 1 percent of the time, the duration of those events was greater than NSMv.4.5 predictions. Extreme low water events were also reduced in the Initial Draft Plan compared to the 2050 base. The Initial Draft Plan showed four additional low water events over the period of record in the southern part of Water Conservation Area 2A, a situation that would not protect peat soils. Overall, northern Water Conservation Area 2A would have a very non-NSM-like hydropattern and southern Water Conservation Area 2A would have exaggerated extreme high water conditions and lengthy hydroperiods. Together, they create uncertainty about projected future marsh conditions in this area. It appears that there would be trade-offs between the northern and southern parts of Water Conservation Area 2A that may be solvable by operations. More detailed design is needed to determine if a balance can be achieved that promotes sustainable marsh conditions in both the north and the south.

K.7.1.3 Water Conservation Area 2B

Water Conservation Area 2B was one of the two most problematic regions in the northern and central Everglades from the standpoint of restoration to more natural hydrologic conditions. Although the overall hydroperiod in this area is similar to that in the NSM, all the alternatives exhibit too frequent extremes of high water, low water, or both. In the Initial Draft Plan, the occurrence of extreme high-water events is substantially less than it is in the 2050 base; however, there still remains a combination of frequent drought conditions and frequent extreme high-water events that occupy 16 percent of the total simulation period. Such frequent extremes imply that this area will not be able to function sustainably as either a shorter or a longer hydroperiod Everglades wetland.

Although Water Conservation Area 2B had good NSM-like inundation patterns as a result of the Initial Draft Plan, problems with extreme high water, extreme low water, or both, caused it to fail to meet the targets. The Initial Draft Plan reduced high water extremes over the 2050 base, but depths greater than 2.5 ft still occurred 10-11 percent of the time, far from the NSM value of 1 percent. Although the Initial Draft Plan shows significant improvement relative to the 2050 base, the frequent occurrence and long duration of extreme high and low water makes it unlikely that this area would function in a sustainable manner as either a shorter or longer hydroperiod Everglades wetland. More attention needs to be given to this area during detailed design.

K.7.1.4 Water Conservation Area 3A

The most dramatic improvement is in the southernmost part of Water Conservation Area 3A. Here the occurrence of extreme high-water events is reduced from 6 percent of time in the 2050 base, to only 1 percent of time in the Initial Draft Plan. These benefits are clearly owing to the removal of the L-29 levee along the southern boundary of Water Conservation Area 3A, since significant reduction in the intensity of flooding occurs only in the Initial Draft Plan and B, the two alternatives in which this levee is removed. On the other hand, although extreme depths are largely eliminated from southern Water Conservation Area 3A, the overall hydroperiod of the area is increased, with periods of inundation that are much longer than those predicted by the NSM. These extended hydroperiods are most pronounced in the area immediately to the south of Alligator Alley. Here the model predicts only 11 marsh dryouts during the 31-year simulation, as compared with 18 events in the 1995 base and 24 events in the NSM. This lengthening of hydroperiods is a result of the relocation and increased operational capacity of the S-140 structure, which leads to greatly increased discharges directly northwest and upstream of south-central Water Conservation Area 3A (near to Alligator Alley). Hence, although the reduction in predicted tree island flooding would be a dramatic step toward ecological restoration of southern Water Conservation Area 3A, the ecological effects of a general shift toward longer hydroperiods is uncertain.

In the region to the east of the Miami Canal, the performance of the Initial Draft Plan is problematic. In addition to uncertainty about the effect of hydrologic changes on rookery vegetation in this region, the Initial Draft Plan also predicts that northeastern Water Conservation Area 3A will continue to experience drought conditions frequently enough to raise concern about continued impacts to peat soils.

The Initial Draft Plan makes substantial progress toward remedying the two most significant causes of habitat degradation in Water Conservation Area 3A. The first of these is flood damage to tree islands, with attendant loss of upland tree species, willow strands in northeastern Water Conservation Area 3A, and tropical hardwood hammocks in southwestern Water Conservation Area 3A. The second major cause of habitat degradation has been the destruction of peat soils, marsh vegetation, and tree islands as a result of wildfires brought on by drought conditions in the north. Together, the reduction in the frequency and intensity of these two sources of environmental damage should be expected to lead to substantial restoration within this large portion of the remnant Everglades ecosystem.

Nevertheless, there continues to be uncertainty about several aspects of the predicted hydrologic change. First, the ecological effect of prolonged inundation periods on the overall functioning of the Everglades ecosystem is not known. Comparison of predicted hydroperiods for the overall Water Conservation Area 3A region indicates that the entire landscape will, on average, be shifted toward inundation duration's that are longer than those predicted by the NSM. Second, it is uncertain whether hydropattern restoration will lead to cattail proliferation in the north, as a possibly inevitable consequence of antecedent soil conditions and changed topography.

Northwestern Water Conservation Area 3A performed better under the Initial Draft Plan than the 2050 base on all performance measures. In the Initial Draft Plan, inundation patterns match NSM planning targets, high water extremes are minimal and low water extreme events are much improved over the 2050 base. There remains some concern that the area just north of Alligator Alley, and west of the Miami Canal, within north Water Conservation Area 3A may still be likely to experience more extreme low water than will be sufficient to protect peat soils. However, it may not be possible to further reduce low water events without causing trade-offs such as increased risk of cattail proliferation in ponded areas.

Northeastern Water Conservation Area 3A would have a problem with a tendency toward both too frequent high and low water conditions that would not be completely solved by the Initial Draft Plan. For inundation pattern, the Initial

Draft Plan was close to NSM target values. The frequency of high water events is greater than in the 2050 base. This increase raises concerns about potential negative effects on wading bird nesting habitat in this region. Changes in stormwater treatment area operations, additional storage, or re-routing of floodwaters might alleviate or reverse this negative impact for some rookery sites. Low water events are a problem whenever protection of peat soils is desired and the best target for this area is the one with the fewest extreme low water events. For extreme low water events, the 2050 base had fewer events than NSM, although the duration of the events is same. The Initial Draft Plan did better than NSM targets, but had a few more events than the 2050 base. While the Initial Draft Plan performed the best of the alternatives in reducing low water extremes relative to 2050 base case, the predicted frequency and duration of low water events still seems large and may not ensure protection of peat soils.

None of the alternatives approached NSM targets in eastern Water Conservation Area 3A (just north of Holiday Park). The area east of the Miami Canal and south of Alligator Alley is deeply ponded in the 2050 base. High water extremes are most notable in this area. High water extremes in the Initial Draft Plan are still far from matching the NSM target of 0 percent high water. This may be the result of changes in operations and retention of a portion of the L-67A Canal, which allows more rapid removal of water from this area. Overall, the eastern Water Conservation Area 3A is far from reaching its target values. However, unlike the predictions for Water Conservation Area 2B, extreme high water is not combined with an increased frequency of extreme low water events.

In central and southern Water Conservation Area 3A, the Initial Draft Plan performed reasonably well by reducing the frequency of high water events, thereby eliminating flooding of tree islands during high rainfall years. While the Initial Draft Plan showed increased inundation duration's, with fewer marsh dryouts than NSM, especially within central 3A, it meets the important target for tree island communities because of the greatly reduced frequency of extreme high water events.

K.7.1.5 Water Conservation Area 3B

Water Conservation Area 3B is the second of two remaining high quality marsh areas within the northern and central Everglades, the other being central Water Conservation Area 3A. Although generally drier than it was prior to construction of the C&SF Project, the area is characterized by good water quality and intact wet prairie and sawgrass communities and hardwood hammock and bayhead tree islands. Southeastern Water Conservation Area 3B is part of the pre-drainage channel of Shark River Slough. Although it is substantially drier, at least in its southeastern reaches, than in pre-drainage estimates, and has suffered significant soil loss in this area, tree islands have been largely unimpacted by flood, drought, or human activity. Overall, the Initial Draft Plan leads to an inundation and depth pattern in Water Conservation Area 3B that more closely matches NSM predictions for mid-Shark River Slough than it does for Water Conservation Area 3B itself. This pattern represents a substantial deviation from both current conditions in Water Conservation Area 3B and from NSM predictions of the predrainage hydrology. Hence, although the Initial Draft Plan appears likely to prevent damage to higher hammock tree islands in Water Conservation Area 3B, impacts on less elevated tree islands still may occur.

In the central region of Water Conservation Area 3B, the Initial Draft Plan predicts fewer drydowns and longer periods of inundation than the 2050 base. The effect of very lengthy periods of inundation on Water Conservation Area 3B is uncertain. The Initial Draft Plan significantly reduced the frequency of events enough to prevent damage to higher hammock tree islands, but impacts on less-elevated tree islands may still occur. For extreme low water events, the Initial Draft Plan had either a few more events or events of slightly longer duration than the NSM targets. Given the removal of the eastern portion of L-29, combined with the restoration of long hydroperiods and deeper water in Northeast Shark River Slough, it appears inevitable that water depths and inundation duration's in Water Conservation Area 3B would increase.

K.7.1.6 Holey Land Wildlife Management Area

Comparison of the Initial Draft Plan to the revised 1995 and 2050 bases is not realistic, because the revised bases modeled a 0 to 2-foot regulation schedule that has been abandoned and is unlikely ever to be reimplemented in the future within the Holey Land Wildlife Management Area. For this reason, the interpretation of the Initial Draft Plan for Holey Land Wildlife Management Area must be made by comparing performance to the unrevised 1995 base, which assumed a 0 to 1-foot regulation schedule more like that which is currently in use. When this comparison is made, the performance of Holey Land Wildlife Management Area in the Initial Draft Plan is overall similar to the revised 1995 base. Advantages of using the rainfall based operations, as opposed to the fixed schedule in the 1995 base, cannot be discerned at the level of resolution of the SFWMM. Drought conditions still occur during about 3 to 4 percent of the simulation period in the Initial Draft Plan. The minimum depths and durations needed to protect peat soils are still not well understood, but as long as the plan provides for dry season deliveries of adequately treated water via the stormwater treatment areas, it should be possible to adjust operational details so as to avoid further soil loss.

K.7.1.7 Rotenberger Wildlife Management Area

Predicted conditions are largely consistent with overall current management goals for Rotenberger Wildlife Management Area. These goals are the restoration of natural hydropatterns; the avoidance of extreme high-water events that would drown remaining tree islands and promotes cattail proliferation; and the prevention of extreme drought conditions that cause soil oxidation and risk of muck fires. The model results show a reduced frequency of drought conditions (when the water table drops to more than one foot below the ground surface) relative to the 2050 base. However, drought conditions still occur during about 3 to 4 percent of the simulation period in the Initial Draft Plan. The minimum depths and duration's needed to protect peat soils are still not well understood, but, so long as the plan provides for dry season deliveries of adequately treated water via the stormwater treatment areas, it should be possible to adjust operational details so as to avoid further soil loss.

K.7.2 Fish and Wildlife

Presented below is a discussion of affects to fish and wildlife resources within the Water Conservation Area region where they are expected to occur under the Initial Draft Plan.

K.7.2.1 Water Conservation Area 2A

The ability of the Initial Draft Plan to support appropriate densities of Everglades fish and wildlife within Water Conservation Areas 2A and 2B will depend strongly on the results of detailed project design and the operational rules that accompany it. On the one hand, it is possible that water management could promote protection of remaining tree islands in northern Water Conservation Area 2A along with recovery of previously damaged islands in southern Water Conservation Area 2A. Such protection would provide nesting areas for wading birds and reptiles, as well as improved wading bird foraging habitat. On the other hand, it is also plausible that extremes of high and low water could result in soil loss in southern Water Conservation Area 2A, deterioration of remaining tree islands, and spread of cattails throughout the north.

K.7.2.2 Water Conservation Area 2B

Similarly, the deep water in Water Conservation Area 2B might support fish and apple snail populations and provide refuges for aquatic organisms during all but the most extreme dry periods. However, if water management in this area allows Water Conservation Area 2B to dry out for extended periods, it will not be able to serve such ecological functions.

K.7.2.3 Water Conservation Area 3A

Based on ATLSS fish model results, the Initial Draft Plan hydrologic conditions should produce higher average fish abundance compared with the 2050 base, as expected hydroperiods increase consistent with NSM. In particular, increased hydroperiods in northeast Water Conservation Area 3A should lead to greater fish abundance. This should also be true when only prey-sized fish at appropriate wading bird foraging depths are counted.

The region to the east of the Miami Canal is the area that has had the most successful wading bird nesting in recent years, although rookery vegetation was substantially damaged by the high water event of 1994-95 (T. Towles, GFC, pers. comm.). The performance of the Initial Draft Plan is problematic in this area. In the northeastern region, north of Alligator Alley, the frequency of extreme high water events is higher than it is in the 2050 base, and simulated depths and duration's during the high rainfall years of 1994-95 are worse than in the 1995 base. This increase in predicted flooding raises concerns about potential negative effects on wading bird nesting habitat in this region, which already suffered damage during the 1995-96 high water event. The problem in the Initial Draft Plan appears to be caused by excess discharges from Stormwater Treatment Area-3/4 during high rainfall years. In contrast, to the south of the 3A-3 gage, northeastern and eastern Water Conservation Area 3A are predicted to experience reduced depths and flooding compared to the 1995 base. Since eastern Water Conservation Area 3A has suffered from extreme high water events in recent years, rookery sites in eastern Water Conservation Area 3A might be expected to do better under the Initial Draft Plan than under current conditions. The Initial Draft Plan makes substantial progress toward remedying flood damage to willow strands that serve as wading bird nesting sites in northeastern Water Conservation Area 3A. Tropical hardwood hammocks in southwestern Water Conservation Area 3A, and habitat throughout the Water Conservation Area for island dependent organisms such as nesting reptiles, white-tailed deer, and migratory and nesting songbirds.

Since ATLSS wading bird results are not available for the Initial Draft Plan, predicted effects to wading birds must be inferred from the ATLSS high resolution hydrology results and other sources. A review of performance measures for Water Conservation Area 3A shows that the Initial Draft Plan, compared to the 2050 base, provides mixed results for wading birds in Water Conservation Area 3, with improvements in southern Water Conservation Area 3A (due to reduced high water) and in northern Water Conservation Area 3A (due to reduced drydowns), and losses in northeastern Water Conservation Area 3B (due to increased high water).

However, it is difficult to predict how wading bird nesting and foraging will be affected by changes in depth patterns in northeastern Water Conservation Area 3A. The more northerly parts of this area (represented by model output for the 3A-4 gage) are predicted to become wetter, while to the south, areas east of the Miami Canal will remain deeper than the NSM values, but will have much reduced high water frequencies compared to the 1995 base. These conditions could be expected to improve suitable rookery sites in some areas, but could possibly damage others; and the distribution of suitable foraging areas will undoubtedly be changed. Although overall restoration of the Everglades watershed is expected to improve nesting habitat for wading birds regionally, the timing of development of suitable breeding sites to the south, relative to changes in current nesting sites, could have significant effects on regional wading bird populations. A more detailed analysis of anticipated effects of the Initial Draft Plan on wading bird breeding and foraging habitat, combined with a plan for system-wide monitoring, will be important components in implementing the plan.

ATLSS white-tailed deer results are also not available for the Initial Draft Plan, so predicted effects on deer must be inferred from the ATLSS high resolution hydrology results and other sources. A review of performance measures for Water Conservation Area 3A indicator regions shows that the Initial Draft Plan reduces many of the excessive high water conditions and excessive inundation duration's that had caused concern for eastern Water Conservation Area 3A and southern Water Conservation Area-3A in several previous alternatives. Overall, increased hydroperiods in most of the Water Conservation Areas under the Initial Draft Plan as compared to the 2050 base would likely slightly decrease habitat quality in these marginal deer habitats. Small areas of northeastern and southern Water Conservation Area-3A are exceptions.

K.7.2.4 Water Conservation Area 3B

Under the Initial Draft Plan, Water Conservation Area 3B is neither restored in an historical sense, nor is its current ecological value conserved. Overall, the Initial Draft Plan makes flooding in Water Conservation Area 3B deeper and longer lasting than predicted by the NSM. This pattern represents a substantial deviation from both current conditions in Water Conservation Area 3B and from NSM predictions of the predrainage hydrology. It is doubtful that Water Conservation Area 3B could tolerate much deeper conditions than those seen in the Initial Draft Plan without causing a net degradation in fish and wildlife resources in this area.

Based on the ATLSS fish model results, the Initial Draft Plan hydrologic conditions should produce higher average fish abundances compared with the 2050 base, as expected hydroperiods increase consistent with NSM. In particular, increased hydroperiods in Water Conservation Area 3B should lead to greater fish abundance. This should also be true when only prey-sized fish at appropriate wading bird foraging depths are counted, except for the deepest parts of Water Conservation Area 3B.

Since ATLSS wading bird results are not available for the Initial Draft Plan, predicted effects to wading birds must be inferred from the ATLSS high resolution hydrology results and other sources. A review of performance measures for Water Conservation Area 3B shows that the Initial Draft Plan reduces many of the excessive high water conditions and excessive inundation duration's that had caused concern for Water Conservation Area 3B in several previous alternatives. When compared to the 2050 base, the Initial Draft Plan provides mixed results for wading birds in Water Conservation Area 3, with losses in Water Conservation Area 3B due to increased high water.

ATLSS white-tailed deer results are also not available for the Initial Draft Plan, so predicted effects on deer must be inferred from the ATLSS high resolution hydrology results and other sources. A review of performance measures for Water Conservation Area 3B indicator regions shows that the Initial Draft Plan reduces many of the excessive high water conditions and excessive inundation duration's that had caused concern for Water Conservation Area 3B in several previous alternatives. Overall, increased hydroperiods in most of the Water Conservation Areas under the Initial Draft Plan as compared to the 2050 base would likely slightly decrease habitat quality in these marginal deer habitats.

K.7.3 Threatened and Endangered Species

The preliminary biological opinion of the USFWS transmitted by letter dated August 7, 1998, and certified as the final biological opinion on March 1, 1999 under provisions of the Endangered Species Act included the following determinations concerning effects of the Initial Draft Plan on listed species occurring in the Water Conservation Areas.

K.7.3.1 Effects on Listed Species

The snail kite would likely be slightly benefited overall by the proposed action through improved quality in foraging habitat and a reduction in high water damage to nesting substrate. Although these beneficial effects would slightly improve the species' chances for recovery, the proposed changes are not beneficial in all areas; some areas will likely be improved, while others will be degraded. Therefore, sequencing of project elements will be crucial in ensuring that improved habitat quality is already available to offset anticipated losses in other areas. This will give the species time to adjust to the changing landscape with a low level of risk. The wood stork should be benefited overall due to improved timing and volume of water flow that should substantially increase nesting success, particularly in the estuarine areas of Everglades National Park, adjacent to Florida Bay. The proposed action may adversely affect the bald eagle and indigo snake, but the level of adverse effect is not likely to jeopardize the continued existence of these species.

K.7.3.2 Effects on Critical Habitat

The action would not likely adversely modify designated Critical Habitat for the snail kite. There is no other designated Critical Habitat in the Water Conservation Areas.

K.7.4 Water Management

Water management within the Water Conservation Area region has been substantially modified under the Initial Draft Plan, particularly in Water Conservation Areas 2 and 3. Management of flows to and from the Arthur R. Marshall Loxahatchee NWR (WCA 1) will remain unchanged from existing water management operations.

K.7.4.1 Water Conservation Area 2

The Initial Draft Plan introduced operational changes in Water Conservation Area 2A that improved inundation patterns in the north, but in so doing increased the frequency of extreme drought conditions in the south. It appears that water management in Water Conservation Area 2A imposes tradeoffs between providing improved marsh conditions in some areas but worse conditions in others. It is also possible that restoration of a more natural hydropattern to this portion of the Everglades is hampered by constraints imposed by water management elsewhere, notably the fixed regulation schedule in Water Conservation Area 1 that may be amplifying high and low water conditions in Water Conservation Area 2A. If rainfall based operational rules are adopted for Water Conservation Area-1 in the future, such unnatural fluctuations in depth in Water Conservation Area 2A may be alleviated.

The overall most significant component affecting performance in Water Conservation Areas 2A and 2B is the Central Lake Belt storage facility, which takes water from southern Water Conservation Area 2B (as well as from eastern Water Conservation Area 3A and 3B) and routes it to the Central Lake Belt reservoir for later delivery to Everglades National Park or other areas. This design leads to continued flow through and a very different set of water management issues than those of the present C&SF Project. Rather than exhibiting high water in the south combined with over-drainage in the north, as is currently the case in all of the Water Conservation Areas, the Initial Draft Plan predicts longer hydroperiods near the Stormwater Treatment Area 2 input in the north, increased drying in the south, and accumulation of water at the "bottom" in Water Conservation Area 2B. As a result, those areas that most closely match hydrologic performance targets are those nearest to the locations of gages that trigger inflow/outflow operations. A more detailed study of the effects of different operational rules will be needed in order to identify the ecologically most beneficial method of water management for this region.

K.7.4.2 Water Conservation Area 3

A number of components in the Initial Draft Plan lead to significant predicted changes in hydrologic conditions in Water Conservation Area 3A. Those components having the most direct effects on the conservation area are: (1) the changes in the location and magnitude of water deliveries along the northern and western boundaries; (2) the Central Lake Belt reservoir and its operation; (3) the L67-A canal and levee changes; and (4) the removal of the L-28, L-28 tieback, and L-29 levees.

The Initial Draft Plan came closest to providing conditions that are more NSM-like throughout WCA 3. The natural slope of the land directs water toward the eastern boundary of Water Consesrvation Area 3A and Water Conservation Area 3B. A persistant problem in all the alternatives was that water tended to pond on the eastern sidees. Only D-13R came close to solving this problem. It did so by using a combination of 1) using the L-67A canal to speed flows south, 2) removing the L-28, L-28 Tieback, and L-29 to restore flows, and 3) developing a conveyance system east of the L-30 and L-33 levees (including the Central Lake Belt) to compensate somewhat for loss of the eastern Everglades. While depths and inundations increase in the eastern Everglades in the Inditial Draft Plan, conditions are not as extreme as earlier plans and hydropatterns resemble an Everglades slough system. In addition, the Initial Draft Plan predicts a lower frequency of extreme high water events than that predicted for the 2050 base, although 2050 base conditions in Northeast Shark River Slough are far drier than their restoration targets.

K.7.4.3 Holey Land Wildlife Management Area

The principle hydrological restoration needs for the Holey Land Wildlife Management Area are: the provision of clean water during both wet and dry seasons, in quantities suitable to provide natural hydropatterns; the avoidance of extreme high water events that would drown remaining tree islands and promote cattail proliferation; the gradual increase in hydroperiods and water levels over time until a final hydrologic regime is implemented and; the prevention of extreme drought conditions that cause soil oxidation and risk of muck fires. Although the Restudy alternatives do not include significant structural alterations to the Holey Land Wildlife Management Area, the Initial Draft Plan contains some potentially beneficial components, including: (1) an inflow/outflow operational schedule that would deliver water to the Holey Land Wildlife Management Area during dry as well as wet seasons; and (2) rainfall based operational rules that provide for natural depth variations, but with high and low limits imposed to prevent extreme flood or drought conditions; and (3) improvement of additional outflow structures in Holey Land Wildlife Management Area as needed to support the outflow operations. The overall performance of the Initial Draft Plan appears to be largely satisfactory in the Holey Land Wildlife Management Area.

K.7.4.4 Rotenberger Wildlife Management Area

The principle hydrological restoration needs for this area are: the provision of clean water during both wet and dry seasons, in quantities suitable to provide natural hydropatterns; the avoidance of extreme high water events that would drown remaining tree islands and promote cattail proliferation; and the prevention of extreme drought conditions that cause soil oxidation and risk of muck fires. Although the Restudy alternatives do not include significant structural alterations to this Wildlife Management Area, the Initial Draft Plan contains some potentially beneficial components, including: (1) an inflow/outflow operational schedule that would deliver water to the Rotenberger Wildlife Management Area during dry as well as wet seasons; and (2) rainfall based operational rules that provide for natural depth variations, but with high and low limits imposed to prevent extreme flood or drought conditions. The overall performance of the Initial Draft Plan appears to be largely satisfactory in the Rotenberger Wildlife Management Area.

K.7.5 Water Quality

The below discussion is excerpted from an analysis of water quality affects on the Water Conservation Area region conducted by the U.S. Environmental Protection Agency, and Florida Department of Environmental Protection (FDEP).

K.7.5.1 Water Conservation Areas

The primary pollutant of concern in the Water Conservation Areas and Rotenberger and Holeyland Wildlife Management Areas is phosphorus. A principal assumption for purposes of evaluating the effect of the Initial Draft Plan on water quality in the Water Conservation Areas is that the Everglades Forever Act is fully implemented, and that all discharges into Everglades Protection Area comply with all water quality criteria, including the yet-to-be-established phosphorus criterion. Accordingly, the evaluation focused upon projected increases and decreases of structural flows into the Water Conservation Areas.

Other pollutants/constituents of concern in the Water Conservation Areas and Rotenberger and Holeyland Wildlife Management Areas include nitrogen compounds (NOx), dissolved oxygen, conductivity, and mercury.

Many of the components of the Initial Draft Plan are designed to achieve hydrologic targets in Loxahatchee National Wildlife Refuge (Water Conservation Area 1) and Water Conservation Areas 2 and 3 and downstream in Everglades National Park and Florida Bay. Generally, these components are to be operated to increase the volume of water delivered into and retained in the Water Conservation Areas and to optimize the timing of those deliveries. The following components are expected to affect hydrologic conditions in the Water Conservation Areas and downstream in Everglades National Park/Florida Bay:

Modified regulation schedule for Lake Okeechobee to provide increased environmental deliveries to the Water Conservation Areas and Everglades National Park;

Rain-driven operations in Water Conservation Areas 2 and 3 to improve hydropatterns and hydroperiods in the Water Conservation Areas and Everglades National Park;

Water Conservation Area 3A/3B levee seepage management;

Western C-11 basin diversion (eliminates discharges of urban runoff to eastern Water Conservation Area 3A via S-9 pump station);

Central Lake Belt Storage Area, operated to improve hydropatterns and hydroperiods in Water Conservation Area 3B;

Additional water control structures between Water Conservation Area 3A & 3B;

Lake Okeechobee aquifer storage and recovery to increase storage of lake water for environmental and water supply deliveries;

Increased capacity of Everglades Construction Project pump station G-404 to improve hydropatterns and hydroperiods in Water Conservation Area 3A;

Internal L-7 and L-40 canal structures to improve hydropatterns and hydroperiods in Water Conservation Area1 (LNWR);

Decompartmentalization of Water Conservation Area 3 to reestablish ecological and hydrologic connection between Water Conservation Area-3A and 3B and NESRS;

Relocation and increase in capacity of pump station S-140 to improve hydropatterns and hydroperiods in central Water Conservation Area 3A;

Increasing capacity of S-150 to discharge Lower East Coast water supply deliveries to US 27 borrow canal (potential adverse impact in Water Conservation Area-3A associated with relocation of Miami canal water supply deliveries to North New River Canal);

Storage of excess flows in Water Conservation Area 3A and 3B in Central Lake Belt storage area, to be returned to Water Conservation Area 3A to achieve preferred hydropatterns and hydroperiods;

Conservation of water use in Lower East Coast; expected to benefit Water Conservation Areas through reducing water supply demand from Water Conservation Areas/regional system;

L-28I levee modifications;

Storage of excess flows from Water Conservation Area 2A & 2B in Central Lake Belt storage area, to be returned to Water Conservation Area 3B to achieve preferred hydropatterns and hydroperiods.

Collectively, these components will result in an increase in the average annual volume of water (and phosphorus and nitrogen loads) delivered to the Water Conservation Areas compared to current (1995) and future (2050) base conditions. Utilizing the water budget data generated from the SFWMM simulations of the base conditions and the alternatives, 31-year average structural flows into the Everglades Protection Area are projected to increase from approximately 2,092,000 acre-feet per year (2050 base condition) to 2,181,000 acre-feet per year in the Initial Draft Plan (SFWMD, 1998).

The projected increase in average annual volume is not, however, simply an accumulated incremental increase for all of the existing and proposed water control structures discharging into the Everglades Protection Area. For example, the volume of water delivered by some of the structures contained in the Initial Draft Plan discharging water into the Water Conservation Areas is predicted to increase greatly (e.g., S-140 pump station, 31-year average increase in volume is approximately 285,000 acre-feet; S-150 pump station, 31-year average increase in volume is approximately 32,000 acre-feet), whereas other structures will be significantly decreased (e.g., S-9 pump station, 31-year average decrease in volume is 185,000 acre-feet; S-190 water control structure, 31-year average decrease in volume is 89,000 acre-feet, 2050 base flows from S-190 eliminated.

Decreases in average annual structural flows containing significant pollution loads (e.g. S-9, S-190) would be expected to improve water quality conditions in those areas within the Water Conservation Areas impacted by those discharges. Conversely, increases in structural discharges (e.g., S-140, S-150) may create potential water quality problems if treatment strategies are not included in the Initial Draft Plan. For modified pump station S-140 in particular, the majority of the projected increase in volume is flow out of Stormwater Treatment Area-3\4 directed west along the L-5 and L-4 borrow canals via modified pump station G-404. However, a portion of the water discharged via S-140 would include runoff from cattle pasture on the Seminole and Miccosukee tribal reservation lands adjacent to northwest Water Conservation Area-3A. The Seminole Tribe has identified treatment facilities for discharges from the Big Cypress Reservation.

The affect of in flows and attendant pollution loads into the WCAs resulting from the implementation of IDP components will be evaluated in future detailed design studies and may affect the final design of treatment facilities. Implementation of the IDP is not expected to alter mercury concentrations (which is primarily atmospheric in origin), or conductivity within the canals and marsh areas. Similarly, dissolved oxygen levels are not expected to be affected by IDP components.

Even with such modifications in place, the net phosphorus load delivered into the Everglades Protection Area may increase compared to projected 2050 base conditions as a result of the Initial Draft Plan. However, any increase in the net phosphorus load delivered to the Water Conservation Areas and Everglades National Park would be delivered at a concentration which would not cause the numeric phosphorus criterion to be exceeded.

K.7.6 Water Supply

With the removal of the southern confining levees of Water Conservation Area 3A and 3B, their present water supply function as a project purpose through water management would be replaced by a water supply function that is incidental to the water levels maintained for ecosystem restoration purposes. There is no specific water supply function served by the Holey Land and Rotenberger Wildlife Management Areas.

K.7.7 Socio-Economics

The Water Conservation Area region generates indirect income to neighboring counties through tourism (including private and Tribal airboat concessions) fishing, hunting and other recreational activities that occur in this area. The Water Conservation Areas, do not support residential development, other than that which exists outside of the perimeter levees, and about two dozen private camps, based mostly on tree islands within the Water Conservation Areas. The Initial Draft Plan is expected to lead to significant improvement in fish and wildlife habitat, and has been predicted to improve habitat for alligators, increases in forage fish populations, and improved foraging and nesting success for colonial wading birds, among other wildlife. These improvements may cause an increase in visitation and possibly prolonged stays in and near the Water Conservation Areas by these visitors. Therefore, the indirect income generated by Water Conservation Area regional visits by sportsman, tourists and day visitors can be expected to increase, relative to 1995 and 2050 base conditions.

K.7.8 Land Use

There will be no impacts on land-use within the Water Conservation Areas or within the Holey Land and Rotenberger Wildlife Management Areas. They will remain as undeveloped wetland areas.

K.7.8.1 Agriculture

There are no active agricultural practices within the Water Conservation Areas or within the Holey Land and Rotenberger Wildlife Management Areas.

K.7.9 Recreation Resources

If native wildlife populations, especially large consumers (alligators and raptors) and wading bird colonies, increase substantially under the Initial Draft Plan as predicted, there will be a greater abundance of "watchable wildlife" within the Water Conservation Area region. This should increase visits to the region for bird watching, photography and other wildlife-related recreation. The removal of certain levees and filling in of canals will result in a certain adverse impact to recreational fisheries and boater and possibly bicycle or pedestrian access. The removal of the L-29 borrow canal will affect fishermen from the area who fish this popular canal by boat and fish along the bank. Several boat launches are also expected to be removed as a result of implementation of the Initial Draft Plan. Filling in 6 miles of the southern end of the L-67A canal, of the 72 total miles of canal anticipated to be filled-in under the Initial Draft Plan, will reduce the size and accessibility of this important state fishery. It will directly impact boater access from several boat launches along Tamiami Trail, although access from Holiday Park, at the north end of the L-67 will still be possible. This fishery, of statewide importance (GFC, pers. comm.) is both a popular and important one, particularly for large-mouth bass fisherman. The construction of several in-ground and above ground storage reservoirs and new canals (413 total miles of new levees/borrow canals is planned for the Initial Draft Plan), several within the Lower East Coast are being proposed under the Initial Draft Plan. Depending on the ultimate purposes of these facilities, they represent a potential significant fishery and recreational resource, which could offset or even surpass that, lost through the degradation of existing open water bodies used for boating and fishing. For a detailed discussion of recreation resource affects, reference Annex A, GFC, Fish and Wildlife Coordination Act Report.

K.7.10 Aesthetic Resources

Removal of the L-29 levee and bridging of part of Tamiami Trail should lead to an improvement in the visual aesthetics along the southern Water Conservation Area boundary. This is a busy highway, and travelers should now be able to appreciate the viewscape of the Everglades with greater ease with removal of the L-29 levee. More NSM like flows and water stages within the Water Conservation Area region is expected to lead to enhanced conditions for wildlife. Greater numbers of animals, including wading birds and raptors, may enhance the wilderness aesthetic to the casual observer. Also, the viewer who penetrates into the marsh and slough system of the central Everglades, would be expected to observe a healthier, sustainable and more vibrant native plant community among the marsh, slough, and tree island communities. Signs of stressed and dead trees on tree islands, as was evidenced during recent high water events, would be expected to be reduced under the Initial Draft Plan.

K.7.11 Unavoidable Adverse Environmental Effects

Implementation of the Initial Draft Plan should not result in any net ecologically adverse effects within the Water Conservation Areas or the Holey Land and Rotenberger Wildlife Management Areas in excess of that expected under the 2050 base condition.

K.7.12 Relationship Between Short-Term Uses and Long-term Productivity

Construction of the structural features of the Initial Draft Plan and the physical removal of the existing structural features called for in the plan would cause minor short-term environmental impacts on wetland habitats, aesthetics, and air and water quality. These would be immeasurably offset by the long-term beneficial effects of ecosystem restoration that would subsequently occur.

K.7.13 Irreversible and Irretrievable Commitments of Resources

There would be no irreversible and irretrievable commitments of resources other than the human and economic resources utilized in constructing the plan. All of the physical changes that would be implemented could be decommissioned just as those constructed in the original C&SF Project are now proposed to be.

K.7.14 Cumulative Effects

The proposed action in the Water Conservation Areas and Holey Land and Rotenberger Wildlife Management Areas would act cumulatively with other elements in the Initial Draft Plan to provide significant ecosystem restoration in the Everglades. No cumulative adverse effects are anticipated.

K.8 LOWER EAST COAST AND BISCAYNE BAY

The following presents a discussion of affects to the various resources within the Lower East Coast region, including the developed areas east of the Everglades

Protection Area, within Broward, Miami-Dade, and Palm Beach Counties. The Lower East Coast region also includes Biscayne Bay.

K.8.1 Vegetation

The Initial Draft Plan includes deep water (depth > 4 feet) and shallow water (depth < 4 feet) above ground storage reservoirs. Both types of reservoirs will provide habitats different from existing natural wetlands in the area. Any deep-water reservoir sited over an existing wetland system will convert wetland to open water habitat. Shallow water, above ground impoundments used as Storm Water Treatment Areas will create wetland habitat for the portion of the year they are flooded. This wetland will be different in character than existing vegetation (it will flood more deeply and have a longer hydroperiod).

All proposed below ground reservoirs are sited in the vicinity of existing rock mining operations and in areas deemed suitable for rockmining by the Miami-Dade County Lake Belt Plan Implementation Committee. Existing rock mines were former wetlands. Areas permitted for future mining are currently wetlands or converted wetlands. Wetland losses resulting from previously permitted mining operations will be mitigated for under a Lake Belt Plan currently being developed. The C-51 and southern L-8 Reservoir, composed of 1,200 acres and 40 feet of working storage depth is sited in Palm Beach County. This site was upland that has been converted to farmland. Building this reservoir will not impact existing wetlands.

The western half-mile of the proposed C-9 stormwater treatment area is currently a wetland system. This wetland will be converted to an above ground impoundment (stormwater treatment area), reducing the acreage of short hydroperiod natural wetland in the subregion. The stormwater treatment area will also provide improvements to surface water discharges to WCA 3A by reducing pollutants and high flow events.

No adverse effects on wetlands or other sensitive natural lands are expected as a consequence of siting aquifer storage and recovery facilities, including wells, pumps and reservoirs. Many of the aquifer storage and recovery facilities will be sited in areas considered having less potential for wetland and natural resource value. Siting will be adjacent to existing canals or associated with reservoirs and will not cause additional impacts to existing wetlands.

The impacts of the use of seepage barriers on adjacent and eastern (down gradient) wetlands must be evaluated. In addition, the impoundment effects of these structures upgradient must be more thoroughly investigated. The costs and technical feasibility of removing these structures are unknown. These structures would constitute irretrievable and irreversible commitment of resources and further analysis of the impacts of these structures is necessary.

Interim targets for Biscayne Bay were used in the alternative evaluation process. Models are currently being developed to better identify the water quantity and quality needs of Biscayne Bay. Except for flows out of North Biscayne Bay (G-58, S-28, S-27), existing surface flows to Biscayne Bay were modified by the Initial Draft Plan. Flows out of Snake Creek (S-29) exceed the wet season target by 15 percent and dry season flows are short of the target by 72 percent. Annual surface flows out of the Miami River (S26, S-25B, S-25) were reduced by 69 percent when compared to the 1995 base flows. Both wet and dry season flows to Central Bay (G-97, S-22, S-123) are below targeted flows. Wet and dry season flows to South Biscayne Bay exceed the targets by 13 percent and 27 percent, respectively.

In general, maintaining existing flows are expected to continue to support existing seagrass and coastal communities. Decreasing existing flows or failing to meet targets may result in increased salinity thereby depressing productivity and/or seagrass cover. Until further studies are conducted, it is unclear as to the effects of significantly reduced flows from the Miami River. However, due to the amount of channelization which has occurred over the past 100 years including Government Cut, decreases in flows from the Miami River may have little deleterious impact upon vegetation in Biscayne Bay.

Additional dry season flow to Biscayne Bay in south Miami-Dade County, coupled with the overland flow distribution network Other Project Element, the Biscayne Bay Coastal Wetlands Project should benefit the coastal areas and may maintain a more stable coastal estuarine community nearshore. While algal and seagrass communities currently dominate the estuarine zone in this area, redistributing the pulse, high flow discharge events across the mangrove wetlands are expected to benefit coastal and submerged plant communities. Until further modeling is conducted, the effects of “more estuarine” conditions upon existing sea grass communities remains unclear.

The additional flows in south Miami-Dade are from treated wastewater provided by the proposed south Miami-Dade County Reuse Facility. The potential exists to increase nutrients, particularly phosphorus, loading to southern Biscayne Bay as a result of this component. If water quality is not consistent with ambient water quality of the mid-portion of South Biscayne Bay, then the wastewater reuse component could have a negative impact on submerged aquatic vegetation. Sea grasses would potentially become overgrown with epiphytes and in some areas undesirable planktonic or benthic algae may encroach.

Severely decreased freshwater to north Biscayne Bay from Snake Creek may negatively impact this extremely restricted area, and decrease the extent of seagrass cover due to stress. It may also depress productivity of this area due to decreased inflow and restricted circulation. Projected discharges from Snake Creek would be expected to cause significant fluctuations in salinity, which may adversely affect existing vegetation.

K.8.2 Fish and Wildlife

The Initial Draft Plan will restore estuarine and marine conditions in Lake Worth Lagoon and enhance estuarine conditions in Biscayne Bay. Substantial fish and wildlife benefits will be provided to both systems. Restored seagrass and desirable algal communities in Lake Worth Lagoon should be recolonized. Many important fishery species including spotted seatrout, mangrove snapper and others should benefit. Establishing more estuarine conditions in southern Biscayne Bay by improving the timing and distribution of flows and increasing dry season flows should provide improved habitat for juvenile fish and fish that spawn under estuarine conditions. In southern Biscayne Bay, if more estuarine conditions are achieved using freshwater with water quality that constitutes a nutrient loading, there may be impacts to water clarity and some hardbottom communities. However, if water used to achieve more estuarine conditions is comparable in quality to that of the main portion of southern Biscayne Bay, then fish nursery habitat within the bay will improve.

In the terrestrial sections of the Lower East Coast, improved hydroperiods should improve wetlands and conditions for the organisms associated with them. Some of the water storage areas with long (twelve-month) hydroperiods should support a viable freshwater fish population. These areas could become forage areas for a number of piscivorous animals including birds, reptiles, and mammals.

Significant benefits to wildlife are anticipated if the Bird Drive Recharge Area is operated to enhance wetlands. Additionally, the increased freshwater to the North Fork of the New River and Pond Apple Slough in Broward County should enhance the wildlife in those areas.

K.8.3 Threatened and Endangered Species

Increasing estuarine conditions in the nearshore environment of southern Biscayne Bay should provide suitable habitat for the American Crocodile. Increasing freshwater flow, compared to the 2050 base, should decrease salinity in the nearshore environment and provide nursery habitats for crocodile hatchlings. If the salinity is low enough, favorable habitat for the reproduction by adult crocodiles will be restored. Additionally, the manatee is expected to benefit from increased freshwater flow to southern Biscayne Bay. Greater freshwater input should favor colonization of the bay bottom by seagrasses, an important food source for manatees.

Generally, threatened and endangered plants in the Lower East Coast will not be affected by the Restudy components. Threatened and endangered fish and wildlife should benefit. Longer hydroperiods in the western sections of the Lower East Coast should produce greater numbers of forage fish for wading birds, wood storks and bald eagles. In addition, the US Fish and Wildlife Service noted in its biological opinion on the Initial Draft Plan, that the endangered Eastern Indigo snake may be present in one or more areas proposed for water storage, and that some mortality of this species may be expected. The Cape Sable seaside sparrow, known to exist in the Southern Glades Wildlife Management Area, is expected to benefit due to increased hydroperiods and reduced fire periodicity of essential breeding habitat.

K.8.4 Water Management

The proposed changes in water management associated with Biscayne Bay will be due to structures associated with the overland flow distribution of discharges and the addition of reuse water to Biscayne Bay's water budget. Reuse water discharged to Biscayne Bay will be treated with superior technology and will meet the stringent low nutrient levels of the main bay and the coral communities of the Biscayne National Park.

No adverse impacts on flood protection are expected as a result of any of the seepage barrier or seepage control methods proposed by the Initial Draft Plan. However, further analysis is needed to assess impacts to adjacent agricultural areas and to verify that components are designed to function so that the rise in groundwater elevation will not cause a loss of storage in the affected area. Alternatively, seepage impacts will be mitigated through the addition of seepage pumps and improved or new secondary collection systems. In addition, the effects of these barriers on prevailing groundwater movement and gradients must be evaluated with respect to their impacts on existing groundwater contamination sites, landfill leachate plumes, and well field drawdown zones.

Excess water from the South Miami-Dade Wastewater Treatment Plant (SDRWTP) with superior treatment technology will be sent to deep injection wells to avoid impacting flood protection. Since the overland flow aspect of this component was not modeled, further analysis is needed to assess effects upon neighboring agricultural lands. The future West Miami-Dade Wastewater Treatment Plant (WDWTP) with superior treatment technology will send reclaimed water to the Bird Drive Recharge Area. Excess water, when available, will be sent to the South Miami-Dade Conveyance System, and Northeast Shark River Slough, to offset regional supplies, and lastly, deep injection wells.

The effects of above ground storage on flood protection will be positive. Creating storage areas within a drainage basin and pumping surface water into storage areas during storm events will reduce the occurrence of flooding in that basin and reduce the volumes of runoff reaching canals during storm peaks. This will allocate larger shares of the canal's capacity to the remaining drainage basin and allow faster drainage of flooded lands. The storage areas will discharge off peak, when the canal capacity is restored, or retain the peak flow to meet future demands on the regional system. The western C-4, C-9 and Hillsboro basins are currently flood prone basins. Above ground storage areas should greatly reduce flooding in those areas during storm events. However, improvements to the C-9 and the local stormwater infrastructure may be required due to increased stages at S-29 over existing conditions.

The effects on flood protection by in ground storage areas will be positive. In ground storage, and pumping to this storage during storm events, will reduce the occurrence of flooding, and reduce the volumes of runoff reaching canals during storm peaks. This will allocate larger shares of the drainage canal's capacity to other parts of the basin, and allow improved rapid flood drainage on these lands. The storage areas will discharge off peak when the canal capacity is restored or retain the peak flow to meet demands later. The difference in flood protection between above and below ground storage is that the below ground storage area will not require seepage collection and control because water is not stored above existing groundwater table elevations.

The below ground storage area adjacent to the L-8 Canal, in the southern L-8 basin and the Indian Trail Improvement District, will provide flood protection currently not provided to this area by the regional system. The North Lake Belt Storage Area (NLBSA) will provide a greater level of flood protection to the flood prone western C-9 basin. Runoff from the western C-11 basin is currently discharged to WCA 3A via the S-9 pump station. The construction of the NLBSA will allow the runoff currently discharged from the S-9 to be redirected, reducing pollutant loads to the Everglades Protection Area. The western reach of the C-6 Canal will also be back-pumped to NLBSA. This will require a water control structure in the C-6 Canal holding the water table higher in the area. This is likely to require improvements and/or creation of a secondary drainage system between NLBSA and the C-6 Canal to maintain flood protection in that area.

Aquifer storage and recovery wells in the Lower East Coast are usually associated with a reservoir to store water to feed the wells. These aquifer storage and recovery wells increase the effectiveness of the reservoirs by steadily drawing down the reservoir and creating storage in the reservoir, enabling the next rainfall event to be captured within the reservoir. The Site 1 storage area will be more effective with the addition of aquifer storage and recovery. The use of aquifer storage and recovery results in an additional 78 percent of water captured that was lost to tide under the 2050 base case.

K.8.5 Water Quality

Water quality conditions in portions of the Lower East Coast and Biscayne Bay are currently degraded. Florida Department of Environmental Protection, listed approximately 90 water bodies or segments of water bodies within the Lower East Coast sub-region as not presently meeting water quality standards (FDEP, 1998). Pollutants and constituents of concern include phosphorus, nitrogen compounds (NOx), dissolved oxygen, mercury, coliform bacteria, volatile organic compounds, heavy metals, pesticides, tri-butyl tin (TBT), and salinity.

There are several components in the Initial Draft Plan designed to achieve public water supply and salinity control objectives in the Lower East Coast sub-region (Palm Beach, Broward, and Miami-Dade Counties), and to meet environmental targets in Lake Worth Lagoon and Biscayne Bay. The following components are expected to affect hydrologic conditions in the Lower East Coast:

Southern L-8 basin improvements to enhance water supply function in Palm Beach County Water Catchment Area;

Relocate coastal wellfield operations to minimize threat of saltwater intrusion;

Site 1 reservoir adjacent to Hillsboro Canal; supplemental storage for Lower East Coast water supply;

C-9 Canal impoundment/diversion canal for treatment of water supply deliveries from North Lake Belt Storage Area;

Central Lake Belt storage area; provides regional storage for public and environmental water supply, and salinity control;

C-4 Canal divide structures for seepage control and coastal wellfield recharge;

Bird Drive basin reservoir; seepage control, flood attenuation, and water supply deliveries to South Miami-Dade Conveyance System;

Backpumping of urban runoff from C-17 Canal and C-51 Canal watersheds to supplement water storage/supply in West Palm Beach Water Catchment Area;

Improvements to Miami-Dade-Broward Levee to reduce seepage losses, enhancing Miami-Dade County Northwest Wellfield;

Improve Broward County secondary canal system to enhance wellfield recharge and salinity control functions;

C-51 Canal aquifer storage and recovery water supply and salinity control;

Palm Beach County Agricultural Reserve reservoir to increase water supply storage in central and southern Palm Beach County;

C-111N Spreader Canal; improve flows to Model Lands/ southern Biscayne Bay;

North Lake Belt storage area to provide public water supply, canal stage (salinity) control, and to achieve salinity targets in Biscayne Bay;

Diversion of excess flows out of WCA 3A & 3B to enhance function of Central Lakebelt storage area;

Increased conservation of regional system water delivered to Lower East Coast public water supply/distribution systems;

Reuse of treated wastewater to meet salinity targets in Biscayne Bay;

Higher stages in C-102 and C-103 Canals for urban and environmental (Biscayne Bay) water supply;

C-51 Canal/Southern L-8 basin reservoir to achieve salinity targets in Lake Worth Lagoon, control flooding, and provide additional water supply to Lake Worth Drainage District;

West Miami-Dade County wastewater reuse to enhance ground water recharge and provide additional water supply for salinity control and to meet environmental targets in Everglades National Park.

Construction and operation of these components is expected to result in a net improvement in water quality conditions in the Lower East Coast. Water quality improvements are expected simply through the attenuation function (and attendant pollutant load reduction, particularly nutrients and heavy metals) of the storage components for those surface waters presently discharged to coastal canals and estuaries. Storage and attenuation facilities may also improve bacteriological quality through attenuation of surface waters containing coliform bacteria and will improve dissolved oxygen conditions where existing conditions have been adversely affected by increases in biochemical oxygen demand (BOD) loading. Salinity regimes are also expected to improve consistent with ecological targets.

Additionally, water quality conditions are expected to improve as a result of the incorporation of treatment features into the design and operation of several components. Where the design and operation of a component could increase pollution loads in groundwater or downstream receiving waters through aquifer injection or diversion of surface waters, treatment facilities necessary to meet water quality standards have been included in the design and cost estimates for those components (e.g., chlorination treatment prior to aquifer injection, stormwater treatment areas associated with diverting runoff into reservoirs/storage areas, treatment works at wastewater reuse facilities to produce effluent meeting water quality standards). These facilities, depending upon location and further detailed design (volumes, attenuation times, discharge points), could result in a net reduction of pollutants in receiving water bodies compared to existing and future base conditions.

The beneficial effect of such facilities is not quantifiable at the feasibility investigation stage, for several reasons. First, exact locations of the components and volumes of water added to downstream receiving waters have not been determined. This information will be determined at the detailed design stage of project implementation. Second, and most importantly, existing and projected pollution loads and total maximum daily loads (TMDLs) in receiving waters affected by the operation of the components of the Initial Draft Plan necessary to achieve ecologically sustainable conditions have not been determined, particularly for nutrients. According to Florida Department of Environmental Protection's draft 1998 303(d) list, 90 of the 169 listed water bodies and/or segments of water bodies designated by the Florida Department of Environmental Protection as not meeting water quality standards criteria in the Restudy area are within the Lower East Coast sub-region (FDEP, 1998). TMDLs have not been established for any of these water bodies.

There is a concern that the water from the reuse plant must be as clean as the water naturally found within the main portion of south Bay. With the volume of reuse water to be supplied, a slight increase in nutrients or contaminants from background levels could generate a huge nutrient or contaminant load for Biscayne Bay. The reuse facilities will utilize superior technology and provide suitable water quality. The facilities should, at a minimum, remove total phosphorus and nitrogen to background levels of the main portion of southern Biscayne Bay and should not increase pollutant loading to the bay. Data analysis conducted to date by the Biscayne Bay Water Quality Group has identified main bay background levels for total phosphorus of 5ppb, nitrite/nitrate of 10 ppb, and dissolved total nitrogen of 20 ppb.

While it is expected that components of the Initial Draft Plan would improve water quality for Lake Worth Lagoon and Biscayne Bay compared to existing and projected future conditions additional analysis is needed to fully quantify the water quality objectives for these areas. Construction and operation of those components of the Initial Draft Plan affecting hydrologic conditions in the Lower East Coast are not expected to affect mercury concentrations and loads, the primary source of which is atmospheric deposition.

Some of the seepage management proposed for west of Biscayne Bay may impact the groundwater resources feeding into Biscayne Bay. Groundwater recharge is a natural cleaning process and much of the water entering the bay through the groundwater is very clean.

K.8.6 Water Supply

The SFWMM's predicted frequency of water restrictions over the 31 year period of record indicate that North Palm Beach County and Lower East Coast Service Area 1 have exceeded their targets under the Initial Draft Plan, with one year less of water restrictions than the target. The model output for Lower East Coast Service area 2 and Lower East Coast Service area 3 display 2 and 1 additional years of restrictions above the target, respectively. In the Lower East Coast, water supply should be improved due to deliveries from the regional system in general, holding stages higher in secondary canals and the West Palm Beach Water Catchment Area, and directing regional water deliveries to wellfields.

Canal stages for the primary coastal canals are maintained and meet their respective saltwater intrusion criteria. The C-51, C-17, C-16, C-15, C-14, C-9, C-6, C-4, C-2, and Hillsboro Canal will prevent saltwater intrusion into the Biscayne Aquifer by maintaining regional groundwater levels. There is a reduced potential for localized saltwater intrusion due to increased well field demands

In general, the control of saltwater intrusion into the Biscayne Aquifer in Miami-Dade County improves as a result of the Initial Draft Plan in that the majority of canal stages at the salinity control structures are being held at or above saltwater intrusion criteria. However, saltwater intrusion criteria have not yet been developed for the southern portions of the Biscayne Aquifer in Miami-Dade County and, therefore, the adequacy of the Plan in controlling salt encroachment in that area needs further assessment.

Above ground impoundments are designed to capture stormwater being lost to tide during a rainfall event. The stormwater directed to an impoundment will be stored and then used to meet demands during a drier time. It is anticipated that storage within the above ground impoundments will not be available over extended dry periods due to evapotranspiration (ET) and seepage losses.

The below ground impoundments work much the same as above ground impoundments, only more effectively. Whereas building the above ground impoundments will increase seepage and evapotranspiration losses over base conditions, the in-ground storage areas will be rock mines. ET will not increase beyond what is expected. Seepage barriers are proposed for these areas to eliminate water infiltrating into the surrounding ground water table.

Stormwater treatment areas in the Everglades Agricultural Area require maintenance of water six inches above the surface to prevent drying out, otherwise stormwater treatment areas lose their water cleansing function if they dry out. During dry periods, these stormwater treatment areas are water consumers. The stormwater treatment areas proposed along the Lower East Coast do not need to be wet at all times. However, to maintain a viable wetland for treatment, certain minimum criteria for water levels below ground surface must be met. Under dry conditions, water levels must not be less than 1.0 - 1.5 feet (depending on soil type) below ground surface for 30 days or less with a frequency of not more than one in four years (SFWMD, 1998).

The positive effects of regional aquifer storage and recovery on water supply are due to their use in conjunction with above ground reservoirs. Aquifer storage and recovery increases the efficiency of above ground reservoirs more efficiently by providing long-term storage and efficiently capturing stormwater that would otherwise be lost to tide. Long-term storage under ground eliminates losses to ET. In addition, pumping stored water out of the impoundment and into the regional canal system regains storage capacity within the impoundment that will be used to capture flows from the next storm.

K.8.7 Socio-Economics

Many significant socio-economic effects can be expected from the implementation of a plan as large and complex as the Initial Draft Plan. Three potential areas of impacts have been identified. One area of impact within the Lower East Coast would be the effects of the taxing and spending needed to implement the alternative. The second will reflect the economic impacts due to the utilization of resources to meet project purposes instead of the economic purposes they would be used for without the project. The third will consider the potential impacts due to project output. All these impacts will be the result of complicated economic interactions that can be identified, but not be quantified within the scope of the Programmatic Environmental Impact Statement.

Some of the potential impacts and factors influencing the significance of the impacts that are related to the taxing and spending associated with project implementation are: Federal funds used to implement the Initial Draft Plan will almost entirely be additional expenditures and will increase economic activity throughout the project area. State funds used to implement the Initial Draft Plan will to a significant extent represent additional expenditures and will also increase the economic activity throughout the project area. Taxes raised by the local sponsor, the South Florida Water Management District, will come largely from the Lower East Coast, while a portion of the expenditures will be on projects outside this area. This will tend to decrease economic activity within the Lower East Coast. Because of the economic dominance within the study area, businesses in the Lower East Coast will capture some of the additional business generated by the project and the operations and maintenance of the projects outside the Lower East Coast. If the local funds are raised by the issuance of a bond, the increase in economic activity will occur when these bond funds are spent. On the other hand, the decrease in economic activity caused by the taxes to pay off the bonds will occur gradually over an extended period of time. A significant portion of the funds will be used for land purchases, and land purchase only represents a change in wealth form, and does not directly effect economic activity. These transactions will diminish the significance of the spending on the economy of the Lower East Coast area.

Other impacts are those due to the utilization of resources to meet project purposes instead of the economic purposes they would be used for without the project. This would occur, for instance, if land that was in agriculture is purchased for a project reservoir and there were no economically feasible sites to transfer the agricultural production. Some of the lands proposed for the water preserve area and reservoirs in the Lower East Coast area would probably have had an urban land use, especially low density residence, as the alternative land use. These urban land uses can generally be accommodated on other vacant lands, or by increased density elsewhere. Furthermore, the Lake Belt reservoirs are not expected to diminish the land use for rock mining or impinge on productive agriculture land since permitted rock mines will complete their desired excavations. One exception to this is the Palm Beach County reservoir; it is proposed for location in the agriculture reserve in Palm Beach County. Thus, the implementation of the Initial Draft Plan will remove a substantial amount of this Palm Beach agricultural reserve land out of production and represent a loss of revenue.

The third type of impact is the impacts of project outputs. Flood control and water supply improvements provided by the project are not expected to alter the nature or intensity of agriculture or urban development in the Lower East Coast. However, impacts to urban and landscape due to public water supply shortages are expected to be reduced as a result of the project. Larger economic impacts might result from the environmental improvements expected. Potential areas of increased economic activity could include additional recreation in the ecologically restored areas due to increases in wildlife populations, improved fishing or other related characteristics. The environmental improvements will be beneficial to both residents and visitors from outside the study area. The tourists will help to increase the economic activity and are expected to spend a good portion of their vacation expenditures in the Lower East Coast, even when visiting Everglades

National Park or other parts of the project area. Additionally, commercial fishing may improve as a result of improved fish habitat and fish nursery functions in Biscayne Bay and Lake Worth Lagoon.

K.8.8 Land Use

Seepage management should not cause changes to existing land use. Minimal land is required for the wells and physical barrier methods. Where groundwater recharge is proposed by raising groundwater controls, limited development has occurred. The State of Florida will acquire lands where groundwater controls would be raised. Therefore, no changes in the existing land uses are expected as a result of the seepage barrier/control method selected. The seepage control component along eastern Water Conservation Areas 3A and B is located on wetlands. This feature will lengthen the hydroperiods of the adjacent wetlands.

Several thousand acres of land will be needed for above ground storage facilities in the Lower East Coast area on lands deemed suitable, according to the Land Use Suitability Analysis completed in 1997. The in ground storage areas will be located in existing rock mines/borrow pits. Therefore, a land use change from rock mining to storage will occur. The stormwater treatment areas will be located on uplands or impacted wetlands.

K.8.8.1 Agriculture

Agricultural producers in South Miami-Dade County are concerned about the continuation of flood control benefits in their region. As a result of urban sprawl from the city of Miami, agricultural production has shifted westward over the last several years until it now abuts the eastern boundary of Everglades National Park. The close proximity of the park and farming activities has created ongoing water management conflicts between the water needs of the Everglades ecosystem and flood control for the neighboring farmland. The problem is exacerbated by high seepage rates from the park to the east, which tend to dry the park and raise ground water levels and compromise flood control on farmland. The Initial Draft Plan includes levee improvements to L-31N for seepage management to address this issue and help restore hydropatterns in Everglades National Park. The features are intended to eliminate levee seepage throughout the year and eliminate ground water seepage during the wet season. Another component of the Initial Draft Plan is modified C-111 canal operations intended to both improve water deliveries to the Park and decrease potential flood risk to nearby farmland.

The flood control benefits of these components east of L-31N are uncertain. The South Florida Water Management Model (SFWMM) is not intended for use in flooding and flood control estimation due to its coarse spatial scale, and, therefore, only limited conclusions can be drawn regarding flooding impacts to agriculture in this region. Model outputs include simulated ground water levels for specified cells that may indicate if ground water might occur within the crop root zone. Of the seven model cells in this region for which ground water stages were reported, six had stages comparable to or slightly higher than the future without-project condition. These results indicate a level of flood protection comparable to the future without-project condition. Three of the seven model cells do not meet performance targets indicating a possible risk of flood damages in these areas.

The future without-project condition includes the federally authorized C-111 Project and Modified Water Deliveries to Everglades National Park Project. These projects are intended to maintain existing flood control in agricultural areas while restoring specific elements of the park ecosystem. However, due to the limitations of the modeling tools currently available, it is very difficult to determine flooding effects in agricultural areas. Research is now underway to develop field scale modeling applicable to South Miami-Dade County agriculture (Savabi, 1998). When the results of this research become available, flood control in South Miami-Dade County can be more accurately assessed. The effects of the Initial Draft Plan together with the C-111 and Modified Water Deliveries Projects can then be determined. Adverse effects to flood control in this region would compromise the sustainability of agriculture on this unique farmland.

K.8.9 Recreation Resources

The proposed C-111N spreader canal, associated culverts, and backfilling of C-111 (south of C-111N to S-197), C-110, removal of S-197, S-18C, and the construction of an stormwater treatment area is planned to supply Southern Glades and Model Lands. These proposals could produce temporary interruption of use of recreation resources that would cease once construction had been completed. The stormwater treatment area could provide increased recreational fishery resources and subsequent recreation fishing if access is provided.

Other components in the Lower East Coast should provide additional recreational opportunities. The water preserve areas and perimeter canals will be suitable habitat for many of the important recreational fish including bass and sunfish. However, the filling in or degrading various canals could remove these areas from being viable fishing sites.

Overall, the proposed construction of storage reservoirs, seepage control systems, reuse plants, and aquifer storage and recovery, should not adversely affect the total amount of recreation resources in the Lower East Coast. Some temporary interruption of recreation resources could be experienced during project construction but would cease once construction is completed.

K.8.10 Aesthetic Resources

The proposed construction of storage reservoirs, seepage control systems, reuse plants, and aquifer storage and recovery should not adversely affect aesthetic resources. The stormwater treatment areas and storage reservoirs will be similar in appearance to other artificial impoundments in the subregion. Conveyance canals and surrounding levees will be similar in appearance to existing canals and levees. During construction, site preparation will include such typical activities as removal of vegetation, grading by means of heavy machinery, earth-movement, construction of temporary roads, removal and off-site or on-site disposal of excess material, import of fill materials for levees, movements of heavy dump trucks through public roads, etc. These activities will last during the construction phase only, and operations would be planned to minimize disruption to surrounding urban and residential uses. Most adverse visual effects would not persist after construction is complete. Appropriate finishing procedures should be completed to blend the disturbed areas into the landscape.

The proposed C-111N spreader canal, associated culverts, and the backfilling of C-111 (south of C-111N to S-197) and C-110, removal of S-197, S-18C, and the construction of a stormwater treatment area is planned to supply Southern Glades and Model Lands water. These proposals could produce temporary impacts to aesthetic resources that would cease once construction had been completed. Construction of the stormwater treatment area could adversely affect aesthetic resources depending on stormwater treatment area size, design, disposal of excavated material, and proximity to visual corridors and populated areas.

The proposed West Miami-Dade Wastewater Treatment Plant will be located south of Bird Drive and treat wastewater for supply to the Bird Drive Recharge area. Excess water will be directed to the South Miami-Dade Conveyance System, NESRS, or deep injection wells. Adverse effects on aesthetic resources could occur depending on treatment plant size, design, disposal of excavated material, and proximity to visual corridors and populated areas.

K.8.11 Unavoidable Adverse Environmental Effects

Storage areas will modify land use by converting an unspecified amount of upland habitat or natural wetland areas to open water. These land use and habitat modifications represent an unavoidable effect upon the environment whether they are in existing upland or wetlands. Most of the wildlife of the Lower East Coast consists of common species that are tolerant of the dense human population. However, the water storage structures will convert all the area inside their perimeter into open water habitat. The terrestrial wildlife will be displaced to adjoining lands, and some mortality is likely as a result. These impacts will depend on future project development, and site-specific environmental documentation would be prepared at that stage of design.

K.8.12 Relationship Between Short Term Uses and Long Term Productivity

Storage sites, seepage control structures, and water reuse plants represent a significant short-term disruption to the environment, and possible unintentional direct and indirect environmental consequences. Short-term effects due to construction activities (vehicular access, creation of staging and turnaround areas, etc.) such as impacts to wildlife habitat, aesthetics, wetlands, noise, air and water quality will be minimized wherever possible. BMP's to control erosion from construction sites will be implemented to minimize impacts to water quality and sedimentation. It is not possible to predict the type or magnitude of these short-term losses at this stage of the Restudy. However, all the recommended modifications to the water supply and water management system will have an overall beneficial long-term and permanent effect on the Lower East Coast and some of the high quality wetlands in the associated watersheds. The Initial Draft Plan provides the best combination of improvements to water supply and improvements to sensitive regional ecosystems, including the southeastern glades, Biscayne Bay, Lake Worth and other Lower East Coast estuaries.

K.8.13 Irreversible and Irretrievable Commitments of Resources

The proposed construction of storage sites, seepage control structures, and wastewater reuse plants, canals, pumps, levees, and appuerant structures may represent an irreversible and irretrievable commitment of fiscal and land resources. These resources would include lands, state and Federal funding, labor, energy and project materials and equipment to build the storage sites, and the structures associated with the operation of these storage sites.

K.8.14 Cumulative Effects

Overall, the Restudy project elements may cumulatively slow or stop expansion of the Lower East Coast cities toward west of the protected levee, and may make other residential or potentially residential lands more valuable. It will likely prompt county and municipal governments to review and update their comprehensive plans to make them consistent with the new water management functions on site. An increase in development of multilevel structures may be one outcome of the Initial Draft Plan project features within the Lower East Coast.

Restudy project components are not expected to result in a cumulative negative effect to the environment of the Lower East Coast. Project components in the Lower East Coast, especially storage, seepage control, and water reuse plants, will act cumulatively to restore more natural freshwater flows to Biscayne Bay, but should not result in negative environmental effects or effects unfavorable to the restoration of the natural environment.

K.9 EVERGLADES NATIONAL PARK AND FLORIDA BAY

The following assessment includes possible affects of the Initial Draft Plan relative to the 2050 base, and in some instances the 1995 base, in Everglades National Park, including the Florida Bay estuaries, Florida Bay proper, Whitewater Bay, and the Ten Thousand Islands.

K.9.1 Vegetation

This assessment includes separate discussions of affects to vegetation attributable to the Initial Draft Plan within 1) the Everglades ecosystem and 2) within the estuarine ecosystem of Florida Bay, Whitewater Bay and the Ten Thousand Islands.

K.9.1.1 Everglades Vegetation

Vegetation responds directly and indirectly (*eg.* through effects on soil development) to hydrological conditions. Under the Initial Draft Plan, changes in vegetation patterns can be expected in several areas of the southern Everglades. These changes will necessarily include effects on soil production and compositional changes resulting from shifts in the vegetation that overlays them. Under the Initial Draft Plan, maintenance of tree islands, slough, and marsh plant communities can be expected in the deeper sloughs (Northeast Shark River Slough, Shark River Slough, Taylor Slough). Northeast Shark River Slough is expected to benefit from increases in water depths and hydroperiods, including favorable shifts in periphyton communities and an improvement in peat-forming conditions. The greatest degree of vegetation change should occur in the Rocky Glades/Eastern Marl Prairies, particularly among the graminoid plant communities, where conditions for the formation of sawgrass and other long hydroperiod plant communities, will be enhanced. In this area, tree islands (bayheads and hammocks) will reflect the reduction in fire frequencies that should result from increased water levels and duration. Woody plant invasion, including the establishment of “upland-type” exotic tree species, will also be curtailed.

Partial decompartmentalization of the system under the Initial Draft Plan will have significant effects on exotic plants by eliminating the deep-water habitats created by canals that support infestations of aquatic weeds. In addition, the removal of levees and other artificial, elevated sites will curtail the establishment of exotic “upland” woody species and grasses that spread along these corridors and are dispersed into wetland habitats. By approaching NSM conditions, restoring natural fluctuations in hydropatterns, and removing canals and levees, the Initial Draft Plan will reduce exotic plant establishment and spread in Everglades National Park.

K.9.1.2 Florida Bay and Estuarine Vegetation

Submerged vegetation along the coastal basins of the Bay will undergo significant seasonal change under the Initial Draft Plan as opposed to base conditions. Hydrologic performance measures under partial decompartmentalization of the Everglades system would likely lead to an increase in upland, low-salinity, fresh-water associated species such as Widgeon grass (*Ruppia)* and a freshwater alga (*Chara)*; particularly during the wet season in the upstream mangrove-associated creeks/rivers. An increase in shoal-grass (*Halodule*) and widgeon grass (*Ruppia)* would be likely in the four coastal basins during the wet season when compared to base conditions and provide foraging/shelter areas for decapod crustaceans such as juvenile pink shrimp. Increased water flow during the dry to wet season transition period would probably result in a decline of turtle grass (*Thalassia* sp.) in the coastal basins. This response would likely occur during the wet season, mimicking vegetation responses reported for the Whitewater Bay estuary, near the North River mouth during significant fluctuations in salinity prior to the opening of the Buttonwood Canal. Macroalgal green calcareous species, including *Udotea* and *Batophora* would increase, followed by a reduction in attached *Sargassum* communities near the mouth of the North River.

K.9.2 Fish and Wildlife

The following is a discussion of the affects to fish and wildlife resources within the freshwater environment of Everglades National Park and the estuarine environment of Florida Bay and its estuaries.

K.9.2.1 Aquatic Invertebrates and Fishes

The discussion below begins with the lower trophic animals and fishes of the freshwater Everglades and estuarine waters of Everglades National Park.

K.9.2.2 Everglades Aquatic Invertebrates and Fishes

The changes resulting from the Initial Draft Plan in the hydrology and infrastructure of the water-delivery system reflect a positive direction of change for aquatic animals relative to the 1995 and 2050 base conditions. Native fish and aquatic invertebrate communities in the southern Everglades should respond to the changes from the Initial Draft Plan in several ways. The degradation of levees and infilling of canals along the southern and western edges of WCA-3A, and elsewhere, will allow freer movement by aquatic animals across that landscape. Populations that have been virtually isolated since the mid-1960’s will be brought into contact to interbreed. Aquatic animals will be able to move across the landscape between Everglades National Park and Big Cypress National Preserve, or among Everglades habitats, in response to changing hydrological conditions. Presently, and under the 2050 base, movements of these organisms are blocked by levees, which can trap them in unfavorable habitats during dry-down. The reduction of canal habitats under the proposed plan will decrease potential for invasions by non-indigenous aquatic biota into natural habitats and reduce the unnaturally high population sizes of both native and non-native predatory fishes supported by canals. Canals will no longer serve as dry-season sinks for native fish and invertebrates. The removal of canals will allow these organisms to remain in the shallow wetlands where they will be available to wading birds and other predators. This improvement is seen in the ATLSS output for the Initial Draft Plan relative to the 2050 base.

The Initial Draft Plan closely resembles NSM hydroperiod and ponding depths for Northeast Shark River Slough and Shark River Slough. An additional benefit of the Initial Draft Plan was the reduction in the number of drying events for Shark River Slough. This condition should enhance aquatic animal community development and survival.

Currently, the Rocky Glades are among the most degraded aquatic habitat within the southern Everglades. Adequate hydrologic conditions in this area are only marginally recovered under the Initial Draft Plan. In the Rocky Glades, the mean duration of flooding was 12 weeks under 1995 and 23 weeks under 2050 base conditions, respectively, and only improved to 30 weeks under the Initial Draft Plan, compared with 44 weeks in NSM. The timing of this flooding is important to animals. Under a 30 week duration of flooding, water would be above ground surface from approximately June 1 to December. This average annual hydroperiod would create improved foraging conditions for wading birds during the early dry season, but would not recover ideal habitat for marsh fishes. Fish breeding season begins in winter and early spring. A mean duration of flooding of 30 weeks would not coincide with the early portion of fish breeding season, resulting in a truncated breeding season and a concomitant decrease in fish recruitment. Under NSM, flooding duration would last until April, translating into potentially higher recruitment of animals and a shorter amount of time spent in dry season refuges, where mortality is high.

An important hydrological factor that affects the ecology of aquatic animals and plants in the Rocky Glades is water depth below ground surface during the dry season. Although there is not a good measure of this minimum depth range under NSM, it is assumed that it was higher than under the 1995 and 2050 base cases. Back-cast modeling by Everglades National Park hydrologists several years ago supported this assumption (Loftus, Johnson and Anderson, 1992). The lower the water level drops in the dry season, the fewer solution holes remain wetted, thus reducing the survival of aquatic animals and the seed stocks for the following wet season.

Although the Initial Draft Plan went farther than the 1995 and 2050 base cases and most of the previous alternatives in providing hydrological conditions closer to those predicted for NSM, there are still opportunities for improvement either through a future detailed planning stage and/or adaptive management operational strategies. This is clearly shown in the achievement indices of 82 percent and 76 percent for Shark River Slough and the Rocky Glades, respectively.

K.9.2.2.1 Florida Bay and Estuarine Invertebrates and Fishes

Conditions expected under the Initial Draft Plan, when compared to base conditions, particularly along the northern Bay coastal basins, produce better nursery and foraging conditions for juvenile pink shrimp. These improved habitat conditions are expected to occur as a result of a greater frequency in the number of low salinity events in coastal basins. Data on sponges and spiny lobster in the coastal basins, however, are too spotty to predict changes in their populations based on the Initial Draft Plan conditions verses base conditions.

The effects of the Initial Draft Plan onselected larger species of estuarine-dependent, resident or transient sportfish, such as spotted seatrout, snook, and red drum were reviewed Initial Draft Plan salinity conditions appear to be biologically important, demonstrating major improvement over 1995 and 2050 base conditions. Spawning and reproductive conditions are expected to improve for spotted seatrout in Crocodile Point, Terrapin Bay, and Garfield Bight areas. This improvement should result in an increase in distribution and abundance of this very popular sportfish in north-central Florida Bay, based on the decrease in frequency of high salinity events. Although this is a major improvement over base conditions, low salinity conditions (<20ppt) east of Terrapin Bay (Little Madeira and Joe Bays) are less than optimum for spotted seatrout spawning activities. Spotted seatrout reproductive activities would likely move west of this area.

Compared to base conditions, the Initial Draft Plan should also lead to the increased survival, abundance, and distribution of snook. This assessment is based on an increase in lower salinity nursery areas within coastal basins in or near the northern Florida Bay shoreline. The increase in the frequency of desirable lower salinity events, which should improve conditions for red drum from Garfield Bight to Little Madeira Bay. Red drum in Florida Bay are mostly comprised of larger juveniles, subadults and adult-sized fish. The area from Garfield Bight to Little Madeira Bay supports nursery and foraging activities for this species.

The improved salinity conditions resulting from the Initial Draft Plan may be expected to have both positive and negative affects on non-game native and exotic species of fish in the Bay. The distribution and abundance of the smaller, native, non-game, species of fish including benthic, canopy and pelagic resident or transient species (i. e. killifishes, mojarras, gobies, engraulids) may be expected to benefit when the Initial Draft Plan salinity conditions are significantly lower than the base cases. Planktivorous feeding pelagic estuarine species, such as bay anchovy, would be expected to increase during lowered salinity periods, particularly at the tidally influenced western Bay coastal basins than at the east Bay basins. Lowered salinity conditions occur primarily during the wet season, as a result of high rainfall and runoff. Upstream of the Bay coastal basins, the conditions resulting from the Initial Draft Plan would be expected to produce a greater number of low salinity, mangrove associated species, including certain killifishes and livebearers (*Poeciliidae*). Exotic fishes, such as Mayan cichlids, can be expected to show substantial increases in reproductively viable populations as a result of any lower salinity conditions within the freshwater transition zones in the Bay. The problem of increasing reproductive populations of these and other exotic fish due to restoring salinity regimes will occur under any alternative lowering salinity in Florida Bay and must be addressed during detailed design.

K.9.2.3 Alligators

One of the major environmental variables influencing the annual production of alligator hatchlings within Shark River Slough is surface water conditions antecedent to each nesting season. Surface water conditions influence the number of females nesting each year and the resultant total production of eggs. More alligators nest when water conditions are higher in the early wet season. During years in which low water levels occur or there is extensive drying during the late dry season, few females attempt to nest during the subsequent wet season months. For these reasons, a priority for ecological restoration related to alligators in Shark River Slough should be the re-establishment of higher antecedent surface water conditions preceding each nesting season. These antecedent conditions must also follow natural topography and natural rainfall repeat frequencies that occur within the Everglades catchment area. These conditions are best simulated by the Natural Systems Model.

The 1995 base and 2050 base are significantly different from NSM and do not in any way approach restoration of antecedent surface water conditions that are important to alligators. The Initial Draft Plan shows significant improvement over the 1995 and 2050 base conditions in improving antecedent surface water conditions. For the Initial Draft Plan, the late dry season water depths in Shark River Slough suggest that the final drying pool is more persistent over the 31-year evaluation period. Under this alternative dry downs occur only 5-15 percent of the time compared with the current 35 - 45 percent under the 1995 base conditions. Dry downs under NSM, however, are predicted to occur only 5 percent of the time in Southwest Shark River Slough and not at all in Mid-Shark River Slough or

Northeast Shark River Slough. So while the Initial Draft Plan represents a distinct improvement over both base conditions, and can be described as moving towards full restoration, further attention to this issue during the detailed planning phase will benefit the plan overall.

Differences in predicted alligator population sizes for the natural system simulation model compared with proposed water management scenarios, have been related to increased nesting effort and success and reduced drought-related mortality (NPS, 1990). This increased nesting effort was apparently a result of the increased stage duration that occurred during the peak mating period (late April/early May). Although much improved over base conditions, the shortcomings of the Initial Draft Plan in duration of uninterrupted flooding and duration of dry conditions may be biologically significant to the alligator. However, in the absence of an appropriate model for alligators in the Southern Everglades, there is a high degree of uncertainty about these effects.

Major and frequent dry downs, as predicted for the 1995 and 2050 base conditions, also adversely impact aquatic prey populations that are important food sources for alligators. Following major dry downs, several years are required for recovery of aquatic food organisms. Major dry down intervals, occurring as frequently as predicted by the 1995 and 2050 bases, would probably prevent such recovery and lead to a downward trend in overall aquatic productivity and capacity to support higher order consumer populations, such as the alligator. Compared with the base conditions, the Initial Draft Plan should improve overall aquatic productivity in Shark River Slough, benefiting the alligator. However, the frequency and duration of dry conditions remain a problem during the alligator mating season.

In the Rocky Glades/Eastern Marl Prairies, the Initial Draft Plan predicts enhanced hydrological conditions compared with the 2050 base, so it is expected to increase nesting effort, nesting success, and abundance of alligators in this area. There may also be a corresponding increase in the number of occupied alligator holes to serve as drought refugia and increase habitat heterogeneity.

K.9.2.4 Wading Birds

For short- and long-legged wading birds, the Initial Draft Plan shows an improvement over 2050 base conditions. Based on the ATLSS modeling, foraging conditions are slightly improved in the peripheral marshes. Under high rainfall conditions, foraging conditions are better than 2050 base conditions in the peripheral wetlands east and west of Shark River Slough. Under low rainfall, the Initial Draft Plan indicated better foraging conditions compared with 2050 base conditions due to a persistent pool of water in the lower end of central Shark River Slough. The Initial Draft Plan shows an overall improvement in wading bird foraging conditions over both 1995 and 2050 bases. This improvement in foraging conditions should benefit the endangered wood stork.

K.9.3 Threatened and Endangered Species

Of the eighteen listed plant and animal species submitted by letter from the USFWS as likely to be affected by the C&SF Restudy, seven are thought to occur within the affected area of Everglades National Park. A brief description of affects to these State and Federally listed threatened and endangered species follows.

K.9.3.1 Snail Kite

Project modifications, proposed under the Initial Draft Plan, are expected to restore more natural hydroperiods to Shark River Slough and the peripheral wet prairies on the east and west sides of the slough. These hydrological improvements, although still short of NSM, will likely provide conditions beneficial to the snail kite. Overall, across all years, the ATLSS snail kite model predicts slightly higher foraging index conditions along the eastern and western edges of Shark River Slough, under the Initial Draft Plan compared with the 2050 base. There is very little difference between the Initial Draft Plan and 2050 in a typical rainfall year. There is also no difference in snail kite foraging conditions between the Initial Draft Plan and 2050 base in a low rainfall year. ATLSS predicts no suitable foraging conditions in either scenario during a regional drought (such as 1990). In keeping with the vagility of the snail kite in Florida as described by Bennetts and Kitchens (1997), under drought conditions the kite would be expected to disperse great distances to other parts of its potential breeding range. ATLSS predicts that under high rainfall years, the Initial Draft Plan will produce slightly higher snail kite index conditions along the east and west sides of Shark River Slough compared with the 2050 base, and lower index conditions in central Shark River Slough. The Initial Draft Plan is not expected to result in adverse modifications to designated snail kite critical habitat.

K.9.3.2 Cape Sable Seaside Sparrow

The Initial Draft Plan is a improvement over the 2050 and 1995 base conditions, which provides more natural hydroperiods in the peripheral wet prairies that the Cape Sable Seaside Sparrow inhabits. Maintaining longer hydroperiods in the Rocky Glades should curtail the invasion of woody vegetation and reduce the frequency and intensity of fires in sparrow habitat east of Shark River Slough. The results of the ATLSS individual based modeling, in a sub-population west of Shark River Slough, show that the Initial Draft Plan is more conducive for sparrow production than the 2050 base and suggests that the sparrow population could reach higher levels more often under the Initial Draft Plan. Model results show that the Initial Draft Plan produces a more stable sparrow population, which appears to be more responsive to breeding population recovery after a decline than under 2050 base conditions. The Initial Draft Plan is not expected to result in adverse modifications to designated Cape Sable seaside sparrow critical habitat.

K.9.3.3 Wood Stork

The Initial Draft Plan shows an overall improvement in wading bird foraging conditions over both 1995 and 2050 bases. This is supported by both the ATLSS high resolution hydrology results and inspection of the Shark River Slough inundation duration and mainland estuary flow volume information, which show significant improvements in hydroperiods, volume and timing of flows relative to the 2050 base. This improvement in foraging conditions should benefit the endangered wood stork, particularly in the Florida Bay estuaries which historically supported the majority of wood stork nesting.

K.9.3.4 American Crocodile

Freshwater flows to Florida Bay estuaries and Shark River Slough are significantly enhanced under the Initial Draft Plan, relative to the 2050 and 1995 bases. Critical habitat has been designated by the USFWS, and extends throughout Florida Bay and the Florida Bay estuaries from about Turkey Point to Cape Sable. According to acknowledged crocodile experts (F. Mazzotti, pers. comm.) these enhanced conditions extend to critical nesting areas including Little Madeira Bay and Joe Bay, which are among the most critical crocodilian habitat. Implementation of the Initial Draft Plan is reasonably expected to benefit the American crocodile, through increased freshwater flows, and decreased salinities in Florida Bay and Shark River Slough estuarine habitats, including its designated critical habitat.

K.9.3.5 West Indian Manatee

As with the crocodile, increased freshwater flows, and decreased salinities in the Florida Bay estuaries and Shark River Slough will likely benefit, and may greatly benefit, the West Indian manatee. Implementation of the Initial Draft Plan is not likely to adversely modify designated critical habitat for the manatee.

K.9.3.6 Eastern Indigo Snake

Eastern indigo snakes inhabit the pine forests and hardwood hammocks of Everglades National Park. Since hydrologic affects are expected to be largely limited to hydroperiod enhancements to existing or historic wetlands, no significant affects would be expected to this upland reptile species.

K.9.3.7 Florida Panther

The Florida panther is known to utilize upland forested habitats pinelands and hammocks, and generally avoids habitats such as sloughs and mangrove forests. The ATLSS model results showed greatest affects on the white-tailed deer, a preferred panther prey species, to be outside of Everglades National Park, in the Water Conservation Areas. No direct affects on panthers are anticipated within Everglades National Park, although some affects on panther dispersal within their present range may result.

K.9.4 Hydrology

Hydrological patterns are a major determinant of plant and animal communities in the Everglades, so matching historical hydropatterns is a critical step in the restoration of plant and animal distributions. The Initial Draft Plan is a definite improvement over the 1995 and 2050 base conditions. Both base conditions are predicted to constitute serious ecological degradation compared with historical Everglades communities. Positive elements of the plan include reasonable matches with NSM conditions of hydroperiod, ponding depths, timing of flows, and the number of drydown events. The Initial Draft Plan has less emphasis on water deliveries via the Lake Belt flowway and reservoir, which reduces the diversion of water from the natural system.

The partial decompartmentalization of the system (removal of L-28, L-29, L-67C, and the Miami Canal) and the nearly complete decompartmentalization of the northern boundary of Everglades National Park with WCA-3A, under the Initial Draft Plan is one of the most important, positive components of the plan and will lead towards restoration of the system. Mean NSM hydroperiod matches (within 30 days shorter or longer) for the Initial Draft Plan, indicate over 95 percent of the Everglades National Park match or nearly match the performance measures. While this performance measure averages values across several hydrologic basins, it does provide a valuable indices of how well the Initial Draft Plan performs in achieving restoration targets within Everglades National Park. Relative to the 2050 base, the Initial Draft Plan improves hydroperiods in over 51 percent of the total Everglades National Park area. Furthermore, mean NSM ponding depths under the Initial Draft Plan are improved throughout Everglades National Park over the 2050 base, with 100 percent of the area matching NSM compared to about 86 percent for the 2050 base and 81 percent for the 1995 base.

As indicated above, the Initial Draft Plan shows an improvement in achieving NSM like conditions in most areas of Everglades National Park. Several of the important areas within Everglades National Park where the Initial Draft Plan demonstrates an improvement over the 2050 and 1995 bases are discussed below, beginning in the northern area of Everglades National Park and proceeding southwards. In Northeast Shark River Slough just south of the Tamiami Tail and east of the L-67 extension (gages NESRS 1-2), the Initial Draft Plan shows a definite improvement in stage duration, increasing flood stages towards the NSM target, although it does not attain the NSM target in stages > 1.25 feet. Average annual overland flows over the Tamiami Trail into Everglades National Park are improved relative to the 2050 base both east and west of the L-67 extension, conveying over 52 percent more flow volume into Northeast Shark River Slough than the 2050 base in the wet season, and 47 percent more in the dry season. Average monthly flows also show this improvement, varying between 7,000 ac-ft and about 70,000 ac-ft more flow volume into Northeast Shark River Slough between May and October, than that predicted under the 2050 base.

Although flow volume, as modeled by the SFWMM, in this and other areas fall short of the NSM target, it is important to note that flow is actually driven by stage, and stage is the more accurate hydrologic criterion to assess conditions which may then be used to assess ecological affects. It is generally accepted that it is the *products* of NSM such as inter-annual variability, frequency of drydowns, and the duration of uninterrupted hydroperiod that are the critical criteria that hydrologic targets strive to replicate, not an exact match of the NSM hydropattern. The conceptual ecological model for the southern Everglades sloughs suggests that changing patterns of hydroperiod and stage are the hydrological parameters which explain most of the adverse ecological responses in a managed system. Since the hydroperiod and stage targets are largely met, it is reasonable to conclude that the Initial Draft Plan should result in substantially improved conditions for native vegetation, and fish and wildlife habitat.

Downstream of the above area, the rockland marl marsh stage duration (gage G-1502) shows substantial improvement towards the NSM target under the Initial Draft Plan. Further south, within the C-111 basin, the Initial Draft Plan stages resemble NSM values, although show no clear improvement over either bases. Within Taylor Slough and at the southern end of Taylor Slough (Gage THSO and Gage NP-207 respectively), stage duration curves show stages under the Initial Draft Plan to be a moderate improvement over both bases particularly at the upper and lower stages. In both cases, the Initial Draft Plan very nearly replicates the NSM targets.

Stages in southern WCA-3A and flows across the Tamiami Trail, west of the L-67 levee are reduced, and resemble NSM more under the Initial Draft Plan than the 2050 base in both the wet and dry seasons. A marsh stage hydrograph, just south of the S-12 structures in Northern Shark River Slough (gage NP 201) shows a good approximation of the NSM characteristics deemed ecologically desirable as discussed above. Stage hydrographs of the alternatives indicate that the Initial Draft Plan more closely approximates the performance measures than does the 2050 base, although does not predict drawdowns as extreme as NSM in some years. In the marl lands, west of Shark River Slough, stage hydrograph and stage duration curves indicate a very close approximation to NSM conditions for all of the alternatives. The 2050 base actually shows a slightly closer approximation to NSM conditions, although the difference is slight, and this may be outside the precision of the model. In northwestern and central Shark River Slough, the Initial Draft Plan shows substantial improvement in depth and duration of flooding over both bases, as measured at gages NP 33 and NP 36 respectively. Stage hydrographs clearly demonstrate an improvement in matching the performance measures under the Initial Draft Plan, especially in reducing the regular extreme (relative to NSM) drydown depths associated with both base cases. In the marl lands east of Shark River Slough (NP 38) moderate improvements are demonstrated under the Initial Draft Plan relative to both bases and target hydroperiods are largely achieved.

K.9.5 Water Quality

The excellent water quality conditions in freshwater regions of Everglades National Park are not expected to be significantly changed by implementation of the Initial Draft Plan compared to the 1995 and 2050 base conditions. Water quality conditions in the estuarine portion of Everglades National Park and in Florida Bay are expected to be improved by the Initial Draft Plan relative to the 1995 and 2050 base conditions. The key water quality parameters of concern in the Everglades National Park and Florida Bay are total phosphorus (TP), mercury and salinity.

Currently Everglades National Park freshwater marshes are oligotrophic (nutrient poor) with TP concentrations in the Everglades National Park marsh routinely below 10 ppb. A primary evaluation tool used by the Restudy Water Quality Team to evaluate the relative water quality effects of the various Restudy alternatives reviewed during the Restudy Plan Formulation and Evaluation Phase (October 1997 - June 1998) was the Everglades Water Quality Model (EWQM) (SFWMD, 1998). The EWQM simulates phosphorus transport in the Everglades Protection Area (Everglades National Park and WCAs) and links to hydrologic output from the South Florida Water Management Model. The EWQM evaluation of the Restudy alternatives and the 1995 and 2050 base conditions indicated that Alternatives B and the Initial Draft Plan were the preferred alternatives from a water quality perspective. This conclusion is tied closely to the decompartmentalization aspects of the Initial Draft Plan and Alternative B, which reduce structural flows into Everglades National Park and increase surface water sheetflow of waters entering Everglades National Park. The EWQM results suggest and the Restudy Water Quality Team concluded that maximizing surface water sheetflow of hydrologic flows entering Everglades National Park would reduce the net nutrient load within Everglades National Park.

The following Initial Draft Plan components are of particular interest relative to potential positive and negative effects they may have on water quality conditions in Everglades National Park:

Western C-11 basin diversion (eliminates discharges of urban runoff to eastern WCA 3A and Everglades National Park via S-9 pump station);

Relocation of a portion of L-31 North canal with new water control structures (S-356 A&B) to increase flows to NE Shark River Slough (Everglades National Park);

Modified operation of S332- A/B/D structures in Everglades National Park, Taylor Slough area to increase flows delivered to Everglades National Park and Florida Bay;

Relocation and increase in capacity of pump station S-140 to improve hydropatterns and hydroperiods in WCA 3A, Everglades National Park and Florida Bay;

Big Cypress-L-28 Interceptor Canal modifications and stormwater treatment areas: convert existing canal flow discharge into western WCA 3A to surface water sheetflow through Everglades marsh and add two stormwater treatment areas to clean water prior to sheetflow.

The Western C-11 diversion impoundment and the L-28 Interceptor canal modifications will have beneficial effects on water quality conditions in Everglades National Park. The C-11 diversion will relocate the discharge of C-11 west basin stormwater runoff at the S-9 pump structure, which now discharges to WCA 3A, south to the North Lake Belt storage area with eventual routing of these flows to Biscayne Bay. The Initial Draft Plan will result in 185,800 acre feet/year (SFWMM 31 year average) less water being discharged from S-9 into WCA 3A then the 2050 base condition. This feature will therefore result in a significant reduction of pollutant loading into WCA 3A and downstream Everglades National Park. Modifications to the L-28 Interceptor Canal will also result in a reduction of pollutant loading to the western portion of WCA 3A and the downstream Everglades National Park. Structure L28WQ, shows that average flows (SFWMM 31 year average) from the L-28 I canal will be reduced from 89,300 acre feet/year in the 2050 base condition to zero.

Construction of the S-356 A&B structures, modifications to C-111 Canal operations in south Miami-Dade County, and relocation and enlargement of Pump Station S-140 will result in increased flows entering Everglades National Park as a result of Initial Draft Plan hydrological restoration actions. The Initial Draft Plan components will result in 263,600 acre feet/year, 106,000 acre feet/year and 285,000 acre feet/year (SFWMM 31 year average) greater water discharges into WCA 3a and Everglades National Park than the 2050 base condition. Although these increased flows are important to future restoration of the WCAs, Everglades National Park and Florida Bay, it is important to note that the implementation of the Initial Draft Plan will have to ensure that all additional flows greater than 2050 base condition flows will have to be adequately treated in order to meet all State/Tribal water quality standards in the receiving waterbodies (Everglades National Park is an Outstanding Florida Water). For these three Initial Draft Plan components it is assumed that additional waters delivered to the Everglades Protection Area by these structures will be adequately treated consistent with the water quality requirements of the Everglades Forever Act.

The focus of the Restudy Water Quality Team's water quality evaluation for Florida Bay relates to restoring ecologically desirable freshwater flows to the Bay, thereby restoring seasonal salinity conditions across the Bay to as close to historic conditions as possible.

The following Initial Draft Plan components are expected to operate synergistically in a manner which will improve estuarine water quality conditions in the Everglades National Park/Florida Bay region:

The Modified regulation schedule for Lake Okeechobee would provide increased environmental water delivers to the WCAs, Everglades National Park and Florida Bay;

The Everglades Agricultural Area reservoir - 60,000 acres at a maximum of 6 feet depth, would result in increased environmental water delivers to the WCAs, Everglades National Park and Florida Bay;

Everglades rain-driven operations in WCAs 2 and 3 would improve hydropatterns and hydroperiods in the WCAs and Everglades National Park;

The Central Lake Belt Storage Area would be operated to improve hydropatterns and hydroperiods in WCA 3B and Everglades National Park;

The Bird Drive Basin recharge area would store water, control seepage, attenuate peak floods in C-4 basin, and deliver water to the South Miami-Dade Conveyance System;

L 31 North levee improvements would provide seepage management, eliminating seepage to the east out of Everglades National Park from NE Shark River Slough, maintaining higher water stages and longer water duration in NE Shark River Slough;

Additional water control structures between WCA 3A and 3B will increase flows to Everglades National Park;

Relocation of a portion of L-31 North canal, with new water control structures (S-356 A&B) to increase flows to NE Shark River Slough, Everglades National Park;

Regional-scale Lake Okeechobee Aquifer Storage and Recovery (1000 MGD) would improve water flows to WCAs and Everglades National Park;

Modified operation of S332- A/B/D structures in Everglades National Park, Taylor Slough area will increase flows delivered to Everglades National Park and Florida Bay;

Removal of L-68 A levees, L-67 C levee, backfilling L-67A canal, removal of L-29 levee and canal; removal of L-28 and L-28 tieback levees, and backfilling Miami Canal, will partially de-compartmentalize WCA-3Aand reestablish historic hydrologic sheetflow between WCA 3 and Everglades National Park;

Relocation to the south and increase in capacity of pump station S-140 would improve hydropatterns and hydroperiods in WCA 3A, Everglades National Park and Florida Bay;

The C-111N Spreader Canal and backfilling of C-110/lower C-111 canal systems, removal of the S-197/S-18C structures and eastward extension of C111N will improve water management for the Everglades National Park panhandle area and Northeast Florida Bay;

Diversion of excess WCA 2B water to NE Shark River Slough or Central Lake Belt storage area would enhance hydropatterns/hydroperiods in NE Shark River Slough, Everglades National Park and Florida Bay;

Storage of excess flows from WCA 2A/B & WCA 3A in a new Central Lake Belt storage area, to be returned to WCA 3B, and Everglades National Park would assist in to achieving preferred hydropatterns and hydroperiods, and would provide benefits to downstream Florida Bay also;

The West Miami-Dade Reuse component would enhance groundwater recharge in Bird Drive basin and provide additional water supplies to the South Miami-Dade Conveyance System to enhance seepage control in eastern Everglades National Park.

Considering cumulative water quality benefits to Florida Bay, several hydrological performance measures developed by the Restudy, relating to improved freshwater flows to Florida Bay and improved salinity conditions in Florida Bay, demonstrate the positive synergistic effect of the above listed 16 Initial Draft Plan components. The hydrological performance measures entitled "Average Annual Flows toward Florida Bay across Taylor Slough for the 31 yr. Simulation" indicates that Initial Draft Plan freshwater flows from Taylor Slough to Florida Bay are closer to the Natural System model target than either the 1995 or 2050 base condition flows. Another relevant hydrological performance measures in the Florida Bay area entitled "Average Annual Overland Flows toward Whitewater Bay and Florida Bay for the 31 year simulation period" indicates that: 1) Initial Draft Plan flows from the Shark River Slough are closer to the Natural System model target than either the 1995 or the 2050 base condition Shark River Slough flows (Shark River Slough freshwater flows enter the western portion of Florida Bay) and 2) Total southward flows to the northeastern portion of Florida Bay from three Everglades National Park basins indicate that the Initial Draft Plan freshwater flows are much closer to the NSM target then the 1995 base condition flows and are generally equal to 2050 base condition freshwater flows.

Relative to hydrological performance measures that relate to restoration of ecologically beneficial salinity conditions in eastern Florida Bay, which receives flows from the Taylor Slough/River, the hydrological performance measures entitled "Number of Months high/low Salinity Criteria Exceeded for Little Madeira Bay" is especially important. Little Madeira Bay receives freshwater from Taylor Slough/River in a portion of northeastern Florida Bay where ecologically damaging hypersalinity conditions have been documented in the past decade. This hydrological performance measures clearly indicated that the Initial Draft Plan salinity characteristics in Little Madeira Bay are much closer to the Natural System model salinity targets than either the 1995 or 2050 base conditions.

In summary, the above discussed hydrological performance measures indicate that improved hydroperiods and hydropatterns of Initial Draft Plan (synergistic effect of above referenced 16 Initial Draft Plan components) freshwater flows to Florida Bay, relative to both the 1995 and 2050 base conditions, will result in improved water quality conditions in Florida Bay.

K.9.6 Socio-Economics

Everglades National Park is operated by the National Park Service, United States Department of the Interior. As Federal land, it does not directly produce an economic output. The Park generates indirect income to neighboring counties through eoctourism, operation of its three visitor concessions, and through spending of Park visitors in adjoining communities. The Initial Draft Plan is expected to lead to significant improvement in fish and wildlife habitat, and has been predicted to improve habitat for alligators, increases in forage fish populations, and improved foraging and nesting success for colonial wading birds, among other Park wildlife. These improvements may cause an increase in Park visitation and possibly prolonged stays in and near the Park by these visitors. Therefore, the indirect income generated by Park visits can be expected to increase, relative to 1995 and 2050 base conditions.

K.9.7 Land Use

No significant changes in land use are expected inside Everglades National Park.

K.9.8 Agriculture

There is no significant agricultural production in this region.

K.9.9 Recreation Resources

If native wildlife populations, especially large consumers (alligators and raptors) and wading bird colonies, increase substantially under the Initial Draft Plan as predicted, there will be a greater abundance of "watchable wildlife" in the park. This should increase visits to the Park for bird watching, photography and other wildlife-related recreation. Florida Bay fisheries are also expected to increase, which may lead to increased sport fishing trips and increased demand for guide and outfitter services.

K.9.10 Aesthetics

Removal of the L-29 levee and bridging of part of Tamiami Trail should lead to an improvement in the visual aesthetics along this northern Park boundary. Partial re-flooding of the marl prairie regions on either side of Shark River Slough should likewise increase the visual diversity of this area, as observable from access points and observation towers, and probably attract more birdlife into these areas, especially during the winter drydowns.

K.9.11 Unavoidable Adverse Environmental Effects

Compared to either the 1995 or 2050 base conditions, most environmental effects resulting from implementation of the Initial Draft Plan would be positive. There will be temporary adverse effects related to construction of some project elements that impinge on the Park, with temporary intrusion of heavy machinery into Park borderlands during construction or demolition of water management structures. Implementation of the Initial Draft Plan in general should not result in significant unavoidable adverse effects. Localized, slight to moderate environmental effects may occur in the vicinity of project construction sites. Of note would be project features requiring extensive and prolonged use of heavy machinery and possibly blasting, in the vicinity of, or within the Everglades marsh. This would likely be the case with the proposed degradation of the L-67Extension, L-29 levee, filling in of borrow canals, and removal of associated water conveyance systems. Moreover, the construction of a bridge, causeway, or other such structure which would replace the Tamiami Trail, while fulfilling the intended project purposes as outlined in the Initial Draft Plan, may pose important localized effects to the marsh ecosystem for the duration of construction activities. Noise and disruption of the viewscape are probably the most significant adverse environmental effects. Some wading bird roosts may be temporarily disturbed, as has occurred in the past during modification of water management structures. Adverse impacts to Park trust resources would be minimized by scheduling work outside major life-cycle periods (e.g., nesting or peak foraging cycles of breeding birds).

K.9.12 Relationship Between Short Term Uses and Long Term Productivity

Removal of the L-67 Extension, and L-29 levees, backfilling of borrow canals, and removal of associated water control facilities represents a significant short-term disruption to the environment, and possible unintentional direct and indirect environmental consequences. Localized impacts to water quality, and possible disruption to, and taking of fish and wildlife due to construction and possibly blasting may result. The L-67A, immediately north of Everglades National Park, may represent another proposed project feature, which could represent a trade-off between recreation within the canal versus sheetflow restoration within Shark River Slough. Short-term effects due to construction activities such as use of heavy machinery, vehicular and equipment access, creation of staging and turnaround areas etc.) may also include localized impacts to aesthetics, wetlands, noise, air quality during the construction phase of the project. These impacts will be minimized wherever possible.

Once completed, the area impacted should quickly return to a more natural state. Vegetation would be expected to regrow over the existing project footprint and over time, the area would return to providing the natural qualities and functions that it provided historically. In addition, these modifications to the water management system will have a beneficial long-term effect on Everglades National Park by restoring more natural overland flows and hydroperiods to these areas. This in turn, it is expected, will result in providing the conditions necessary for a healthier sustainable ecosystem, including appropriate conditions to sustain native vegetation assemblages, and fish and wildlife habitat.

K.9.13 Irreversible and Irretrievable Commitment of Resources

The proposed degradation of levees, backfilling of canals, and removal of structures, as described above, represents, in all likelihood, an irreversible and irretrievable commitment of resources. These resources would include state and Federal funding, labor, energy and project materials and equipment to degrade the existing levees proposed for removal, back filling the canals, and removal of the existing water conveyance structures. It is possible that certain of the water conveyance structures may be retrievable for use elsewhere, however since the levees upon which they are built would no longer exist, they would no longer be able to function at their existing location. Upon implementation of upstream project features which would affect headwater elevations in WCA-3A, regional water flow, distribution and timing, these structures would no longer be necessary, and their removal would facilitate more natural flows through Shark River and Taylor Sloughs, enhance de-compartmentalization and reduce fragmentation of the natural landscape and its ecological components.

K.9.14 Cumulative Effects

The restoration of the more natural flows from WCA 3A, WCA 3B, and Big Cypress National Preserve, greater overland flow volumes, and additional flows beyond the existing flow sources relative to the 2050 base, is not expected to result in a cumulative negative effect to the environment of Everglades National Park. Project features designed to restore more natural flows result in substantially enhanced and more NSM like hydroperiods throughout much of Everglades National Park and downstream estuaries. These changes, a result of various project elements, involve minimal construction and structural features within Everglades National Park itself, although there are important project features under the Initial Draft Plan which occur at the boundary of Everglades National Park (see sections 9.12 and 9.13, above).

K.10 BIG CYPRESS REGION

The area of the Big Cypress region primarily affected by the Initial Draft Plan lies within the Big Cypress National Preserve (BCNP) boundary, the BCNP addition lands, the Big Cypress Seminole Indian Reservation and Miccosukee Indian Reservation. Components of the Initial Draft Plan affecting the hydrology, and thus the ecology of this area include: 1) modifications to the L-28 Interceptor canal that would reroute water from the West and North feeder canals to wetlands in northeast Big Cypress, including degradation of the southwest L-28 Interceptor levee and filling in the adjacent canal to enhance sheetflow into the BCNP addition lands; 2) Pump stations and spreader canals built or relocated along the L-28 Interceptor in order to facilitate sheet flow off of the Seminole and Miccosukee reservations; 3) Assumption that this alternative will comply with the Seminole Indian Tribes' Conceptual Water Conservation System master plan; 4) construction of two stormwater treatment area to ensure acceptable water quality prior to discharge from the North and West Feeder canals; and 5) Degradation of the L-28 levee (south of the gap with the L-28 Interceptor), L-28 Tieback and L-29 Levee between Forty-mile bend and the L-67, and removal of all associated structures, including the S-344, S-343(A), S-343(B) and the four S-12 (A-D) structures. Reference Section 9 for a detailed description of the Initial Draft Plan.

In general, given the location of the operational and structural changes to the existing C&SF system described above, and the fact that the Big Cypress represents a distinctly different hydrologic and ecological region than the adjacent Everglades, only limited and somewhat scattered effects should be expected due to the Initial

Draft Plan. These effects would be in the lands along the eastern boundary of the BCNP, along the L-28 Interceptor and in the sloughs draining the BCNP towards the Gulf of Mexico south of Loop Road. Hydrologic effects should be most dramatic and widespread in the area southwest of the L-28 Interceptor, where the Initial Draft Plan converted hydroperiods to NSM conditions (M. Duever, pers. comm.).

Finally, as the water quality entering the northeastern Big Cypress from the Feeder canals is, at present, of poor quality, it is important that the recommended plan ensure adequate water quality treatment prior to restoring more natural flows from this area. It is assumed, for planning purposes, that compliance with the Big Cypress Seminole Water Conservation Master Plan, in combination with the two proposed stormwater treatment area along the Western and Northern Feeder canals, will achieve these water quality standards. Without successful achievement of water quality targets, flows entering the northeastern Big Cypress may, in fact, cause more harm than good to the receiving waters (M. Duever, pers. comm.).

K.10.1 Vegetation

Implementation of the Initial Draft Plan would not likely result in a significant change to existing vegetation and cover within the affected area, assuming inflows from the Feeder canals are treated to acceptable standards prior to discharge into northeastern Big Cypress, except in the area southwest of the L-28 Interceptor. This area is expected to return to NSM conditions, which would benefit native vegetation through more natural timing, depth, and duration of flooding. Communities in western BCNP, including extensive areas of pinelands, cypress/mixed swamp, freshwater marl prairie, and cypress prairie, would likely not be affected by the alternative, as hydrologic conditions in these areas are nearly unchanged between the Initial Draft Plan and the 1995 and 2050 base cases. The primary effects to vegetation and cover would occur as a result of more natural flow characteristics, including inundation time, depth and flood duration, generally in the eastern region of BCNP, east of Monroe Station. Hydroperiods along the eastern region of the BCNP more closely match natural hydroperiods as simulated by the NSM model in many of the key indicator regions, particularly in the area of the L-28 Interceptor, the gap between the L-28 Interceptor and the L-28 Tieback, both north and south of the L-28 Tieback, and south of Loop Road in the Lostmans Slough area (southeast BCNP; T26; Row 21, C11-16). These changes produce hydrologic conditions more suitable to sustaining viable and healthy populations of native vegetation, including medium to longer hydroperiod vegetation classes indicative of the eastern BCNP. Uplands and hardwood hammocks within this eastern area will remain largely unaffected by hydrologic change resultant from implementation of the Initial Draft Plan.

Plant communities that may benefit from hydroperiods more closely resembling those of the NSM include the cypress prairie communities, which typically have hydroperiod ranges from 90 to 270 days (Duever et al., 1978; Duever, 1980, Weakley et al., 1996); mixed-hardwood cypress strand (125 to 365 days; Gunderson and Loope, 1982a; USDI, 1991); and cypress strand/cypress dome (240 and 340 days; Duever et al., 1986; Olmstead et al., 1980; USDI, 1991). Cypress strands and cypress domes are found in abundance within the BCNP, particularly north of Hwy 41 and west of the L-28 levee in an area that is expected to experience the greatest hydroperiod benefit. Extensive areas of graminoid marsh south and west of Forty-mile bend would also benefit from more natural hydrologic conditions under the Initial Draft Plan, relative to the 2050 base, by reducing average annual overland flow to more NSM like conditions. This vegetation type, with a hydroperiod of 220 to 365 days (Gunderson and Loope, 1982b; Olmstead et al., 1980; Weakley et al., 1996; USACE, 1990), would likely benefit by the somewhat lower water levels, although there are slightly fewer but longer periods of inundation than for NSM or either of the two bases under the Initial Draft Plan.

K.10.2 Fish and Wildlife

Fish and wildlife resources would not be directly affected by implementation of the Initial Draft Plan (the Initial Draft Plan). Restoration of the natural hydropattern characteristics in the eastern Big Cypress may result in minor shifts in habitat structure. No effect either positive or detrimental would be expected in the western region of the BCNP due to the negligible hydrologic changes. Restoration of the NSM hydropattern and fire regime should provide for optimum wildlife habitat conditions in the eastern BCNP and Lostmans Slough area.

The Initial Draft Plan also demonstrates variable improvement in overland flows toward the Gulf of Mexico in terms of volume and timing that may affect estuarine species. Volume and timing of freshwater flow in the Lostmans Slough area shows improvement over the 2050 base case and existing conditions, nearly replicating the NSM. However, in the eastern Big Cypress the Initial Draft Plan flows are only slightly closer to NSM as compared to current or 2050 conditions.

Significant improvements to the water regime in northeast Big Cypress, in the gap between the L-28 Interceptor and the L-28 Tieback and in the vicinity of the L-28 Tieback, would be expected to benefit water-dependent species such as the gallinule, the snowy egret, and the American alligator. The endangered wood stork may also benefit by an improvement to the availability of quality foraging habitat.

Critical upland wildlife habitat, such as pine forests and hardwood hammocks, is not expected to be significantly affected by the modifications to the existing hydrologic regime. Fish and other water dependent species will not likely be directly affected by implementation of the Initial Draft Plan throughout most of the Big Cypress region, although some species may benefit in terms of reproductive success, through longer, more natural hydroperiods in the eastern Big Cypress and northeast BCNP addition lands. The Initial Draft Plan produces flows closer to NSM flows in the Lostmans Slough area south of Loop Road. The reduction in overland flow volume may result in somewhat lower biomass of large fish due to the shallower depths, but is likely to increase the density of smaller fish as well as their availability to predators. The Initial Draft Plan may produce conditions more favorable to wading birds then than the 2050 base condition by enhancing their forage base.

K.10.3 Threatened and Endangered Species

Of the eighteen listed plant and animal species submitted by the USFWS as likely to be affected by the C&SF Restudy, seven are thought to occur within the affected area of the Big Cypress region. A brief description of effects to these state and federally listed threatened and endangered species follows.

K.10.3.1 Florida Panther

The Florida panther (*Felis concolor coryi*) known to reside within the Big Cypress region is one of the most endangered large mammals in the world. Although it is listed as endangered by the USFWS and GFC, no critical habitat has been designated. The panther prefers upland habitat, hardwood hammocks and pine flatwoods being a preferred habitat. White-tailed deer, feral hogs, raccoon, and armadillo are preferred prey species, which reside primarily within the higher elevation areas of the Big Cypress. The Initial Draft Plan is expected to affect mainly the wetland areas of the Big Cypress, and mainly within the eastern section of the Preserve. No effect is anticipated to the panther, its preferred habitat or its forage base, as a result of modified hydroperiods within the eastern Big Cypress.

K.10.3.2 Snail Kite

In a letter dated July 15, 1996 from the USFWS, the L-28 levee was identified as the western boundary for designating critical habitat for the snail kite (*Rostrhamus sociabilis plumbeus*), a Federal and state listed endangered raptor. Project modifications proposed under the Initial Draft Plan are expected to restore more natural hydroperiods to the eastern Big Cypress, an area that may be frequented by the snail kite. These hydroperiod improvements should provide conditions beneficial to the snail kite and its primary food source, the apple snail, to the extent that this habitat supports kite foraging.

K.10.3.3 Red-cockaded Woodpecker

The USFWS has listed the Red-cockaded woodpecker (*Picoides borealis*) as endangered, due largely to destruction of its habitat, and fragmentation of its historic home range. It is listed as threatened by the GFC. Red-cockaded woodpeckers make their home in pine dominated hardwood stands, with longleaf and hydric slash pine a preferred nesting habitat. There are about 24 nesting colonies (clusters) identified in the BCNP within the area expected to be affected by the Initial Draft Plan (USFWS 1998). Hydrologic modifications made under the Initial Draft Plan are closer to the NSM target (nearly 100 percent match in areas known to contain woodpecker clusters) relative to the 2050 base. In the long term, this alternative should act to restore and maintain quality habitat, by maintaining a more natural fire periodicity, and impede invasive exotic vegetation. As a whole, restoration of conditions similar to NSM in the north Big Cypress and within the pinelands located westward of the L-28 Tieback, should result in a slight benefit to Red-cockaded woodpeckers by protecting and restoring habitat quality.

K.10.3.4 Wood Stork

The USFWS and the GFC list the wood stork (*Mycteria americana*) as an endangered species. Environmental conditions, including more NSM like flows throughout much of the eastern Big Cypress, in the vicinity of Loop Road, should provide moderate benefits to the wood stork. Stage duration curves and stage hydrograph data for this area indicate that the Initial Draft Plan provides hydroperiods closer to the NSM than does the 2050 base throughout most of the year. Similar data for the southeastern Big Cypress, at gauge NP-34, near the border with Everglades National Park, are less conclusive, with most of the alternatives following similar trends, and the Initial Draft Plan flows slightly below that of the NSM target and the 2050 base throughout most of the year. Although not conclusive, this data would seem to indicate slightly poorer conditions for the wood stork for this area, beyond those conditions expected under the 2050 base. The ATLSS fish model did predict slightly better conditions for predicted fish density within this area, which would benefit storks. The ATLSS long-legged wading bird model overall predicts little change, with an overall slight benefit in foraging conditions in the central and eastern areas of the BCNP, and slightly poorer conditions relative to the 2050 base in the southeastern Big Cypress.

K.10.3.5 Cape Sable Seaside Sparrow

Cape sable seaside sparrows (*Ammodramus maritima mirabilis*) are listed as endangered by the USFWS and the GFC. Disparate populations of sparrows exist within the physiographic region of the Big Cypress, and are located primarily within the short-hydroperiod marl prairies along the west side of Shark River Slough (SRS), and the Stairstep area of BCNP and Everglades National Park. Results of the ATLSS breeding potential index (BPI) for these populations, predict overall positive effects to sparrow breeding potential in typical rainfall (1977), low rainfall (1990), and mean years for most of the northern and western most populations and slightly poorer breeding potential for the southern most portion of the western population. This is probably due to substantially lengthened hydroperiods within Shark River Slough due to project modifications outside the sphere of influence of those described above for the Big Cypress region. Curnutt et al. (1998) concluded that the Initial Draft Plan produced lower BPI values relative to the 2050 base in the southern portion of the western breeding area under most hydrologic conditions. The results of the individual based model (SIMSPAR), which accounts for detailed effects of localized water dynamics on individual bird growth, survival, and reproduction, suggested that the sparrow population may be able to reach higher levels under the Initial Draft Plan than the 2050 base. Moreover Curnett et al. (1998) suggested that conditions under the Initial Draft Plan predict a more stable sparrow population and conditions appeared to be more conducive to breeding population recovery after a decline relative to the 2050 base. It is therefore reasonable to conclude that conditions under the Initial Draft Plan may favor a healthier and sustained population of Cape sable sparrows west of SRS beyond that predicted by the 2050 base or that which exists today.

K.10.3.6 Bald Eagle

The bald eagle (*Haliaeetus leucocephalus*) is listed as threatened by both the USFWS and the GFC. The effects on hydrology through water management practices proposed under the Initial Draft Plan as well as the levee proposed for removal, should have minimal effect on bald eagles. Increased overland flow through the eastern Big Cypress, at all times of the year, towards the Gulf of Mexico, may result in slight benefits to eagle foraging.

K.10.3.7 Eastern Indigo Snake

The eastern indigo snake (*Drymarchon corais couperi*) is a large, black, non-venomous snake and occurs within every major physiographic region within the study area. The USFWS and GFC list it as a threatened species. Water level changes under the Initial Draft Plan would not be expected to impact upland areas such as tropical hammocks, pine flatwoods, coastal dunes or other areas where indigo snakes are known to reside. No effects to indigo snakes are expected under the Initial Draft Plan.

K.10.4 Water Management

Management of freshwater flows to the Big Cypress region will be moderately affected by the proposed modifications to the L-28 Interceptor, L-28, L-28 Tieback, L-29 and all associated water control and delivery structures. Since the Big Cypress is distinct physiographically, topographically, and hydrologically from the adjacent Everglades system, the effects of these water management changes are somewhat scattered, and largely localized to the eastern side of the BCNP, extending from the Seminole Big Cypress Indian Reservation, through the BCNP addition lands, and into the Lostmans Slough area to the Everglades.

In an effort to re-establish sheet flow south of the Western Feeder Canal, and rehydrate wetlands in the northeast Big Cypress, sheet flow will be allowed at designated locations south of the Western Feeder Canal. The L-28 Interceptor will be degraded and the canal filled at a point south of the S-190 structure, and S-190 will be converted to a pump station. Hydroperiods in the Initial Draft Plan were improved over a large area from the southern end of the Western Feeder Canal, along the L-28 Interceptor, to just south of the L-28 Tieback. This is probably due to flows from the Western Feeder canal and the removal of the southwest L-28 Interceptor levee and filling of the adjacent canal (M. Duever, pers. comm.). Too much water is allowed to accumulate below the S-190 pump station and along the extreme eastern boundary of the Big Cypress physiographic region (outside and to the east of the BCNP addition lands), at the southern end of the L-28 Interceptor. According to the model, these hydroperiods have overshot the NSM by greater than 30 days, and in some cases longer. These areas may be experiencing biologically significant amounts of flooding, which could have localized negative impacts to vegetation and wildlife habitat.

Average monthly overland flow towards the Gulf of Mexico through the eastern Big Cypress and Lostmans Slough areas are variably improved under the Initial Draft Plan. In the eastern Big Cypress overland flow volume, duration and timing are slightly improved over the 2050 base case during the period June though December. The Initial Draft Plan flow volume falls short of the NSM target by between 1,000-6,000 acre-feet during this period. The remainder of the time, the Initial Draft Plan overland flow is similar to the base condition and nearly matches the NSM. In Lostmans Slough, the Initial Draft Plan overland flows are significantly improved over the 2050 base, which overshoots the NSM the entire year. the Initial Draft Plan mimics the NSM well particularly from May to September, then falls slightly short of the NSM target from about October through December. In all cases however the Initial Draft Plan is a significant improvement in attaining more natural flows through the southeastern Big Cypress than does the 2050 base condition.

Average annual overland flows to the Gulf in the Big Cypress, are variable geographically, but tend to support the monthly overland flow scenario described above. For the Eastern Big Cypress, the Initial Draft Plan overland flows increased just more than 10 percent towards NSM flows in the wet season, and little change in dry season flows beyond the 2050 base case. In the Lostmans Slough area, there is a significant reduction in overland flow volume towards the NSM target in both the wet and dry season. The Initial Draft Plan overland flows nearly match the NSM in both seasons, while the 2050 base case overshoots the NSM by about 25 percent in the wet season and over 35 percent in the dry season.

These changes in flow volume, timing and duration are probably attributable to the increased flows from the L-28 Interceptor area and through the area of the L-28 Tieback (now removed). Removal of the L-28 and the water control structures S-344, S-343(A) and S-343(B), may also have an effect on flows, but modeling by the

SFWMM appears to show that these project modifications have a relatively minor effect in the case of flows through the southeastern Big Cypress and act to diminish flows through the eastern Big Cypress. Removal of the L-28, and S-344 probably has less of an effect on the southeastern Big Cypress than does removal of the L-29 and the S-12(A-D) structures (M. Duever, pers. comm.).

K.10.5 Water Quality

Water quality conditions in the Big Cypress Region are expected to improve compared to both the 1995 and 2050 base conditions through implementation of the Initial Draft Plan. The key water quality parameters of concern in the Big Cypress region are: TP, NOx and DO. The largest beneficial effect of the Initial Draft Plan on Big Cypress water quality conditions will result from implementation of modifications to the L-28 Interceptor Canal. Less significant beneficial effects to Big Cypress water quality conditions are expected to result from implementation of decompartmentalization of WCA 3A.

Implementation of Initial Draft Plan component, Big Cypress / L-28 Interceptor Modifications would result in the backfilling of the southern portion of the L-28 Interceptor canal south of existing structure S-190 (approximately 12 miles) and degrading the existing levee on the southwest side of the L-28 I canal. Current canal water flows in the west feeder and north feeder canals upstream from structure S-190 will be modified to be surface water sheetflows south across the Big Cypress National Preserve, downstream from the Seminole Tribe's Big Cypress Reservation, using several pump stations and a spreader canal system. Additionally, Structure S-190 would be converted from a gated structure to a pump station to maintain upstream flood protection. Two new stormwater treatment areas would be constructed adjacent to the west and north feeder canals to treat stormwater runoff from upstream basins prior to entering the Seminole Tribe's Big Cypress Reservation. The two stormwater treatment areas, a 1100-acre stormwater treatment area adjacent to the north feeder canal and a 800-acre stormwater treatment area adjacent to the west feeder canal are sized to reduce TP and other pollutant loads entering the downstream waters of the Seminole Tribe, the BCNP, the Miccosukee Tribe Reservation and ultimately WCA 3A, so as to assure that Tribal and State water quality standards in the receiving waterbodies are met. Modification of the existing west and north feeder canal flows and L-28 I canal flows to Initial Draft Plan surface water sheetflows across the BCNP is also anticipated to provide beneficial water quality treatment for the downstream nutrient sensitive waterbodies.

Initial Draft Plan component, Decompartmentalization of Water Conservation Area 3 would result in the partial decompartmentalization of WCA-3A. Of particular relevance to Big Cypress region water quality conditions is the degradation of the L-28 and L-28 Tieback levees with backfilling of the adjacent borrow canals and removal of the S-343A and S-344 structures in the L-28 levee. Removal of the L-28 and L-28 Tieback levees/canals and S-343A/344 will enable wet season surface water sheetflows in the western region of WCA 3A to flow in a southwesterly direction across the eastern region of BCNP. Therefore, existing pollutant loading being delivered to the southeastern region of BCNP and the westernmost region of Everglades National Park through the S-343A/S-344 structures will be spread out across an approximate 15 mile long front in the eastern area of BCNP. Replacing the existing structural point source wet season flows from WCA 3A with broad dispersed surface water sheetflows will result in pollutant uptake and sequestration by the native vegetation in the area and generally improve water quality conditions in the eastern BCNP.

K.10.6 Water Supply

The area of the Big Cypress, which may be affected by this project, is wilderness and largely undeveloped, other than some residential development along Loop Road, Preserve infrastructure and scattered municipal and private sector development. Potable water supplies are from wells, which capture underground water from the surficial aquifer. Modifications to flow volume, timing and duration due to implementation of the Initial Draft Plan are thought not to be of sufficient magnitude to affect local water supply needs, either existing or future.

K.10.7 Socio-Economics

Implementation of the Initial Draft Plan and concomitant moderate changes to the hydrology of the eastern portion of BCNP is not expected to have material effects to the socio-economic conditions in either the short or long term.

K.10.8 Land Use

The following description of effects on land use is organized into three sections. One section discusses land use within the BCNP, the second for those areas such as state and Federal protected lands outside of the BCNP, and thirdly, agricultural land use, primarily on the Seminole reservation, and northeastern Big Cypress.

K.10.8.1 Big Cypress National Preserve

Land use within the Big Cypress basin will not likely be significantly affected by implementation of the Initial Draft Plan. Removal of the L-29 includes raising SR 41, either by construction of a bridge or causeway. Residential development and future Miccosukee Indian residences along Loop Road will not be affected by flow modifications to southeast Big Cypress. Permitted uses within the BCNP such as the Dade-Collier Transition and Training Airport (Jetport), oil and gas fields located at Bear Island, and Raccoon Point will not be significantly affected by the Initial

Draft Plan. Roads, canals, levees and borrow pits, other than those canals and structures proposed for degradation or removal in the Initial Draft Plan alternative, will remain unaffected by modifications to the areas hydrology.

Traditional use of lands within BCNP, guaranteed to the Miccosukee Tribe of Indians of Florida and members of the Seminole Tribe of Florida under Public Law 93-440, would not be affected by implementation of the Initial Draft Plan. This would include tribal use of Federally acquired lands within the BCNP for tribal activities including hunting, fishing, trapping on a subsistence basis and traditional tribal ceremonies.

K.10.8.1.1 Urban Areas

The urban areas along the coast, including the municipalities of Naples, Everglades City, and Marco Island are outside the area of hydrologic influence of the Initial Draft Plan and land use will be unaffected by the project.

K.10.8.2 Land Use Outside the Big Cypress National Preserve

Lands west of the Big Cypress National Preserve, including Fakahatchee Strand State Preserve, Southern Golden Gate Estates, and Florida Panther National Wildlife Refuge, will be unaffected by modifications made by the Initial Draft Plan, nor will this preclude or materially affect possible future, separable restoration efforts in these areas.

K.10.8.3 Agriculture

The Initial Draft Plan substantially improves water supply to the Big Cypress Reservation over the future without-project condition due to increased water deliveries from Lake Okeechobee and Rotenberger Wildlife Management Area. Irrigation demands not met are reduced from 17.6 percent under the 2050 base to only 1.6 percent under the Initial Draft Plan. This represents a substantial benefit to irrigated agricultural production in the Reservation. Modifications to the L-28 Interceptor Canal and S-190 Structure are planned to rehydrate the Northeast Big Cypress south of the West Feeder Canal. Model results from the Initial Draft Plan indicate that there will be overland flow and ponding in this area, which contains native vegetation. No effect is expected north of the West Feeder Canal where agricultural production takes place.

K.10.9 Recreation Resources

Forecasted water flows under the 2050 base plan show minor changes in marsh or marl land water elevations in the region (Stage Hydrographs for Loop Road, Big Cypress National Preserve Gage BCNPA9, Cell R23 C13 – SFWMM V3.5). Projected decreased water sheet flows towards the Gulf of Mexico could provide additional recreational access for bird watching, environmental interpretation, and ORV use. Recreational fishing, levee hiking and biking would be unaffected. Recreational boating could be more difficult in some locations of the Big Cypress region. Airboat access to tree island hunting encampments could be restricted by low water levels (T. Towles, pers. comm.). This could decrease recreational hunting in the marsh, sawgrass, and slough areas of the Big Cypress region.

Overall, the proposed Initial Draft Plan hydroperiods will not substantially change the water flows or levels in a significant manner according to daily stage hydrographs for the Big Cypress region. The southern portion of the region, where levee degradation is proposed, will promote sheet water flows to the south. Some site specific, popular recreation resource areas would be adversely affected by dike and levee degradations. The improved hydroperiods and flows could facilitate easier access to hunt camps on tree islands and increase hunting in these areas (T. Towles, pers. comm.). Some overland and water-based access could be impeded if not completely removed.

The proposed levee degradation, canal backfill, construction of stormwater treatment areas, and resulting increased outflows are forecasted to improve sheetflow in a more natural and historical manner to the south. Boat access to high quality fishing areas could be limited or denied due to the L-28 canal backfilling. Levee bank fishing, hiking, and biking access could be limited or removed due to the L-28 levee and tie-back levee degradation (T.Towles, pers. comm.).

The proposed development of approximately 1900 acres of stormwater treatment area in the northeast Big Cypress region could provide recreational fishing if these areas are constructed to provide adequate fish habitat. Depending on the stormwater treatment area, excavated material disposal, access for bank fishing, hiking, biking, and other recreation activities could be developed. The 2050 base plan would propose no such component.

K.10.10 Aesthetic Resources

Restoration of this region, primarily by modifications (degradation or removal) to existing canals, and levees, and their conveyance structures, will provide a more natural scenic panoramic environment and viewshed than the existing canals and levees now provide. The project does not propose increasing the visibility of existing or future project features such as structures, beyond that which is existing. The resulting hydroperiod restoration is expected to contribute to the long-term maintenance of natural Big Cypress landscapes and visible natural features. Removal of man-made features, in combination with a re-establishment of more natural flows should enhance conditions, which lend high aesthetic appeal to this area.

K.10.11 Unavoidable Adverse Environmental Effects

Implementation of the Initial Draft Plan should not result in unavoidable adverse effects other than possible moderate localized ponding below the new S-190 pump station, along the L-28 Interceptor. This action may have long-term, localized negative impacts to native vegetation and wildlife habitat due to high tailwater elevations below the S-190.

K.10.12 Relationship Between Short Term Uses and Long Term Productivity

Construction of the S-190 pump station, water treatment areas, and removal of the L-28 Interceptor levee, L-28, L-28 Tieback, and L-29 levees and associated water control facilities represents a significant short-term disruption to the environment, and possible unintentional direct and indirect environmental consequences. Short-term effects due to construction (levee removal and backfilling of canals, vehicular access, creation of staging and turnaround areas etc.) such as impacts to wildlife habitat, aesthetics, wetlands, noise, air and water quality will be minimized wherever possible.

Once completed, the area impacted should quickly return to a more natural state. Vegetation would be expected to reestablish over the existing project footprint and over time, the area would return to providing the natural qualities and functions that it provided historically. In addition, these modifications to the water management system will have a beneficial long-term effect on the northeastern, eastern and southeastern Big Cypress area by restoring more natural overland flows and hydroperiods to these areas. This in turn, it is expected, will result in providing the conditions necessary for a healthier sustainable ecosystem, including appropriate conditions to sustain native vegetation assemblages, and fish and wildlife habitat.

K.10.13 Irreversible and Irretrievable Commitments of Resources

The proposed degradation of levees and backfilling of canals, as described above, represents, in all likelihood, an irreversible and irretrievable commitment of resources. These resources would include state and Federal funding to build the S-190 pump station, labor, energy and project materials and equipment to degrade the existing levees proposed for removal, back filling the canals, and removal of the existing water conveyance structures. It is possible that certain of the water conveyance structures may be retrievable for use elsewhere, however since the levees upon which they are built would no longer exist, they would no longer be able to function at their existing location. Upon implementation of upstream project features which would affect headwater elevations in WCA-3A, regional water flow, distribution and timing, these structures would no longer be necessary, and their removal would facilitate more natural flows through the Big Cypress, enhance decompartmentalization and reduce fragmentation of the natural landscape and its ecological components.

K.10.14 Cumulative Effects

The restoration of the eastern Big Cypress region is not expected to result in a cumulative negative effect to the environment. Project features designed to restore more natural flow results in only moderate changes to the overall hydroperiod and only to the eastern side of the Big Cypress. These changes, a result of various project elements, involve minimal structural component development within the Big Cypress itself. The major action that acts to modify flows, and in itself is an improvement to water flow and hydroperiod, is the construction of the S-190 pump station, water treatment areas, and degradation of the L-28 Interceptor levee, L-28 South, L-28 Tieback, and L-29 levee as described above. This action in combination with the other project features located in this area such as relocating the S-140 pump station, spreader canals and implementation of the Big Cypress Seminole Tribes Water Conservation Plan, may act cumulatively to restore more natural flows to the Big Cypress, but should not result in negative environmental effects or effects unfavorable to the restoration of the natural environment.

K.11 CALOOSAHATCHEE RIVER REGION

This assessment will cover only those consequences realized within the Caloosahatchee River geographic planning region. The project features of the Initial Draft Plan that would affect the hydrology and ecological sustainability of the Caloosahatchee River region are: (1) a large scale above ground storage reservoir, with an associated aquifer storage and recovery system; and (2) a stormwater treatment area with backpumping facilities. These changes will provide a substantial net increase in regional storage capacity, provided in the past by Lake Okeechobee. An approximately 20,000 acre above ground storage reservoir would be built, at a location to be determined, with a maximum design depth of 8 feet, and with inflow pump capacity and outflow structure size to be determined during detailed design. In conjunction with this reservoir, aquifer storage and recovery is being proposed, to provide additional storage while reducing evaporative loss, and to reduce the amount of land that would be needed for above ground storage alone. Forty-four 5-MGD (million gallons per day) aquifer storage and recovery wells and associated infrastructure are proposed. Water from the storage reservoir that will be injected into the aquifer storage and recovery wells will need to meet Everglades Protection Area coliform standards before injection. Efficiency of aquifer storage and recovery is estimated for planning purposes to be about 70 percent, although there is considerable uncertainty associated with this estimate. Recovery rates may vary depending on area geology and other factors.

Additionally, a stormwater treatment area, about 5,000 acres in size, with associated backpumping facilities, will be built in the upper Caloosahatchee basin. The backpumping facilities will consist of 1 pump of 2000 cfs capacity to take water from the lower Caloosahatchee Basin to the upper Caloosahatchee Basin; 1 pump of 2000 cfs capacity to take water from the Caloosahatchee River into the stormwater treatment area; and 1 pump of 2000 cfs capacity to discharge water from the stormwater treatment area to Lake Okeechobee.

The report below will address potential effects (beneficial or harmful) of the Initial Draft Plan compared to the 2050 base, on several key physical, ecological and socio-economic resources of the Caloosahatchee River region.

K.11.1 Vegetation

Approximately 25,000 acres of agricultural lands, with included wetlands and upland, would be converted to a water storage reservoir and stormwater treatment area under the Initial Draft Plan. Small amounts of upland forest (pine flatwoods) and wetlands would be included in the total acreage. These lands would be permanently removed from agricultural production, and are expected to develop emergent or floating vegetation, depending on depth. The 4-foot deep areas (stormwater treatment area) will function as emergent marsh and probably become dominated by cattails. The deep (8') reservoirs will become colonized by floating and rooted aquatic vegetation. Many of these sites are located near marginal wetlands that could be enhanced through active management or passively through seepage from the storage facility. The storage sites will remove sediments and some nutrients, particularly phosphorus.

K.11.2 Fish and Wildlife

It is difficult to predict what aquatic plan communities will be present in the water storage areas, due to the unusual hydrologic patterns they will experience. These areas will act primarily as “surge tanks,” storing large amounts of excess water during wet periods and drying out completely during dry times. These alternating wet and dry conditions may last only a few days or may last for many months to more than a year, and water depths will vary widely, from as deep as 6 feet to only a few inches, depending on rainfall conditions and operational demands. These irregular hydrological patterns will certainly cause profound and widespread changes in wildlife habitats existing in these areas at the time of construction. Any trees standing in areas converted to deep water storage areas are expected to die. If they presently serve as roosting or nesting habitat for raptors or water birds, they will eventually be lost.

Under some conditions, large areas of habitat suitable for foraging wood storks, snail kites, bald eagles, and Audubon’s crested caracaras may be created and may provide some benefits to these and other wildlife species. However, the USFWS is concerned that these areas would become “attractive nuisances” when temporarily favorable conditions are created, drawing in opportunistic wildlife species. Favorable conditions could induce species such as wood storks, snail kites, bald eagles and others to nest nearby, and could produce artificially inflated populations of some species. When reservoir operations then cause a rapid change in conditions, widespread nesting failures and direct mortality of adult individuals due to loss of foraging resources could result. In addition, the rapid filling of storage areas that have been dry for extended periods would likely result in direct mortality due to drowning of less mobile species such as the eastern indigo snake.

K.11.3 Threatened and Endangered Species

Of the eighteen listed plant and animal species submitted by the USFWS as likely to be affected by the C&SF Restudy, seven are thought to occur within the affected area of the Caloosahatchee River region. A brief description of effects to these state and Federally listed threatened and endangered species follows.

K.11.3.1 West Indian Manatee

The West Indian manatee (*Trichechus manatus*) has been recognized as an endangered species since 1967. Both the USFWS and GFC list it as an endangered species. In this region, manatees are most prominent year round in the Estero Bay and Caloosahatchee River areas. Manatees feed on a variety of submergent, emergent and floating vegetation and usually forage in shallow grass beds adjacent to deeper channels. The primary threats to manatees today are due to collisions with watercraft, degradation of seagrasses and accidents occurring at water control structures. Implementation of the Initial Draft Plan is not anticipated to adversely affect the manatee.

K.11.3.2 Wood Stork

The wood stork (*Mycteria americana*) is listed as an endangered species by the USFWS and the GFC. Wood storks forage in freshwater marshes, seasonally flooded roadside or agricultural ditches, narrow tidal creeks, shallow tidal pools, managed impoundments, and depressions in cypress heads and swamp sloughs. No adverse effect on the wood stork is anticipated due to construction of water storage facilities in this region. Under some conditions the water storage areas may provide suitable habitat for foraging wood stork. However, the USFWS is concerned that these areas would become “attractive nuisances” when temporarily favorable conditions are created, drawing in opportunistic wildlife species. Temporary favorable conditions could induce species such as wood storks, snail kites, bald eagles and others to nest nearby; but nesting success would depend on continued favorable foraging conditions. Short term success could produce artificially inflated populations of some species. When reservoir operations then cause a rapid change in conditions, widespread nesting failures and direct mortality of adult individuals could result due to loss of foraging resources.

K.11.3.3 Audubon's Crested Caracara

The Florida population of this resident, non-migratory raptor is listed as threatened by the USFWS and GFC. The caracara (*Polyborus plancus*) commonly occurs in dry or wet prairie areas, as well as improved or semi-improved pasture. The region of greatest abundance is a five county area north and west of Lake Okeechobee, including Glades, DeSoto, Highlands, Okeechobee, and Osceola counties (Kissimmee River and Caloosahatchee River regions). Their numbers continue to decline throughout their range due largely to loss of habitat. Implementation of the Initial Draft Plan components in this region could impact this species through loss of habitat. No effect on the caracara is anticipated at this conceptual level of planning, until definitive sites are identified and selected for the project features it is impossible to determine precise impacts to caracara or caracara habitat.

K.11.3.4 Bald Eagle

The bald eagle (*Haliaeetus leucocephalus*) should benefit by implementation of the Initial Draft Plan water storage components in this region due to the reduction of lake level fluctuations. Lake Okeechobee levels, with fewer occurrences of lake stages in the vicinity of 11-12 feet NGVD and below should benefit the bald eagle by providing for a more sustainable and reliable foraging ground within the shallow littoral areas. The regular occurrence of lake level recessions, would concentrate prey fish over an extended period of time, which may further benefit the eagle. Both the USFWS and GFC currently list the bald eagle as a threatened species.

K.11.3.5 Eastern Indigo Snake

The eastern indigo snake (*Drymarchon corais couperi*) could potentially be affected by construction of storage reservoirs, the stormwater treatment area and their associated facilities. No effect is anticipated at this conceptual level of planning. When definitive sites are identified and selected, it will be possible to determine precise impacts. The USFWS and the GFC classify the eastern indigo snake as a threatened species.

K.11.3.6 Red-cockaded Woodpecker

The Red-cockaded woodpecker (*Picoides borealis*) is listed as endangered by the USFWS, due largely to destruction of its habitat, and fragmentation of its historic home range. It is listed as threatened by the GFC. Active colonies of red-cockaded woodpeckers are interspersed throughout the study area, most notably in

Osceola, Highlands, St. Lucie, Palm Beach, Glades, Charlotte, Lee, and Monroe Counties. Pine stands, or pine-dominated hardwood stands, with a low or sparse understory and ample old-growth pines, constitute primary red-cockaded woodpecker nesting and roosting habitat (USFWS 1998). Longleaf pine provides critical nesting habitat where available, however cavities are also constructed in other pines, and in southwest Florida, the hydric slash pine is preferred. The Red-cockaded woodpecker could potentially be affected by construction of storage reservoirs, the stormwater treatment area and their associated facilities. No effect is anticipated at this conceptual level of planning. When definitive sites are identified and selected, it will be possible to determine precise impacts.

K.11.3.7 Florida Scrub-jay

The Florida scrub-jay (*Aphelocoma coerulescens*) is known to inhabit well drained, sandy uplands, typical of a xeric oak scrub habitat. A "core population" of scrub-jays is also located within the Lake Wales Ridge sub-region, northwest of Lake Okeechobee. An essential feature of the Initial Draft Plan is the construction of a 20,000-acre above ground storage reservoir and a 5,000-acre stormwater treatment area with backpumping facilities. Although no definitive site has been selected for these project features, preliminary sites identified are outside of the Lake Wales Ridge sub-region. No effect on the scrub-jay is anticipated at this conceptual level of planning, until definitive sites are identified and selected for the project features it is impossible to determine precise impacts to scrub-jays or scrub-jay habitat.

K.11.4 Water Management

Under the Initial Draft Plan all flood control releases to the Caloosahatchee River estuary are expected to be eliminated except pulse releases in zone A of the regulation schedule for Lake Okeechobee. The Caloosahatchee Basin storage reservoir and aquifer storage and recovery system will capture local basin runoff and releases from Lake Okeechobee. Water from the reservoir will be used to provide environmental deliveries to the Caloosahatchee estuary, to meet demands in the Caloosahatchee Basin, and to inject water into the aquifer storage and recovery wellfield for long-term (multi-seasonal) storage. Water from the aquifer storage and recovery facilities will be used to meet the environmental demands of the estuary and local basin demands. Any estuarine demands not met by basin runoff, the reservoir and the aquifer storage and recovery system will be met by Lake Okeechobee, as long as lake stages are above 11.5 feet NGVD. Lake Okeechobee water will also be used to meet any remaining local basin demands subject to supply-side management.

The Caloosahatchee Basin storage reservoir and aquifer storage and recovery system will be operated in conjunction with the Caloosahatchee backpumping facilities, which include a stormwater treatment area for water quality treatment.

This component operates after estuary and agricultural/urban demands have been met in the basin and when the level of water in the storage reservoir exceeds 6.5 feet and Lake Okeechobee is below the pulse release zone. When this situation occurs, then water is released from the reservoir and delivered to the stormwater treatment area at the capacity of the backpumping /treatment system of 2000 cfs. The stormwater treatment area water is then backpumped to Lake Okeechobee.

The operation of project components in the Caloosahatchee Basin will significantly improve regional water managers' abilities to meet local basin agricultural/urban demands as well as the environmental needs of the downstream estuary.

K.11.5 Water Quality

Water quality conditions in the Caloosahatchee River Region are expected to improve, compared to both 1995 and 2050 base conditions through implementation of the Initial Draft Plan. The key water quality parameters of concern in the Caloosahatchee River region are: TP, NOx, DO, conductivity, coliforms and pesticides. The following Initial Draft Plan components are expected to operate synergistically in a manner that will improve freshwater and estuarine water quality conditions in the Caloosahatchee River basin:

Storage North of Lake Okeechobee - 20,000 acres at a maximum of 10 feet depth, Kissimmee River watershed; regional storage reduces flood discharges from Lake Okeechobee to the Caloosahatchee River;

C-44 (St. Lucie) Canal reservoir - 10,000 acres at a maximum of 4 feet depth, increases C-44 basin and regional storage capacity and reduces need to release Lake Okeechobee flood discharges to the Caloosahatchee River basin;

Caloosahatchee (C-43) Canal reservoir with aquifer storage and recovery wells - 20,000 acres of reservoir at a maximum of 8 feet depth, 44 five MGD aquifer storage and recovery wells (220 MGD maximum capacity) increases Caloosahatchee River basin storage and reduces Lake Okeechobee flood releases to the Caloosahatchee estuary;

Environmental water supply deliveries to the Caloosahatchee estuary to achieve optimal salinity;

Modified regulation schedule for Lake Okeechobee to provide increased environmental deliveries to the WCAs/Everglades National Park and reduce flood discharges to the Caloosahatchee estuary;

Everglades Agricultural Area reservoir - 60,000 acres at a maximum of 6 feet depth; regional system storage that reduces Lake Okeechobee flood releases to the Caloosahatchee estuary;

Regional-scale aquifer storage and recovery of Lake Okeechobee water - 1000 MGD maximum capacity, reduces Lake Okeechobee flood discharges to the Caloosahatchee estuary and improves low flow augmentation from Lake Okeechobee to the Caloosahatchee River/estuary during dry periods;

Caloosahatchee River (C-43) stormwater treatment area with backpumping to Lake Okeechobee - increases regional water storage by capturing C-43 excess stormwater runoff, and after water quality treatment via a 5000-acre stormwater treatment area, diverts stormwater flows to Lake Okeechobee when Lake Okeechobee is at appropriate water level.

Acting together, the above Initial Draft Plan components improve water quality in the Caloosahatchee River and estuary, by substantially reducing the levels of non-point source pollutants reaching basin waters from annual wet season rain events. They also reduce Lake Okeechobee flood control discharges by capturing these runoff waters in the regional water storage facilities. Of particular importance to water quality improvement in the C-43 basin are the 20,000-acre reservoir in the basin and the 60,000 acre reservoir in the Everglades Agricultural Area. When wet season stormwater runoff is retained in the regional water storage facilities, sedimentation processes will sequester pollutants. Further, biological uptake processes in the water storage facilities will sequester dissolved pollutants. Operation of the water storage facilities will reduce loading of TP, NOx, coliforms and pesticides to C-43 basin waters. Additionally, operation of the aquifer storage and recovery facilities in the C-43 basin and around Lake Okeechobee, implementation of the modified Lake Okeechobee regulation schedule and operation of the C-43 backpump / stormwater treatment area facility will reduce wet season peak flows to the Caloosahatchee River and estuary, thereby reducing non-point source pollutant loading to the river and estuary.

Conversely, during the dry season, when maintenance of adequate low flows to the river and estuary dominates water quality concerns in the region, the Initial Draft Plan components that increase flows to the river/estuary are important. The components that improve dry season river/estuary water quality conditions are the C-43 and Lake Okeechobee aquifer storage and recovery facilities and improved environmental flows from Lake Okeechobee. These components are expected to specifically improve DO and conductivity conditions in the river/estuary, identified as key water quality parameters in the basin.

K.11.6 Water Supply

The Initial Draft Plan will significantly improve the regional irrigation supply. Demands not met would drop from 22.4 percent for the future without-project condition to 2.6 percent in the Initial Draft Plan. This is a substantial improvement to the agricultural irrigation supply, but the change in water supply source is a concern. This region has historically relied primarily upon Lake Okeechobee for its supplemental irrigation water. More than half of the C-43 Basin irrigation supply would come from the storage reservoir and aquifer storage and recovery facilities with the Initial Draft Plan. The agricultural community is reluctant to relinquish the Lake Okeechobee water source and rely upon reservoir and aquifer storage and recovery technologies that are new to this basin.

K.11.7 Socio-Economics

Implementation of the Initial Draft Plan is not expected to have material effects to the socio-economic conditions in either the short or long term.

K.11.8 Land Use

The Initial Draft Plan would alter several different types of existing land uses within the Caloosahatchee River region. These existing land uses include agriculture, ranching, and forestry. However, agriculture is the predominant land use in the basin and will be the type most impacted by the Initial Draft Plan. The below discussion on impacts to agriculture will include all existing land uses except urban.

K.11.8.1 Agriculture

A 20,000 acre storage reservoir is proposed for the C-43 Basin to capture basin runoff and water releases from Lake Okeechobee for eventual use for water supply and environmental demands. This reservoir will likely be located in an area currently used for agricultural production and designated as unique farmland. Conversion of 20,000 acres from agriculture to reservoir would be an approximately 4 percent reduction of agricultural acreage, in a region that has experienced recent expansion of agricultural production.

K.11.9 Recreation Resources

The two principal features proposed in the Initial Draft Plan which may affect recreation resources are the construction of a 20,000 acre storage reservoir and an approximately 5,000 acre stormwater treatment area. Neither site has been definitively sited, although conceptual sites identified to date do not appear to affect any existing recreational areas. Important recreation benefits may be realized by both components depending on final design and operational management decisions. Potential recreation benefits include fishing, waterfowl hunting, wildlife viewing, day hiking, bird watching, camping, and nature interpretation. The Everglades Nutrient Removal Project (a trial stormwater treatment area) has shown to provide significant wildlife habitat potential, and similar benefits may be realized by the proposed stormwater treatment area within the Caloosahatchee River region.

Water quantity and quality improvements to the Caloosahatchee River estuary and Charlotte Harbor are expected to enhance conditions for seagrasses, benthic invertebrates and fishes. These improved conditions should also benefit other animals that rely on seagrass beds such as endangered manatees, which support recreation activities including manatee viewing by boaters.

K.11.10 Aesthetic Resources

The main visual components of the C&SF Restudy in the Caloosahatchee River region are the low levees of the reservoir and stormwater treatment area, water control structures, and pump stations. These features are not unlike existing features in the region. From a distance, the storage reservoir and stormwater treatment area would appear similar to flooded agricultural fields or marsh. The project components do not include any tall structures that would interrupt the existing landscape profile. The Initial Draft Plan would not significantly affect aesthetic resources within the Caloosahatchee River region.

K.11.11 Unavoidable Adverse Environmental Effects

The following unavoidable adverse effects are expected to occur with implementation of the project features described above, which are expected to have an affect within the Caloosahatchee River physiographic region.

Construction of 25,000 acres of above ground storage reservoir and stormwater treatment area with their associated facilities will take large tracts of agricultural lands out of production, and possibly remove the functional values of lesser amounts of wetlands, prairie, or other natural areas. There will be a change in the dominant plant cover (from emergent or crop to floating aquatic) and dominant animal groups (common terrestrial wildlife to aquatic birds, reptiles, amphibians, fish and invertebrates).

K.11.12 Relationship Between Short Term Uses and Long Term Productivity

Construction of the reservoir storage, stormwater treatment area, and associated facilities represents a significant short-term disruption to the environment, and possible unintentional direct and indirect environmental consequences. Short-term effects due to construction activities (clearing, grubbing, levee building, installation of structures, equipment noise, etc.) may be visually unpleasant and annoying to adjacent landowners. However, the storage areas will be sited in rural zones. Grading and restoration will improve the visual quality of the landscape when construction is finished, and adverse effects will be minimized wherever possible.

Once completed, vegetation would be expected to colonize the levees and reservoirs. In addition, these modifications to the water management system will have a beneficial long-term and permanent effect downstream throughout the Caloosahatchee River region. The construction of large Water Storage reservoir Areas and numerous Aquifer Storage and Recovery wells would capture and store much of the excess water available during wet periods. This makes more water available to the remaining Everglades system when it is needed to provide natural flow volumes, reduces damaging freshwater releases to estuaries, and reduces damage to Lake Okeechobee littoral zone habitats though attenuation of extreme high and low lake levels.

K.11.13 Irreversible and Irretrievable Commitments of Resources

The proposed construction of a 20,000 acre reservoir storage site and a 5,000 acre stormwater treatment area represents, in all likelihood, an irreversible and irretrievable commitment of land and monetary resources. These resources would include, in addition to the lands themselves, state and Federal funding, labor, energy and project materials and equipment to build the storage site and the structures associated with the operation of these facilities. Fish and wildlife habitat, located within the proposed component footprint would likely be inundated for much of the year, would be permanently altered and could represent a irreversible commitment of land and/or wetland resources.

K.11.14 Cumulative Effects

Restudy project components are not expected to result in a cumulative negative effect on the environment of the Caloosahatchee River physiographic region. Project components in the Caloosahatchee region, especially reservoir storage, will act cumulatively to restore more natural freshwater flows to the downstream estuary. To achieve restoration will require substantially more storage in the Caloosahatchee region then presently exists, in order to provide the correct quantity, quality, timing, and duration of flows. The land spatially occupying these Caloosahatchee areas once provided these important functions to the basin system. Today, they are largely developed, drained, and ditched agricultural lands. The restoration of these important natural functions will require some reversal of the current trend in order to provide the retention area for holding, storing and treating water prior to its discharge downstream. The proposed project features, along with a restored Lake Okeechobee, able to provide important storage functions, are necessary for the overall restoration of the study area downstream. The commitment of 25,000 acres of land represents a huge investment in funding and land resources. It may also cause some adverse consequences locally. However the overall benefit to the regional system will be far greater than the localized adverse effects. The localized adverse effects will not result in a detrimental cumulative effect within the region.

K.12 FLORIDA KEYS

The Florida Keys are not physically connected to the surface water management features of the C&SF system. They are also outside of the geographic envelope of the Restudy Performance Measures, the 2 x 2 hydrologic model and the NSM. Therefore, the Restudy cannot predict direct quantitative or semi-quantitative beneficial or adverse effects on Keys ecosystems. However, it is reasonable to expect some positive, though indirect, benefits from construction of the recommended plan. The Keys are "downstream" of Florida Bay, where a major Keys fishery (pink shrimp) depends on the seagrass communities. The Initial Draft Plan will change timing and volume of freshwater deliveries to this Bay, and may assist in restoration of some seagrass cover. Therefore, potential beneficial and adverse indirect effects of building the recommended plan will be discussed briefly in this chapter.

K.12.1 Vegetation

No component of the Initial Draft Plan will change terrestrial plant communities. No component of the Initial Draft Plan will directly affect marine plant communities fringing the Keys, but some indirect positive effects on algal flats and seagrass beds on the Bay side of the Keys may occur. If improved Florida Bay haloperiods help to reverse the spread of plankton blooms, coral growth may improve on the Florida Reef Tract, but this is speculative. It is believed that phytoplankton blooms near the Keys may be triggered by a combination of factors, and only one aspect of the Bay water quality could be changed as a result of the Initial Draft Plan implementation: timing and volume of freshwater discharges into the northern Bay.

The Initial Draft Plan components will send more fresh water, with a more natural seasonal timing, to Florida Bay through Shark Slough and Taylor Slough.. The receiving waters are the waters adjacent to the Bay's north shore, distant from the Keys. This additional fresh water should moderate extreme salinity in the north of Florida Bay, at least during some seasons of some years. Although the reasons for the seagrass die-off in Florida Bay are probably complex, and hypersalinity may be only one of the problems now stressing benthic plant communities, this improvement in Bay hydrology should benefit the seagrass community. In turn, partial restoration of the seagrass community may decrease the frequency and severity of algal blooms in the water column, as seagrasses utilize water column nutrients and remove them from solution. Most scientists believe that there are multiple causes for plankton blooms in the shallow waters surrounding the Keys, so predicting a more direct connection is speculative.

The shallow coral communities fringing Keys shorelines, as well as the offshore Florida Reef Tract, are dominated by animals (hard corals) whose symbiotic algae allow them to grow and deposit new carbonate skeletal materials. Because coral animals host living plant cells in their tissues, and the plants need ample light to survive and reproduce, reef corals need an environment of high water transparency in order to grow and spread. Blooms of microscopic plankton (algae) suspended in the water column block light to the reef, shading out the corals and causing them to die back. Colored, turbid water containing plankton blooms reduces visibility and makes the reefs less attractive to recreational divers.

It is thought that low-transparency water from Florida Bay negatively affects the reef tract by shading out the corals and providing increased nutrients. This may be one of the causes of observed decreases in hard coral cover. If plankton and nutrient exports from Florida Bay to the reef decrease, it is expected to allow affected reef areas to recover, showing increased coral cover and decreased algal overgrowth.

K.12.2 Fish and Wildlife

No positive or negative direct effect on land wildlife is expected as a consequence of any alternative considered in the Restudy. Some positive indirect effects on predatory and wading birds may occur. Many species of birds residing in the Keys fish in Florida Bay. Terns, skimmers, ospreys and bald eagles feed directly on fish. Wading birds, including ibis, wood stork and egrets of several species, also consume small fish and invertebrates. These species formerly utilized the seagrass covered shallows as foraging grounds, roosting in mangrove canopies both on the mainland and on the Keys. The Initial Draft Plan will improve fresh water deliveries and haloperiod of Florida Bay. It is expected that the production of small "bait" fish, invertebrates and larval fish dependent on the seagrass community may increase. These fish, in turn, may support larger populations of fish-eating birds.

To the extent that the Initial Draft Plan fosters re-growth of seagrasses in Florida Bay, some recovery of the commercial pink shrimp fishery may also occur, because the seagrass beds are vital shrimp maturation habitat. Although water deliveries under this alternative have not reached 100 percent of the restoration target for this part of the system, the Initial Draft Plan provides the best combination of actions to increase volume and timing of water deliveries over base conditions.

K.12.3 Water Management

The Keys are outside the geographic scope of all proposed changes in surface water management. Surface and groundwater management in the Keys will not be affected under any alternative considered by the Restudy.

K.12.4 Water supply

The Florida Keys water supply is provided by Miami-Dade County wellfields. The water conservation components in the Initial Draft Plan will reduce water demand. Other components will improve groundwater recharge to Miami-Dade County wellfields. Overall, there would be no adverse effects to water supply, and a potential benefit.

K.12.5 Water Quality

Water quality conditions in the Florida Keys are not expected to be significantly effected by the Initial Draft Plan relative to the projected 2050 base condition. Implementation of the Florida Keys Water Quality Protection Program established pursuant to the Florida Keys National Marine Sanctuary Plan is a significant element of projected 2050 base condition. Major water quality parameters of concern in waters of the Florida Keys are: DO; TP; NOx; turbidity; chlorophyll A and coliforms. For the purposes of this study, the waters of the Florida Keys are evaluated as those waters within the boundaries of the Florida Keys National Marine Sanctuary (FKNMS). The waters of Florida Bay are contiguous with Florida Keys waters on the northern side of the Keys. Salinity conditions in Florida Keys waters are dominated by marine influences, although in the area of northeast Florida Bay, freshwater runoff from the southern Everglades to the north seasonally influences Florida Keys water quality conditions.

Although Initial Draft Plan components, Modification to South Miami-Dade-Southern Portion of L-31N and C-111, and the C-111N Spreader Canal will alter freshwater flows to coastal waters near Key Largo, no evidence exists that these Restudy water management effects will significantly modify Florida Keys water quality relative to the 2050 base condition. Modification to South Miami-Dade-Southern Portion of L-31N and C-111 will increase freshwaters flows to the Taylor Slough/Florida Bay coastal region. C-111N Spreader Canal will eliminate C-111 canal flows and increase surface water sheet flows from the southern Everglades to coastal portions of northeast Florida Bay and, Blackwater Sound.

Further development of the Florida Bay hydrodynamic and water quality models currently under development should provide more information relative to the potential effects of Restudy components on water quality conditions in the Florida Keys. Also, the Restudy Feasibility Report and EIS may recommend initiation of a Florida Bay Feasibility Study. If this feasibility study is initiated, it is likely that future evaluations of potential removal/culverting of portions of Florida Keys highway causeways, currently restricting upper Florida Keys hydrological flushing, would be conducted. Future potential removal/culverting of highway causeways in the upper Florida Keys could have significant beneficial effects on water quality conditions in Florida Keys waters.

K.12.6 Socio-Economics

The Florida Keys are the object of a separate carrying capacity study. Tourism is the largest income producer in the Keys, and would not be impacted either positively or adversely by the Initial Draft Plan. As noted previously, pink shrimp are an important commercial fish species. This fishery is now in decline. If the pink shrimp fishery is indirectly benefited by the Initial Draft Plan features, a multiplier effect would be expected on the local economy, especially in Key West, home of the shrimp fleet.

K.12.7 Land Use, Recreation, and Aesthetics

No land use changes in the Keys are contemplated by the Restudy. Since no construction is proposed for this region, there will be no interruptions or enhancements of recreational use, and the visual characteristics will not be altered. The recommended plan is neutral in its environmental consequences.

K.12.8 Unavoidable Adverse Environmental Effects

No direct physical effects of any kind on Keys lands or waters are considered under any Restudy alternative. There would be no unavoidable adverse environmental effects.

K.12.9 Relationship between Short Term Uses and Long Term Productivity

No short term uses are proposed for any significant features of the human or natural environment of the Keys under this study. No trade-off of long-term productivity for short-term gain are proposed. The purpose of the Restudy is to improve ecosystem characteristics regionwide.

K.12.10 Irreversible and Irretrievable Commitments of Resources

No resources of the Keys would be committed under the Initial Draft Plan.

K.12.11 Cumulative Effects

The Florida Keys are the object of a separately funded, cooperative carrying capacity study. All identified indirect effects of the Initial Draft Plan by the Restudy on the Keys would be positive. It is possible that other measures recommended in the separate Carrying Capacity Study, when it is finished, might combine with the Initial Draft Plan to cause a much more significant cumulative improvement of the Keys' natural environment, if implemented. However, at this time, the study is still underway, and no specific improvement or management measures are known.

APPENDIX L

PRIOR STUDIES, REPORTS, AND PROJECTS

This appendix describes the authorizations for this study and the authorizations for the Central and Southern Florida (C&SF) Project. Also discussed are the discretionary changes made to the project and operation and maintenance responsibilities for the project.

L.1 STUDY AUTHORITY

The C&SF Project Comprehensive Review Study is authorized by *Section 309(l) of the Water Resources Development Act of 1992 (P.L. 580, 102nd Congress, 2nd Session,* approved October 31, 1992) which states:

> *"(1)CENTRAL AND SOUTHERN FLORIDA. -- The Chief of Engineers shall review the report of the Chief of Engineers on central and southern Florida, published as House document 643; 80th Congress, 2d Session, and other pertinent reports, with a view to determining whether modifications to the existing project are advisable at the present time due to significantly changed physical, biological, demographic, or economic conditions, with particular reference to modifying the project or its operation for improving the quality of the environment, improving protection of the aquifer, and improving the integrity, capability, and conservation of urban water supplies affected by the project or its operation."*

This study is also authorized by two resolutions of the Committee on Public Works and Transportation, United States House of Representatives, dated September 24, 1992. The first resolution states:

> *"Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Board of Engineers for Rivers and Harbors, is requested to review the report of the Chief of Engineers on Central and Southern Florida, published as House Document 643, Eightieth Congress, Second Session, and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at the present time, in the interest of environmental quality, water supply and other purposes."*

The second resolution states:

> *"Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Board of Engineers for Rivers and Harbors, is requested to review the report of the Chief of Engineers on Central and Southern Florida, published as House Document 643, Eightieth Congress, Second Session, and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at the present time, in the interest of environmental quality, water supply and other purposes for Florida Bay, including a comprehensive, coordinated ecosystem study with hydrodynamic modeling of Florida Bay and its connections to the Everglades, the Gulf of Mexico, and the Florida Keys Coral Reef ecosystem."*

L.2 C&SF PROJECT AUTHORIZATIONS

The Corps of Engineers role in providing flood control in south Florida has its beginnings with the *Rivers and Harbors Act of 1930*. Passage of the *Flood Control Act of 1948* authorized the Central and Southern Florida Project. Subsequent authorizations since 1948 have resulted in the further development of the project as it exists today. This section describes these project authorizations.

L.2.1 Rivers and Harbors Act of 1930

It is generally understood that the birth of the C&SF Project began with the *Flood Control Act of 1948*, however, the Federal participation began much earlier with the *Rivers and Harbors Act of 1930*. There were even earlier efforts by private, local, State, and Federal interests. Following the disastrous hurricanes of 1926 and 1928, Congress provided disaster relief in the form of flood control and navigation in the 1930 Act. Potential land reclamation benefits were recognized at the time. Prior to the 1948 Act, the project was known as the Caloosahatchee River and Lake Okeechobee Drainage Areas (CR&LODA) Project. The flood control features were extended and incorporated into the C&SF Project. The navigation features were included in the Okeechobee Waterway Project. The *1930 Act (P.L. 520, 71st Congress,* approved July 3, 1930) reads as follows:

> *Miami River, Florida: The Secretary of War is hereby authorized to improve the Miami River with a view to securing a channel one hundred and fifty feet wide and fifteen feet deep for a distance from the mouth of three miles, thence one hundred and twenty-five feet wide and fifteen feet deep to a point four and one-eighth miles from the mouth, thence ninety feet wide and fifteen feet deep to a point five and one-half miles from the mouth; each section to have suitable side slopes; and there is authorized to be appropriated for the prosecution of this work the sum of $800,000: <u>Provided</u>, That no expense shall be incurred by the United*

States for acquiring any lands needed for the purpose of this improvement: Provided further, That local interests shall provide all needed spoil-disposal areas.

Caloosahatchee River and Lake Okeechobee drainage areas, Florida, in accordance with the report submitted in Senate Document Numbered 115, Seventy-first Congress, second session, and subject to the conditions set forth in said document, except that the levees proposed along Lake Okeechobee shall be constructed to an elevation of thirty-one feet instead of thirty-four feet above sea level and shall be so built as to be capable of being raised an additional three feet, and that the United States shall perform the work of constructing all levees: Provided, That the State of Florida or other local interests shall contribute $2,000,000 toward the cost of the above improvements, in lieu of the contributions called for in the aforesaid document: And provided further, That no expense shall be incurred by the United States for the acquirement of any lands necessary for the purposes of this improvement.

[Note that elevations were based on the Punta Rassa datum, later found to be -1.44 feet in error--i.e., the thirty-one foot elevation was actually 29.56 feet, NGVD.]

The 1930 Act authorized the following features:

a. Improvements to the Caloosahatchee River and Canal from Lake Okeechobee to the Gulf of Mexico to provide a 2,500 cfs capacity outlet from Lake Okeechobee and a navigation channel at least 6 feet deep.

b. Improvements to Taylor Creek to provide a 6 feet deep channel from Okeechobee City to Lake Okeechobee.

c. A levee to elevation 31 feet, Lake Okeechobee datum, which is 1.44 feet below National Geodetic Vertical Datum (NGVD) of 1929, and a channel 6 feet deep following in general the south shore of the lake from Fisheating Creek to the St. Lucie Canal.

d. A levee to elevation 31 feet, Lake Okeechobee datum, on the north shore of the lake from the Kissimmee River to Nubbin Slough.

e. Improvements to the St. Lucie River to provide a channel 6 feet deep.

f. Protection works in the St. Lucie Canal for erosion control.

Table L-1 lists CR&LODA Project features incorporated into the C&SF Project. The 1930 Act also provided for the Miami River project which authorized a 15 feet deep channel by 150 feet wide from the mouth for a distance of 3 miles, then 125 feet wide for a distance to 4.5 miles from the mouth, then 90 feet wide to a point 5.5 miles from the mouth. Even though this was a navigation project, it served as an excellent flood control outlet for part of the Miami urban area.

L.2.2 Flood Control Act of 1948

The 1948 Act modified and extended the CR&LODA Project. It created the Central and Southern Florida Project for Flood Control and Other Purposes and changed the project to conform with flood control law and regulations. Project purposes are for flood control, drainage, control of water, and other related purposes. These are preservation of fish and wildlife, regional groundwater control, salinity control, and navigation. The first phase of the Comprehensive Plan for the C&SF Project was authorized for construction. The first phase consisted of levees and channels and control works of Lake Okeechobee, protection and major drainage of the Everglades agricultural area, conservation of water for control of regional groundwater levels, the protection of east coast urban areas from overflow from the Everglades, flood control and water control for salinity control in the existing urban areas along the east coast, and the main outlets for the water conservation areas. The authorization contained in the *1948 Act (P.L. 858, 80th Congress, 2nd Session,* approved June 30, 1948) is as follows:

CENTRAL AND SOUTHERN FLORIDA

> *The project for Caloosahatchee River and Lake Okeechobee drainage areas, Florida, authorized by the River and Harbor Act of July 3, 1930, as amended, is hereby modified and expanded to include the first phase of the comprehensive plan for flood control and other purposes in central and southern Florida as recommended by the Chief of Engineers in House Document Numbered 643, Eightieth Congress, subject to the conditions of local cooperation prescribed therein, and there is hereby authorized to be appropriated the sum of $16,300,000 for partial accomplishment of said plan.*

Table L-2 lists project features authorized or authorized to be modified by the 1948 authorization.

L.2.3 Flood Control Act of 1954

The 1954 Act authorized the remainder of the Comprehensive Plan for the C&SF Project. This included flood control, water conservation, and navigation in the Upper St. Johns and Kissimmee River Basins; an increase in the outlet capacity of the Caloosahatchee River from Lake Okeechobee; the remainder of protective levees for the Everglades agricultural area and the water conservation areas; and the remaining salinity barrier in south Dade County. The 1954 authorization is contained in *P. L. 780*

(83rd Congress, 2d Session, approved September 3, 1954). The authorization pertaining to the C&SF Project is as follows:

CENTRAL AND SOUTHERN FLORIDA

> *The authorization for the comprehensive plan for flood control and other purposes in central and southern Florida given by the Flood Control Act of June 30, 1948, as amended, is hereby modified and expanded to include the entire comprehensive plan of improvement as recommended by the Chief of Engineers in House Document Numbered 643, Eightieth Congress, with such modifications thereof as the Congress may hereafter authorize, or as in the discretion of the Chief of Engineers may be advisable: Provided, That the conditions of local cooperation for the authorized first phase heretofore approved by said flood control Act shall apply to that authorized first phase, but for all work over and beyond that previous authorization such conditions shall apply on an interim basis only until they shall be modified as deemed appropriate by the Congress, based on recommendations to be submitted at the earliest practicable date by the Chief of Engineers, through the Bureau of the Budget to the Congress: Provided further, That whatever conditions of local cooperation are established by the Congress as the result of such recommendations shall be retroactive to any units of the comprehensive plan authorized in this Act which may be started prior to establishment of the exact conditions of local cooperation: And provided further, That in addition to previous authorizations there is hereby authorized to be appropriated the sum of $7,000,000 for partial accomplishment of said plan.*

Table L-3 lists project works authorized by the 1954 Act.

L.2.4 Flood Control Act of 1958

The 1958 Act authorized cost sharing for the project works authorized by the 1954 Act. It also authorized changes to the Comprehensive Plan presented in *House Document 85-186* which deleted the project works listed in Table L-4. The Act also authorized flood protection for 64 square miles of Hendry County west of Levees 1, 2, and 3. The Hendry County plan was superseded by the *Flood Control Act of 1965.* The 1958 authorization is contained in *P. L. 85-500 (85th Congress,* approved July 3, 1958). The portion applicable to the C&SF Project follows:

CENTRAL AND SOUTHERN FLORIDA

> *In addition to previous authorizations there is hereby authorized to be appropriated the sum of $40,000,000 for the prosecution of the comprehensive plan for flood control and other purposes in central and*

> *southern Florida approved in the Act of June 30, 1948, and subsequent Acts of Congress, and such comprehensive plan is hereby modified as recommended by the Chief of Engineers in House Document Numbered 186, Eighty-fifth Congress, and to include the following items:*
>
> *The project for canals, levees, water control structures on the west side of the Everglades agricultural and conservation areas in Hendry County, Florida, substantially in accordance with the recommendations of the Chief of Engineers contained in Senate Document Numbered 48, Eighty-fifth Congress, at an estimated cost of $3,172,000.*

Project works authorized by the 1958 Act are listed in Table L-4.

L.2.5 Flood Control Act of 1960

The 1960 Act authorized flood protection for the Nicodemus Slough area, Glades County, Florida and authorized the name of all the levees around the shore of Lake Okeechobee to be the Herbert Hoover Dike. The 1960 authorization is contained in *P. L. 86-645 (86th Congress,* approved July 14, 1960). The portion applicable to the C&SF Project follows:

CENTRAL AND SOUTHERN FLORIDA

> *In addition to previous authorizations, there is hereby authorized to be appropriated the sum of $23,000,000 for the prosecution of the comprehensive plan for flood control and other purposes in central and southern Florida approved in the Act of June 30, 1948, and subsequent Acts of Congress, and such comprehensive plan is hereby modified to include the following:*
>
> *The project for canals, levees, and water control and drainage structures in the Nicodemus Slough area, Glades County, Florida, is hereby authorized substantially in accordance with the recommendations of the Chief of Engineers contained in Senate Document Numbered 53, Eighty-sixth Congress, at an estimated cost of $318,000.*
>
> *That the levees around Lake Okeechobee, Florida, authorized by the Rivers and Harbors Act approved July 3, 1930, and modified by the Flood Control Act approved June 30, 1948, and subsequent Acts, shall be known and designated as Herbert Hoover Dike, and any law, regulation, document, or record of the United States in which such levees are referred to under any other name or designation shall be held to refer to such levees as the Herbert Hoover Dike.*

Project features authorized by the 1960 Act are shown in Table L-5.

L.2.6 Flood Control Act of 1962

The 1962 Act authorized modification and extension of the C&SF Project for flood control and major drainage. The 1962 authorization is contained in *P.L. 87-874 (87th Congress, 2nd Session*, approved October 23, 1962). The portion applicable to the C&SF Project follows:

CENTRAL AND SOUTHERN FLORIDA

> *The comprehensive plan for flood control and other purposes in central and southern Florida approved in the Act of June 30, 1948, and subsequent Acts of Congress, is hereby modified to include the following items:*
>
> *The project for flood protection of West Palm Beach Canal is hereby authorized substantially as recommended by the Secretary of the Army and the Chief of Engineers in Senate Document Numbered 146, Eighty-seventh Congress, at an estimated cost of $3,220,000.*
>
> *The project for flood protection on Boggy Creek, Florida, is hereby authorized substantially as recommended by the Chief of Engineers in Senate Document Numbered 125, Eighty-seventh Congress, at an estimated cost of $1,176,000.*
>
> *The project for South Dade County, Florida, is hereby authorized substantially in accordance with the recommendations of the Secretary of the Army and the Chief of Engineers in Senate Document Numbered 138, Eighty-seventh Congress, at an estimated cost of $13,388,000.*
>
> *The project for Shingle Creek, Florida, between Clear Lake and Lake Tohopekaliga, for flood control and major drainage is hereby authorized substantially as recommended by the Chief of Engineers in Senate Document Numbered 139, Eighty-seventh Congress, at an estimated cost of $3,250,000: Provided, That no obligation shall be incurred for development of Reedy Creek Swamp as a wildlife management area unless the State or one or more other non-Federal entities shall have entered into an agreement in advance to assume at least 50 per centum of the cost associated with that feature of the project.*
>
> *The project for flood protection in the Cutler drain area, Florida, is hereby authorized substantially in accordance with recommendations of the Chief of Engineers in Senate Document Numbered 123, Eighty-seventh Congress, at an estimated cost of $2,063,000:*

> *Provided, That local interests shall receive credit in the Contributed Fund Account of the project for moneys shown to have been spent after March 1, 1960, for construction of units of the authorized plan for Cutler Drain: Provided further, That such completed work must be inspected and accepted by the Chief of Engineers as constituting useful parts of the authorized plan: And provided further, That the credit established shall be in accordance with cost sharing arrangements for the central and southern Florida flood control project in an amount not to exceed $124,000.*

The 1962 authorization affected the following areas:

a. West Palm Beach Canal, east of Water Conservation Area 1, to provide for removal of 30-percent standard project flood from the west agricultural reaches of the canal simultaneously with the 60-percent standard project flood runoff from the east urban reaches,

b. Boggy Creek, tributary to East Lake Tohopekaliga in the Kissimmee River Basin, to remove without damaging ponding the 30-percent standard project flood from the entire 80.5-square-mile drainage area,

c. South Dade County, to remove the 40-percent standard project flood runoff from the entire 206-square-mile effective drainage area, to reduce depth and duration of larger floods, and to provide water control to prevent overdrainage in the area,

d. Shingle Creek, tributary to Lake Tohopekaliga in the Kissimmee River Basin, to remove the 30-percent standard project flood runoff from the area directly tributary to Shingle Creek, to provide sufficient capacity in the lower reach to accommodate the future runoff from Reedy Creek Swamp and its tributaries, to create a wildlife management area in the Reedy Creek Swamp area, to reduce depth and duration of larger floods, and to provide water control to prevent overdrainage in the area, and,

e. Cutler Drain area of Dade County, to remove the 40-percent standard project flood runoff from the entire 38.4-square-mile contributing drainage area, to reduce depth and duration of larger floods, to provide water control for the area by maintaining optimum water levels, and provide means for diversion of waters (when available) from the C-1 and C-2 canals for salinity and water control purposes.

Table L-6 lists project features authorized by the 1962 authorization.

L.2.7 Flood Control Act of 1965

The 1965 Act authorized a new plan for Hendry County west of levees L-1, 2, and 3. The new plan provided for flood protection and major drainage for 261 square miles. It provided for protection of the original 64-square-mile pumped area comparable to that provided in the agricultural area to the east. In addition, it provided for removal of the 10-year flood runoff from the 197-square-mile area west of the proposed interceptor canal; for reduction in the depth and duration of floods of greater magnitude than the 10-year flood; and for water control in the area, insofar as possible. The Act also provided for a seasonal flood protection plan in Southwest Dade County. The plan would provide levees, canals, water control structures, and pumping stations capable of removing 15 inches of runoff per month plus seepage into the area following a 10-year flood. The plan would enable desirable levels for winter agriculture to be achieved by October 10 in a dry year, by October 20 in a normal year, and by November 10 following a 1-in-10-year flood. During a 1-in-10-year flood during the November through April period the pumps would permit 0.50 to 0.75-inch a day runoff removal from the 118-square-mile drainage area. This area is known as the East Everglades area and is authorized for addition to Everglades National Park except for the developed areas. The 1965 authorization is contained in *P.L. 89-298 (89th Congress, 1st Session*, approved October 27, 1965).

CENTRAL AND SOUTHERN FLORIDA BASIN
Comprehensive Plan

> *The comprehensive plan for flood control and other purposes in central and southern Florida approved in the Act of June 30, 1948 and subsequent Acts of Congress, is hereby modified to include the following items:*
>
> *The project for flood protection in Hendry County, west of levees 1, 2, and 3, Florida, is hereby authorized substantially as recommended by the Chief of Engineers in House Document Numbered 102, Eighty-eighth Congress, at an estimated cost of $4,986,000.*
>
> *The project for flood protection in southwest Dade County, Florida, is hereby authorized substantially in accordance with the recommendations of the Chief of Engineers in Senate Document Numbered 20, Eighty-ninth Congress, at an estimated cost of $4,903,000.*

Project features authorized by the 1965 Act are shown in Table L-7.

L.2.8 Flood Control Act of 1968

The *1968 Act (Public Law 483, 90th Congress, 2nd Session*, approved August 13, 1968) authorized modification to the existing project in the interest of improved conservation and distribution of available water and extended flood protection. The Act authorized an interrelated system of canals, levees, a pumping station, and other structures necessary to supply irrigation water, to maintain optimum water-control levels, and to remove flood runoff for portions of St. Lucie and Martin Counties. The authorization also included provisions to meet the long-term needs of urban and agricultural users and the Everglades National Park. Authorizations for the C&SF Project contained in the 1968 Act are as follows:

CENTRAL AND SOUTHERN FLORIDA

> *The project for Central and Southern Florida, authorized by the Flood Control Act of June 30, 1948, is further modified in accordance with the recommendations of the Chief of Engineers in Senate Document Numbered 101, Ninetieth Congress, at an estimated cost of $8,072,000, and in accordance with House Document Numbered 369, Ninetieth Congress, at an estimated cost of $58,182,000.*

Senate Document Numbered 101 contains the plan of improvement for the Martin County Plan. *House Document Numbered 369* contains the Water Resources Plan for Central and Southern Florida. The project features authorized include:

a. Martin County. For Martin and St. Lucie Counties:

(1) Main channel improvements - including 59 miles of canal, 7 highway bridges, 3 railroad bridges and secondary improvements to convey runoff to project canals.

(2) Primary control structures—including 11 gated spillways, 2 gated culverts, and 1 pumping station.

(3) Inlet structures—provided at existing and proposed inflow points to protect the project canals from siltation and to prevent erosion.

b. Water Resources for Central and Southern Florida. For conservation and conveyance of additional water supplies to users:

(1) Facilities for pumping excess water from east coast areas into storage in Lake Okeechobee and the water conservation areas;

(2) A system of interrelated canals, levees, pumping stations, and control structures for conveyance and distribution of water to demand areas;

(3) Deepening the navigation channel across Lake Okeechobee;

(4) Construction of recreation facilities;

(5) Raising the Lake Okeechobee levees to provide for an increase of about 4 feet in the authorized regulation Stages;

(6) Deletion of the deepening of the St. Lucie Canal from the authorized project; and

(7) The construction of the small craft lock in Buttonwood Canal.

Project features authorized by the 1968 Act are shown in Table L-8.

L.2.9 River Basin Monetary Authorization and Miscellaneous Civil Works Amendments Act of 1970

The *1970 Act (P.L. 282, 91st Congress, 1st Session*, approved June 19, 1970) provided funding for the accelerated construction of borrow canal L-70, canal C-308, canal C-119W, and pumping station S-326 in order to meet the increased water requirements of the Everglades National Park. The Act further provided for the delivery from the project to Everglades National Park a minimum of 315,000 acre-feet of water according to a monthly distribution and to locations stated in the National Park Service letter of October 20, 1967, to the Chief of Engineers, or 16.5 percent of total project deliveries for all purposes, whichever is less. *S.D. 91-895*, which accompanied the law, provided a formula for deciding when the 16.5 percent quantity applied. The formula was found to be faulty and hasn't been applied since the earliest months following enactment. The following is a quote from this act:

> *SEC. 2. In addition to previous authorizations, there is hereby authorized to be appropriated the sum of $25,000,000 for the prosecution of the central and southern Florida comprehensive plan for flood control and other purposes approved in the Flood Control Act of 1948, and subsequent Acts of Congress: Provided, That not to exceed $5,000,000 of this authorization shall be available solely for the accelerated construction of borrow canal L-70, canal C-308, canal C-119W, and pumping station S. 326, together with such other works in the plan of improvement as the Director of the National Park Service and the Chief of Engineers agree are necessary to meet the water requirements of the Everglades National Park: Provided further, That as soon as practicable and in any event upon completion of the works specified in the preceding proviso, delivery of water from the central and southern Florida project to the Everglades National Park shall be not less than 315,000 acre-feet annually, prorated according to the monthly schedule set forth in the*

> *National Park Service letter of October 20, 1967, to the Office of the Chief of Engineers, or 16.5 per centum of total deliveries from the project for all purposes including the park, whichever is less.*

L.2.10 Small Boat Navigation Authorization of 1970

Authorization for navigation improvements suitable for recreational craft were approved in *H.D. No. 394 (91st Congress, 2d Session).* These improvements were authorized by the Committee on Public Works on December 12, 1970, under provisions of *Section 201 of the Flood Control Act of 1965.* Project features included a number of small navigation locks with connecting channels in the Upper Kissimmee River Basin and a separate system of locks and channels in the Upper St. Johns River Basin.

The facilities authorized are shown on Table L-9.

None of the features authorized in *H.D. 91-394* have been constructed; therefore, these features were deauthorized January 1, 1990, under the authority of the *Water Resources Development Act of 1986 (P.L. 99-662)* and the *Water Resources Development Act of 1988 (P.L. 100-676).*

L.2.11 Economic Update, C&SF Project, November 1973

H.R. 93-327 required the Corps of Engineers to update the economics of the C&SF Project. As a result, several project features were deleted from the project and many others were relegated to inactive status.

L.2.12 Supplemental Appropriations Act of 1984

This act modified the schedule for delivery of water from the Central and Southern Florida Project to Everglades National Park as required in the *River Basin Authorization and Miscellaneous Civil Works Amendments Act of 1970.* Furthermore, it authorized an experimental program for the delivery of water to Everglades National Park for the purpose of determining an improved schedule for water delivery. The Act of 1984 is contained in *P.L. 98-181 (98th Congress, 1st Session*, approved November 30, 1984), which modified the water delivery schedule to Everglades National Park. Below is an excerpt from this act:

> *SEC. 1302. The Secretary of the Army is authorized, for a period of two years beginning with the enactment of this Act with the concurrence of the Director of the National Park Service and the South Florida Water Management District, to modify the schedule for delivery of water from the central and southern Florida project to the Everglades National Park required by section 2 of the River Basin Monetary Authorization and Miscellaneous Civil Works Amendments Act of 1970*

(Public Law 91-282) and to conduct an experimental program for the delivery of water to the Everglades National Park from such project for the purpose of determining an improved schedule for such delivery.

The Secretary of the Army is further authorized to acquire such interest in lands currently in agriculture production which are adversely affected by any modification of schedule for water delivery to Everglades National Park under the preceding paragraph. The Secretary shall acquire any interest in land at the fair market value of such interest based on conditions existing after the construction of the project described in the preceding paragraph of this section and before any modification of such delivery schedule. The Secretary is also authorized to construct necessary flood protection measures for protection of homes in the area affected by any modification of such delivery schedule, at an estimated cost of $10,000,000.

This law has since been amended twice to extend the experimental program for water deliveries to the Everglades National Park. The first such amendment was contained in *P.L. 99-190 (99th Congress, 1st Session,* approved December 19, 1985).

L.2.13 Water Resources Development Act of 1986

Public Law 662 (99th Congress, 2nd Session) was approved November 17, 1986. This act authorized a study by the Corps of Engineers in conjunction with the Environmental Protection Agency of the water quality and water supply potential of Lake Okeechobee. The Act also authorized a study of various alternatives for flood protection in the Upper St. John's River Basin. The following are excerpts from this act:

SEC. 733. LAKE OKEECHOBEE STUDY

(a) The Secretary, in consultation with the Administrator of the Environmental Protection Agency, is authorized to undertake a study of the water supply potential of Lake Okeechobee in Florida, with particular emphasis on determining the causes of water quality deterioration in the lake and the impact, if any, that the Central and Southern Florida Irrigation [sic] Project may have on water quality in the lake. In undertaking the study authorized pursuant to this section, the Secretary shall coordinate with the State of Florida and shall assess the impact of short- and long-term solutions proposed by Federal, State, and local entities to alleviate the water quality and water supply problems of Lake Okeechobee.

(b) Within two years after the first appropriation of funds for the study, the Secretary shall report to the Committee on Public Works and

Transportation of the House of Representatives and the Committee on Environment and Public Works of the Senate on the results of the study authorized pursuant to this section and any recommendations of the Secretary concerning measures which may be implemented at the Federal, State, or local level to improve the water quality and the water supply potential of Lake Okeechobee.

(c) There are authorized to be appropriated $1,000,000 for fiscal years beginning after September 30, 1986, to carry out this section.

SEC. 1153. UPPER ST. JOHN'S RIVER BASIN, FLORIDA

(a) For any survey, planning, or design of any water resources project for the Upper St. John's River Basin, Florida, the Secretary shall give equal consideration to structural, nonstructural, and primarily nonstructural alternatives including, but not limited to, floodproofing of structures; flood plain regulation; acquisition of flood plain lands for recreation, fish and wildlife, and other public purposes; relocation; reductions in water demand; water-borne traffic scheduling; and vessel modification with a view toward formulating the most economically, socially, and environmentally acceptable means of solving the water resources problem.

(b) Cost sharing applicable to nonstructural local flood protection projects shall apply to any water resources project on the Upper Saint John's River Basin, consistent with section 903(c).

L.2.14 Water Resources Development Act of 1988

This act authorized several different items that pertain to the Central and Southern Florida Project. First, a simulation model of the hydrologic ecosystem for use in predicting the effects of modifications to the project, changes in operation of the project, and other activities in the vicinity of the project was authorized. Second, the Supplemental Appropriations Act of 1984 was amended by extending the date for completion of the modified water delivery schedule to Everglades National Park. Third, a demonstration project on the Kissimmee River was authorized. Last, a study of the need for internal drainage in the Frog Pond agricultural area of south Miami-Dade County was authorized. *Public Law 100-676 (100th Congress)* was approved November 17, 1988. The following are excerpts from the Act:

SEC. 11. SIMULATION MODEL OF SOUTH CENTRAL FLORIDA HYDROLOGIC ECOSYSTEM

(a) IN GENERAL. - The Secretary, in cooperation with affected Federal, State, and local agencies and other interested persons, may

develop and operate a simulation model of the central and southern Florida hydrologic ecosystem for use in predicting the effects--

(1) of modifications to the flood control project for central and southern Florida, authorized by the Flood Control Act of 1948,

(2) of changes in the operation of such project, and

(3) of other human activities conducted in the vicinity of such ecosystem which individually or in the aggregate will significantly affect the ecology of such ecosystem, on the flow, characteristics, quality, and quantity of surface and ground water in such ecosystem and on plants and wildlife within such ecosystem. Such model shall be capable of producing information which is applicable for use in evaluating the impact of issuance of proposed permits under section 10 of the Act of March 3, 1899 (30 Stat. 1151; 33 U.S.C. 403), commonly known as the River and Harbors Appropriation Act of 1899, and under section 404 of the Federal Water Pollution Control Act.

(b) AVAILABILITY TO STATE AND LOCAL AGENCIES - The Secretary shall allow Federal, State, and local agencies to use, on a reimbursable basis, the simulation model developed under this section.

(c) COST SHARING - The Federal share of the cost of developing and operating the simulation model under this section shall be 75 percent.

SEC. 40. EXTENSION OF MODIFIED WATER DELIVERY SCHEDULES, EVERGLADES NATIONAL PARK.

The first sentence of section 1302 of the Supplemental Appropriations Act, 1984 (97 Stat. 1292-1293) is amended by striking out "January 1, 1989" and inserting in lieu thereof "January 1, 1992".

SEC. 46. KISSIMMEE RIVER, FLORIDA.

The Secretary is directed to proceed with work on the Kissimmee River demonstration project, Florida, pursuant to section 1135 of the Water Resources Development Act of 1986.

SEC. 47. WATER RESOURCES STUDIES.

(a) INTERNAL DRAINAGE SYSTEM, FROG POND AGRICULTURAL AREA, FLORIDA - The Secretary shall conduct a study for the purpose of determining the need for an internal drainage

system in the Frog Pond agricultural area of south Dade County, Florida. Within 1 year after the date of the enactment of this Act, the Secretary shall submit to Congress a reconnaissance report on the need for such system.

L.2.15 Everglades National Park Protection and Expansion Act of 1989

The purpose of the Everglades National Park Protection and Expansion Act of 1989 (P.L. 101-229) was *"To modify the boundaries of the Everglades National Park and to provide for the protection of lands, waters, and natural resources within the park, and for other purposes". Public Law 101-229 (101st Congress)* was approved on December 13, 1989. This act also authorized the construction of modifications to the Central and Southern Florida Project to improve water deliveries to the park and to the extent practicable permits steps to restore the natural hydrological conditions within the park. These modifications are *"justified by the environmental benefits to be derived by the Everglades ecosystem in general and the park in particular".* The following are excerpts from the Act:

SEC. 104. MODIFICATION OF CERTAIN WATER PROJECTS.

(a) IMPROVED WATER DELIVERIES.

(1) Upon completion of a final report by the Chief of Army Corps of Engineers, the Secretary of the Army, in consultation with the Secretary [of the Interior], is directed to construct modifications to the Central and Southern Florida Project to improve water deliveries into the park and shall, to the extent practicable, take steps to restore the natural hydrological conditions within the park.

(2) Such modifications shall be based upon the findings of the Secretary's experimental program authorized in section 1302 of the 1984 Supplemental Appropriations Act (97 Stat. 1292) and generally set forth in a General Design Memorandum to be prepared by the Jacksonville District entitled "Modified Water Deliveries to Everglades National Park". The Draft of such Memorandum and the Final Memorandum, as prepared by the Jacksonville District, shall be submitted as promptly as practicable to the Committee on Energy and Natural Resources and the Committee on Environment and Public Works of the United States Senate and the Committee on Interior and Insular Affairs and the Committee on Public Works and Transportation of the United States House of Representatives.

(3) Construction of project modifications authorized in this subsection and flood protection systems authorized in subsections (c) and (d) are justified by the environmental benefits to be derived by the

Everglades ecosystem in general and by the park in particular and shall not require further economic justification.

(4) Nothing in this section shall be constructed to limit the operation of project facilities to achieve their design objectives, as set forth in the Congressional authorization and any modifications thereof.

(b) DETERMINATION OF ADVERSE EFFECT.

(1) Upon completion of the Final Memorandum referred to in subsection (a), the Secretary of the Army, in consultation with the South Florida Water Management District, shall make a determination as to whether the residential area within the East Everglades known as the "Eight and One-Half Square Mile Area" or adjacent agricultural areas, all as generally depicted on the map referred to in subsection 102(a), will be adversely affected by project modifications authorized in subsection (a).

(2) In determining whether adjacent agricultural areas will be adversely affected, the Secretary of the Army shall consider the impact of any flood protection system proposed to be implemented pursuant to subsection (c) on such agricultural areas.

(c) FLOOD PROTECTION; EIGHT AND ONE-HALF SQUARE MILE AREA. - If the Secretary of the Army makes a determination pursuant to subsection (b) that the "Eight and One-Half Square Mile Area" will be adversely affected, the Secretary of the Army is authorized and directed to construct a flood protection system for that portion of presently developed land within such area.

(d) FLOOD PROTECTION; ADJACENT AGRICULTURAL AREA. - If the Secretary of the Army determines pursuant to subsection (b) that an adjacent agricultural area will be adversely affected, the Secretary of the Army is authorized and directed to construct a flood protection system for such area. Such determination shall be based on a finding by the Secretary of the Army that:

(A) the adverse effect will be attributable solely to a project modification authorized in subsection (a) or to a flood protection system implemented pursuant to subsection (c), or both; and

(B) such modification or flood protection system will result in a substantial reduction in the economic utility of such area based on its present agricultural use.

(2) No project modification authorized in subsection (a) which the Secretary of the Army determines will cause an adverse effect pursuant to subsection (b) shall be made operational until the Secretary of the Army has implemented measures to prevent such adverse effect on the adjacent agricultural area: Provided, That the Secretary of the Army or the South Florida Water Management District may operate the modification to the extent that the Secretary of the Army determines that such operation will not adversely affect the adjacent agricultural area: Provided further, That any preventive measure shall be implemented in a manner that presents the least prospect of harm to the natural resources of the park.

(3) Any flood protection system implemented by the Secretary of the Army pursuant to this subsection shall be required only to provide for flood protection for present agricultural uses within such adjacent agricultural area.

(4) The acquisition of land authorized in section 102 shall not be considered a project modification.

(e) PERIODIC REVIEW. - (1) Not later than 18 months after the completion of the project modifications authorized in subsection (a), and periodically thereafter, the Secretary of the Army shall review the determination of adverse effect for adjacent agricultural areas.

(2) In conducting such review, the Secretary of the Army shall consult with all affected parties, including, but not limited to, the Secretary, the South Florida Water Management District and agricultural users within adjacent agricultural areas.

(3) If, on the basis of such review, the Secretary of the Army determines that an adjacent agricultural areas has been, or will be adversely affected, the Secretary of the Army is authorized and directed, in accordance with the provisions of subsection (d), to construct a flood protection system for such area: Provided, That the provisions of subsection (d)(2) shall be applicable only to the extent that the Secretary, in consultation with the Secretary of the Army, determines that the park will not be adversely affected.

(4) The provisions of this subsection shall only be applicable if the Secretary of the Army has previously made a determination that such adjacent agricultural area will not be adversely affected.

(f) CURRENT CANAL OPERATING LEVELS. - Nothing in this section shall be construed to require or prohibit the Secretary of the Army or the South Florida Water Management District from maintaining the

water level within any project canal below the maximum authorized operating level as of the date of enactment of this Act.

(g) NO LIMITATION ON OTHER CLAIMS. - If the Secretary of the Army makes a determination of no adverse effect pursuant to subsection (b), such determination shall not be considered as a limitation or prohibition against any available legal remedy which may otherwise be available.

(h) COORDINATION. - The Secretary and the Secretary of the Army shall coordinate the construction program authorized under this section and the land acquisition program authorized in section 102 in such a manner as will permit both to proceed concurrently and as will avoid unreasonable interference with property interests prior to the acquisition of such interests by the Secretary under section 102.

(i) WEST DADE WELLFIELD. - No Federal license, permit, approval, right-of-way or assistance shall be granted or issued with respect to the West Dade Wellfield (to be located in the Bird Drive Drainage Basin, as identified in the Comprehensive Development Master Plan for Dade County, Florida) until the Secretary, the Governor of the State of Florida, the South Florida Water Management District and Dade County, Florida enter into an agreement providing that the South Florida Water Management District's water use permit for the wellfield, if granted, must include the following limiting conditions: (1) the wellfield's peak pumpage rate shall not exceed 140,000,000 gallons per day; (2) the permit shall include reasonable, enforceable measures to limit demand on the well field in times of water shortages; and (3) if, during times of water shortage, the District fails to limit demand on the wellfield pursuant to (2), or if the District limits demand on the wellfield pursuant to (2), but the significant adverse impacts on the resources of the Park, the Governor shall require the South Florida Water Management District to take necessary actions to alleviate the adverse impact, including, but not limited to, temporary reductions in the pumpage from the wellfield.

(j) PROTECTION OF NATURAL VALUES. - The Secretary of the Army is directed in analysis, design and engineering associated with the development of a general design memorandum for works and operations in the "C-111 basin" area of the East Everglades, to take all measures which are feasible and consistent with the purpose of the project to protect natural values associated with Everglades National Park. Upon completion of a general design memorandum for the area, the Secretary shall prepare and transmit a report to the Committee on Energy and

> *Natural Resources and the Committee on Environment and Public Works of the United States Senate and the Committee on Interior and Insular Affairs and the Committee on Public Works and Transportation of the United States House of Representatives on the status of the natural resources of the C-111 basin and functionally related lands.*

Project features authorized by this act are shown on Table L-10.

L.2.16 Water Resources Development Act of 1990

This act authorized a feasibility study for the purpose of determining modifications to the Kissimmee River portion of the Central and Southern Florida Project for the environmental restoration of the Kissimmee River. *Public Law 101-640 (101st Congress)* was approved November 17, 1990. The following are excerpts from the Act:

Sec 107(h) KISSIMMEE RIVER,
CENTRAL AND SOUTHERN FLORIDA

> *(1) STUDY. - The Secretary shall conduct a feasibility study of the Kissimmee River in central and southern Florida for the purpose of determining modifications of the flood control project for central and southern Florida, authorized by section 203 of the Flood Control Act of 1948 (62 Stat. 1176), which are necessary to provide a comprehensive plan for the environmental restoration of the Kissimmee River. The study shall be based on implementing the Level II Backfilling Plan specified in the Kissimmee River Restoration, Alternative Plan Evaluation and Preliminary Design Report, dated June 1990, published by the South Florida Water Management District.*
>
> *(2) REPORT. - Not later than April 1, 1992, the Secretary shall transmit to Congress a final report of the Chief of Engineers on the results of the study conducted under this subsection, together with such modifications as are recommended by the Secretary.*
>
> *(3) POST-STUDY WORK. - All work necessary to prepare the project recommended by the Chief of Engineers, as modified by the Secretary, for construction bidding, including Feature Design Memoranda, shall be completed by June 1, 1994.*

L.2.17 Water Resources Development Act of 1992

This act *(Public Law 580, 102nd Congress, 2nd session, approved October 31, 1992)* which authorized the C&SF Project Comprehensive Review Study also authorized the Kissimmee River Restoration Project, including the Headwaters

Revitalization Project. Construction of a quarantine facility for melaleuca control was also authorized. Pertinent sections of the Act follow:

> *Section 101 (8) Kissimmee River Restoration, Florida.*
>
> *The project for the ecosystem restoration of the Kissimmee River, Florida: Report of the Chief of Engineers, dated March 17, 1992, at a total cost of $426,885,000, with an estimated Federal cost of $139,943,999 and an estimated non-Federal cost of $286,942,000. The Secretary is further authorized to construct the Kissimmee River headwaters revitalization project in accordance with the report prepared under section 1135 of the Water Resources Development Act of 1986 (100 Stat. 4251 - 4252) for such headwaters project and any modifications as are recommended by the Secretary based on the benefits derived for the environmental restoration of the Kissimmee River basin, at a total cost of $92,210,000, with an estimated Federal cost of $46,105,000 and an estimated non-Federal cost $46,105,000. The Secretary shall take such action as may be necessary to ensure that implementation of the project to restore the Kissimmee River will maintain the same level of flood protection as is provided by the current flood control project.*
>
> *Section 108. Quarantine Facility.*
>
> *a. Construction. The Secretary, in consultation with the Governor of Florida, shall construct a research and quarantine facility in Broward County, Florida, to be used in connection with efforts to control Melaleuca and other exotic plant species that threaten native ecosystems in the State of Florida.*
>
> *b. Operation and Maintenance. After construction, the Secretary shall transfer the facility constructed under this section to the Secretary of Agriculture. The facility shall be jointly maintained and operated by the Department of Agriculture and an appropriate agency or agencies of the State of Florida.*
>
> *c. Authorization of Appropriations. There is authorized to be appropriated for fiscal years beginning after September 30, 1992, $1,000,000 for the construction of the facility described in subsection (a). Such sums shall remain available until expended.*

L.2.18 Everglades Forever Act, 1994

The Florida Everglades Statutes 373.4592 passed after many years of litigation involving the United States, the State of Florida, the SFWMD, the DEP, and certain large agricultural interests to determine how and at whose expense pollution of the Everglades should be abated. The Everglades Forever Act established two funding sources for pollution abatement in the Everglades Agricultural Area (EAA): the Everglades agricultural privilege tax, and the levy of a 0.1 mill ad valorem tax on property within the Okeechobee Basin. Therefore, the law in effect at the time of the adoption of Amendment 5 was designed to divide the burden of the costs of pollution abatement on the public by the 0.1 mill tax and the agricultural users by the privilege tax of $24.89 per acre. The Florida Constitution was amended after this Act to direct the legislature to make those in the EAA who cause water pollution in the EAA and Everglades Protection Area (EPA) "primarily responsible" for the costs of cleaning up the pollution.

L.2.19 Water Resources Development Act of 1996

This act *(Public Law 843, 104th Congress)* authorizes cost sharing changes for flood control and environmental restoration and protection projects, a number of significant environmental provisions, and clarification of cost sharing for dredged material disposal facilities. Pertinent sections of the Act follow:

Section 315 Central and Southern Florida, Canal 51.

The project for flood protection of West Palm Beach, Florida (C-51), authorized by section 203 of the Flood Control Act of 1962 (76 Stat. 1183), is modified to provide for the construction of an enlarged stormwater detention area, Storm Water Treatment Area 1 East, generally in accordance with the plan of improvements described in the February 15, 1994, report entitled "Everglades Protection Project, Palm Beach County, Florida, Conceptual Design", with such modifications as are approved by the Secretary. The additional work authorized by this section shall be accomplished at Federal Expense. Operation and maintenance of the stormwater detention area shall be consistent with regulations prescribed by the Secretary for the Central and Southern Florida project, and all costs of such operation and maintenance shall be provided by non-Federal interests.

Section 316 (a) Central and Southern Florida, Canal 111.

In General. - - The project for Central and Southern Florida, authorized by section 203 of the Flood Control Act of 1948 (62 Stat. 1176) and modified by section 203 of the Flood Control Act of 1968 (82 Stat. 740-741), is modified to authorize the Secretary to implement the recommended plan of improvement contained in a report entitled "Central and Southern Florida Project, Final Integrated General Reevaluation Report and Environmental Impact Statement, Canal 111 (C-111), South Dade County, Florida", dated May 1994, including *acquisition by non-Federal interests of such portions of the Frog Pond and Rocky Glades areas as are needed for the project.*

Section 528 Everglades and South Florida Ecosystem Restoration.

(a) The Secretary is to expeditiously develop a comprehensive plan for restoring, preserving, and protecting the South Florida ecosystem including water quality, fresh water supply, flood control, and water supply.

(b) NLT July 1, 1999, provide a report on the comprehensive plan and complete the feasibility phase of the Central and Southern Florida Project.

(c) The Secretary may proceed with any features authorized under the Central and Southern Florida Project and other independent critical restoration projects compatible with the overall task force framework.

(d) All activities should be integrated with other ongoing State and Federal projects and activities.

(e) Establishes a South Florida Ecosystem Restoration Task Force to provide consultation with the Secretary during development of the comprehensive plan, and provide a forum for developing consistent policies and strategies for restoring the South Florida ecosystem and coordinating information with the public and other related organizations. The task force will provide a biennial report to Congress.

A summary of the authorized project purposes and the applicable authorizations is found on Table L-11.

L.3 DISCRETIONARY PROJECT CHANGES

The Comprehensive Plan for flood control and other project purposes was presented in the report to the Chief of Engineers on Central and Southern Florida, published as *House Document 643 (80th Congress, 2d Session)* in 1948. The project was partially authorized by the *Flood Control Act of 1948 (Public Law 858, 80th Congress, 2d Session).* That authorization included most of the works necessary to afford flood protection to the rich agricultural development south of Lake Okeechobee and to the highly developed area along the lower east coast. The remaining works of the Comprehensive Plan as presented in *House Document 643*, were authorized by the

Flood Control Act of 1954, approved September 3, 1954 *(Public Law 780, 83rd Congress, 2d Session).* This authorization specifically recognized that the plan of improvement would require refinement and that modifications, within the scope and purpose of the authorization, could be made at the discretion of the Chief of Engineers.

The Central and Southern Florida Project for Flood Control and Other Purposes resulted in a comprehensive series of reports and design memorandums used in planning and designing the water control system. Many of these reports recommended additions and/or deletions and modifications to the originally authorized project. These recommendations were made as a result of more detailed studies, or at the request of the local sponsor. The original local sponsor for the project was the Central and Southern Florida Flood Control District (C&SFFCD) created by the Florida Legislature in 1949. However, in 1972 the State of Florida reorganized the flood control districts and the new local sponsors became the South Florida Water Management District (SFWMD) and the St. Johns River Water Management District (SJRWMD). What follows is an account of project features by area which were added, deleted, or modified by the District Engineer after authorization. Tables L-1 through L-10 summarize the status of project features by authorization.

L.3.1 Kissimmee River Basin

Project works in the basin were authorized by the *Flood Control Act of 1954*, approved September 3, 1954 (*Public Law 780, 83rd Congress, 2d Session).* However, earlier *Congressional Acts in 1937, 1939, and 1946* had directed that studies on regulating the Kissimmee River and its tributaries be made at the request of State interests. The existing project works now in the Kissimmee -Lake Istokpoga basin conform closely with the general plan outlined in the 1948 report to Congress. The major lakes of the upper basin which are used as water conservation reservoirs, are connected by channels, in most cases channels excavated by Hamilton Disston in the 1880s but enlarged to varying degrees under the Congressionally authorized plan. Nine control structures regulate water levels and flows in the lakes channel system. Five water control structures control water elevations in the lower basin canal and regulate flows originating in both the upper and lower basins. These structures also have locks which provide year-round navigability within and through the Kissimmee basin.

a. Part II, Supplement 5, - General Design Memorandum. Kissimmee River Basin dated October 8, 1956, presents the results of hydrologic and hydraulic investigations for development of the plan of improvement of the Kissimmee River basin. The report recommended several significant changes from the original comprehensive plan. First, this report recommended that the following project features not included in the Comprehensive Plan be included in the plan of improvement. This included the construction of canals 29, 45, 46, and 47 and structures 62, 63, 63A, 86, 87, 87A, 87B, 88, 88A, and 88B, plus all necessary secondary drainage structures. Secondly, the report recommended that structures 56 and 65F be deleted from the plan. These recommendations were approved by the Chief of Engineers on February 27, 1957.

b. Part II, Supplement 5, Section 2, dated April 11, 1969, recommended the following additions to the authorized plan: construction of Canal 46A and spillway structure 87C, and the inclusion of tieback levees at structures 87, 87A and 87B. The memorandum also requested that the construction of the recommended project features (C-46, C-46A, S-87, S-87A, S-87B, and S-87C) be deferred until they were economically justified. In a follow-up letter dated February 24, 1983, the District Engineer requested that S-87 be deleted from the plan of improvements. To date C-46, C-46A, S-87, S-87A, S-87B, and S-87C have not been constructed.

c. Letter to the Chief. In a letter to the Chief of Engineers, dated October 6, 1961, the District Engineer recommended the deletion of structure 64 from the authorized plan. This request was made following Resolution 462 requesting this action by the Governing Board of the Central and Southern Flood Control District on September 8, 1961. The Flood Control District reanalyzed the regulation schedules for Lakes Kissimmee, Cypress, and Hatchineha. They determined that Lake Kissimmee could be regulated approximately one-half foot higher and Lakes Cypress and Hatchineha could be regulated one-half foot lower than proposed in the *General Design Memorandum (Part II, Supplement 5).* This eliminated the need for the control structure (S-64) at the outlet of Lake Hatchineha. The flood storage in Lakes Kissimmee, Hatchineha, and Cypress did not appreciably change with this modification. In a letter dated October 10, 1961, the Chief of Engineers concurred with the elimination of S-64 from the authorized project as recommended by the Jacksonville District.

d. SFWMD Alteration. On December 1, 1976, an extreme drawdown of Lake Kissimmee was begun in order to eliminate by exposure and drying most of the hyacinths found at elevations 44.0 ft. and above. To accomplish this drawdown an earthen plug was placed in C-37 between Lakes Hatchineha and Kissimmee and a temporary bypass structure was constructed adjacent to the mouth of C-37 as it enters Lake Kissimmee. The variable crest structure (stop-log riser) is capable of controlling upstream elevations between 46.0 and 49.5 ft. Once the drawdown had been completed and the lake stage had returned to the normal elevation, the plug in C-37 was removed. However the temporary bypass structure remained to provide drawdown capabilities in the future. The design, construction, and maintenance of the structure was accomplished by the SFWMD with a Department of Army Permit. Approval for the extreme drawdown of Lake Kissimmee was received from the Chief of Engineers on November 2, 1976.

L.3.2 Lake Istokpoga

Part II, Supplement 2, Design Memorandum, Hydrology and Hydraulic Design, Lake Istokpoga - Indian Prairie Area, dated November 28, 1955, specifically dealt with the project features in these areas. This report recommended the following changes to the authorized plan. First, that Levee 46 along the south shore of Lake Istokpoga be retained as an unplanned item of the authorized project, but that its construction be deferred for consideration when the need therefore becomes apparent. Under the recommended plan in this report, authorized canal 39 and structures 73 and 74 would not be constructed. The plan further recommended the addition of canal 41A and structures 82, 83, and 84 to the plan of improvement for the Lake Istokpoga-Harney Pond-Indian Prairie Canal Area. The original purpose of canal 39 would be accomplished by canal 41A and the purpose envisioned in the project document for structures 73 and 74 would be accomplished by structures 72 and 75 respectively. Inasmuch as the functions of canal 39 and structures 73 and 74 would be accomplished by the recommended plan, it was recommended that they be deleted. The Division Engineer and Chief of Engineers in approving the recommended plan of improvements, both requested that further studies be made into need for Levee 46. In a follow-up letter dated October 16, 1956, the District Engineer recommended the deletion of Levee 46 from the project. However, in a letter dated October 31, 1956, and a letter dated December 13, 1956, both the Division Engineer and the Chief of Engineers, respectively, rejected the arguments for the deletion of Levee 46.

a. <u>The Survey-Review Report on Central and Southern Florida Project - Water Resources for Central and Southern Florida</u>, dated February 15, 1968, examined the water supply potential in the C&SF project. Raising the Lake Istokpoga regulation schedule about four feet was considered. This amounted to a potential storage of approximately 130,000 acre-feet. However, the costs of necessary levees and modifications were relatively high and the net increase in deliveries would be only a fraction of the potential storage. It was estimated that the small amounts of water that could be delivered by this plan would cost about $23 per acre-foot. Subsequently, this plan was rejected.

b. <u>Letter Report</u>. Currently, the Jacksonville District is preparing a letter report for the placement of weirs downstream of S-68, S-82, and S-83. These weirs are necessary due to tailwater constraints resulting from a design deficiency that does not permit design capacity discharges through S-68.

L.3.3 Upper St. Johns River Basin

The original plan presented in the project document (*House Document 643, 80th Congress, 2d Session*) has undergone major modifications twice under discretionary authority of the Chief of Engineers (OCE) since authorization. The initial comprehensive plan of improvement for the basin contemplated improvements of Lake Poinsett, Washington, and Wilmington (Blue Cypress Lake). Levees and control works were provided downstream from Lakes Poinsett and Washington, and outlet channels with control works were to be provided from each of the three lakes to the Indian River with capabilities of discharging floods up to the maximum of record. The original plan was authorized in 1954. Control structures were provided to prevent overdrainage of lakes during dry periods, and the outlet canals were to permit discharges during flood periods and prevent salt water intrusion from the Indian River.

a. Authorized Plan (Part III, Supplement 2). The Comprehensive Plan (authorized plan) prepared March 20, 1957 required several hundred thousand acres of valley lands for water storage and was not acceptable to landowners and local groups. This led to the development of a new plan to provide for flood control and irrigation for the Upper St. Johns River Basin. The first change was approved by Chief of Engineers on September 17, 1957. In this action the plan was changed from primarily a diversion plan to a plan emphasizing valley floodways and conservation areas. Basically, levees would provide for flood protection of developed areas and control structures would permit retention of sufficient water to supply irrigation needs during the dry season. The plan included two conservation areas and a control structure below Lake Poinsett. C-26, S-51, C-27, S-52, C-28, S-54 canals and control structures intended to divert the Upper St. Johns River floodwater to the Indian River were deleted from the plan. The method of flood control was changed from diversion to storage, making these works unnecessary. They were replaced by L-52, L-53, L-54, L-55, L-56, S-95, S-96, and S-98. No improvements were proposed in the Upper St. Johns River Basin below Structure 55.

b. Addendum 1 (1962 Plan). *Addendum 1 to the General Design Memorandum* was prepared on February 15, 1962. This modification emphasized a combination of upland and valley reservoirs, channelization, and diversion. With some subsequent minor revisions, this was the plan under construction that was halted in 1972 for environmental reasons. The 1957 plan proposed that the majority of marshlands in the basin be used as either floodways or water conservation areas. However, that plan was unacceptable to the various interests involved because over 200,000 acres of land in the flood plain above Lake Poinsett was included in the conservation areas. In May 1960, the Flood Control District (now SFWMD) proposed a plan of improvement consisting of a limited floodway in the valley, seven upland retention reservoirs on the western slope of the basin, and a diversion canal from Blue Cypress Lake (Lake Wilmington) to Indian River for discharge of excess floodwaters. The plan developed was essentially a modification of the Flood Control District's plan, with expansion of certain basic features. The seven small upland reservoirs in the Flood Control District's plan were interconnected to form three larger upland reservoirs, thus permitting greater flexibility in releases between those upland reservoirs and to the valley reservoirs. Runoff from a drainage area of 540 square miles (nearly half of the total Upper St. Johns River Basin area) would have been stored and regulated by the upland reservoirs. The advantage of interconnecting channels between the two northerly upland reservoirs was that storage could be released into any one or all of the valley lakes.

c. Addendum 2 (1969 Plan). On March 17, 1969, *Addendum 2 to the General Design Memorandum* was prepared. Because encroachment of development into the Blue Cypress Lake (Lake Wilmington) valley reservoir created land acquisitions problems, and the limited conservation storage available in the Fort Drum and Blue Cypress upland reservoir areas made the value of those storage areas questionable, the Flood Control District (now SFWMD) requested reconsideration of project plans in the Blue Cypress Lake area. In addition, changes in drainage patterns and levee alinement were necessary due to construction activities which took place after the 1962 plan was developed. These activities included construction of Florida's Turnpike, large scale drainage projects, and private dike and floodway construction. For these reasons, a modified plan was developed for the Blue Cypress Lake, Fort Drum, and Blue Cypress Reservoirs. The plan called for elimination of conservation storage in the upland Fort Drum and Blue Cypress areas; modification of Blue Cypress Lake Reservoir limits resulting a reduction of 5,000 acres (15 percent) in the reservoir area; revised alinement for retention levees in Fort Drum and Blue Cypress areas; and provision of a tieback levee at the downstream end of Blue Cypress Lake Reservoir. L-44 and L-45, levees crossing the valley in Upper St. Johns River area, were replaced by a revised levee system as a result of the change from a diversion plan to a storage plan. On July 11, 1969 the *Addendum* was approved by the Chief of Engineers subject to the satisfaction of comments.

d. Addendum 3 (1985 Plan). The current plan uses valley conservation areas and floodways, some diversion, and upland detention areas. While the scope of the project remains relatively unchanged, the current plan is more compatible with the environment of the basin. The current plan eliminated the upland detention areas consisting of L-71, L-72, S-159, S-160, S-162; the Wolf Creek portion of the Jane Green Reservoir including S-163; the Blue Cypress Reservoir including C-52 and C-53S; the Lake Washington Reservoir, including C-55 and S-53; the Lake Poinsett Reservoir, including C-56, and S-55; and the weir on Puzzle Lake. The plan also modified a portion of the Jane Green Reservoir making it a detention area. The plan also added the Fort Drum Marsh Conservation Area, including L-78, L-79, S-252A,B and C; the Blue Cypress Marsh Conservation Area including L-74W, L-75, S-250A,B and C, and S-96C; the St. Johns Water Management Area including L-74E, S-96B; new levees and structures north of the Fellsmere Grade including L-74N, L-80, L-81, L-82, S-255, S-256, and S-257; and a new structure in the Jane Green Detention Area, S-161A. This plan was approved by the Chief of Engineers on September 1, 1986.

L.3.4 Fisheating Creek

Part II, Supplement 4, General Design Memorandum - Hydrology and Hydraulic Design, Fisheating Creek Area, dated April 24, 1956, recommended the deletion of Canal 22 and control Structure 69. The report further recommended that no further studies be made of the upper Fisheating Creek basin under existing survey-review-report authorization. These recommendations were made because flood protection to the area could not be economically justified. In a letter dated July 13, 1956, the Chief of Engineers declined to delete the two project works and instead classified them as "inactive" since the possibility of future development in the basin may justify flood protection and the report did not indicate whether the Flood Control District had concurred with the decision to delete them. In a letter dated December 4, 1956, the District Engineer again requested that Canal 22 and Structure 69 be deleted from the project since the Flood Control District concurred with the decision to delete them from the project. In a letter dated December 7, 1956 from the Division Engineer to Chief of Engineers the following was stated, *"The agreement to delete rather than defer project works in the Fisheating Creek area is in accordance with instructions given by Chief of Engineers representatives during conference on cost-sharing report held in Jacksonville District office August 14-15, 1956".*

L.3.5 Moore Haven-Newhall Area

Part II, Supplement 1, Design Memorandum, Moore Haven-Newhall Area, dated July 21, 1955 recommended the following changes. Control structures 47A and 47C be deleted from the authorized project works since their function could be carried out with minor changes made to structures 47B and 47D. The enlargement of Structures 47G and 47H (existing Lake Okeechobee culverts 5 and 5A) could not be economically justified. Canal 19A, Structure 47E, and secondary drainage also could not be economically justified and also were recommended for deletion from the authorized plan. The deletion of these structures was approved by the Chief of Engineers on February 7, 1956.

L.3.6 Lake Okeechobee

The original Comprehensive plan included modifications to raise the levee system (Herbert Hoover Dike) around Lake Okeechobee to permit conservation of additional water for use during dry periods and provide full protection during severe hurricanes. The plan also called for the construction of outlet works to move water to the rich agricultural areas to the south. Additional outlets were authorized by the *Flood Control Act of 1954*. Along with the 1948 authorization, they included most of the works necessary to afford flood protection to the rich agricultural development south of Lake Okeechobee and to the highly developed urban area along the lower east coast of the State. *Part IV Supplement 2 - Hydrology and Hydraulic Design, Section 7 - General Design Memorandum, Combinations of Hydrologic and Hydraulic Factors Affecting Height of Levees,* dated February 25, 1959, recommended the plan of improvement that provided for project works to maintain a conservation pool in Lake Okeechobee which varies seasonally from 15.5 to 17.5 ft, and that the Caloosahatchee River be enlarged to a regulatory capacity of 9,300 cfs. The plan included the following items in order of priority: (1) Construct levees on the northwest and northeast shores of Lake Okeechobee, (2) Raise existing levees, (3) Construct the primary canals and pumping stations to protect the area behind the existing north shore levees from increased flooding when the Lake levels are raised, (4) Increase the lake-regulation capacity of the Caloosahatchee River to 9,300 cfs, and (5) Stabilize the banks of the St. Lucie Canal to prevent erosion when releases are made. The Chief of Engineers approved the report on June 3, 1959 subject to the satisfaction of the Division Engineer's comments.

a. St. Lucie Canal. The Port Mayaca lock and spillway (S-308B & S-308C) were presented in *House Document 369 (90th Congress, 2d Session)*, and subsequently authorized by the *Flood Control Act of 1968* approved August 13, 1968 *(Public Law 90-483*). C&SF Report entitled *Part IV, Supplement 31 - General and Detail Design Memorandum, Port Mayaca Lock (S-308B) and Spillway (S-308C),* dated November 30, 1972, recommended the following change. The authorized plan contained in the *Water Resources Report* provided for these structures as one part of an overall scheme to raise the ultimate lake range to 19.5 to 21.5 ft. Studies had shown that with the interim lake range, the stability of St. Lucie Lock and Dam (located downstream) under hurricane tide conditions was questionable. The higher canal stages would also render numerous local structures inoperable. Modification of the St. Lucie Lock and Dam and local structures would be very costly and would not solve future water control or hurricane tide problems under the ultimate lake range. The proposed plan in the G&DDM called for the early construction of the Port Mayaca Lock and Spillway for the interim lake range (15.5 to 17.5 ft.). The proposed plan provided hurricane tide protection, permitted water control in the St. Lucie Canal and eliminated the expense of costly modifications to the existing structures. On October 23, 1973, Chief of Engineers gave approval to the recommended plan subject to the satisfaction of the comments of the Division Engineer and the Chief of Engineers. On November 30, 1973, all comments had been satisfied and final approval was received.

b. Northeast Shore Area. *Part IV, Supplement 21, General Design Memorandum - Lake Okeechobee Northeast Shore Area*, dated March 12, 1963, recommended the following additions to the works included in the Comprehensive Plan. Levees 62, 63, 64, and 65, Tieback levees at St. Lucie Canal, Lettuce Creek and Taylor Creek, Pumping Stations 133, 134, and 135 and Structures 152, 153, and 154 and three recreation areas. No items were recommended for deletion.

(1) Addendum 1. In a letter dated November 24, 1964, *Addendum 1 to Part IV, Supplement 21* was presented. The District proposed changes to the plan of improvement presented in the *General Design Memorandum*. The letter recommended the addition of the following project features: Canal 59, Levees 63(N) and 63(S), Control Structures 191 and 192, and Structure 193 (navigation lock at HGS 6). The following features were recommended for deletion from the approved plan: Levee 63, tieback levees at Taylor Creek and Lettuce Creek, Pumping Station 134, and Structure 152. In a letter dated February 1, 1965, the Chief of Engineers approved the changes subject to comments.

(2) Addendum 2. In a letter dated December 20, 1966, *Addendum 2 to Part IV, Supplement 21*, was presented. The plan of improvement presented in addendum 1 had been modified at the request of the local sponsor to better serve the areas involved. Specifically, the proposed plan provided for the realinement of the Taylor Creek diversion canal (L-63(N)), increased the capacity of that canal and Canal 59, modified structure 191, and added an additional pumping unit at Pump Station 133. The plan also called for the addition of S.A.L. Railroad bridge (B-142) to the recommended plan. These changes were approved on January 25, 1967 by Chief of Engineers.

(3) *Addendum 3*, dated February 12, 1969, revised the plan presented in addendum 2. These changes were brought about by the needs of both the interim Lake Okeechobee schedule (15.5 to 17.5 ft.) and the ultimate plan (19.5 to 21.5 ft.) and authorized by the survey-review report on *Water Resources for Central and Southern Florida (Flood Control Act of 1968*, adopted August 13, 1968 under *Public Law 90-483*). The new plan called for shifting unconstructed portions of the interceptor levees from the 20-foot contour to the 25-foot contour, and providing protective interceptor and tieback levee grades for ultimate lake levels. The plan also revised the design of structures 191 and 193 for higher lake stages, and Structure 192 was moved to the new junction of Levee 63(N) and Taylor Creek. No project features were added or deleted in addendum 3. On June 4, 1969, the Chief of Engineers gave his approval to the revised plan by letter.

(4) *Part IV, Supplement 27, Lake Okeechobee and Outlets - Detail Design Memorandum*, dated October 20, 1969, presented a plan of improvement that was basically the same as that presented in *Addendums 1, 2, and 3 to Part IV, Supplement 21*. There were some changes, the electric sump pump at Pumping Station 133 would be relocated to Control Structure 192, the addition of a gated culvert in L-62 at Popash Slough, and minor changes to the levee alinements, all of which were requested by local interests. The design memorandum and the requested changes were approved on December 12, 1969.

(5) *Part IV, Supplement 28, Lake Okeechobee and Outlets - Detail Design Memorandum Lock Structure 193*, dated June 5, 1967, proposed the following changes from the approved *General Design Memorandum*. The report recommended that the lock be outfitted with a sector gate in lieu of the vertical gate proposed in the GDM to provide unlimited vertical clearance. These changes were approved by the Chief of Engineers on June 27, 1968.

(6) During October 30 through November 2, 1979, a Florida Power and Light (FP&L) containment levee of a power plant cooling water reservoir failed. Approximately 80,700 acre-feet of water moved westward washing out the adjacent Florida East Coast Rail line and Levee 65. The water continued to flow north, west,

and south causing extensive flooding and damage to S-135 and S-153. These structures and L-65 were repaired following the preparation of a *Rehabilitation Report (under PL 84-99 authority).* In an August 1982 letter, the Jacksonville District gave permission to SFWMD to modify S-153 by splitting the lift gates in half so that the two top sections could be lifted while the bottom sections remained closed, or the sections could be operated in unison. With the segment gates unlatched, accidental, or possibly vandalic, drawdown of the water level in the L-65 Borrow Canal below the tops of the closed, bottom gate sections could not occur. This would decrease the possibility of jeopardizing the stability of the adjacent FP&L reservoir and avoid another potential failure.

c. Northwest Shore Area. *Part IV, Supplement 7, - General and Detailed Design Memorandum, Lake Okeechobee Northwest Shore Levees*, dated May 29, 1959, the following changes were made to the original authorized plan. The plan recommended the addition of Pumping Stations 127, 128, 129, 130, 131, and 132; and three interceptor dikes L-59, L-60, and L-61. No deletions from the authorized plan were recommended. These improvements were recommended based on the need to mitigate the effect on the northwest shore of raising the conservation level of Lake Okeechobee to provide irrigation water for lands south and east of the lake. On September 30, 1959, the Office of the Chief of Engineers (OCE) returned the design memorandum. OCE questioned the land values and method used to calculate the cost-benefit ratios. On November 10, 1959, the Jacksonville District responded to OCE comments and requested further guidance on how to proceed. In this letter, the District Engineer stated that the design memorandum was prepared on the assumption that the project was intended to prevent flood damages and to protect the lands of the area rather than to buy easements, flood the land, and remove it from production. The District also submitted further information on the land values in question using appraisals from both the Corps and the Flood Control District. The District Engineer stated *"that a decision on whether to build levees or to purchase easements involves policy and multiple considerations other than engineering and economics. If levees are the most tenable solution under the objectives of the flood control project, it would appear that little purpose would be served in revising the report except for the pending changes described in the latter part of paragraph 1, above. ... Consideration of the above remarks is requested, together with further advice as to policy and other pertinent matters."* A conference was held on November 24-25, 1959 to discuss the direction of the project. On December 4, 1959, the Chief of Engineers agreed to the changes and additions to the authorized plan as requested by the Jacksonville District subject to comments. In a letter dated February 17, 1960, the Central and Southern Florida Flood Control District presented a new alinement for Levee 48 as a solution to a dispute between the Florida Game and Fresh Water Fish Commission, which insisted on an upland alinement, and local landowners who favored a more lakeward alinement. On March 1, 1960, the District presented requested approval for this change from the Chief of Engineers. These changes were incorporated into *Part IV, Supplement 13, - Detailed Design Memorandum, Pumping Stations 127, 129, and 131* dated September 7, 1960.

(1) *Part IV, Supplement 13, Detailed Design Memorandum - Pumping Stations 127, 129, and 131*, dated September 7, 1960, presented the construction of 3 pumping stations in lieu of the 6 proposed in the *General Design Memorandum*. The three pumping stations were adopted because they provided a more economical solution to the problem. The report also recommended that the pumping stations be located on the landside of the lake levees with the pump discharge tubes installed through the levees. This change was made to protect the pumping stations from hurricane forces. These forces were not fully considered in the *General Design Memorandum*. In addition, the capacity of the pumping stations was increased to account for the increased drainage area caused by upland relocations of the interceptor levees. On December 27, 1960, the Chief of Engineers approved the recommended changes subject to satisfaction of OCE comments. On December 27, 1960, the District Engineer requested clarification of SAD comments concerning *"removal of gravity flow from the leveed area by operating the pumps"*. The Division Engineer contended that the pumps could be used as siphons and thereby eliminate the culverts. However further analysis done by the Jacksonville District showed that there was a need for gravity drainage at these pump sites in order to insure flood damage did not occur to the pumps prior to starting them. In a letter dated January 6, 1961 the Division Engineer responded that culverts could be added to the pump stations during the preparation of plans and specifications if they were economically justified. In a letter dated January 11, 1961, the District Engineer justified the culverts by the reduction of standby personnel, particularly during (a) the interim lake regulation period when possibilities of gravity drainage will exist almost yearly, and (b) the infrequent long-duration droughts which can be expected about once in 10 years and extend for as long as 18 months. During these periods, use of the pumps as siphons would not be a comparable alternative, as personnel must be available to prime the pumps. In a letter dated February 6, 1961, the Division Engineer recommended culverts be included in the plan.

d. <u>Caloosahatchee River (Canal 43)</u>. The *River and Harbor Act of July 3, 1930*, authorized improvement of the Caloosahatchee River and Canal (C-43) as recommended in the report published as *Senate Document 115 (71st Congress, 2d Session)*. Under the authority of the *River and Harbor Act of March 2, 1945*, the river was improved to provide a navigation channel eight feet deep and 90 feet wide.

(1) *Part IV, Supplement 6, Lake Okeechobee and Outlets - General Design Memorandum, Caloosahatchee River and Control Structures (Canal 43 and Lock and Spillway Structures 77, 78, 79)*, dated April 24, 1957 presented a plan of improvement that provided for the removal of runoff from a storm equal to 30-percent standard project flood, reduced the depth and duration of floods of greater magnitude than the 30-percent standard project flood and if feasible, permit discharge of 4,200 cfs from

Lake Okeechobee during periods when the canal capacity was not required for drainage of its tributary area. The report also recommended that secondary capacity of 9,300 cfs be provided at a later time. The limiting factor for the existing 4,200 cfs canal was the canal size above Ortona Lock. This approval of the report by the Chief of Engineers was withheld in the 2nd endorsement dated June 20, 1957. The Chief stated, *"It is believed that the discharge capacity of the Caloosahatchee River should be as large as it is practicable to provide from an engineering and economic standpoint, in order to provide flexibility of operation for regulation of Lake Okeechobee. This factor should be given further consideration and coordinated with the preliminary analyses made for the scheduled design memorandum, Section 7 of Part IV - Lake Okeechobee and Outlets, Supplement 2, 'Combination of Hydrologic and Hydraulic Factors Affecting the Height Of Levees.'"*.

Part IV Supplement 2 - Hydrology and Hydraulic Design, Section 7 - General Design Memorandum, Combinations of Hydrologic and Hydraulic Factors Affecting Height of Levees, dated February 25, 1959 and approved June 3, 1959, recommended the plan of improvement that provided for project works to maintain a conservation pool in Lake Okeechobee which varies seasonally from 15.5 to 17.5 ft, and that the Caloosahatchee River be enlarged to a regulatory capacity of 9,300 cfs. An addendum to *Part IV, Supplement 6* was prepared dated August 28, 1959, which revised the plan of improvement for Canal 43 to agree with *Part IV Supplement 2, Section 7*. The addendum included the plan for further improvements in the Caloosahatchee area between Moore Haven Lock at Lake Okeechobee and Ortona Lock. The revised plan increased from 4,200 to 9,300 cfs the regulatory discharge capacity from Lake Okeechobee when the Canal 43 capacity is not required for drainage of its tributary area. The addendum was approved on November 19, 1959 by the Chief of Engineers.

(2) *Part IV, Supplement 15, Lake Okeechobee and Outlets - Detail Design Memorandum, Canal 43 Section 2 (Caloosahatchee River),* dated August 4, 1961, requested the deletion of inlet structures previously recommended in *Part IV, Supplement 6*. On October 2, 1961, the Chief of Engineers approved these changes subject to the satisfaction of comments of the Division Engineer. On November 6, 1961, all comments had been addressed and approval of the deletions was finalized.

(3) *Part IV, Supplement 16, Lake Okeechobee Outlets - Detailed Design Memorandum, Structure 79, Lock and Spillway on Canal 43*, dated July 7, 1961, made the following changes to the approved *General Design Memorandum*: the lock size was changed to meet the Corps minimum of 56' X 400', the location was moved about one mile above the site proposed in the *GDM*, and the spillway crest was lowered. On October 4, 1961, OCE approved these changes subject to the satisfaction of comments. After several endorsements trying to resolve the comments, the plan of improvements was approved on November 21, 1961 by the Chief of Engineers.

(4) *Part IV, Supplement 20, Lake Okeechobee and Outlets, Detailed Design Memorandum, Structures 77 and 78 on Canal 43*, dated November 15, 1962, recommended the following departures from the approved *GDM*. Structure 77 was modified to obtain a more economical structure by changing to an open type structure with a service bridge rather than a culvert-type structure. The structure would have four 20-foot gate bays in lieu of the three 26-foot bays proposed in the *GDM*, and the apron elevation was raised from minus 4.5 to elevation 0.0. Structure 78 was changed from a rounded crest to a more efficient ogee crest spillway. The intake channel was deepened to reduce the water velocities at the structure. An upstream approach slab and additional downstream riprap were added to prevent erosion. On January 15, 1963, the recommendations were approved subject to the comments of the Division and Chief of Engineers. On March 1, 1963, the Chief of Engineers gave his final approval on the requested changes.

e. <u>South Shore Area</u>. The original Comprehensive plan included modifications to raise the levee system (Herbert Hoover Dike) around Lake Okeechobee to permit conservation of additional water for use during dry periods and provide full protection during severe hurricanes. However, modifications were needed for Hurricane Gate Structure (HGS) Numbers 3, 4, and 5 to operate as water control structures under higher lake levels. Stilling basins were needed for operations under the higher heads. The modifications were considered corrections to the Herbert Hoover Dike system and were considered a part of the 1948 Authorization. For the conversion of HGS-4 to spillway structure *Part IV, Supplement 33, General Design Memorandum - Spillway Structure 351 (HGS-4)*, dated June 29, 1984 was prepared. Approval for the modifications was received on November 27, 1984. For the conversion of HGS-5 to spillway structure *Part IV, Supplement 35 - General Design Memorandum, Spillway Structure 352 (HGS-5)*, dated August 20, 1985, was prepared. Approval for the modifications was received on October 9, 1985. For the conversion of HGS-3 to spillway structure *Part IV, Supplement 36, General Design Memorandum - Spillway Structure 354 (HGS-3)*, dated December 1986, was prepared. Approval for the modifications was received on August 28, 1987.

(1) Canals 21A, 21B, and 21C were authorized by the *Flood Control Act of 1948*. These canals were deleted from the project in *House Document 186 (85th Congress, 1st Session). House Document 186 (Appendix B, pg 40)* stated, *"C-21A, C-21B, C-21C: Lateral drainage canals leading to pumping stations on south shores of Lake Okeechobee. These canals are not compatible with Flood Control District's secondary drainage plan and are not required."* Local interests later requested that C-21A be reinstated to the project because of the increased stages in Lake Okeechobee, as recommended in the Water Resources Plan. Reinstatement of C-21A (Miami Stub Canal) as an authorized item in the Central and Southern Florida Project was approved by the Office of the Chief of Engineers October 17, 1968.

(2) *Part I, Supplement 46, General and Detail Design Memorandum - Pumping Station 236*, dated February 28, 1972, presented the hydraulic design and detail design criteria for the structure. Pumping Station 236 was designed to provide drainage to an area which discharged directly to the lake by a local pumping plant. The local pumping plant could not operate efficiently with the new authorized increase in the Lake Okeechobee regulation levels. The structure was designed to remove 3/4 inch per day plus 50 cfs seepage for its tributary area. Pumping Station 236 was provided to protect an agricultural area of about 10.2 square miles located just south of Lake Okeechobee in lieu of providing the authorized Canal 21A project feature. Alternative plans were considered and it was concluded that C-21A would be more costly than S-236 and the canal could cause adverse effects on the adjacent roadbed of U.S. Highway 27. C-21A was originally included in the 1948 authorization. It was subsequently deleted from the project because it was not compatible with the secondary drainage canals in the area. In 1968, local interests requested that C-21A be reinstated because of the increased stages in Lake Okeechobee as recommended in the Central and Southern Florida Water Resources Plan. C-21A was reinstated by the Chief of Engineers on August 9, 1968. The plan to build S-236 in lieu of C-21A was approved subject to the satisfaction of comments by the Chief of Engineers in a letter dated August 30, 1972.

(3) The Herbert Hoover Dike began as a project of the State of Florida with the construction of 47 miles of low levees in 1927. Work was again done on the levees around Lake Okeechobee when the Caloosahatchee River and Lake Okeechobee drainage areas project was adopted and authorized by the *River and Harbor Act of July 3, 1930*. This was later modified by the *River and Harbor Act of August 3, 1935* to provide for maintenance of all project works completed. Construction of the levees under the *River and Harbor Act of 1930* was started in 1931 along the south shore of the lake and by 1937, 69.2 miles of continuous levee along the west, south, and east shore of Lake Okeechobee was completed. In 1948, the levee works around the lake were included in the Comprehensive plan. In January 1961 the levee system around the lake was dedicated and renamed the Herbert Hoover Dike in honor of former President Herbert Hoover and the part he played in implementing the construction of these levees. The Herbert Hoover Dike was raised and improved from 1962 to 1967 as part of the 1948 plan. The *Flood Control Act of 1968 (Public Law 483, 90th Congress, 2d Session*) included further raising of the Lake Okeechobee regulation schedule and accordingly the Herbert Hoover Dike. A letter report was prepared August 29, 1975 recommending improvements to 60.3 miles of the dike. The letter report was approved December 12, 1975.

(a) *Addendum 1* was prepared in January 1980 recommending stone revetment for the portion of levee from Moore Haven to Port Mayaca, approximately 50 miles with the first priority given to a reach south of Port Mayaca around the Pahokee State Park. In March 1980, the *Addendum* was returned by the Division Engineer for resubmission. The Division Engineer contended that the report did not contain economic justification for the project and also required the testing of stone sources for the rock. A revised *Addendum 1 to the Letter Report* was prepared and sent on July 8, 1982. In August 1982 the report was approved by SAD and OCE subject to the satisfaction of comments. Final approval was received in October 1982. Subsequent reaches of the dike improvements have been submitted as addendums to the original letter report.

(b) *Addendum 7 to the Letter Report* was dated November 29, 1989. On July 12, 1990, the report was returned from SAD, stating that the costs were too high for slope protection and continued efforts in this direction should be terminated. Any future work required to restore eroded sections of the dike will need to be incorporated into the maintenance program. When work on the Herbert Hoover Dike was terminated, six construction contracts had been completed totaling 24.3 miles of the 72.6 miles of levee that had been scheduled for slope protection.

L.3.7 Everglades Agricultural Area (EAA)

a. Nine-Mile Canal. *Part I, Agricultural and Conservation Areas, Supplement 39 - General Design Memorandum, Nine-Mile Canal Area, (C-20, C-21, L-D1 Borrow Canal, S-4, S-47, S-169, S-170, Railroad Bridges, Etc.)*, dated March 29, 1963, recommended additions to the Comprehensive Plan. The items added were connections of the Levee D1 borrow pits, extension of Canal 21 to join Industrial Canal, including two railroad bridges (B-136 and B-137), S-169, a 2-barrel gated culvert in C-21, S-170, a 2-barrel gated culvert in Industrial Canal, and railroad bridge B-135 over Canal 20. No items were recommended for deletion. These additions were approved by the Chief of Engineers on August 5, 1963. On June 6, 1969, *Part I, Supplement 45, Agricultural and Conservation Areas, Detail Design Memorandum Canal 21 and Control Structure 169* recommended several changes to the plan presented in the previous report. The alinement of C-21 was changed resulting in reduced costs. Structure 169 was modified to include a third 72-inch barrel. The report further recommended that the alinement of Canal 20 be studied further and that Structure 170 be retained in the authorized plan although the need for it would depend on the Canal 20 studies. The recommendation was made to delete railroad bridges B-136 and B-137. On November 22, 1971 a Letter Report entitled *Nine Mile Canal Area (Part)* presented a modified plan for C-21 and S-169, and the design criteria for C-20 (Section 1) which was necessary for C-21 to be effective, and design criteria for L-D1 and L-D3 Connecting Canal and S-235. During the studies for C-20 it became apparent that it was impractical to drain about 28-1/2 square miles of the S-4 area to the pump. However, the construction of S-4 was about 50% complete and it was not economical to alter S-4, therefore S-4 has an excess capacity of about 570 cfs. The report recommended that S-169 and C-21 should be enlarged to pass an additional 570 cfs (equal to the excess capacity of S-4), and as a result of deleting the 28-1/2 square mile area from the C-20 basin, that S-233 and S-47 be deleted from the project. Furthermore the report recommended that a portion of C-20 be constructed to connect the existing drainage outlet of the Sugarland Drainage District and C-21 and

Pumping Station 4. This section of C-20 was needed, regardless of the final design of C-20. The L-D1 and L-D3 Connecting Canal and Structure 235 were recommended in *Part I, Supplement 47 - Detail Design Memorandum, Canal 20, Levees D1 and D3 Connecting Canal, and Control Structures 47, 233, 234, and 235,* but this report had not been approved due to differences with the local sponsor over C-20. Therefore these features were included in the letter report also. In a letter dated June 6, 1972, the Division Engineer approved the construction of the L-D1 and L-D3 Connecting Canal and S-235 because they were considered necessary for operational flexibility. However the modification of C-21, S-169 and the remaining work were not approved since the plan presented did not demonstrate that it was the most economical plan and that it would be more economical to provide Pumping Station 236 than the alternative plan to utilize excess capacity at Pumping Station 4. Therefore C-21 and S-169 were approved as designed in *Part I, Supplement 45*. In a memorandum, which followed the letter report dated August 15, 1972, S-169 was changed during the preparation of plans and specifications to three 84-inch barrels.

(1) In December 1970, C&SF report entitled *Part I, Agricultural and Conservation Areas, Supplement 47 - Detail Design Memorandum, Canal 20, Levees D1 and D3 Connecting Canal, and Control Structures 47, 233, 234, and 235* made the following changes to the authorized plan. The L-D1 and D3 Connector Canal and Structures 233, 234, and 235 were additions to the plan and considered refinements. This plan was later withdrawn from consideration due to differences with the local sponsor. In June 1972, C&SF report entitled *Part I, Agricultural and Conservation Areas, Supplement 47 - Revised Detail Design Memorandum Canal 20* revised the previously presented plan. The plan presented a shorter, refined plan for Canal 20 and included a gated culvert in Canal 21. It also recommended that Structure 47 be eliminated from the project as it was no longer a part of the proposed plan for C-20. Control Structure 233, previously located upstream of the intersection of C-20 and C-21 was eliminated at the request of the local sponsor and not included in the *Revised Detail Design Memorandum*. These changes were approved by the Division Engineer on March 14, 1973 in the 3rd Indorsement to the report.

b. Agricultural Canals. Four major agricultural canals (West Palm Beach, Hillsboro, North New River and Miami) were dug by the State of Florida for drainage of lands, principally into Lake Okeechobee, and to provide a source of water for agricultural use. It was originally thought that the canals would drain water from Lake Okeechobee and discharge into the Atlantic Ocean. However because of the small hydraulic slope and insufficient cross section, the four canals were not effective in removing water from the lake during flood periods. The comprehensive plan provided for the construction of canals and pump stations to serve the agricultural area. However, Congress authorized only the first phase of the plan which provided the principal water-control structures to serve a small area. In the reports following, several changes were made to the authorized plan to better serve the agricultural area.

(1) *Part I, Supplement 8, Agricultural and Conservation Areas - Design Memorandum, Development of Plan of Protection for Agricultural Area,* dated February 6, 1953, recommended that Levees 10 and 12 (West Palm Beach Canal), 14 and 15 (Hillsboro Canal), and Levees 19 and 20 (North New River Canal) be constructed to the size required to remove 3/4 inch of run-off a day from the tributary area. It also recommended Levees 17, 22, 26, and the western portions of levee 24 and 15 be constructed to a height and cross-section required to serve as a main encircling levee for the agricultural area. Pumping stations S-2, S-3, S-5A, and S-6 were recommended to be constructed to their authorized capacity and Pumping Station 1 was recommended to be deleted from the project. In a letter dated July 20, 1953, these changes were approved by the Chief of Engineers subject to satisfaction of comments.

(2) *Part I, Supplement 18, Agricultural and Conservation Areas, - Design Memorandum, Revision of Hydrology and Hydraulic Design of West Palm Beach, Hillsboro, North New River, and Miami Canals,* dated November 16, 1953, proposed the improvement of these canals be carried out in two stages.

<u>First-stage development</u> provided water control for their tributary areas. A small capacity for regulatory discharge from Lake Okeechobee would be provided. Providing water control would involve (1) removing excess rainfall; (2) supplying irrigation water; (3) protecting lands adjacent to the canal from overflow by canal stages; and (4) maintaining optimum water elevations insofar as possible. Design of the levees and canals was based on satisfying the first three criteria.

<u>Second-stage development</u> for North New River and Miami Canals is identical to that for the first-stage development. In addition to water control provided by first-stage development for West Palm Beach and Hillsboro Canals, second-stage development would provide diversion capacities from Lake Okeechobee equivalent to capacities of pump stations at the conservation area ends of those two canals. This was approved by the Office of the Chief of Engineers on January 7, 1954. In a letter dated February 19, 1954, the Jacksonville District requested that *"this office be authorized to advise the Flood Control District that plan 3 [first-stage development] will be constructed first and that plan 4 [second-stage development] will be constructed only if and when it has been established that there is a definite need for it."* Economic analysis showed that plan 4 would be more expensive than increasing the capacity of the St. Lucie Canal. In a letter dated April 27, 1954, the Chief of Engineers approved the *"first-stage construction of the West Palm Beach and Hillsboro Canals will conform with Plan 3 and modification to conform with Plan 4 will not be undertaken until required for project purposes and economically justified".* The project was later justified in the 1968 report entitled *"Water Resources for Central and Southern Florida".* Finally, in C&SF report dated March 1978, entitled, *Part I, Supplement 51, Agricultural and Conservation Areas - General and Detail Design*

Memorandum, L-18 & L-19 (North New River Canal) and L-24 & L-25 (Miami Canal) - Hump Removal, approved the removal of humps from the bottom of the North New River and Miami Canal and eliminated the need for the authorized deepening of the St. Lucie Canal for greater flood discharge capacity. On October 29, 1979, the report was approved.

(3) *Part I, Supplement 19, Agricultural and Conservation Areas, Design Memorandum, North New River Canal*, dated December 1, 1953 requested that Levees 20 and 19 of the North New River Canal be enlarged to provide adequate capacity for water control for the highly developed farm lands along its banks and the development of other lands with high capabilities within its tributary area for the entire length of the canal and that improvement of the unauthorized portion of the canal (Levee and Canal 18) be deferred pending authorization of the greater encirclement plan of improvement. The plan provided for the capacity of the canal to be adequate to provide 4.3 cfs a square mile of irrigation water from the lake for the entire Miami Canal drainage area and 3/4 inches a day (20 cfs a square mile) of agricultural drainage from the same area. The Chief of Engineers approved this recommendation in a letter dated March 8, 1954.

(4) *Part IV Supplement 2 - Hydrology and Hydraulic Design, Section 7 -General Design Memorandum, Combinations of Hydrologic and Hydraulic Factors Affecting Height of Levees*, dated February 25, 1959, recommended the plan of improvement that provided for project works to maintain a conservation pool in Lake Okeechobee which varies seasonally from 15.5 to 17.5 ft, and that the Caloosahatchee River be enlarged to a regulatory capacity of 9,300 cfs. The plan included using the existing capacity of 3/4 inches a day for the determining the capacity of primary canals and pumping stations. The Chief of Engineers approved the report on June 3, 1959 subject to the satisfaction of the Division Engineer's comments.

(5) A letter dated August 21, 1961 from the Central and Southern Florida Flood Control District requested the construction of water control structures near the mid-points of the Miami and North New River Canals. After the completion of design studies the District Engineer recommended that control structures be built on these canals as part of the authorized project. This recommendation was made by letter dated May 22, 1963. The letter specifically recommended the construction of sheet pile stoplog structures in North New River (S-2A) and Miami (S-3A) Canals, with the cost sharing as specified in the 1954 authorization. In the 2nd Indorsement from the Chief of Engineers dated December 24, 1963, these project features were approved except that cost sharing was based on the 1948 Authorization. The structures were redesigned several times in the following years. Finally, in C&SF report dated March 1978, entitled, *Part I, Supplement 51, Agricultural and Conservation Areas - General and Detail Design Memorandum, L-18 & L-19 (North New River Canal) and L-24 & L-25 (Miami Canal) - Hump Removal*, recommended that structures 2A and 3A be

deleted from the project as they were no longer desired by the local sponsor. On October 29, 1979, the report was approved.

(6) *Part I, Supplement 20, Agricultural and Conservation Areas, Design Memorandum - Miami Canal*, dated February 5, 1954, requested that Levees 24 and 25 of the upper Miami Canal be enlarged for the entire length of the canal and that improvement of the unauthorized portion of the canal (Levee and Canal 23) be deferred pending authorization of the greater encirclement plan of improvement. The enlargement was based on satisfying agricultural and drainage requirements. The capacity of the canal would be adequate to provide 4.3 cfs per square mile of irrigation water from the lake for the entire Miami Canal drainage area and 3/4 inches per day (20 cfs a square mile) of agricultural drainage from the same area. The Chief of Engineers approved this recommendation in a letter dated April 5, 1954.

L.3.8 Water Conservation Areas - General

The plan of improvement for the Water Conservation Areas was recommended in the 1948 Authorization with subsequent modifications recommended in the 1954 Authorization. The functions of the conservation areas were considered to be (1) to act as a depository for excess water from the agricultural areas; (2) to provide the levees needed to prevent Everglades floodwaters from inundating the east coast; (3) to aid in recharging underground freshwater reservoirs; (4) to provide a water supply for east coast agricultural lands; (5) to benefit fish and wildlife in the Everglades; and (6) to release excess water to Everglades National Park and water from storage to assist in restoring and maintaining natural conditions by reducing damage from drought and fire.

a. Water Conservation Area 1. The original plan envisioned a series of levee-encircled pools for the conservation of floodwaters. Levee 39, along Hillsboro Canal, would separate Water Conservation Areas 1 and 2. Spillway 10, located in the eastern portion of Levee 39, would serve as an outlet for the passage of floodwaters from Water Conservation Area 1 to Water Conservation Area 2. Inflow to Water Conservation Area 1 would be contributed by: (1) Levee 8 area north of Water Conservation Area 1, (2) rainfall over Water Conservation Area 1, and (3) pumped inflow at the rate of 1/2 inch a day from the area served by Pumping Stations 5 and 6 on West Palm Beach and Hillsboro Canals respectively. S-10 would consist of four 100-foot spillway units with a crest elevation of 11.5 feet.

(1) *Partial Definite Project Report, Part I (basic report) Agricultural and Conservation Areas (With Preliminary Information on Lake Okeechobee and Principal Outlets)*, dated July 10, 1951. In this report inflow to Water Conservation Area 1 was changed as a result of studies made for Part I (basic report), which increased the pump capacity to 3/4-inch daily removal. The studies also included a maximum conservation stage in Water Conservation Area 1 at elevation 17.0 ft. after considering the storage required and flooding elevations in the Levee 8 area. The report

contemplated that Levee 39 would be constructed to a grade providing a 3-foot freeboard allowance above the standard project pool elevation. It was expected that the levee would be overtopped during hurricanes. However, since the levee separated two conservation areas, danger to life and private property from overtopping by wind tides and waves was not expected. The plan for the agricultural areas proposed the elimination of Pumping Stations 1 and 2 at the lake end of West Palm Beach and Hillsboro Canals. (That proposal was not approved by higher authority.) The capacities of Pumping Stations 5A and 6, at the conservation area ends of the canals, were increased to serve the entire drainage areas tributary to the respective canals. Pumping Station 5A would discharge into Water Conservation Area 1 and Pumping Station 6 would discharge into Water Conservation Area 1 when the stage was below the conservation stage of 17.0 ft; at other times the discharge would be into Water Conservation Area 2. The stations would pump lake-regulation releases from Lake Okeechobee when the need existed and canal and pump capacity was available.

(2) *Partial Definite Project Report, Part IV, Section I - Modified First Phase Plan*, dated March 26, 1952. To protect the existing agricultural development along the southerly shores of Lake Okeechobee during the construction program in that area, the Modified First Phase Plan proposed that the lake pumping stations be constructed to full capacity based on 3/4-inch daily removal rate. Since Pumping Station 2 would remove agricultural drainage from a portion of the Hillsboro Canal drainage area, Pumping Station 6 capacity was decreased.

(3) Plan Selected at Conference of August 29, 1952. At the conference held at the Jacksonville District Office, August 29, 1952, attended by representatives of the Office of the Chief of Engineers, South Atlantic Division, and Jacksonville District, the conclusion was reached that Pumping Station 6 should be constructed to a capacity required to remove 3/4-inch of runoff a day from the drainage area within the 1948 authorized encirclement.

(4) *Partial Definite Project Report, Part I, Supplement 8 - Design Memorandum, Development of Plan of Protection for Agricultural Area,* dated February 6, 1953. This plan proposed that Pumping Stations 5A and 6 be constructed to full capacities based on the requirement to remove 3/4-inch of runoff a day from the drainage area with the larger encirclement included in the 1954 authorization.

(5) *Partial Definite Project Report, Part IV, Section 4 - Modified First Phase Plan, 1953*, dated February 20, 1953. This report proposed the deletion of Pumping Station 1 from the authorized project. Pumping Station 5A would be built to transfer all runoff from the West Palm Beach Canal agricultural area southward to Water Conservation Area 1 to effect greater benefits and to make the water available to east coast interests. The canal and Pumping Station 5A would also be used to transfer water from Lake Okeechobee to the conservation area when such transfer was

desirable and when their full capacities were not needed for drainage of the agricultural area.

(6) *Partial Definite Project Report, Part I, Supplement 9 - Design Memorandum, Hydrology and Hydraulic Design of Hillsboro Canal and Related Works (L-14, L-15, S-2 and S-6)*, dated June 8, 1953. These studies made in connection with the hydraulic design of Pumping Station 6 and Hillsboro Canal indicated that Pumping Station 6 should discharge into Water Conservation Area 1 at all times and that additional spillway capacity should be provided through Levee 39.

(7) *Part I, Supplement 25 - General Design Memorandum, Plan of Regulation for Conservation Area 1*, dated November 29, 1957. Subsequent to submission of the design memorandum for Levee 39 and Spillway 10, the general design memorandum covering the plan of regulation of Water Conservation Area 1 had been approved as a basis for the more detailed design of an interim plan for construction of Structure 10 and Levees 39, 40, and 7. The decision as to whether raises in grades for Levees 7 and 40 would be necessary was deferred for future consideration. In accordance with the request from the Chief of Engineers, *Part I, Supplement 23, Design Memorandum, Levee 39, Spillway 10, and Interim Modifications to Levees 7 and 40* was revised and resubmitted July 16, 1958. The new plan of improvement for Water Conservation Area 1 would provide for seasonal regulation between elevations 14 and 17 ft., levees, and 3 spillway units capable of performing the following functions: (1) Store seasonal floodwaters for use during dry periods; (2) provide a reasonable degree of erosion resistance against wind tides and wave action caused by hurricanes; and (3) provide adequate spillway capacity to prevent flood crests from exceeding elevation 17.3 ft. This report was approved on July 23, 1958 by the Chief of Engineers.

(8) *Part I, Supplement 23 (Revised), Design Memorandum, Levee 39, Spillway 10, and Interim Modifications to Levees 7 and 40, resubmitted July 16, 1958*. This report superseded *Part I, Supplement* 23 dated June 20, 1955. The plan of improvement recommended in the revised report proposed Levee 39 and S-10, three spillway units capable of performing the following functions: (1) Store floodwaters within Water Conservation Area 1 up to elevation 17.3 ft. under standard project flood conditions; (2) withstand normal steady wind-produced wind tides and waves and provide a reasonable degree of erosion resistance against overtopping and wave action caused by hurricane forces; and (3) provide adequate spillway capacity to prevent the peak ponding stage from exceeding elevation 17.3 ft. in Water Conservation Area 1. This plan was approved by the Chief of Engineers on April 8, 1959.

(9) *Part I, Supplement 31 - Detail Design Memorandum, Levees 35B and 38 (Section 3), Spoil Islands - Levees 35B and 38 (Section 2), and Control Structure 38,* dated October 13, 1959 presented several changes to the approved plan contained in the *General Design Memorandum (Part I, Supplement 27)*. These changes were: (1) relocating Levee 38 (Section 3) approximately 100 feet west to allow for future

expansion of U.S. Highway 27; (2) the L-35B berm was reduced from 40 ft. to 30 ft. in order to reduce excavation quantities; (3) the side slopes of the L-35B borrow canal were steepened to 1 vertical on 1 horizontal; (4) the gated culvert in the North New River Canal through L-35B was reduced from 4-72 inch barrels to 2-72 inch barrels since irrigation discharges for the east coast in excess of the capacity of S-34 would not be required; and (5) the structure in L-38E was changed from a gated 2-72 inch pipe culvert to a steel sheet pile spillway. These changes were approved subject to the satisfaction of the Division Engineer's comments on November 24, 1959 by the Chief of Engineers. The Division Engineer gave his final approval on January 13, 1960.

b. Water Conservation Area 2. The plan of improvement for Water Conservation Area 2 was presented in the *Partial Definite Project Report, Part I (basic report) Agricultural and Water Conservation Areas (With Preliminary Information on Lake Okeechobee and Principal Outlets)*, dated July 10, 1951. Water Conservation Area 2 was authorized as an area where excess water could be stored to supply irrigation needs in developed areas south and east of the pool and as floodway to allow excess water to be released into Water Conservation Area 3.

(1) *Part I, Supplement 27 - General Design Memorandum, Plan of Regulation for Conservation Area 2*, dated February 28, 1958 recommended the following changes to the previously authorized plans of improvement. The modifications included that no change to the existing grades of Levees 6, 35, 35A, and 36, except that a portion of the landward side of Levee 36 be changed from 1 on 2 to 1 on 3 for greater stability, that interior Levee 35B with culverts be constructed from S-11A to Levee 36; the reach of L-38 east of the highway between S-34 and S-11A be constructed on the existing spoil bank elevation and that two 72-inch gated culverts be placed in the levee to allow regulation of pool 2B; the reach of L-38 east of the highway between S-11C and S-7 be constructed to a grade varying from 18 ft. at S-11C to 19 ft. at S-7; that US Highway 27 between S-11A and S-11C be raised to elevation 17.5 ft; the reach of L-38 west of the highway between L-37 and S-11A be constructed to elevation 17 and that two 72-inch gated culverts be placed in the levee so that irrigation releases could be made from Water Conservation Area 3 when desired; the reach of L-38 west of the highway between S-11C and S-7 be constructed to elevation 16.7 and two 72-inch gated culverts be placed in the levee, however, construction of the levee would be deferred; S-38 be constructed in L-36 near Canal 14; and a provision be retained in the cost estimates for deferred construction of additional facilities which may be required if marsh vegetation does not prevent wind tides and waves from attacking the levees. The recommendations also requested the deletion of Structure 35 since it would not be needed under the recommended plan. This plan was approved by the Chief of Engineers on April 16, 1959.

(2) *Part I, Supplement 21 - Design Memorandum, Agricultural Area Levees, Levees 4 (East), 5, and 6* dated November 1, 1954. This report recommended the following changes to the approved plan. First, the crown width of L-5 was increased to

15 ft. to permit access to Pumping Station 8 at Miami Canal from U.S. Highway 27. Secondly, it recommended that construction of these levees should be undertaken in two stages, with construction of the first stage to intermediate grades established in the interim report and completion to final grades in the second stage when pumping stations 7 and 8 are constructed and the lower agricultural area is developed. If backflow up the North New River and Miami Canals were controlled, the intermediate grade levees would prevent floodwaters in Water Conservation Area Nos. 2 and 3 from flowing into the agricultural area and would permit orderly development of the area within the encirclement. Damages that might result from overtopping of levees by waves and wind tide would not be extensive until such time as pumping stations 7 and 8 were constructed and the outer agricultural area developed. If construction of pumping stations and canals in the outer encirclement was delayed and the area remained undeveloped, considerable savings in annual charges on the greater costs of higher levees could be realized during the period of development of the area. Reduction in the final grade may possibly be achieved by more detailed study and analysis. A levee grade of 4 feet above average ground elevation was adopted as a minimum intermediate grade. The plan was approved by the Chief of Engineers in a letter dated March 3, 1955, however the use of excavated peat material in the base of the levee was not approved. The Chief of Engineers also left the final approval with the Division Engineer. In the 4th indorsement dated June 30, 1955, the Jacksonville District revised the levee design and the excavated peat was mixed with rock to provide a suitable base material. This was approved by the Division Engineer on August 9, 1955.

(3) *Part I, Supplement 42 - Detail Design Memorandum, Levee 38 (West), Section 1*, dated February 11, 1965 presented a plan very similar to the plan proposed in Part I, Supplement 27, except for the following deviations: (1) the levee had been relocated 350 ft. from the centerline of U.S. Highway 27 to allow for widening of the highway; and (2) the two 72-inch gated culverts located under the levee was reduced to a single gated culvert since studies indicated that seepage would be greater than first thought. These changes were approved by the Division Engineer in a letter dated March 23, 1965.

c. <u>Water Conservation Area 3</u>. The project document (*House Document 643*) provided for encircling Water Conservation Area 3 with levees so that floodwaters from adjacent areas could be put into the area and stored for beneficial uses or released into Everglades National Park. Pumping Stations 8 and 9 were to discharge into the pool from adjacent agricultural areas and Pumping Station 7 was to discharge into either Area 2 or Area 3, depending on relative water levels. A gated spillway (S-11) was to release water into Area 3 from Area 2, and another gated spillway (S-12) was to discharge water from Area 3 into the undeveloped Everglades south of Tamiami Trail. A structure (S-31) in the eastern levee at Miami Canal was to allow irrigation releases and discharges for control of salt-water intrusion. The levees along the east coast (Levees 30, 33, and 37), the gated spillways (Structures 11 and 12), Pumping Station 9, and Structure 31 were included in the 1948 authorization. The remaining Water Conservation Area 3 works were authorized in 1954.

(1) Subsequent to approval of the Comprehensive Plan, several minor changes were approved. The location of Levees 4 and 5 and Pumping Station 8 was moved about 3 miles south to the Palm Beach-Broward County line. The alinement for Levee 28 was moved from 1 to 4 miles east of the original alinement along the Collier County line to minimize construction costs through the cypress heads. This excluded a portion of the lands in the State Seminole Indian Reservation from the conservation area. The location of Spillway 12 (A-D) was moved from the vicinity of L-30 to the western end of the area so as to discharge directly into Everglades National Park. Pumping Station 7 was designed to discharge only into Water Conservation Area 2.

(2) *Part I, Supplement 33 - General Design Memorandum, Conservation Area 3*, dated June 22, 1960. The plan of improvement presented the facilities needed to regulate water levels in Water Conservation Area 3 during a standard project flood and prevent water in the Everglades from aggravating flood problems on adjacent lands. The plan added the following project features to the authorized plan: Levee 67, Levee 67 Extension, Levee 68, Levee 28 Extension, Structure 12E, Structure 24B, Structure 150, and Structure 151. In the second indorsement, dated August 25, 1960 the Chief of Engineers approved all the recommended additions to the project except the approval of L-67 Ext. and L-28 Ext. was deferred until further studies for the survey report on Southwest Dade County were completed and until planning and cooperative arrangements were further coordinated with the Park Service. The report was approved by the Chief of Engineers on January 13, 1961.

(3) On August 15, 1960 the District Engineer forwarded minutes of a conference held August 4-5, 1960 along with the views of the National Park Service on the proposed plan of improvement. The letter also recommended the deletion of S-147 (a pump station) from the L-28 plan; however, the Chief of Engineers on September 13, 1960, elected to put S-147 in deferred status rather than delete the structure.

(4) On December 6, 1960, the District Engineer requested guidance on building a berm for wildlife enhancement along L-67A. The Florida Game and Fresh Water Fish Commission had recommended this provision in their comments and had the backing of the Flood Control District. In a letter dated December 12, 1960, the Division Engineer stated that additional Congressional authority would be required to permit construction of the berm with project funds, however, the Division Engineer requested comments from the Chief of Engineers. In a subsequent letter dated December 30, 1960, the Chief of Engineers disagreed with the Division Engineer. The Chief stated that the *Fish and Wildlife Coordination Act* applied to any segment of the C&SF project that was less than 60 percent complete as of August 12, 1958. Therefore the proposed modification for mitigation of potential damages to wildlife could be made under the authority of the *Fish and Wildlife Coordination Act* if justified, and no

additional Congressional authority was required. However, the Chief stated that the information provided was insufficient to evaluate the merits of the proposed berm. In a letter dated January 19, 1961, the District Engineer withdrew his proposal for adding a berm to L-67A due to the cost and construction difficulties. Instead of providing a berm for the deer, the proposed modification was to provide a 12-inch peat layer above elevation 11.0 ft. and along the crown of the levee to support a lush growth of grass. This grass would be suitable for deer grazing. In a letter dated February 7, 1961, the Division Engineer gave his approval to this modification.

(5) *Part I, Supplement 30 - General Design Memorandum, Levee 28 (Section 2) and Related Works*, dated September 15, 1959, proposed the following changes to the project. Under the recommended plan of improvement, the following additions to the authorized project were required. Pumping Stations 139 and 140; a diffusion canal from Levee 4(W) borrow canal to Water Conservation Area 3; inlet structures at points of local inflow; enlargement of Levee 3 tieback and Levee 4(W) borrow canals; and two new canals (Big Cypress Canal and Levee 28 (Section 2) borrow canal). Structure 16 would not be needed and was recommended for deletion from the project. In a letter dated October 1, 1959 the Division Engineer returned the design memorandum for revision. The Division Engineer contended that Pump Station 140 would be one of the largest pumping stations in the world. The pump station had a very high initial cost, very high maintenance and depreciation cost and was considered not a good engineering or economic solution to the drainage problem of the area. The Division Engineer recommended that a gravity canal beginning near the upper end of Big Cypress Canal and running to the vicinity of S-140 be investigated. The other recommendations included an alternate alinement to L-28 (Section 2) that would provide storage for the drainage area, the deletion of Big Cypress Canal and pump station 139 and sizing pump station 140 to handle a larger drainage area. In a letter dated October 20, 1959, the District Engineer addressed the Division Engineer's concerns on the plan of improvement. The District Engineer recognized the need for more detailed studies to improve the details of the plan, however there was a need to expedite a solution. The District Engineer stated that the provision of a gravity canal from the upper end of Big Cypress Canal to the vicinity of Pumping Station 140 would not serve an area which had formerly been provided with drainage into Big Cypress Canal; that moving the alinement of L-28 would provide additional storage however at the expense of the conservation area; and the deletion of Pumping Station 139 and enlarging the capacity of pumping station 140 could not be economically justified unless the effect of the rearrangement of pumping station inflows on the design of secondary facilities were considered. Insofar as the plan of improvement recommended, it was possible that additional studies would refine some details, but it did not appear that a material change in the recommendations would be found feasible or reduce the overall costs. A conference was held on November 24, 1959 with representatives of SAD, OCE, and the Jacksonville District in attendance. In a follow-up letter from the Division Engineer to the Chief of Engineers the approval to extend L-28 approximately five miles was given. The Division Engineer also requested that

further investigations into the alinement and grades for the balance of L-28; the economics of reducing pumping capacities by utilizing a ponding area; and the magnitude of the problem for conveying and utilizing water south of L-29 be submitted in future design memorandums.

(a) Addendum 1. On May 24, 1960 the District Engineer submitted *Addendum 1, to Part I, Supplement 30. Addendum 1* was concerned with the drainage problem in the area west of L-28. The plan recommended in addendum 1 would remove runoff from the 1-in-10 year storm without appreciable damages. Approval of the plan would add the following works to the project: Interceptor canal; Big Cypress Canal; enlargement of Levee 4(W) borrow canal and Levee 3 tieback borrow canal; Pumping stations 139, 140 and 147; culverts in L-28; and inlet structures along L-28 borrow canal. Pumping station 147 construction would be deferred until warranted by increased land use in the area it would serve. Structures 16 and 17 would be deleted and structure 14 would remain in the plan of improvement. In a letter from the Division Engineer to the Chief of Engineers, dated June 21, 1960, this plan was recommended for approval. However, the Chief of Engineers stated in a letter dated August 31, 1960 that no action would be taken on this plan until the views of the Flood Control District were furnished.

(b) *Addendum 2.* In a letter dated June 13, 1961 the District Engineer presented a new plan in *Addendum 2* which incorporated the views of the Flood Control District. This addendum provided a single pumping station (S-140) for the northerly portion of the area under consideration in lieu of two pumping stations (S-139 and S-140); extended the interceptor canal to the northern and western extremities of the Seminole Indian Reservation to provide an outlet for excess water; placed the southern pumping station (S-147) in deferred-construction status; and left an 11-mile gap in L-28 immediately south of the interceptor canal with filling the gap in deferred status until the development of eastern Collier County. Additions to the authorized project were Pumping Stations 140 and 147; the interceptor canal, including two feeder canals, each with a headwater control structure; two culverts in L-28 south of the interceptor canal; Levee 3 tieback borrow canal enlargement; and the necessary lateral inflow culverts along the two feeder canals along the upper reaches of L-28 borrow canal, and along L-3 tieback borrow canal. The plan also recommended the deletion of Structures 16 and 17. *Addendum 2 to Part I, Supplement 30* was approved by the Chief of Engineers on August 28, 1961.

(6) *Part I, Supplement 32 - Detail Design Memorandum, Levee 28, Sections 2, 3, and 5* dated March 2, 1962 recommended that the previously approved Section 5 be modified to tieback to higher ground. This was necessary due to placing Section 4 in a deferred status. The tieback would block any discharge from Water Conservation Area 3 through the gap and would eliminate the possibility that water would be discharged south along the west side of Levee 28. The addition of the tieback levee was approved in a letter from the Chief of Engineers on April 11, 1962.

(7) *Part I, Supplement 37 - Detail Design Memorandum, Structures 24B, 31, and 150 (Conservation Area 3)* dated April 27, 1962 presented the same basic plan as was proposed in *Part I, Supplement 33*. However, Structure 31 was changed from a concrete box culvert to a 3-barrel, 84-inch corrugated metal-pipe culvert, and Structure 150 was changed from a concrete box culvert to a 5-barrel, 84-inch corrugated metal-pipe culvert. In addition the concrete headwalls for all three structures were eliminated and the operating platforms were changed from concrete to timber. These changes were made to arrive at the most economical structures. These changes were approved by the Chief of Engineers on June 8, 1962.

L.3.9 East Coast Canals

Following completion of that initial survey-review report, the *Flood Control Act of 1948* authorized Phase 1 of the C&SF Project. Phase 1 consisted of most of the works necessary to afford flood protection to the rich agricultural development south of Lake Okeechobee and to the highly developed urban area along the lower east coast of Florida. This authorization included a section entitled "Planning for subsequent phases." The *Flood Control Act of 1950* authorized further appropriations for Phase 1. The *Flood Control Act of 1954* authorized Phase 2 of the C&SF Project, that is, the remaining works presented in the Comprehensive Report. The *Flood Control Act of 1958* approved the cost-sharing report (*House Document 186, 85th Congress, 1st Session*) for those portions of the C&SF Project which were approved in the 1954 Act, but did not change local cooperation requirements imposed by the 1948 Act. Authorizations in 1962 and 1968 included further funding, modifications and extensions to the East Coast Canals portion of the C&SF Project.

a. St. Lucie and Martin Counties.

(1) *Part III, Supplement 1, General Design Memorandum - St. Lucie County Canals and Control Structures (Canals 23, 23A, 24 and 25, and Control Structures 48, 49, 50, 97, 98, and 99)*, dated January 23, 1957, presented the results of hydrologic and hydraulic investigations for development of the plan of improvement for the St. Lucie County canals. S-97, S-98, and S-99 were added to the C&SF Project by the Office of the Chief of Engineers by letter dated January 8, 1958. *Part III, Supplement 4, Detail Design Memorandum - Canal 25 (Belcher Canal), and Control Structures 50, 98, and 99*, dated December 10, 1959, presented design criteria and construction methods proposed for the improvement of C-25 and C-25(Ext) and the construction of inlet structures and three spillways. This plan differed from that of the *General Design Memorandum (Part III, Supplement 1)* in the proposed alignment of the Belcher Canal extension. Local interests had requested a realignment (to the northwest rather than along State Road 68) which would eliminate numerous bridge crossings and use spoil material for construction of five miles of proposed L-52 along Water Conservation Area A. The realignment increased the drainage area (from 174 to 184 square miles), and was more compatible to the existing and proposed lateral

system of canals (to include 29 inlet structures). S-98 was to permit withdrawal of irrigation water from Water Conservation Area A (Upper St. Johns Marsh), which would be bounded by proposed L-52. The Office of the Chief of Engineers on April 20, 1962, agreed to delete S-98 and L-52. C-25 Ext was added to the C&SF Project by the Office of the Chief of Engineers on April 9, 1963.

(2) *In Part III, Supplement 2 - General Design Memorandum, Upper St. Johns River Basin, C-26, C-27, C-28, S-51, S-52, S-54, L-44 and L-45* were deleted from the C&SF Project by the Office of the Chief of Engineers on September 17, 1957.

(3) *Part III, Supplement 2 - Addendum 1, February 15, 1962*, revised the plan of improvements for St. Lucie and Martin Counties. After the design memorandum studies on this portion of the project were made, development in the area became so intense that land acquisition costs became prohibitive and the planned conservation area had to be abandoned. (Refer to the Upper St. Johns River Basin description.)

(4) *Part III, Supplement 1, General Design Memorandum - St. Lucie County Canals and Control Structures (Canals 23, 23A, 24 and 25, and Control Structures 48, 49, 50, 97, 98, and 99)*, dated January 23, 1957, also provided for improvement of the channel in North Fork St. Lucie River (C-23A) to accommodate the design discharge from C-24 plus the 30% SPF runoff from North Fork St. Lucie River. That enlarged channel would have adequate depth for navigation (benefits incidental to flood control). C-24 would be improved along its entire length from North Fork St. Lucie River to State Road 68 bridge. Water control structure S-49 would maintain a design water-control elevation of 20.0 feet. Secondary drainage structures at inflow points would control runoff into the canal and protect the canal from silting and erosion. *C&SF Project Survey-Review Report, Water Resources for Central and Southern Florida*, (February 15, 1968) added S-311, which would control discharge from C-25 Ext. to the upper limit of C-24.

(5) *Part III, Supplement 11, General Design Memorandum, Martin County (St. Lucie County Water Supply Element)* dated June 29, 1984 proposed the following departures from the authorized plan. The design studies had revealed that the high lift pumping station required in the authorized alinement was not economical, and a less costly alternate alinement was sought. The plan presented was a surface diversion by means of a canal of Lake Okeechobee waters to St. Lucie County for irrigation water supply.C-131A conveys water at Port Mayaca via St. Lucie Canal (C-44) from upstream of St. Lucie Lock to C-23 upstream of S-97. A pumping station (S-214A) and a spillway structure (S-215A) were required near C-44 and C-23 respectively. C-23 required enlargement in the northern reaches. A spillway structure (S-312) was required at the junction of C-23 and C-24 for both irrigation flows and backflows. However, objection to the plan was raised at the local level and to date none of the proposed plan has undergone further development and no further studies have been done.

b. Palm Beach County.

(1) *Part V, Supplement 16, Design Memorandum - Canal 17 and Control Structures 43 and 44*, dated April 5, 1955 presented some of the improvements in Palm Beach County. The purpose of C-17 is to drain flood waters from the low area west of the coastal ridge between Lake Mangonia and the Earman River. The drainage and flood control needs of the area west and north of West Palm Beach required that an adequate outlet be constructed either to Lake Worth or West Palm Beach Canal. The existing outlet through Stub Canal at the south end of Clear Lake was inadequate, as evidenced by flooding of lands adjacent to the canal. A canal to Lake Worth was thus the only practicable solution. The plan of protection proposed in the Comprehensive Plan provided for the construction of about 9.5 miles of canal with a 50 foot bottom width and a design discharge of 600 cfs at a depth of eight feet. This proposed canal would drain from Lake Mangonia northward to State Road A1A, where the canal would divide. From State Road A1A one leg (C-17E) of the canal would drain eastward to Lake Worth through Earman River and the other leg (C-17N) would drain northeastward to the AIWW north of Lake Worth. Each outlet would be provided with a control structure (S-44 and S-45). *Part V, Supplement 16, Design Memorandum - Canal 17 and Control Structures 43 and 44*, dated April 5, 1955, provided for an 8.3 mile long canal, with a drainage area of 89 square miles, for removal of 60% of the SPF. This plan provided for two spillways which would discharge 800 cfs (S-43) and 2070 cfs (S-44). The then existing Earman River, which ran northwestward from Lake Worth to the site of S-44 and then southward to Lake Park Road, had an irregular hydraulic prism. S-43 was proposed at the upper end of the canal to control water levels in Lake Mangonia and Clear Lake. However, S-43 was deleted from the plan when the city of West Palm Beach purchased Lake Mangonia, Clear Lake, and adjacent lands from West Palm Beach Water Company on December 1, 1955. The city desired to retain full control of water levels within the area to insure there was no encroachment on the rights of the city to regulate water levels in its own interests. In addition, it became apparent that two outlets (each with a spillway structure) could not be justified. Since either outlet would serve the drainage area effectively, a study was made to determine which should be eliminated. The lower outlet, discharging through Earman River, would enter a relatively wide section of Lake Worth, while the northerly outlet (C-17N and S-45) would discharge into a rather constricted section of the AIWW. To eliminate any difficulty due to sedimentation in the AIWW, it was decided to concentrate the discharge from C-17 along the lower alignment, using Earman River, consequently the northerly outlet facilities (C-17N and S-45) were deleted from the project. S-45 was deleted from the C&SF Project by the Office of the Chief of Engineers on March 1, 1956.

(2) *Part I, Supplement 3, Partial Definite Project Report on Central and Southern Florida Project, Design Memorandum on Station 5A*. S-5A(E) was added to the C&SF Project by the Office of the Chief of Engineers on February 15, 1952.

(3) *Part V, Supplement 51, General Design Memorandum - West Palm Beach Canal and Related Areas, with Detail Design Appendix on Pumping Station 319,* dated May 31, 1972. The State of Florida's Everglades Drainage District had constructed the West Palm Beach Canal between 1919 and 1929, including a lock and box-culvert structure near the easterly end of the canal. The Central and Southern Florida Flood Control District installed a vertical lift gate in the lock in 1955. The West Palm Beach Canal (C-51) was partially authorized by the *Flood Control Act of 1948* and additional modifications of improvements to C-51 were contained in *P.L. 87-874 (87th Congress, H.R. 13272, October 23, 1962)* and in *P.L. 90-483 (90th Congress S-3710, August 13, 1968).* At the time of *Supplement 51*, no work had been accomplished on the primary outlet works of the West Palm Beach Canal eastward of S-5AE. Supplement 51 proposed the C-51 improvement of 21 miles to provide 30% SPF protection to agricultural areas and 60% SPF protection to urban and citrus areas. The flood control plan contained in *Supplement 51* differed from the authorized plan in that it recommended backpumping about one-half of the excess runoff to Water Conservation Area 1 rather than discharging all runoff to Lake Worth. The report recommended the addition of S-155A and that priority be given to the construction of Pumping Station 319. A detailed design of S-319 was submitted with the report for the basis of early construction. The Chief of Engineers approved the report on February 9, 1983, subject to the satisfaction of comments of the Division Engineer, however the comments and final approval for the plan was not received until April 19, 1974 from the Division Engineer.

(a) *Part V, Supplement 54 - Detail Design Memorandum, Canal 51 and Control Structures 155 and 155A,* dated November 15, 1972 recommended the same plan as presented in Supplement 51. On December 21, 1981, *Addendum 1* to the report was prepared to identify the significant changes to the project design. In this addendum the crest shape for S-155 was changed, the end sill heights and stilling basin baffle block for S-155 were revised to conform to new criteria, the length of riprap protection for S-155 was increased, and the original cross section for C-51 from S-155 eastward to its junction with Lake Worth was recommended to be enlarged.

(b) *Addendum 2 for Part V, Supplement 54* was prepared on July 26, 1984. This addendum included the redesigning of S-155A and relocating the structure about 1,000 feet west of State Road 7 Bridge, reducing the excavation in C-51 between S-155A and S-319, and reducing the design pumping capacity of S-319. These changes were necessary to enable water management practices in the C-51 basin which are in consonance with management practices in other tributary areas of Lake Okeechobee directed at preserving the lake's water quality. On September 18, 1984, the report was returned to the District by the Division Engineer. The Division Engineer stated that the report did not substantiate the statements that modifications to the authorized plan were necessary to enable water management practices in the C-51 basin which are in consonance with management practices in other tributary areas of

Lake Okeechobee directed at preserving water quality. The Division Engineer stated that the economic analysis for the proposed modification was inadequate.

(c) On November 29, 1989, *Part V, Supplement 54, Addendum 2 (Revised)* and a *Post Authorization Change (PAC) Report* was submitted to the Division Engineer. The changes recommended by the PAC included removing water supply to Water Conservation Area 1 as a project purpose although flood control at the authorized level of protection would still be provided. The major design changes dealt with providing backpumping to a detention area instead of Water Conservation Area 1. Backpumping directly into WCA 1 is not implementable because of State of Florida water quality standards. This requires the construction of a culvert structure (S-360) and levee (L-85) and enlargement of L-40. Pumping Station 319 and Spillway 155A designs were modified to eliminate water supply as a project purpose. A meeting was held on January 22, 1990 with representatives of the Division office to discuss various issues and project formulation guidance. On January 16, 1991, a revised report was forwarded to the Division Engineer for approval.

(4) *Part V, Supplement 24, General Design Memorandum, Canals 15 and 16 and Control Structures 40, 41, and 42*, dated December 31, 1958. *Part V, Supplement 34, Detail Design Memorandum - Canals 15 and 16 and Control Structures 40 and 41*, dated June 28, 1962. Canal 15 (Hidden Valley Canal) selected alignment extends from an existing LWDD canal (E-4) along existing Lateral 38 before turning to the southeast and emptying into the AIWW. This alignment is located in the approximate center of the area requiring additional outlet works, and was found to be the most suitable and economical and also the most preferable to local interests. The Central and Southern Florida Flood Control District requested shifting to the south the alignment of C-15 as planned in the General Design Memorandum, claiming the change would save in overall cost due to reduced land and relocation costs. The Jacksonville District conducted a brief investigation which showed that the estimated savings were reasonable and approved the change. The alinement change was officially accepted by the Chief of Engineers on April 3, 1959.

(5) *Part V, Supplement 34, Detail Design Memorandum - Canals 15 and 16, and Control Structures 40 and 41*, dated June 28, 1962, recommended that S-42 be deleted from the project. The proposed centerline of C-16 was offset about 20 to 40 feet to the north from the FEC Railway to the westerly limit of the work to avoid disturbing the existing south bank, eliminating the need for clearing, degrading of the existing spoil mounds, relocations and erosion control along the south bank and reducing land costs. These changes were accepted by the Office of the Chief of Engineers on August 23, 1962.

c. Broward County.

(1) *Part V, Supplement 23, General and Detail Design Memorandum - Canal 14 and Control Structures 37A, 37B and 38A,* dated May 5, 1958. S-37A and S-37B were added to and S-37 was deleted from the C&SF Project by the Office of the Chief of Engineers in its 6th Endorsement to the South Atlantic Division, dated April 21, 1959, of a letter from the Jacksonville District, dated May 8, 1958. The *1968 Water Resources Report* added C-301 and culvert S-322 to divert water from C-14 to the Hillsboro Canal where it could be backpumped at S-320 and used for water supply.

(2) *Part V, Supplement 1, Design Memorandum - Canal 11, dated January 17, 1952* and revised February 27, 1952, designated C-11 within 14.7 miles of the South New River Canal from S-9 at L-37 (C-11 Station 9+05, near U.S. Highway 27) to Pumping Station S-13 at U.S. Highway 441/State Road 7 (confluence with Dania Cut Off Canal and South New River Canal, and site of proposed L-34). The 6.4 mile improvement would drain the 98 square mile drainage area (of the 111.8 square mile Davie agricultural area) through C-11 to the west to Pumping Station S-9 which would flow into WCA 3. The existing channel in the remaining 8.3 miles was of sufficient capacity. C-11 was enlarged to the north where local interests had obtained rights-of-way. *Part V, Supplement 7, Design Memorandum (revised) - Canal 11 and Control Structure 13A*, dated August 8, 1952, was prepared in response to the concern of local interests for drainage of low lands (below elevation +5 feet NGVD, including the town of Davie). The revised plan limited the channel enlargement to the westernmost 3.6 miles and added culvert S-13A. S-13A divides the 98 square mile drainage area into two separate water control systems: the westerly (high) lands of 71 square miles which would drain westward to S-9 and WCA 3, and the easterly (low) lands of 27 square miles which would drain eastward by gravity to a spillway in pumping station S-13 and tidal waters, except during relatively short periods when pumping would be required (when there are high stages east of S-13). The two areas would be divided by canals and spoil banks extending north and south from C-11 at S-13A. *Part V, Supplement 9, Design Memorandum (revised) - Canal 11 and Pumping Station 13*, dated November 17, 1952. The purpose of this supplement was to show additional information, following further subsurface investigations and modifications to design. The design discharge at S-13A was reduced by 40 cfs due to a revised estimate of seepage from WCA 3. This reduction was not significant to the design of the canal. Addition of S-13B to the C&SF Project was recommended in an *Operations Report - Review of C&SF Flood Control Works in Davie Agricultural Area*, dated January 31, 1958, which was approved by the Office of the Chief of Engineers on April 24, 1958. Structure S-13B was later deleted in favor of a modification of S-13A. The *1968 Water Resources Report* added C-303 and culvert S-323 to allow water supply backpumping of the area to Water Conservation Area 3.

(3) C-42 and related L-35A were substituted for portions of L-35 and L-36 by the Office of the Chief of Engineers on September 21, 1949.

d. North Dade County.

(1) *Part V, Supplement 4, Hydrology and Hydraulic Design, Greater Miami Area (preliminary draft)*, February 23, 1952, provided for canal enlargements designated C-2, C-3, C-7, C-8, and C-9 to remove the SPF runoff from Area A, the developed portion of the Greater Miami Area; and, canal enlargements designated C-3, C-4, and C-6 (above C-4) and extension of C-9 to provide drainage to Area B, the remainder of the Greater Miami Area. The objections of local interests to this plan primarily concerned the lesser degree of protection for Area B, specifically that the plan did not meet the demands of present land use or provide for future urban expansion, was inflexible in meeting that expansion without excessive cost, and did not provide adequate water conservation and utilization. In June 1952, the Flood Control District recommended a plan which did not include the C-3 improvement but would provide protection for Area B by a system of canals and two pump stations at L-30, discharging into WCA 3. *Supplement 4* was superseded by *Part V, Supplement 12, Design Memorandum - Hydrology and Hydraulic Design, Canals in Greater Miami Area (C-2 through C-9) (Revised)*, dated March 23, 1954. Supplement 12 addressed plans for improvement of existing canals in the Miami area (C-3, C-4, C-6, and C-9) for which the Flood Control Acts of 1948 and 1950 had authorized construction and funding, and for improvement of those C&SF canals which were not yet approved (C-2, C-5, C-7, and C-8) but for which the 1948 Act authorized additional engineering studies. Supplement 12 presented the hydrologic and hydraulic criteria used to determine the dimensions and characteristics proposed for six of the eight major canals in the developed portion of the Greater Miami area (no improvement was necessary for C-5; C-9 was under construction). This supplement divided the Miami Area into three sub-areas: Area A consisted of about 164 square miles of developed urban and suburban land lying generally east of a line two miles west of Red Road. Area B consisted of about 224 square miles of low, flat, somewhat marshy, undeveloped land between the line about two miles west of Red Road and the water conservation area levees. Area C consisted of about 27 square miles of scattered areas along which drain to Biscayne Bay, either directly overland or through sewers or indirectly by infiltration and seepage. The planned improvements would not affect Area C. The plan of improvement which had been recommended in the Comprehensive Plan (representing the desires of local interests following the 1947 flood) was confined to Area A and consisted of enlarging existing canals to handle a discharge of about 30% SPF. That plan would provide for drainage of the entire area by gravity since no other facilities had been included to reduce flood damages in Area B. However, discharges at the head of improved sections were to be very small (ranging from 70 cfs for C-2 to 230 and 270 cfs for C-4 and C-6, respectively). The total removal capacity from Area B (available only after removal of the floodwaters from Area A) would have been 1,255 cfs. Supplement 12 did not discuss salt water intrusion or the planned structures near the easterly ends of the major canals. The salt water intrusion was addressed in *Part V, Supplement 13, Design Memorandum,*

Water- and Salinity-Control Structures in Greater Miami Area, dated July 2, 1954. The Office of the Chief of Engineers on August 6, 1954, substituted 3 canals and 3 structures in the Greater Miami Area, authorizing C-2, C-7 and C-8 and S-22, S-27 and S-28 for construction in Phase I in lieu of C-3, C-4 and C-6 and S-23, S-25B and S-26 (the construction of which were deferred until a later date). C-8 Ext and C-7 Ext were added to the C&SF Project by the Office of the Chief of Engineers on December 14, 1954. In planning for C-4 (about 1951), it was found that an additional structure would be needed for control of C-4 near its junction with C-3; S-26 was being planned for the control of C-6 only. The proposed additional structure could not be located east of the selected site because of extensive barge traffic on C-4 in the 4.6 mile reach between S-25B and C-6. S-25B was then included in the 1952 estimates of costs for Comprehensive Plan works, which estimates were subsequently approved by the Office of the Chief of Engineers. C-3 and S-23 and associated railroad bridges were deleted by Office of the Chief of Engineers on July 17, 1962. Part V, Supplement 46 - General Design Memorandum, Canals 4, 5, and 6, and Control Structures 25, 25A, 25B, and 26, dated April 18, 1967, recommended that these improvements be provided for salinity control in the three canals. The plan called for a spillway in C-6 (S-26), a spillway (S-25B) in conjunction with a lock in C-4, and culverts in C-5 be fitted with slide gates to provide upstream (S-25A) and downstream (S-25) control structures. In a letter dated November 15, 1967, the Chief of Engineers approved as recommended the design of S-25 and S-25. However, the approval of S-25B and S-26 were deferred until extensive comments about the structure locations could be answered. In a letter dated March 26, 1968, the District Engineer stated that the plan presented in the *GDM* was a compromise plan developed with other Agencies input. The proposed locations provided a reasonable degree of salinity protection and at the same time continued to serve existing navigation with a minimum of delay. The information provided by this letter was satisfactory and the report was approved by OCE on August 26, 1968.

(2) *Part V, Supplement 3, Design Memorandum - Canal 9 and Structure 29*, dated February 22, 1952. After investigation of the permeability and character of the foundation rock, it was decided to locate S-29 about 375 feet downstream of US Highway 1. *Part V, Supplement 12, Design Memorandum -Hydrology and Hydraulic Design, Canals in Greater Miami Area (C-2 through C-9) (Revised)*, dated March 23, 1954, included elimination of L-32 and the westward extension of C-9 to L-33, which would require relocation of S-30 west of L-33. Elimination of L-32 and addition of the westward extension of C-9 (Sections 4 and 5) to L-33 (and consequent relocation of S-30) were authorized by a letter of July 30, 1953 from the Office of the Chief of Engineers to South Atlantic Division. *Part V, Supplement 15, Design Memorandum - Snake Creek Canal Extension (C-9, Section 4)*, dated December 15, 1954, planned a 4.7 mile westward extension of the Snake Creek Canal to drain the areas west of Ludlum Road as well as to replace the Ludlum Road Bridge. *Part V, Supplement 19, Design Memorandum - Canal 9, Section 1*, dated January 6, 1956, recommended a change in the alignment of C-9. This design memorandum proposed to route C-9 through the

Oleta River and Maule Lake to the AIWW channel in Dumbfoundling Bay for the purpose of reducing the required channel excavation by utilizing a section of the AIWW to Biscayne Bay which would also provide the borrow material to local interests. *Part V, Supplement 27, General and Detail Design Memorandum - Canal 9 (Section 5) and Control Structure 30*, dated April 20, 1959, proposed the westward extension of C-9 to the L-33 borrow canal and the construction of S-30. With this canal extension, C-9 would convey from WCA 3 the water supply necessary to maintain fresh water heads at control structures on C-7, C-8 and C-9. This document completes the planning and design of C-9 as it currently exists.

e. South Dade County.

(1) *Part V, Supplement 30 - General Design Memorandum, Levee 31 and Related Works, S-20F and S-20G* were added to the C&SF Project by the Office of the Chief of Engineers on May 4, 1960.

(2) *Part V, Supplement 37 - General Design Memorandum, South Dade County, C-102N, C-103N, C-103S and S-179* were added to and S-20D and S-20E were deleted from the C&SF Project by the Office of the Chief of Engineers on November 29, 1963. A portion of C-103S within Florida City also deleted.

(3) *Part V, Supplement 37 - General Design Memorandum, South Dade County Addendum 1, S-198* was added to the C&SF Project by the Office of the Chief of Engineers on February 27, 1968. S-199 was added to the C&SF Project by the Office of the Chief of Engineers on October 5, 1967.

(4) *Part V, Supplement 39 - Coastal Areas South of St. Lucie Canal - Detail Design Memorandum Canals 102 (Princeton Canal), 102(N), and Control Structures 165, 194, and 195*, dated November 19, 1964, added S-194 and S-195 to the project. These additions were accepted on February 15, 1965 by the Division Engineer.

(5) *Part V, Supplement 40 - Coastal Areas South of St. Lucie Canal - Detail Design Memorandum, Canals 103 (Mowry Canal), 103 (N) and 103 (S) and Control Structures 20F, 166, 167, 179, and 196*, dated January 22, 1965, added S-196 in C-103. S-196 was required to hold the headwater in C-103 at elevation 6.5 ft. This change to the project was approved by the Division Engineer on March 23, 1965.

(6) The Senate Appropriations Committee, in its *Report 1768* on the Public Works Appropriations Bill, determined that the extension of C-1 to the northwest was within the scope of the authorized C&SF Project. This extension includes the continuation of the main canal westward to L-31 (C-1, Section 2, or C-1W or C-1 Ext) and the addition of a spur canal north of the main canal (C-1, Section 3, or C-1N). C-1 Ext, C-1N, S-148 and S-149 were added to the C&SF Project by letter from the Office

of the Chief of Engineers to the Chairman of the House Committee on Appropriations, dated September 7, 1960.

(7) In September 1967 a letter report entitled Control Structure 197 in Canal 111 was prepared. C-111 was authorized by the *Flood Control Act of October 23, 1962 (PL 87-874, 87th Congress)* and subsequently S-197 was considered part of this authorization. S-197 was requested by the United States Department of the Interior, National Park Service. S-197 enables overland flow of water across C-111 and thence southward to the Everglades National Park and also serves as a barrier against salt water intrusion. S-197 consisted of a three-barrel culvert located in the side of the existing canal in order to provide navigation while functioning and a canal plug. The letter report was approved by the Office of the Chief of Engineers on October 18, 1967. In March 1990, the SFWMD received a Department of the Army permit to modify S-197. An additional ten barrels were added to the structure to permit greater flows to the park.

L.4 C&SF PROJECT O&M RESPONSIBILITIES

All of the project works constructed as a result of the *Rivers and Harbors Act of 1930* were operated and maintained by the Corps of Engineers. Some channels, such as the St. Lucie Canal, were constructed by the State of Florida, and operation and maintenance (O&M) was taken over by the Corps of Engineers as a result of the 1930 Act. When the *Flood Control Act of 1948* approved the creation of the Central and Southern Florida Project for Flood Control and Other Purposes, those features of the old Caloosahatchee River and Lake Okeechobee Drainage Areas (CR&LODA) Project were retained by the Federal Government for operation and maintenance. The flood control features of the CR&LODA project were improved in some cases and incorporated into the C&SF Project. The existing channels and locks were included in the Okeechobee Waterway Project. Locks and channel improvements done as a result of the new project were included in the C&SF Project.

L.4.1 Corps of Engineers

Both the 1948 Act and the 1968 Act included language which spelled out those features of the project which would be operated and maintained by the Corps of Engineers for the Federal Government. The project features to be operated and maintained by the Corps of Engineers are *"the levees, channels, locks, and control works of the St. Lucie Canal, Lake Okeechobee, Caloosahatchee River, and the main spillways of the water conservation areas . . ."* In addition, *". . . 60 percent of the additional pumping costs due to the proposed modification [1968 Authorization], . . . [is] to be reimbursed by the Federal Government except for the additional pumping costs at Pumping Station 9 and for the pumping stations along the northeast and northwest shores of Lake Okeechobee which will be all local . . ."*

The project features operated and maintained by the Corps of Engineers are shown in Table L-12.

L.4.2 Local Sponsor

The C&SF Project has two sponsors. The St. Johns River Water Management District (SJRWMD) is responsible for local cooperation requirements for the Upper St. Johns River Basin. All other project features are the responsibility of the South Florida Water Management District (SFWMD). The local sponsor is responsible for operation and maintenance of all project facilities not operated and maintained by the Corps of Engineers in accordance with regulations approved by the Secretary of the Army.

APPENDIX M

IMPLEMENTATION PLAN SCHEDULING AND SEQUENCING

APPENDIX M
IMPLEMENTATION PLAN SCHEDULING AND SEQUENCING

Figure M-1 provides a graphical representation of the schedule for implementing the components of the recommended Comprehensive Plan. Refer to ***Section 10*** for a complete discussion of this schedule. Each activity is graphically represented by a time scaled bar or diamond which reflects the starting date and ending date based on the estimated duration of that activity. The time scale is over the 41 years (starting in 1999 through 2040) of the project. In the figures that follow, solid gray bars (or black on poor quality copy reproductions) represent activities, hatched bars represent critical path activities, black bars with down pointing carats indicate a rolled up (summary bar) activity, and the black diamonds represent milestones.

APPENDIX N
COMMENTS AND RESPONSES

The Central and Southern Florida Project Comprehensive Review Study Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement (Draft Report) was released to the public in October 1998. The report was released in a 9 volume printed set, in viewable format on CD, and as downloadable files from the Restudy web page (www.restudy.org). Notification of the report's availability was provided in the Federal Register on 23 October 1998. A period of time was set aside in accordance with the National Environmental Policy Act (NEPA) to provide all interested parties an opportunity to comment on the contents of the Draft Report. The comment period was open between 23 October 1998 and 31 December 1998.

During the comment period a number of public meetings were held in south Florida for all interested parities. The public meetings provided an opportunity for the public to become familiar with the major concepts associated with the Draft Report through review of displays and interaction with Restudy Team members. The public meetings included a forum for interested individuals to make public comment to the attending audience and the Restudy Team. Detailed information regarding these public meetings is available in Section 11 of this report.

In addition, written comments were received in response to the Draft Report. This Appendix is a compilation of the written comments and the responses to them.

Comment letters were received from Federal, state, and local governments, native American tribes, various non-governmental organizations, and individuals. The comments were summarized and categorized into the following groups: plan formulation, water quantity and modeling, ecological, compliance with NEPA and other relevant policies, socio-economics, real estate, water quality, plan implementation and monitoring, authorization/funding, and public outreach. In this appendix, each category of comments is presented in a comment/response format where the comment is paired with its response and includes a number for tracking purposes. Many comments received were similar in nature and have been answered with a single response.

The letters received during the Draft Report comment period are listed in the following ***Section N.1***. The list of letters includes the following information for each letter received: the author; group or organization represented; author's address; the date of the letter; and a list of comment numbers. The comment numbers correspond to the categories of comments outlined above.

It should be noted that a number of letters were received that did not require a specific response. This group of letters included form letters and general letters of support for the recommended plan outlined in the Draft Report. Further, some comments received were editorial in nature, recommending specific text changes to the report. These comments have been considered and incorporated in the report, as appropriate.

N.1 LETTERS RECEIVED DURING THE COMMENT PERIOD

More than 350 letters, faxes, and e-mailed comments were received during the draft report comment period. Many of these letters were quite lengthy and had specific comments regarding the effects of the recommended Comprehensive Plan. Others were more general in nature. Many offered support for the recommended plan. Others were less supportive and more critical of the recommended plan.

N.1.1 Federal Agencies

Miccosukee Tribe of Indians of Florida
P.O. Box 440021
Tamiami Station
Miami, FL 33144
December 30, 1998

The Miccosukee Tribe of Indians of Florida had the following comments: 48,188,366,439, 440 – 443 and 476 – 478.

Program Management Committee
Florida Bay and Adjacent Marine Systems
Attn: John Hunt and Tom Armentano
Florida Bay Interagency Science Office
98630 Overseas Highway
Key Largo, FL 33037
December 1, 1998

The Florida Bay and Adjacent Marine Systems had the following comments: 193 - 195, 227 – 229 and 271 – 273.

Seminole Tribe of Florida
Lewis, Longman & Walker
1700 Palm Beach Lakes Blvd
Suite 1000
West Palm Beach, Fl 33401
December 30, 1998

Lewis, Longman & Walker, representing the Seminole Tribe of Florida had the following comments: 112 – 116, 159 –161, 290, 357, 465, 511, 512, 515, 565 and 567.

U.S. Department of Commerce
Office of the Under Secretary for Oceans and Atmosphere
Washington, DC 20230
December 30, 1998

The U.S. Department of Commerce, Office of the Under Secretary for Oceans and Atmosphere had the following comments: 42, 108, 308, 469 and 515.

U.S. Department of Commerce
National Oceanic and Atmospheric Administration
National Marine Fisheries Service
Southeast Regional Office
9721 Executive Center Drive N.
St. Petersburg, FL 33702
December 24, 1998

The National Marine Fisheries Service, Southeast Regional Office had the following comment: 42.

U.S. Department of Commerce
National Oceanic and Atmospheric Administration
National Ocean Service
Florida Keys National Marine Sanctuary
P.O. Box 500368
Marathon, FL 33050
December 29, 1998

The Florida Keys National Marine Sanctuary had the following comments: 42 and 308.

U.S. Department of Commerce
National Oceanic and Atmospheric Administration
National Marine Fisheries Service
Southeast Fisheries Science Center
75 Virginia Beach Drive
Miami, FL 33149
December 29, 1998

The National Marine Fisheries Service, Southeast Fisheries Science Center had the following comments: 35, 42, 69, 77, 108, 120, 191, 192, 226, 266, 468, 514, 527 and 541.

U.S. Department of Health & Human Services
Centers for Disease Control and Prevention (CDC)
National Center for Environmental Health
Atlanta, GA 30341-3724
November 24, 1998

The U.S. Public Health Service concurs that the beneficial effects of the Comprehensive Plan outweights any adverse effects that may occur.

U.S. Department of the Interior
Office of the Secretary
Office of Environmental Policy and Compliance
Richard B. Russell Federal Building
75 Spring Street, S.W.
Atlanta, GA 30303

Office of Tourism, Trade, and Economic Development
The Capital
Tallahassee, FL 32399-0001
December 17, 1998

The Office of Tourism, Trade, and Economic Development pointed out that the Comprehensive Plan is consistent with Chapter 288, Florida Statutes, which directs the State to provide guidance and promotion of beneficial development through encouraging diversification and promoting tourism. Further, they state that the Comprehensive Plan appears to have no unreasonable negative impacts on income and employment nor adverse effects to any key Florida industry which will not be justly mitigated, and the Restudy project demonstrates official local agency support. Moreover, the proposed project would achieve the goals of Chapter 288 by developing a long range master plan for south Florida's water resources which would contribute to economic diversification.

South Florida Water Management District
Samuel E. Poole III
Executive Director
3301 Gun Club Road
West Palm Beach, FL 33406
December 28, 1998

The South Florida Water Management District is the co-author of this report. A Letter of Intent, is included in Appendix G that describes their views of the Comprehensive Plan.

Southwest Florida Water Management District
2379 Broad St
Brooksville, FL 34609-6899
November 6, 1998

P.O. Box 1760
Labelle, FL 33975
December 3, 1998

The Hendry County Board of County Commissioners had the following comments: 12, 13, 40, 97, 171, 316 – 318 and 563.

Highlands County Board of County Commissioners
P.O. Box 1926
Sebring, FL 33871-1926
December 29, 1998

The Highlands County Board of County Commissioners had the following comments: 8, 40, 50, 51, 53, 152, 180, 292 and 376.

Lee County Board of County Commissioners
P.O. Box 398
Ft. Myers. FL 33902-0398
November 25, 1998 and November 30, 1998

The Lee County Board of County Commissioners had the following comments: 20, 66, 164, 165, 166, 354, 378, 379, 506, 507 and 561.

Martin County Board of County Commissioners
2401 SE Monterey Road
Stuart, FL 34996
December 29, 1998

The Martin County Board of County Commissioners had the following comments: 375, 487 and 551.

Metropolitan Dade County
Office of County Manager
Suite 2910
111 N.W. 1st Street
Miami-Dade, FL 331218-1994
November 13, 1998

The Metropolitan Dade County had the following comments: 69, 120, 126 – 131, 166, 205, 206, 266, 516-519, 526, 548 and 549.

South Florida Regional Planning Council
3440 Hollywood Boulevard, Suite 140
Hollywood, FL 33021
December 15, 1998

The South Florida Regional Planning Council had the following comments: 160 and 360.

Southwest Florida Regional Planning Council
P.O. Box 3455
N. Ft. Myers, FL 33918-3455
December 23, 1998

The Southwest Florida Regional Planning Council had the following comments: 147, 149, 160, 169 – 174, 205, 322 –326, 504 and 505.

St. Lucie County Board of County Commissioners
Barnes, Cliff
2300 Virginia Avenue
Fort Pierce, FL 34982-5652
December 30, 1998

Mr. Cliff Barnes of the St. Lucie County Board of County Commissioners had the following comments: 487 and 551.

St. Lucie County Board of County Commissioners
Bruhn, John D.
2300 Virginia Avenue
Fort Pierce, FL 34982-5652
December 30, 1998

Mr. John D. Bruhn of the St. Lucie County Board of County Commissioners had the following comments: 487 and 551.

St. Lucie County Board of County Commissioners
Coward, Doug
2300 Virginia Avenue
Fort Pierce, FL 34982-5652
December 30, 1998

Mr. Doug Coward of the St. Lucie County Board of County Commissioners had the following comments: 487 and 551.

St. Lucie County Board of County Commissioners
Hutchinson, Frannie
2300 Virginia Avenue
Fort Pierce, FL 34982-5652
December 30, 1998

Ms. Frannie Hutchinson of the St. Lucie County Board of County Commissioners had the following comments: 487 and 551.

St. Lucie County Board of County Commissioners
Lewis, Paula A.
2300 Virginia Avenue
Fort Pierce, FL 34982-5652
December 30, 1998

Ms. Paula A. Lewis of the St. Lucie County Board of County Commissioners had the following comments: 487 and 551.

Tampa Bay Regional Planning Council
9455 Koger Boulevard, Suite 219
St. Petersburg, FL 33702-2491
November 5, 1998

Tampa Bay Regional Planning Council had no specific comments.

Treasure Coast Regional Planning Council
301 East Ocean Boulevard, Suite 300
Stuart, FL 34994
December 8, 1998

The Treasure Coast Regional Planning Council had the following comments: 490, 552, 554 and 555.

N.1.4 Local Governments

City of Cooper City, Florida
City Commission
P.O. Box 290910
Cooper City, FL 33329-0910
November 10, 1998

The City Commission supports the goals of the Restudy.

City of Ft. Myers
Planning Dept.
P.O. Drawer 2217
Ft. Myers, FL 33902-2217
January 13, 1999

The City of Ft. Myers Planning Department had the following comments: 381 and 513.

City of Hollywood
P.O. Box 229045
Hollywood, FL 33022-9045
December 2, 1998

The City of Hollywood had the following comments: 13, 160, 364 – 366, 368, 521 and 570.

City of Key West
P.O. Box 1409
Key West, FL 33041-1409
305-292-8193
December 7, 1998

Josephine Parker, City Clerk for the City of Key West had the following comment: 42.

City of Layton
Larry Braun, Vice Mayor
P. O. Box 533
Long Key, Florida 33001
Resolution Number: 98-12-01
December 11, 1998

The City of Layton had the following comment*:* 42.

City of Naples, Florida
735 Eighth St. South
Naples, Fl 34102
December 28, 1998

The City of Naples, Florida supports the Comprehensive Plan and in particular, the proposed Southwest Florida Feasibility Study.

Cypress Grove Community Development District
P.O. Box 1057
Loxahatchee, FL 33470-1057
November 10, 1998

The Cypress Grove Community Development District had the following comments: 119, 197 and 198.

Islamorada, Village of Islands
88500 Overseas Hwy. #509
Islamorada, FL 33070
November 15, 1998

Mr. George Giesler, Councilman for Islamorada, Village of Islands, had the following comment: 42.

Village of Wellington
Carmine A. Priore, D.D.S., Mayor
14000 Greenbriar Boulevard

P.O. Box 11387
Naples,FL 34101-1387
December 14, 1998

Collier County Audubon had the following comments: 99, 160 and 330.

Collier County Citizens for Constitutional Property Rights
1221 Cypress Drive
Naples, FL 34120
November 30, 1998

The Collier County Citizens for Constitutional Property Rights had the following comment: 352.

Divers Alert Network
The Peter B. Bennett Center
6 West Colony Place
Durham, NC 27705 USA
December 10, 1998

The Divers Alert Network had the following comments: 42, 134, 160, 362 and 391.

Environmental Economics Council
C/O NAS, 444 Brickell Ave, Suite 850
Miami, FL 33131
December 23, 1998

The Environmental Economics Council had the following comments: 20, 148, 166, 168, 176, 180, 182, 183, 266 and 462.

Everglades Restoration Oversight Group
93351 Overseas Highway, #3
Tavernier, FL 33070
December 28, 1998

The Everglades Restoration Oversight Group had the following comments: A32 and 485.

Florida Audubon Society
1331 Palmetto Avenue
Suite 110
Winter Park, FL 32789
December 30, 1998

The Florida Audubon Society had the following comments: 38, 160, 199 and 202.

Florida Biodiversity Project
1060 Tyler Street
Hollywood, FL 33019
December 28, 1998

Florida Biodiversity Project had the following comments: 4-9, 154, 162, 168, 178, 305, 307, 497 and 564.

Florida Citrus Mutual
P.O. Box 89
Lakeland, FL 33802
December 23, 1998

Florida Citrus Mutual had the following comments: 148 and 355.

Florida Farm Bureau Federation
P.O. Box 147030
Gainesville, FL 32614-7030
December 8, 1998

The Florida Farm Bureau Federation had the following comments: 58, 354, 355, 507, 562 and 563.

Florida Fruit & Vegetable Association
4401 Colonial Drive
P.O. Box 140155
Orlando, FL 32814
December 21, 1998

The Florida Fruit & Vegetable Association had the following comments: 58, 148 and 503.

Florida League of Anglers, Inc.
P.O. Box 1109
Sanibel, FL 33957
December 15, 1998

The Florida League of Anglers, Inc. is no longer a lead organization in conservation and has asked their members to work with and support other conservation organizations in this regard.

Florida Power & Light
Environmental Services Department
P.O. Box 14000
Juno Beach, FL 33408
December 18, 1998

Florida Power and Light had the following comments: 355, 356, 496, 498, 499, 507 and 542.

Florida Water Council
4524 W. Gun Club Road
Suite 203
West Palm Beach, FL 33415
December 1, 1998

The Florida Water Council had the following comments: 67-71, 160, 329, 380, 507 – 510 and 558 – 560.

Fulltrack Conservation Club of Miami-Dade County
email from Jack Moller
LJMoller@aol.com
December 1, 1998

The Fulltrack Conservation Club of Miami-Dade County had the following comment: 98.

Greater Miami Chamber of Commerce
Omni International Complex
1601 Biscayne Boulevard
Miami, FL 33132
December 29, 1998

The Greater Miami Chamber of Commerce had the following comments: 121, 122, 266, 470, 526 and 542.

Highlands Soil and Water Conservation District
4505 George Blvd
Sebring, FL 33872-5837
December 31, 1998

The Highlands Soil and Water Conservation District had the following comments: 8, 40, 50 – 53, 152, 268, 282, 292 – 295, 444, 452.

November 19, 1998

The Ocean Reef Community Association had the following comments: 42 and 54.

St. Lucie River Initiative
P.O. Box 2082
Stuart, FL 34995
December 8, 1998

The St. Lucie River Initiative had the following comments: 62, 184, 185, 240, 241, 375, 487, 488, 489, 552 and 553.

The Nature Conservancy
Florida Chapter
222 S. Westmonte Drive, Suite 300
Altamonte Springs, FL 32714
December 28, 1998

The Nature Conservancy Florida Chapter had the following comments: 42, 91 and 557.

University of Florida
Institute of Food and Agricultural Sciences
18905 SW 280 Street
Homestead, FL 33031
November 17, 1998 and December 31, 1998

The University of Florida Institute of Food and Agricultural Sciences had the following comments: 5, 10 –15, 167, 354, 369, 461 and 496.

World Wildlife Fund
1250 Twenty-fourth Street
NW Washington, DC 20037-1175

World Wildlife Fund had the following comments: 15, 20, 32, 55, 168, 189, 200, 288, 289, 305, 372 – 374, 472 and 502.

N.1.6 Individuals

Alexander, J. D.
PO Box 921
Dania Beach, FL 33004
no date

Mr. Alexander requests that the Corps restore the term “wild” back to the Everglades.

Appelberg, Renee Z.
17758 Park Village Blvd.
Fort Myers, FL 33908-6130
December 20, 1998

Mrs. Renee Z. Appelberg strongly urges the Corps to implement the Restudy.

Avellino, Nancy Carroll
4750 NE 23rd Avenue
Ft. Lauderdale, FL 33308
November 9, 1998

Ms. Nancy Carroll Avellino notes that we must strengthen the protection of wetlands, stop urban sprawl and pollution. Further, we need to add lands to conservation, not pave and destroy.

Ballinger, G.
PO Box161152
Miami, FL 33116
December 24, 1998

G. Ballinger had the following comment: 41.

Bishop, James D. P.
P.O. Box 947
Boca Grande, FL 33921
December 11, 1998

Mr. James D. P. Bishop had the following comment: 147.

Boomer, Anne
E-mail: Aboomer1@aol.com

Ms. Anne Boomer requested that the Corps help the Everglades, implement the Restudy.

Brumfield, Lloyd
11225 Meadowlark Circle
Stuart, FL 34997-2730
December 29, 1998

Mr. Lloyd Brumfield had the following comments: 175, 176, 425 and 460.

Censits, R.
688 Annemoore Lane
Naples, FL 34108
November 21, 1998

Mr. Censits' letter urges the Corps to implement the C&SF Restudy and take strong action to protect the Everglades natural resources, restore lost wetlands, and improve water quality.

Charnoski, Glen
University of Colorado, Faculty
735 University Ave.
Boulder, CO 80302
December 23, 1998

Mr. Glen Charnoski had the following comments: 169, 366 and 392.

Clark, R. H.
Rep. of Broward County League of Women Voters
651 S.W. 6th St. #215
Pompano Beach, FL 34108
December 26, 1998

Ms. Clark, as representative to the South Florida Water Management District's, Lower East Coast Regional Water Supply Plan Advisory Committee, offers the following comments:

The C&SF Comprehensive plan should be supported as a great step forward toward a possibly sustainable future for south Florida's natural resources, and water supply.

Funding on the federal and state levels should be supported so land acquisitions can be made before they are further developed, and pilot projects can be started to find out which technologies are feasible.

More natural levels and flows to the Everglades and Florida Bay are desirable, as well as recharging the aquifer, and the provision of water preserve areas for water storage and seepage management.

Applauds the consideration of water quality (at long last), flows to estuaries, and salinity impacts in the estuaries.

Supports the regional monitoring program and adaptive management strategy.

Hopes that the complexity and scope of the multi-agency, multi-discipline, multi-government level project will not founder in a political quagmire before citizens realize what a once in a lifetime opportunity they have to save south Florida for future generations by supporting Congressional adoption of the study recommendations.

Corcoran, Thomas
P.O. Box 273675
Boca Raton, FL 33427
December 29, 1998

Mr. Tom Corcoran had the following comment: 13, 168 and 538.

Dunavan, G.
1221 Cypress Drive
Naples, FL 34120
November 30, 1998

G. Dunavan had the following comment: 65.

Ellenby, Marc J.
25250 S.W. 194th Ave.
Homestead, FL 33031
November 17, 1998

Mr. Marc J. Ellenby had the following comments: 63 and 183.

E-mail: BahiaBoo@aol.com

BahiaBoo had the following comments: 4, 6, 155, 305 and 359.

E-mail: Candler@ix.netcom.com

Candler requested that the Corps return the Everglades to their natural state by restoring the flow of water.

E-mail: GiGi0708@aol.com

GiGi notes that we need the Everglades, and recommends implementing the Restudy.

E-mail: Harrisrd@aol.com

Harris stated that we cannot save every species of animal life. Leave the Everglades, as they are today, canals and all.

Fisikelli, Alfred
16700 SW 69 Street
Fort Lauderdale, FL 33331-2048

Mr. Alfred Fisikelli had the following comments: 4, 17, 150 and 158.

Flisk, A.
4106 24 Ave West
Bradenton, FL 34205
December 29, 1998

A. Flisk had the following comment: 57.

Fodor, Mark
4370 NE 15th Terrace
Pompano Beach, FL 33064
October 27, 1998

Mr. Mark Fodor had the following comments: 7 and 463.

Forman, M. Austin
Kendall Properties & Investments
C/O Gillis Investments Ltd.
888 Southeast 3rd Ave
Suite 501
Fort Lauderdale, FL 33316
December 28, 1998

Kendall Properties & Investments had the following comments: 69, 94, 138, and 353.

Gammonley, Denise
3000 South Ocean Drive #7J
Hollywood, FL 33019

Ms. Denise Gammonley had the following comment: 63.

Golling, P.
5312 S.W. 11th Pl.
Cape Coral, FL 33914
November 24, 1998

Mr. Golling states that it is clear that restoring the Everglades will benefit not only the wildlife, water quality, and wetland areas, but will benefit the future of other ecosystems which are being or may be restored. He requests that the Corps proceed with the Restudy and the proposed plan.

Hamilton, Patrick and Norma B.
29001 Boyce Road
Punta Gorda, FL 33982
December 13, 1998

Patrick and Norma B. Hamilton had the following comments: 41 and 454.

Hart, Robin L,
5086 Barrington, Circle
Sarasota, FL 34234
December 14, 1998

Robin L. Hart supports the Comprehensive Plan.

Heffernan, J. W.
PO Box 687
Boca Grande, FL 33921
November 23, 1998

Mr. Heffernan writes urging the Corps take up the projected Restudy to restore the Everglades to full health and help bring back the “River of Grass.”

Hepburn, G. G.
6142 Whiskey Creek Dr. Apt 605
Ft. Myers, FL 33919
December 7, 1998

G.G. Hepburn states support for Implementation of the Restudy Recommendations based on discussion of the Plans with a team member (Bill Hunt) at a December 1, 1998, public meeting in Ft. Myers.

Holmes, Charles F.
E-mail: Cfholmes@mindspring.com

Mr. Charles F. Holmes recommends implementing the Restudy and resisting the enticement of developers and agriculturists.

Huesman, Richard & Joan
19329 Green Valley Court
North Ft. Myers, FL 33903

Richard & Joan Huesman strongly urges that the Corps implement the Restudy.

Hutchins, M.
27063 Allan Street
Bonita Springs, FL 33923
December 24, 1998

M. Hutchins had the following comment: 65.

Johnson, Lois L.
7072 W. County Club Drive North
Sarasota, FL 34243-3513

Lois L. Johnson recommended restoring the ecosystem in the Everglades, and hopes the plan is endorsed.

Kirschner, M.
1401 SW 128th Terrace #H409
Pembroke Pines, FL 33027
December 8, 1998

Mr. M. Kirschner recommneds leaving nature alone and that the money should be used to repay the national debt.

Klein, Helene
P.O. Box 14394
Fort Lauderdale, FL 33302
October 27, 1998

Ms. Helene Klein had the following comments: 63 and 100.

Larsen, Paul
Larsen and Associates
First Union Financial Center, Suite 2940
Miami, FL 33131
December 27, 1998

Larsen and Associates had the following comments: 69, 155, 200, 201 and 202.

Levitis, Esther G.
2055 Harwood E
Deerfield Beach, FL 33442
December 26, 1998

Esther G. Levitis commented for support of immediate land acquisition and would like the Corps to address the hydrologic needs of the Everglades.

Martin, Richard
2301 Ringling Blvd
Sarasota, FL 34237

Mr. Richard Martin had the following comments: 149 and 150.

Moss, T.
2436 Pinewoods Circle
Naples, FL 34105
No date

T. Moss had the following comment: 359.

Murchie, Stephen B.
901 NE 18 Court, #202
Ft. Lauderdale, FL 33305
October 27, 1998

Mr. Stephen B. Murchie had the following comments: 7, 63, 186, 187, 239, 332, 337 and 464.

Myers, Arno R.
100 Glenview Place #505
Naples, FL 34108

Arno R. Myers strongly urges the Corps to implement the Restudy.

Oehlbeck, Barbara
Grassy Run Muse
Rt. 1 Box 1771
Labelle, FL 33935
December 12, 1998

Mrs. Barbara Oehlbeck had the following comments: 96, 156, 319, 467,

Oehlbeck, Luther W.
Grassy Run Muse
Rt. 1 Box 1771
Labelle, FL 33935
December 12, 1998

Mr. Luther W. Oehlbeck had the following comments: 7, 149 and 157.

Oltmans, Judy
No return address provided
November 16, 1998

Ms. Judy Oltmans had the following comments: 7, 100 and 160.

Pedersen, Amy
1725 N.W. 91 Ave.
Plantation, FL 33322
November 6, 1998

Ms. Amy Pedersen had the following comments: 4, 6, 63, 103, 133, 162, 305 and 545.

Piner, J.A. and D.M.
87851 Old Hwy. Unit P-1
State Road 4-A
Islamorda, FL 33036
December 22, 1998

J.A. and D.M. Piner had the following comment: 392.

Podgor, Joe
244-A Westward drive
Miami Springs, FL 33166
E-mail: podgor@icanect.net
December 31, 1998
(this e-mail was received from six other individuals)

Mr. Joe Podgor and the others had the following comment: 154.

Quackenbos, Max
1778 NW Palmetto Terrace
Stuart, FL 34994
December 31, 1998

Mr. Max Quackenbos noted that ecosystem restoration is no longer the clear project priority, but is co-equal with flood control and water supply.

Rauschenberger, E.
5563 Pendlewood Lane
Fort Myers, FL 33919-2742
November 22, 1998

Mrs. E. Rauschenberger noted that anything that can be done to restore the Everglades to its original design should be done. Our children's grandchildren will never know the wildlife of past generations if nothing is done to restore it.

Reef Relief Environmental Center and Store
201 William Street, P.O. Box 430
Key West, FL 33041
December 10, 1998

The Reef Relief Environmental Center and Store had the following comments: 42, 391 and 438.

Reynolds, S.
345 Shoreland Dr.
Ft. Myers, FL 33905
November 25, 1998

Mr. Reynolds urges the Corps to take necessary action to restore the Everglades. He has canoed parts of the Everglades and finds it beautiful even considering that it has declined 85-90% from what it was originally. Concludes that this generation will not see the full benefit of the restoration, but perhaps future generations will.

Rippeteau, D. D.
1011 NW Third Ave
Delray Beach, FL 33444
December 12, 1998

Mr. Rippeteau expresses strong support of the Draft Plan and requests a copy of the final report. Further states that the damage done to the Everglades and the ecosystem of south Florida by a century of mis-management must be repaired now.

Romeo, Theresa C.
3224 S. Ocean Blvd., #510
Highland Beach, FL 33487
December 15, 1998

Ms. Theresa C. Romeo had the following comments: 42, 305 and 362.

Scharf, K.
4755 NW 3rd Court Apartment C
Deray Beach, FL 33445
November 12, 1998

Ms. Scharf writes to express strong support of the Draft Plan for restoring the Everglades and acknowledges that nowhere in the world has such as plan for restoration of the ecosystem of so large an area ever been undertaken.

Simon, E. & E.
5501 Heron Point Dr. Apt 904
Naples, FL 32232
November 24, 1998

Mr. and Mrs. Simon writes to urge the Corps to implement the Restudy.

Tinnerman, William R.
150 North Federal Highway, Suite 220
Fort Lauderdale, FL 33301
December 7, 1998

Mr. William R. Tinnerman had the following comments: 5, 6, 13, 36, 40, 103, 118 and 471.

Tirrell, Roderick T.
2101 NE 55th Court
Fort Lauderdale, FL 33308-3111
December 21, 1998

Mr. Roderick T. Tirrell had the following comments: 4-7, 35, 85-90, 210, 245 –248, 291, 301, 305 – 307, 309, 387 and 388.

Trabulsy, Norman M. Jr.
P.O. Box 268
Key West, FL 33041
(no Date)

Mr. Norman M. Trabulsy Jr. had the following comments: 42, 123, 320 and 543.

Tunnell, Arthur W. Jr.
2354 Burton Avenue
Fort Myers, FL 33907
November 21, 1998

Mr. Arthur W. Tunnell, Jr., commented to Implement the Restudy and take strong action to protect natural resources, restore lost wetlands, and improve water quality.

van Steenderen, M.
13220 Southampton Drive
Bonita Springs, FL 34135
November 23, 1998

Mr. van Steenderen states that it is absolutely essential that the Corps of Engineers take necessary action to restore the Everglades. States that developers and agri-business have developed lands at an alarming rate that should be checked.

Vecellio, Leo Jr., President
White Rock Quarries
101 Sansbury's Way
West Palm Beach, FL 33416
December 16, 1998

White Rock Quarries had the following comments: 13, 94, 135, 230 and 351.

Weaver, W. A.
230 Salem Street
Swampscott, MA 01907
December 19, 1998

W. A. Weaver had the following comments: 390 – 392.

Weller, S.
65 Belvedere Ave
Belvedere, CA 94920
December 26, 1998

S. Weller had the following comments: 390 – 392.

Wittman, M.
17455 Woodland Trace Apt B
Ft. Myers, FL 33905
no date

Ms. Wittman states that the Army Corps should be the push to get the Restudy going full speed so the Everglades can be restored and thus the habitat also restored.

Yawn, Margaret
No address given
November 15, 1998

Margaret Yawn believes the Army Corps of Engineers has made a proper decision to restore freshwater to the Everglades and Florida Bay and strongly urges the Corps to implement the Restudy.

Yorra, Arnold S.
P.O. Box 5088
Marco Island, FL 34145-5454

Mr. Arnold S. Yorra recommends implementing the Restudy. He also notes that the Everglades belong to all the American People forever and wants the Corps to help stop urban sprawl and the spread of subsidized sugar.

Zorki, Ron & Claudia
1024 Capitan Drive
Forked River, NJ 08731

Ron and Claudia Zorki had the following comment: 42.

N.1.7 Form Letters

129 "form" letters were received during the comment period. An example of that form letter follows.

Mr. Stewart Applebaum
P.O. Box 4970
Jacksonville, FL 32232-0019

November 29, 1998

Dear Mr. Applebaum,

I wish to express my strong support of the Draft Plan for the Restoration of the Everglades as proposed by the U.S. Armay Corps of Engineers.

This plan is a comprehensive proposal for Everglades Restoration and further will provide clean drinking water for the growing population of South Florida.

Nowhere else in the world has such a plan for the restoration of the eco system of so large a region ever been undertaken. The damage done to the Everglades and the eco system of South Florida by a half century of mismanagement must be repaired now. Very soon it will be too late.

Sincerely,
Dora and Ron Linamore

N.2 COMMENTS AND RESPONSES

N.2.1 Plan Formulation

1. There is no discussion of the potential impacts to transportation facilities.

Response: Due to the conceptual nature of the Comprehensive Plan, potential impacts to roads, bridges, utilities, etc are addressed in the construction cost contingencies. Future plan and design studies will fully address site specific impacts as described in the Implementation Plan, Section 10.

2. The need for bridging Tamiami Trail is not justified in the report.

Response: The Comprehensive Plan includes 20 100-foot bridges along Tamiami Trail below Water Conservation Area 3. These bridges are part of a larger component to enhance hydrologic and ecological connectivity between the Water Conservation Areas and Everglades National Park.

3. The Implementation Plan lacks specific information.

Response: The Implementation Plan, Section 10, underwent a major rewrite as a result of comments received during the review of the Draft Report. Further, numerous Federal, State, County and local government agencies as well as stakeholders and the public were given an opportunity to review and comment on this rewrite. The revised Implementation Plan is provided as Section 10 of this report.

4. The flow-way option similar to the option previously included in the Reconnaissance Report should be part of the proposed Comprehensive Plan.

Response: A flow-way between Lake Okeechobee and the Water Conservation Areas has appeal regarding re-connecting the “river of grass” with the Lake. However, modeling has shown that the flow-way concept fails to restore ecological values to the remaining Everglades, given the reduced size and water storage capacity of the remaining natural system compared to pre-drainage conditions. A flow-way regains little of the water storage that is required to deliver adequate quantities of water to the remaining Everglades. To the contrary, a flow-way consumes water that would otherwise be directed to the Everglades for restoration purposes. This is because the flow-way would greatly exacerbate evapotranspiration water losses, seepage losses, and dry-season water demands of the flow-way to maintain it as a viable wetland system.

A flow-way could not operate as a passive “natural” conveyance system under today’s conditions. Soil subsidence in the Everglades Agricultural Area has changed the slope and contour of the land by reducing land elevations. A flow-way in this area would require additional canals, levees, and pumping facilities to get the water into the Everglades.

5. The Comprehensive Plan should be peer reviewed.

Response: The success of the Restudy in achieving ecological restoration is heavily dependent on an adaptive assessment plan. That adaptive assessment strategy, as described in the Implementation Plan, will incorporate external scientific peer review at every stage of the implementation process.

As part of the adaptive assessment strategy, peer review will be an integral part of a number of processes that will be ongoing throughout the next several decades. These include: 1) the refinement of ecological performance measures; 2) the development and oversight of a system-wide monitoring program; 3) the inclusion of new findings from ongoing research and modeling into the planning process; 4) detailed project design and modeling; and, 5) analysis of monitoring results to measure progress toward the achievement of ecological targets and to recommend shifts in the plan to maximize that achievement. These steps commence almost immediately, even before the Comprehensive Plan is submitted to Congress. The Chair of the Restudy Alternative Evaluation Team contacted the Science Coordination Team of the South Florida Ecosystem Restoration Working Group during summer 1998 to request a peer review process to evaluate the science behind the performance measures used in the Restudy.

As of early 1999, the Restudy has undergone more than a year of review by an interdisciplinary, multi-agency team of approximately one hundred scientists, hydrologists and modelers, many of whom have long records of research and management in south Florida ecosystems. The formulation and evaluation of alternative plans underwent a public review through the use of the internet. It must be emphasized that the Restudy is presently a conceptual plan, based on broad-scale hydrologic modeling and performance measures that will be refined continually. The plan at this time is a toolbox of various water management components that have been demonstrated, in combination, to achieve high levels of success in the restoration of ecological values. Based on the adaptive assessment process described above, these components may be combined in any number of ways as more detailed scales of science and modeling are applied over the next several decades. It is here that peer review by external scientists plays an integral and essential role in the Restudy.

The Restudy Team welcomes an ongoing external review by scientists with the highest level of national and international recognition in their fields. Indeed, the Restudy Team has already taken steps to initiate such a review process.

6. More land should be purchased for the project within the Everglades Agricultural Area to reduce the need for "high tech" solutions and provide for greater spatial extent.

Response: Due to soil subsidence and extensive utilization of the land within the Everglades Agricultural Area, conversion of these farmlands to a viable wetland system that could support native flora and fauna would have a significant economic and environmental cost to the remainder of the system.

7. The Comprehensive Plan does not include sufficient dismantling of the existing project features within the remaining natural areas. Further, the report is not clear as to how decisions were made regarding the extent of decompartmentalization (eliminating obstructions to sheetflow within the natural areas).

Response: During the development of alternative plans, one of three decompartmentalization scenarios modeled included unconstrained decompartmentalization of all of the Water Conservation Areas. Hydrologic modeling during the past year has clearly demonstrated that removing all the dikes and levees in the Water Conservation Areas would have devastating effects on the remaining natural system. Upper portions of each Water Conservation Area are over-drained, Lake Okeechobee water levels drop to record lows, and Everglades National Park dries out most years because the free-flowing water runs out early in the dry season. Appendix B describes these scenarios. The full set of performance measures comparing three decompartmentalization scenarios developed for the scenarios modeled after Alternative 3 (unconstrained was one of the three) was posted on the Hydrologic Performance Measures web page on January 30, 1998 and a summary of the results was presented during the February 9, 1998 Restudy Team meeting in West Palm Beach. A more complete description of the extensive modeling results of the decompartmentalization scenarios is included in Section 7 of the report.

8. Aquifer Storage and Recovery should not be implemented at the scale proposed in the Comprehensive Plan. If it is determined to be necessary for urban needs, regional government should fund it without cost to the Federal government.

Response: The uncertainties related to Aquifer Storage and Recovery will be addressed through additional studies and pilot projects before any large-scale projects are recommended for authorization. The Comprehensive Plan does not include Aquifer Storage and Recovery for the sole purpose of providing water supply to urban areas.

9. Seepage barriers should not be included in the Comprehensive Plan due to the technical feasibility, irreversibility, cost effectiveness and the potential for unintended consequences.

Response: The uncertainties related to seepage barrier technology and "unintended consequences" will be addressed through additional studies and pilot projects before any large-scale projects are recommended for authorization.

10. Need topographic information for the C-111 basin for its design and management.

Response: Concur. This task has been identified as an early expedited action and is presently underway by the Corps of Engineers.

11. More precise farm scale data is needed for C-111 basin.

Response: Concur. A number of activities are presently underway to provide such data. The Corps is participating with the Miami-Dade County in conducting a land-use study that will be completed in 2000.

12. The Comprehensive Plan does not have enough detail and there are no disaster contingencies such as pump failures in the plan. Operational plans are needed before construction begins.

Response: The Comprehensive Plan is a large-scale, regional plan that lays a framework for future detailed project planning and design. To address the concerns about the lack of detail in the plan, the Comprehensive Plan includes an Implementation Plan, Section 10, which identifies a process to collect more data and allow for additional public input before construction activities commence. Further, operational plans will be developed as part of detailed project design.

13. Need additional data on Aquifer Storage and Recovery, seepage controls, etc. before being implemented.

Response: Concur. The uncertainties related to Aquifer Storage and Recovery and seepage control alternatives will be addressed through additional studies and pilot projects before any large-scale projects are recommended for authorization.

14. All pilot projects should be given equal priority to balance interests.

Response: Pilot projects have been scheduled based on the guidelines set forth in the Implementation Plan (Section 10).

15. Ongoing restoration efforts should be expedited. There should be maximum integration of ongoing environmental restoration projects such as, the Kissimmee River Restoration Project, the C-111 Project, and the Modified Waters Delivery Project, with the Comprehensive Plan.

Response: Ongoing Federal/State restoration programs including the Everglades Construction Project, the Modified Water Deliveries Project, the C-111 Project and the Kissimmee River Restoration Project are considered in the Restudy's “without project” condition and are key considerations of the Restudy Implementation Plan. These projects are being implemented as quickly as possible.

There has been a considerable amount of coordination and integration of these ongoing projects with the Comprehensive Plan. The Restudy Team, to ensure full integration of these projects, worked closely with engineers and scientists involved in these projects throughout the formulation and design phases of this study. This integration of the ongoing projects with the Comprehensive Plan will continue as each project is fully implemented.

16. The Comprehensive Plan should use the 8.5 Square Mile Area (SMA) in restoring flows to Northeast Shark River Slough.

Response: The flood protection alternative (with flowway) for the 8.5 SMA is included in the future "without project" condition. If the area is acquired as a Locally Preferred Option under the Modified Waters Delivery Project, the Comprehensive Plan will be modified accordingly.

17. The Comprehensive Plan needs to eliminate the hydrologic barrier effect of Tamiami Trail.

Response: The Comprehensive Plan includes 20 100-foot bridges along Tamiami Trail below Water Conservation Area 3. These bridges are part of a larger component to enhance hydrologic and ecological connectivity between the Water Conservation Areas and Everglades National Park.

18. Redevelopment of the former Homestead Air Force Base must be ecologically compatible with the nature and function of Biscayne Bay and Everglades National Parks.

Response: Future land development is not within the scope of the Restudy and shall properly remain a responsibility of state and local governmental entities. Every effort will continue to be made to ensure the widest possible distribution of the Restudy recommended plan and to keep vital information in front of local authorities.

19. Promote more natural sheet flow into Biscayne Bay instead of the current point source discharges.

Response: The Comprehensive Plan includes features to promote natural sheetflow into Biscayne Bay. (see component WW5).

20. The Restudy should investigate additional sources of water. Reuse water should not be used to achieve targets in Biscayne Bay. Other sources of water should be investigated. Reuse is not cost effective.

Response: Subsequent to the release of the draft report, the Restudy Team developed additional scenarios to address the concern of using reuse to achieve targets in Florida Bay. The effort resulted in the evaluation of four scenarios known as D-13R_{1-4}. This investigation revealed that through modification of the Comprehensive Plan (namely Water Preserve Areas features), additional water could be captured and diverted from upstream urban areas and conveyed into the Water Conservation Areas or in canals adjacent to the Water Conservation Areas to Biscayne Bay. However, degraded performance of the plan in other areas as a result of these modifications has not been fully resolved. Consequently, upon resolution of these outstanding issues, the Corps of Engineers is committed to incorporating features of D-13R_{1-4} that allow for the capture and conveyance of additional water to the natural system. It is recognized that reuse features have a high capital and annual operations and maintenance cost. Accordingly, these components have been sequenced late in the implementation in order to take full advantage of other sources that may be identified during future project development.

21. Natural vegetation should be utilized in shoreline protection efforts.

Response: This suggestion will be considered during future detailed design efforts.

22. The Comprehensive Plan should include the use of a floodway to replace canal drainage in the Southern Golden Gates Estates drainage system.

Response: The Southern Golden Gates Restoration Project is included in the Comprehensive Plan as an Other Project Element.

23. The Comprehensive Plan needs to restore pre-drainage water distribution, timing, quality and quantity to the southern Big Cypress National Preserve by modifying or eliminating L-28 and the S-343 and S-344 structures.

Response: Concur. These features are included in the Comprehensive Plan.

24. The Comprehensive Plan needs to restore historical drainage patterns associated with the Western Big Cypress and Fakahatchee Strand.

Response: The Southwest Florida Feasibility Study will address the concerns in this region.

25. Decompartmentalize WCA 3 to maximize hydrologic connectivity. Use passive structures whenever possible.

Response: The Comprehensive Plan removes approximately 228 miles of levees and canals within Water Conservation Area 3.Where removal of levees causes harm to the natural system, earthen weirs are proposed to prevent over-drainage and flooding of these areas.

26. The Comprehensive Plan should include filling and degrading the entire L-67 system.

Response: Hydrologic modeling revealed that removal of the L-67 system would cause extensive ecological damage to the Water Conservation Areas and Everglades National Park. Therefore, a series of earthen weirs are proposed to replace the existing levee system.

27. The Comprehensive Plan should fill and degrade Miami River Canal within the Water Conservation Areas.

Response: This component is included in the Comprehensive Plan.

28. Fill and degrade L-28 and cease discharges of water from L-28 basin into the Water Conservation Areas.

Response: L-28 is removed in the Comprehensive Plan. The L-28 basin provides important water quantity to the Everglades. Stormwater Treatment Areas are proposed in the L-28 basin to ensure that this water achieves the objectives of Everglades restoration.

29. Restoration of the Water Conservation Areas (WCAs) should include mitigation of hydrologic impacts resulting from limerock mining, particularly in the Lake Belt area.

Response: In general, rock mining activities in wetland areas located within, or nearby, the WCAs are regulated under Section 404 of the Clean Water Act as well as State and/or local regulatory authorities. Permits for these activities contain special conditions that require compensatory mitigation to offset unavoidable direct environmental impacts as well as secondary and cumulative impacts. The direct, secondary, and cumulative impacts of the intense mining activity in the Lake Belt Area are being evaluated in a holistic manner through the Lake Belt Committee, an intergovernmental/private sector body. The Draft Programmatic Environmental Impact Statement (PEIS) for the Lake Belt Plan was released in February 1999. The PEIS contains a Recommended Lake Belt Plan as a framework under which limerock would be permitted within specified areas. A principal feature of the Recommended Lake Belt Plan is the creation of a comprehensive hydrologic and wetlands mitigation plan. Development of the Lake Belt Plan has occurred in two phases. Among Phase I activities was development of a Lake Belt Mitigation Plan which includes identification of areas within the Lake Belt suitable for mitigation and, establishment of a dedicated funding mechanism for mitigation activities. Analysis of the hydrologic impacts of mining is being accomplished in Phase II. Specific hydrologic mitigation measures, if necessary, will be recommended for addition to the Lake Belt Mitigation Plan.

30. Lands in the Northwest Miami-Dade County Lake Belt region should be used to offset impacts of rehydrating Water Conservation Area 3B.

Response: The recommend Comprehensive Plan includes the feature designated as BB5 and titled Dade-Broward Levee/Pennsuco Wetlands. This feature includes water control structures and modifications to the Dade-Broward Levee and associated conveyance system located in Miami-Dade County, including the Lake Belt Area. The purpose of this feature is to reduce seepage losses to the east from the Pennsuco Wetlands and southern Water Conservation Area 3B, to enhance hydroperiods in the Pennsuco Wetlands, and to provide recharge to Miami-Dade County's Northwest Wellfield. The Pennsuco Wetlands comprise the western side of the Lake Belt Area and have been designated in the Lake Belt Plan as a mitigation area that will not be mined.

31. Ensure hydrologic connectivity with the Water Preserve Areas footprint.

Response: The Comprehensive Plan provides hydrologic connectivity within and between the Water Preserve Areas components except where land availability precludes this.

32. The Water Preserve Area concept should be used in other areas such as the Upper East Coast.

Response: The Water Preserve Areas concept is an outgrowth of the East Coast Buffer program which was designed to reduce seepage from and provide a buffer between the Water Conservation Areas and suburban development as well as providing for additional storage capacity. The concept of the Water Preserve Areas was extended north into Martin and St. Lucie Counties under the Indian River Lagoon Feasibility Study. Further, the Comprehensive Plan provides many of these same concepts in all other major planning areas.

33. The S-9/C-11 and Acme Basin B initiatives should be coordinated with the Restudy and remain local funding initiatives.

Response: The water quality elements of both initiatives remain local funding responsibilities; however, both also have regional impacts that qualify for federal funding through the Comprehensive Plan. Thus, both remain components/Other Project Elements within the Restudy.

34. The Comprehensive Plan should ensure that maximum ecological, not maximum mining potential is incorporated into the Lake Belt/C&SF Restudy process.

Response: The two concepts are not mutually exclusive. A review of the Lake Belt storage features reflects this fact.

35. At the onset of the Restudy, site, design and construct and use surficial reservoirs to buffer the effects associated with construction activities. Further, Federal funding should go towards ecosystem restoration first.

Response: An Implementation Plan has been developed to guide subsequent efforts. This Implementation Plan provides a logical sequencing of project features to maximize benefits and reduce disruptions.

36. Utilize adaptive assessment and monitoring techniques to adapt design components to eliminate/minimize adverse impacts while implementing the Comprehensive Plan.

Response: The Implementation Plan, Section 10, includes a discussion of how adaptive assessment and monitoring will be used to support future decision making.

37. Land utilization and subregional planning efforts must be coordinated into the implementation phase of the Restudy.

Response: Coordination and information flow has been an important element of the Restudy since the study was initiated. The make up of the Restudy Team draws from state, local and Water Management District representatives, stakeholder groups as well as Federal agencies. Coordination and information flow will continue to be important throughout all phases of the Restudy. However, coordination and information flow must not be disguised as direction. Land utilization must properly remain a responsibility of state and local governmental entities. Coordination and information flow will remain an important objective of the Restudy, but cannot be utilized as anything more than guidance for the authorities that are charged with decisions on local utilization of land.

38. Reservoirs and retention areas should be managed for multiple purposes, e.g., fish and wildlife, water quality.

Response: During the PIR phase of plan development, opportunities to manage these facilities as multi-purpose projects will be investigated.

39. Use "step down" seepage management techniques where possible.

Response: The Water Preserve Areas concept, formerly the East Coast Buffer, is designed based on this premise.

40. The Comprehensive Plan and future studies should more fully develop the reuse and desalinization concepts.

Response: Reuse has been identified as a component where additional regional water sources are required (components BBB6 and HHH6). Several other reuse projects were proposed as Other Project Elements; however, the high cost of reuse could not be justified for inclusion in the initial draft plan. These additional projects may be able to provide benefits to the regional system should some of the less certain or less costly sources turn out to be impractical. Therefore, these applications should be considered as contingency sources. Two of the contingency applications are in Broward County.

The Comprehensive Integrated Water Quality Plan feasibility study recommended in this report will investigate alternative reuse concepts that were originally proposed by the Water Quality sub-team but were not pursued further. During the initial formulation of components, desalinization was considered but was quickly rejected as a practical option due to the quantity of water needed to achieve the goals and objectives of the Restudy. The use of desalinization or other local water supply options would be best addressed by local governments and utilities.

41. Local and regional governments should review and revise water conservation programs to be consistent with Restudy goals and objectives.

Response: Concur. Water conservation is an important element of the Comprehensive Plan and is best implemented at the state, county, and local levels.

42. The Comprehensive Plan should be revised to include Florida Bay, the Keys and the Keys reef tract. Further, waste water treatment in the Keys should be a feature of the Comprehensive Plan.

Response: The Restudy goal to enhance ecological values in south Florida ecosystems includes Florida Bay, the Keys, and the Keys reef tract, even though structural components of the C&SF Project do not extend into these areas. Actions taken in the Everglades, Lower East Coast, and Lower West Coast have high potential to influence water quality conditions throughout Florida Bay and the Keys. The major focus of the Restudy to date has been to address the impact that the C&SF Project has had on that system. Hydrodynamic and water quality models currently under development for Florida Bay will provide the tools necessary for evaluation of the problems in a holistic manner. A feasibility study is recommended to comprehensively evaluate Florida Bay and the Florida Keys to determine the types of modifications that are needed to successfully restore the bay and the Keys.

Improved sewage treatment is a part of the Florida Keys Water Quality Protection Plan developed as part of the Florida Keys National Marine Sanctuary Program. Restudy conclusions support the need for improved sewage treatment in the Keys. However, while the Corps of Engineers agrees that improved sewage treatment is critical to protect public health and the natural environment, including coral reefs, under existing Federal policy, sewage treatment is the responsibility of county or local government. This report (Sections 3 and 5) has been updated to address the need for additional water quality improvements, including improved sewage treatment in the Florida Keys. The Corps, through the Restudy, will continue to work with federal, state, and private sectors interested in restoring and protecting all south Florida ecosystems.

43. Non-structural storage concepts (conservation easements, lake fringes) should be considered.

Response: The Comprehensive Plan includes a vast number of non-structural solutions to meet the Restudy goals and objectives. As detailed planning progresses, additional/alternative means to achieving these goals and objectives will be sought.

44. Additional water quality features such as stormwater treatment facilities should be considered in future planning and design efforts.

Response: Subsequent planning and design efforts have been programmed into the Restudy to address water quality concerns. Specifically, a study to develop a Comprehensive Integrated Water Quality Plan is included in the Comprehensive Plan recommendation. Additionally, the Implementation Plan, Section 10, provides a mechanism to analyze water quality needs and recommend supplemental water treatment facilities if needed during the PIR phase.

45. An additional 14,600 acres of Reservoir-Assisted Stormwater Treatment Areas (RASTAs) around Lake Okeechobee are needed to achieve water quality targets for the lake.

Response: The S-65E basin Stormwater Treatment Area was designed in the existing footprint of the North Lake Okeechobee Reservoir. The remaining RASTA acreage is included in the discussion of Lake Okeechobee RASTAs but has not been fully evaluated due to the late consideration. The Restudy has committed to include these additional RASTAs in future planning documents.

46. The Comprehensive Plan should include enough flexibility to allow for cost share of the Lake Okeechobee Sediment Dredging Study.

Response: The Lake Okeechobee Sediment Dredging Feasibility Study has been added as a component to be investigated as part of the Comprehensive Integrated Water Quality Plan Feasibility Study.

47. The Comprehensive Plan should identify the Ten-Mile Creek as a Restudy project. Further, an additional five projects identified by the St. Lucie Issue Team should also be included in the Comprehensive Plan.

Response: The Ten-Mile Creek project is a Critical Project and is still being pursued as such. If this proves unsuccessful, the Comprehensive Plan has included it in the component UU C-23/24/25 Storage Reservoirs. The other features identified by the St. Lucie Issue Team will be investigated as part of the ongoing Indian River Lagoon Feasibility Study. This study will include recommendations to Congress for the Comprehensive Plan components in Martin and St. Lucie Counties that are not authorized in the Water Resources Development Act of 2000.

48. The 900-acre Miccosukee Water Quality Treatment Area should be included in the Comprehensive Plan. Further, the Plan was sized to treat nutrient inputs of the Tribal lands. When describing this project, please emphasize that the Miccosukee Tribe plans to treat their own pollution before discharge into the Everglades – not the pollution of others.

Response: Concur. This feature has been added as an Other Project Element and is included in the Comprehensive Plan. Although all other inflows in the area are treated either through the Everglades Construction Project or treatment components in the Comprehensive Plan, this specific emphasis will be included.

49. The Comprehensive Plan needs to ensure an adequate and fair allocation of water to the natural system.

Response: The Comprehensive Plan attempts to capture, store and deliver water to natural and urban areas as efficiently as possible. The goal is to provide the target amounts of water specified by the performance measures to natural and urbanized areas. The objective is to eliminate, to the extent possible, water shortages for both the natural system and urban communities. Although there are no guarantees, this approach minimizes the risk that the natural environment will be shorted its required amount of water in the future. Water allocation is a responsibility of the State of Florida.

50. Discussion of Lake Istokpoga in the report should be modified to include the current condition of the Lake. Further, the restoration of the Lake should be included as an Other Project Element.

Response: Lake Istokpoga's aquatic plant problems have been added to the report. A study to address the Lake's operational plan, which is believed to be the long-term solution to this problem, has been added as an Other Project Element of the Comprehensive Plan.

51. What is the relationship of the Kissimmee River Restoration Project and the Stormwater Treatment Area proposed in the S-65D sub-basin as part of the Comprehensive Plan?

Response: The proposed S-65D sub-basin Stormwater Treatment Area component of the Comprehensive Plan will be upstream of the Kissimmee River Restoration Project. This feature is designed to attenuate peak flows before entering the Kissimmee River and retain phosphorus before entering Lake Okeechobee.

52. Identify agencies responsible for the operation, management and performance of each component. Who will pay for the operation and maintenance costs?

Response: The agency responsible for the operation of a completed component will be determined through the terms of local cooperation executed between the Secretary of the Army and the local sponsor. Performance is normally a direct function of the design and construction of the component and will be monitored through a multi-agency, multi-disciplinary, team utilizing an adaptive assessment strategy, before, during, and after component construction. The cost of operating and maintaining the Comprehensive Plan is recommended to be shared equally between the Federal government and the local sponsor on a 50-50 basis.

53. Why did Restudy not consider "local sources first"?

Response: “Local sources first” concept is derived from a State law which exempts the C&SF Project.

54. The Comprehensive Plan should include the tidal restoration of the Dispatch Creek in the Florida Keys.

Response: The Dispatch Creek has been added to the Florida Keys Tidal Restoration Project under the Other Project Elements of the Comprehensive Plan.

55. Lake Okeechobee must be restored and the water supply and flood control pressures alleviated. Further, all backpumping to Lake Okeechobee must be stopped.

Response: Lake Okeechobee is the liquid heart of south Florida. Besides its ecological importance, the lake provides critical water supply and flood control to all of south Florida. The Comprehensive Plan was formulated to improve the ecological conditions of the lake while providing these other critical needs. Under the Comprehensive Plan, the ecology of Lake Okeechobee is much improved. Backpumping to Lake Okeechobee has been dramatically reduced in recent years. The Comprehensive Plan further reduces the need for backpumping untreated runoff.

56. "Adaptive Assessment" should be included in the Recommended Plan.

Response: Adaptive Assessment is a process by which the Comprehensive Plan will be implemented. It is fully discussed in the Implementation Plan, Section 10, of the report.

57. The report should include a complete list of the Other Project Elements and a discussion of the fate of the Critical Projects.

Response: The Other Project Elements appendix (Appendix A5) has been rewritten to include a complete list of the Other Project Elements. Further, the Critical Projects that have not been approved and funded have been added into the Comprehensive Plan as either components of the plan, Other Project Elements, or incorporated into the recommended feasibility studies or as preconstruction engineering and design activities. A new section has been added to describe the status of the Critical Projects Program.

58. Major project elements should have complete engineering and environmental and economic evaluation before submittal to Congress and before land acquisition.

Response: The Comprehensive Plan serves as a framework for future efforts. Included in the Implementation Plan, Section 10, is a discussion of the subsequent activities necessary before authorization of major project components will be sought.

59. The Restudy focused primarily on areas west of the North-South protective levee in Southeast Florida. An assessment of the urban areas might reveal additional ecosystem restoration opportunities that could ultimately reduce the cost of the Comprehensive Plan.

Response: Studies conducted during the Restudy did investigate the potential of using lands in the developed areas of the Lower and Upper East Coast. Due to the land mass needed to store and convey water, the land suitability analysis revealed that these lands were not appropriate for the projects being considered.

60. The Restudy should include plans that limit residential and commercial development. Further, green infrastructure plans should be developed for all urban areas including southeast Florida, southwest Florida, and the Upper East Coast.

Response: Land use planning is a state, county, and local government responsibility. The Corps and SFWMD can work closely with these agencies to ensure current and future land use practices are consistent with the Restudy objectives.

61. Has a cumulative impact assessment been prepared for the Restudy and what are the impacts to south Miami-Dade County and Biscayne National Park?

Response: A cumulative impact assessment of the Comprehensive Plan is included in Section 8 of this report. The Comprehensive Plan was formulated to achieve both economic and ecologic benefits throughout south Florida. The plan should result in positive effects to both south Miami-Dade and Biscayne National Park.

62. The Restudy should use information gleaned from the Upper St. Johns Project. More specifically, a combination of deep and shallow storage should be pursued.

Response: The design for these features was conceptual in nature. As the Indian River Lagoon Feasibility Study progresses, a range of options, including various operating water levels, will be looked at.

63. The Comprehensive Plan should not depend so heavily on canals and pumps.

Response: The Comprehensive Plan actually eliminates many of the levees and canals and water control structures that presently compartmentalize the Everglades. This includes much of L-29 that separates Everglades National Park from the Water Conservation Areas, all of L-28 that separates Big Cypress National Preserve from the Water Conservation Areas, all of the Miami Canal through Water Conservation Area 3A, and most of the L-67 canals and levees that divide Water Conservation Areas 3A and 3B.

With the loss of much of the water storage capacity that once occurred naturally in the pre-drainage Everglades, it is an unfortunate reality that reservoirs, canals and pumps are required to deliver water to the remaining natural system with the proper volume, distribution, and timing. The Comprehensive Plan creates a flow corridor of canals, pump stations and reservoirs to the east of the remaining Everglades to deliver water to Everglades National Park and Biscayne Bay. This replaces a wetland flow corridor that existed in the pre-drainage system but that is now developed. This flow path is essential to achieving restoration goals in the park without creating high water depths that would damage ecological values in the Water Conservation Areas.

It should be emphasized that as adaptive assessment and detailed modeling and design proceed over the next several years, every opportunity will be explored to utilize passive storage and conveyance in the remaining natural Everglades to the maximum extent possible without damaging ecological values due to excessively high or low-water conditions.

64. Use of regulatory-derived wetland mitigation to fund the purchase and construction of the Water Preserve Areas could accelerate the loss of the remaining peripheral wetlands, thus reducing the already scarce spatial extent of wetland habitat of the eastern Everglades in the lower east coast.

Response: The Corps generally concurs. Mixing of regulatory-derived compensatory mitigation projects and Restudy components presents a number of issues that need careful consideration. If a regulatory mitigation site is located within the footprint of a Restudy component several complications can arise. For example in the Water Preserve Areas:

Reduction of the Spatial Extent of Wetland Habitat: The spatial extent of wetland habitat in the Lower East Coast (between the C&SF protective levee and the coastal urban/agricultural areas) has been significantly reduced and the remaining acreage is under mounting development pressure. The wetlands east of the levee, but not within the WPA footprint, will be either 1) permitted for development, 2) used as compensatory mitigation for permitted losses, or 3) preserved/restored through some other public program. Assuming that item 3) will occur at the same rate regardless of the outcome of the Restudy, the fate of the remaining acreage of wetlands on the WPAs periphery will be determined through the regulatory program. These areas will be either permitted for destruction or preserved/restored as compensatory mitigation sites. When mitigation sites are located within the footprint of the WPAs, the total spatial extent of WPAs "peripheral" wetlands that will be lost to development is thusly increased. This result conflicts with the Restudy goal of increasing the spatial extent of wetland habitat within the study area.

Benefit Allocation: Environmental benefits must be allocated between either the Restudy or the regulatory-derived compensatory mitigation project, <u>but not both</u>. Benefits allocated to the Restudy accrue to the overall public interest and can therefore be used to justify federal participation in the project. Benefits allocated to compensatory mitigation sites are used to offset the wetland losses of the associated permitted development projects. Therefore, if a mitigation site exits within the footprint of a Restudy component, federal participation may be reduced or eliminated.

Operational Compatibility: The operational characteristics of many WPA cells are still being designed. Some hydrologic operational regimes, such as that needed for water storage or flood attenuation, may be incompatible with that necessary for optimum wetland habitat required at compensatory mitigation sites. If a Restudy component adversely affects a regulatory-derived compensatory mitigation site, a separable Restudy component will be needed to offset the loss. This effectively results in Restudy mitigation features for the loss of the regulatory mitigation sites and ultimately increases costs to the Restudy or reduces design flexibility for the WPAs.

Until Congressional approval of the Restudy Comprehensive Plan is received, potential benefits can not be allocated to the Restudy. In the interim, proposals to site regulatory compensatory mitigation sites within the footprint of Restudy components can be expected. Corps of Engineers Regulatory Division personnel are aware of the potential complications listed above and will work closely with Restudy Team members and private sector applicants. The goal will be to develop regulatory mitigation projects that will not be incompatible with, nor supplant potential benefits of, the Restudy. State and local authorities with wetland regulatory responsibility will be encouraged to do the same.

65. The proposed Southwest Florida Feasibility Study should complement the soon to be completed Southwest Florida Environmental Impact Statement. Further, the effect of expansion of agricultural land use in Hendry County needs to be included in the Southwest Florida Feasibility Study.

Response: Concur.

66. Lee County Department of Transportation recommended editorial changes to the Sanibel Island Causeway Other Project Element description. Further, it is premature to recommend the Sanibel Island Causeway Other Project Element at this time.

Response: Concur. The editorial changes have been made. Further, the Restudy recommends that this project be included as an alternative to be evaluated during the Southwest Florida Feasibility Study.

67. The capacity (10mgd) of the Aquifer Storage and Recovery wells exceeds any proven well size presently in operation in Florida.

Response: The capacity of the wells proposed in the Comprehensive Plan is 5 MGD, which is consistent with wells already in operation in Florida.

68. Surface water reservoirs can not retain water over the long term.

Response: Surface storage has two basic functions: to capture flood flows and to help meet water supply needs. If the natural areas are full, a reservoir is the only feature that can catch large flood flows to reduce the floodwater that is lost to tide. Because of evapotranspiration and seepage issues in south Florida, the surface reservoirs are not expected to retain water over the long term. However, by supplying water in the early part of dry seasons, water can be retained in Lake Okeechobee for the longer drought periods. Thus, even short term storage can have significant water supply benefits.

69. Will the seepage management along L-31N be effective and will reductions in flow to Biscayne Bay result from this seepage management and lowering of the south Miami-Dade water table?

Response: The amount of seepage along L-31N is a loss of water in NESRS and greatly diminishes the ability to restore hydroperiods in the ENP. Several management scenarios were modeled for the Restudy including a full “curtain wall.” The curtain wall was created to offset groundwater problems east of L-31N and was eliminated from further consideration. The seepage management component in the Comprehensive Plan represents the best balance between reducing seepage loss and maintaining groundwater stages to the east of L-31. During dry seasons, the seepage is reduced by about 30 percent using a shallow barrier (e.g. subsurface sheet pile wall along the levee); during wet seasons, additional groundwater pumping is included to capture as much seepage as possible.

Modeling for the Restudy showed no adverse problems for the groundwater east of L-31N, but it did show reductions to Biscayne Bay beyond the reductions due to increased water supply demands. In response, reuse water was identified to compensate for the loss of flow to the bay due to reduced both seepage loss and increased water supply withdrawal (2050 Base Case). During January 1999, modifications to D13R were modeled to demonstrate alternative sources for the Reuse water. The wet season groundwater levels can be improved in south Miami-Dade with the seepage management. Dry season levels were not adversely affected because of lesser dry season management and increased availability of regional water for groundwater recharge – improved performances in the saltwater intrusion prevention and water supply were evident.

During the design phase, additional groundwater modeling will be conducted at a higher resolution to evaluate the seepage management components as well as the potential for replacing the reuse water for Biscayne Bay. Given the level of detail and the unrefined demands of Biscayne Bay, the recommended plan represents the best balance possible at this time.

70. The in-ground reservoirs proposed in Miami-Dade County do not appear to be implementable.

Response: Pilot projects have been recommended to address these concerns and assist in the future design and implementation of these components.

71. The Comprehensive Plan should include flood protection.

Response: The Comprehensive Plan includes flood protection as an objective. Due to the scale of the project and the tools used to evaluate alternatives, the flood protection element of the study was not investigated to the level of detail that a typical flood control study would undergo. However, the Restudy Team did investigate potential adverse impacts that could arise from implementing the Comprehensive Plan or opportunities to enhance flood protection in known problem areas. Appendix E includes an inventory of these areas.

72. Canals and backpumping practices should be used where necessary to reduce excessive water depths and to maintain the hydrologic connectivity of the Everglades

Response: The Comprehensive Plan attempts to minimize canals and levees in a manner to promote hydrologic connectivity within the Everglades without causing harm to both the natural system or human system.

73. Reduce nutrient enrichment of Lake Okeechobee by increasing capacity of EAA canals, which will also reduce harmful discharges to the east-west estuaries.

Response: The Comprehensive Plan includes improvement to the major canals in the Everglades Agricultural Area.

74. Institute on-site stormwater treatment for facilities that are hydrologically connected to Lake Okeechobee.

Response: An objective of the Restudy is to improve water quality in Lake Okeechobee. Therefore, components, such as North Lake Okeechobee Storage Reservoir have stormwater treatment areas associated with them.

75. The Restudy should investigate the feasibility of dredging Lake Okeechobee sediments to reduce Phosphorus loads.

Response: The Comprehensive Integrated Water Quality Feasibility Study includes a study to investigate the feasibility of dredging these sediments from Lake Okeechobee.

76. Implement Best Management Practices in the Everglades Agricultural Area.

Response: Best Management Practices are being implemented under the Everglades Forever Act.

77. Improve the performance of the Comprehensive Plan in natural areas including the Water Conservation Areas and Everglades National Park. Further, restore pre-drainage flows, quality and timing via Taylor Slough, Shark River Slough and the C-111 system to provide Florida Bay historical fresh water inputs.

Response: In light of comments made in the draft Fish and Wildlife Coordination Act report, the Corps, along with its partner agencies, have invested considerable effort to identify a process by which key ecosystem features may be further improved through optimization and adaptation of the draft Comprehensive Plan (D-13R). Most notably since November 1998, the study team has developed and run several modeling “scenarios” in which the draft Comprehensive Plan was modified in an effort to improve restoration in key areas of the central and south Florida ecosystem. These scenarios are vital in demonstrating the robust nature of the recommended Comprehensive Plan and its ability to be manipulated to further improve performance.

A major focus for developing these scenarios was to determine if additional water could be captured in the lower east coast urban areas and used to better meet performance measure targets in the Water Conservation Areas and Everglades National Park, as well as investigating alternative sources of water for Biscayne Bay. This effort ultimately resulted in scenario runs $D13R_{1-4}$. Preliminary evaluation by the Alternative Evaluation Team indicates that additional captured water (about 245,000 acre-feet) helps to meet targets for Everglades National Park, Biscayne Bay and some areas within the WCAs. Performance declines relative to D13R in other areas of the WCAs and the Pennsuco Wetlands. In addition, issues relative to treating urban runoff prior to discharge into the WCAs and impacts to secondary canals have not been fully resolved. The Restudy is committed to implementing the final plan in a manner that provides improvements to the operation of the WCAs as well as providing more water for Everglades National Park and Biscayne Bay. Upon resolution of these outstanding issues, the Restudy will incorporate features of $D13R_{1-4}$ or other similar measures that allow for the capture and conveyance of additional water to the southern Everglades and Biscayne Bay. These features will be assessed under the ongoing Water Preserve Areas feasibility study and in subsequent Project Implementation Reports.

78. Utilize the most current local government comprehensive plans or Evaluation and Appraisal Reports to provide a more accurate depiction of future population movement.

Response: The population projections used were based upon the University of Florida Bureau of Economic and Business Research extrapolated to 2050 based on rates of growth projected by the U.S. Department of Commerce Bureau of Economic Analysis. Local comprehensive plans were used to modify these projections, such as in Miami-Dade County, where the evidence to modify was compelling. These choices were basic decisions made by the Restudy Team prior to the start of alternative modeling and were deemed appropriate to provide the most accurate population projections.

79. Include a table that summarizes Comprehensive Plan adoption information throughout the 16-county region to assist local government entities in making local land use decisions.

Response: Future land development is not within the scope of the Restudy. Such decisions shall properly remain a responsibility of state and local governmental entities.

80. If development continues, the Restudy components will be resized based on available land and not performance measures.

Response: While available land is certainly a limiting constraint, proper sizing of components is dependent upon many factors that are not presently based upon the conceptual level of analyses that have been conducted to date. The Restudy will continue to coordinate with responsible local authorities and provide the best information possible upon which to base land use decisions.

81. How will implementation of the Restudy be affected if the Everglades Forever Act deadline is not met, and how will costs be similarly affected?

Response: The Everglades Construction Project construction is on schedule. There is no apparent reason to believe all of the requirements will not be met. The Restudy schedule has been constructed in a manner that provides flexibility to adjust for changes resulting from project implementation. Costs are normally directly affected by market conditions during the time of delay. It is difficult to predict future market conditions.

82. Who pays for costs incurred in the Restudy as a result of the above referenced delays?

Response: Both cost increases and decreases will be shared by the federal government and local sponsors.

83. What environmental effects will result from such delays?

Response: Unfortunately, environmental effects usually are not discernible until long after occurrence of the actions that precipitated the effects. The question is comparable to predictions of the future.

84. Use location specific environmental site assessments prior to initiating land acquisition and construction activities.

Response: Such assessments normally precede construction activities and land acquisition.

85. Continue to model a “biologically” based framework and improve design for the remaining Everglades.

R: Concur; there is every intention of doing so.

86. With the present and massive losses in spatial extent, the primary focus must remain on restoring pre-drainage water flows wherever possible. This can only be supported by land acquisition to restore temporal and spatial extent.

Response: A comparison of flows against the Natural System Model indicated that the preferred alternative, D13R, improved the situation in every instance except one and refinements continue to be reviewed to improve the exception. The preferred alternative requires the addition of over 185,000 acres of land for storage, treatment and wetlands retention across the study area.

87. Restudy biological and hydrological science follow engineering regimes and scenarios that have questionable relevance with the science, biology or needs of a passive ecosystem.

Response: The Alternative Evaluation Team, chaired by Mr. Ogden, ensured that the proper measure of biological and hydrological science was used in evaluating engineering scenarios. Albeit an engineering tool, modeling can be an excellent tool in assisting and supporting decisions "based upon natural science regimes" in selecting components and alternatives, as happened in the Restudy.

88. Of 3500 pages of investigation and modeling, I have found only one page that addresses the most critical aspect from the Science Sub-group report.

Response: Perhaps only one direct reference is made to the Science Sub-group report, but the report was a basis for Restudy goals and objectives and inference to the report is made throughout the plan.

89. Where is the full range of reasonable alternatives for analysis? The Restudy Team should model and analyze population growth interests and impacts – air quality, highway impacts, sprawl and all direct and cumulative impacts.

Response: Perhaps under ideal conditions every possible alternative and impact could be reviewed, modeled and analyzed. Unfortunately, expedited schedule, personnel, budget and sheer magnitude of effort do impose reasonable constraints. The team has utilized available resources to model and analyze six different alternatives, four hybrid alternatives, 13 different scenarios, several revisions and various sensitivity analyses and case studies to develop a Comprehensive Review Study of the C&SF project. The team has fostered consensus development among state, local and federal governmental representatives; concerned individuals; citizen groups and stakeholders in the component development and evaluation and preferred alternative selection. Widespread distribution of developmental information and continued public involvement in the Restudy process are objectives that have far exceeded statutory requirements for a study of this nature. The Restudy is fully committed to achieving the best plan possible and will continue to improve the plan as it goes forward through authorization, further planning, pilot projects, and design and construction phases.

90. Federal taxpayers should not pay for research and testing of Restudy technical enhancement scenarios related to urban water supply and expensive curtain walls to stem seepage through permeable limestone in the West Miami-Dade Lake Belt area.

Response: One of the stated objectives of WRDA 96 is "The comprehensive plan shall include such features as are necessary to provide for the water related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the C&SF Project." The Comprehensive Plan includes components that meet these objectives in addition to restoration.

91. The role of fire should be included in the Comprehensive Plan.

Response: The role of fire in natural systems ecology is recognized in this report. Typically, it is the responsibility of land managers to develop fire management programs. As restoration proceeds, the Restudy believes that the Working Group should develop a system-wide burning program plan to assist land managers.

92. Decisions can not be made until the uncertainties are analyzed.

Response: A more complete uncertainty analysis is included in Appendix O.

93. There does not appear to be a tradeoff analysis among the various C&SF Project purposes.

Response: Some trade-off analyses were done through modeling scenarios by reducing urban water demands in the Lower East Coast. These are described in Section 7 of the report. The objective of the Restudy was to improve the functioning of the natural system, water supply, and other authorized C&SF Project purposes. The initial precept was that it would be necessary to give up water supply or other project purpose to enhance ecological values in the natural system. As planning progressed, it became apparent that all sectors could be improved without detrimentally impacting any particular sector. In fact, the Restudy found through these modeling scenarios that little benefit is achieved by reducing or eliminating one project purpose for the benefit of another. Despite the apparent win-win situation, there could be adverse impacts related to project implementation. Nevertheless, it is the Restudy's intention to do every thing possible to minimize these impacts by working closely with those who could be impacted.

94. The Lake Belt storage areas will require relocation and removal of existing rock mining processing equipment which will interfere with the miner's removal and processing ability. These issues need to be addressed.

Response: The Restudy Team is working with the rock miners to address such issues. The Comprehensive Plan recognizes the need to allow for continued limestone mining in this region. Every effort will be made to integrate ongoing rock mining operations with the proposed project features in order to reduce adverse impacts to the landowners.

95. The 1995 Base condition should not be used to determine potential flood impacts associated with the Comprehensive Plan. The 1995 Base does not reflect the authorized level of flood protection in the C&SF Project.

Response: Whether the 1995 Base does or does not reflect the authorized level of protection in the C&SF Project is immaterial to the analysis. An objective of the Restudy is to minimize flooding of urban and agricultural areas. The information presented in the report regarding flood protection is only meant to point in the right direction in planning and design efforts. It is important to remember that very little can be said about specific areas that will be impacted negatively by flooding as a result of the Comprehensive Plan. This is because the SFWMM is a regional scale model, not a flood routing model. There was considerable discussion during the study process as to whether anything should be said about flooding at all, given the limitations of the SFWMM for this purpose. As a compromise, the study team decided to do what is presented in Appendix E.6 regarding potential flooding impacts.

The general idea of Appendix E.6 was to point out potential areas that may need more examination and evaluation during the details of project implementation, expected to take place over many years. It is an overview, although it is based on voluminous output of selected SFWMM performance measures. It is important to look at both 1995 and 2050 base conditions since project components are anticipated to be put in place over a 20-30 year period expected to begin some time after 1995, and be completed sometime before 2050.

96. The Comprehensive Plan will have a devastating impact on rural communities while encouraging affluent urbanites to devour the east coast.

Response: There could be adverse impacts related to project implementation. It is the Restudy's intention to do every thing possible to minimize these impacts by working closely with those that could be impacted.

97. Additional water storage on privately owned lands should be considered as an alternative to the reservoir options.

Response: Flood attenuation facilities can serve three functions: flooding in developed or natural areas can be reduced, reductions of water lost to tide may occur, and some water supply benefits may be served. The various reservoirs, located throughout the study area, provide these basic functions. In the Comprehensive Plan, there are no flood attenuation “ponds” recommended, only reservoirs. During the design and implementation phase of the Restudy, such ponds may be added for very localized problems but are not likely.

98. Partially degrading levees and filling canals may provide additional habitat benefits at less cost than the Comprehensive Plan.

Response: The concept of pushing in large sections of the levees into adjacent borrow canals and leaving other sections may have merit. By doing this, the hydrologic effect of the levee and canal will be reduced. At the same time, the levee sections that are left will benefit wildlife similar to the existing tree islands which are considered to be an important part of the system's diversity. Additionally, the remaining ponds will provide aquatic habitat. This concept will be further explored during subsequent planning and design efforts.

99. It is not clear from the report whether there will be impacts to existing wetlands or other natural areas as a result of the projects features.

Response: There is a potential for impacts to existing wetlands and other natural areas as a result of the features as presently designed in the Comprehensive Plan. During subsequent phases of this project, the construction features of the Comprehensive Plan will be designed to avoid and/or minimize any impacts to wetlands or other aquatic sites. Unavoidable impacts to existing wetlands or aquatic sites are expected to be offset by the wetland preservation and/or enhancement that results from the overall restoration achieved by the Comprehensive Plan. Accordingly, separate mitigation features are not included in the recommended Comprehensive Plan for these impacts. Separate mitigation features may be included for impacts to unique or critical habitats, mitigation areas for regulatory permits, and historic or cultural resources.

100. Additional storage in the Everglades Agricultural Area is required.

Response: Component G6 includes 360,000 acre-feet of storage area in the Everglades Agricultural Area. Modeling indicated no benefits would result from additional storage in the area.

101. The draft plan contains inadequate contingency planning to guarantee Everglades restoration in the event of a shortfall in long-term funding, under performance of the costly and untested water storage and seepage control technologies and the projected sea level rise.

Response: Response numbers 16 and 41 address ASR, seepage control and contingency plans. Appendix B reflects the results of a modeling scenario to address the sensitivity of the C&SF Project to a sea level rise. The Implementation Plan addresses adaptive assessment and uncertainties. Regarding funding, the purpose of the Comprehensive Plan is to determine the feasibility of modifying the C&SF project to improve the quality of the environment; improving protection of the aquifer; improving the integrity, capability and conservation of urban and agricultural water supplies; and improving other water-related purposes. Funding, per se, is not a direct purpose of the plan. Rather, the plan should address the findings sufficiently to ensure authorization and appropriation of funds by Congress.

102. More study is needed to address impacts of a predicted sea level rise.

Response: The modeling scenario adequately detailed the primary impacts of a sea level rise relating to increased water demands for prevention of salt water intrusion and increased flood protection. A shift in development patterns is outside the responsibility of the Comprehensive Plan. Zoning and land utilization remain the responsibility of local governments. Most local emergency management functions are already equipped to assess the impacts of sea level rise. The description of sea level rise in Section 4 was revised to more accurately describe how the scenario was used.

103. An analysis of the environmental impacts of the population influx predicted for south Florida over the next 50 years is needed.

Response: WRDA 96 states "The comprehensive plan shall include such features as are necessary to provide for the water related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the C & SF Project." The plan meets those objectives. Growth management and land utilization must properly remain a responsibility of state and local governmental entities. Coordination and information flow will remain an important objective of the Restudy, but cannot be utilized as anything more than guidance for the authorities that are charged with decisions on local utilization of land.

104. Include the acquisition, restoration and management of the remainder of "Unit 11" as a part of the Pal Mar and Corbett Hydropattern Restoration OPE.

Response: Purchase will be considered during future studies relating to the acquisition of land for this OPE.

105. Attenuation and treatment facilities should be added for those basins that continue to backpump to the lake consistent with water quality restoration targets for the lake.

Response: With the additional storage facilities south of the lake and improved conveyance capacity of the canals, less backpumping to the lake should occur as a result of the Comprehensive Plan components.

106. Restoration of bays and lagoons requires reestablishing the quantity, quality, distribution and timing of fresh water inputs and the deconstruction of road barriers for establishing connectivity of tidal flushes to coastal bays and lagoons.

Respond: The Restudy includes components for restoration of Biscayne Bay, Lake Worth Lagoon and Indian River Lagoon and a feasibility study for Florida Bay. Either causeways or bridges are used to connect mainland roads to the barrier islands. The success of the Restudy in achieving ecological restoration is heavily dependent on adaptive assessment. The adaptive assessment strategy, as described in the Implementation Plan, will incorporate external scientific peer review at every stage over the next two or more decades. The strategy combined with the listed components should adequately address restoration of bays and lagoons without complete interruption of vehicular traffic patterns.

107. Restoration of Florida Bay must include further return of natural fresh water flow patterns than what is proposed in the draft comprehensive plan.

Response: The time frame of the draft Comprehensive Plan did not permit a thorough investigation of all of the regional water resource problems of south Florida. Subsequent to the completion of this plan, further feasibility studies are proposed. One of these studies is for Florida Bay and the Florida Keys. Details of the feasibility study are included in Section 9 of the main report.

108. Biscayne and Everglades National Parks and other natural areas are entitled to a water allocation that would ensure the parks' ecological integrity; therefore, a discussion of state and federal statutory and regulatory provision governing water use and allocation is needed.

Response: The purpose of the C&SF Project Comprehensive Review Study is to reexamine the C&SF Project to determine the feasibility of modifying the project to restore the south Florida ecosystem and to provide for the other water-related needs of the region. Nothing in the authorization for the original C&SF Project nor the two acts authorizing the Restudy (WRDA 92 and WRDA 96) establishes water allocation rights. The Corps of Engineers is responsible for water deliveries to Everglades National Park. The Restudy has attempted to provide for all water-related needs of the region, environmental, urban and agriculture, and has balanced those needs predicated on modeling results to meet performance measures established by the Restudy Team. Language that describes assurances to water users can be found in the Implementation Plan, Section 10.

109. Deep injection of wastewater is not prudent and should not be utilized in the Restudy as is required by the wastewater reuse components.

Response: Injection of wastewater is an acceptable method of disposal under the Environmental Protection Agency and the Florida Department of Environmental Protection rules provided specified standards are met. As long as the method is viable and acceptable, there is no reason not to include the method in the tool box of solutions. Similar methods of disposal are prevalent in Florida. If the method is deemed unacceptable in the future, the adaptive assessment strategy should adequately address injection concerns. Subsequent to the release of the draft report, the Restudy Team developed additional scenarios to address a reuse concern regarding meeting Florida Bay and Biscayne Bay targets with reuse water. This analysis revealed that additional water could be captured and diverted from upstream urban areas and conveyed into the Water Conservation Areas or in canals adjacent to the Water Conservation Areas to Biscayne Bay by modifying the preferred alternative, reducing the need for wastewater reuse. Decreased performance of the plan in other areas, as a result of these modifications, has not been fully resolved. Upon resolution of these outstanding issues, the Restudy is committed to the using the most effective features of the additional scenarios. If resolution is not forthcoming then continued reliance on wastewater reuse will be necessary as applicable.

110. Bass fishing or other recreational activities should not be a determining factor in the analysis of canal removal, levee removal or ecological restoration.

Response: During at least one of the public hearings, there were concerns expressed regarding canal removal and the consequent loss of bass fishing sites. No formal comments have been received, and this concern was not a factor considered during the alternative design and evaluation of decompartmentalization. However, any such concerns cannot be discounted as frivolous. WRDA 96 states that “The Comprehensive Plan shall include such features as are necessary to provide for the water-related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the Central and Southern Florida Project.” Providing recreational activities was an objective of the original C&SF Project. In addition, societal sustainability requires the preservation of the rich cultural diversity of the region along with providing and preserving recreational facilities for public use.

111. The USACE should seek an extension to the deadline and use the additional time for peer review, full consideration and response to the public and peer review comments and beneficial modifications to the Restudy.

Response: The success of the Restudy in achieving ecological restoration is heavily dependent on an adaptive assessment plan. That adaptive assessment strategy, as described in the Implementation Plan, Section 10, will incorporate external scientific peer review at every stage over the next two or more decades. Response to public comments are included in this final report. The Restudy Team welcomes an ongoing external review by scientists with the highest level of national and international recognition in their fields. Indeed, the Restudy Team has already taken steps to initiate such a review process; however, that review is more appropriate within the confines of the adaptive assessment strategy which allows timely completion of this report.

112. There is concern that the predicted behavior of the Comprehensive Plan may not be accurate with respect to the Seminole Tribe's lands since the lands are at the edges of or outside the boundaries of the regional computer model used in the Restudy.

Response: While the concern regarding the regional model is reasonable, there is a high degree of probability that the components directly impacting Tribal lands will improve conditions. Component CCC6 improves the water quality of inflow to Seminole lands, reestablishes sheet flow across the natural area, ensures flood protection is either enhanced or not degraded and requires consistency with the Tribe's Water Conservation System master plan. More accurate modeling will occur during detailed design to further ensure the accuracy of regional modeling performance. The success of the Restudy in achieving restoration is also heavily dependent on future adaptive assessment. That adaptive assessment strategy, as described in the Implementation Plan, Section 10, will incorporate external scientific peer review at every stage over the next two or more decades. While the concern is understood, there are also procedures to ensure that such concerns are dealt with in the future.

113. The projected water conservation reductions do not appear to be based on realistic conservation capabilities of the utilities. As a consequence, there is concern of excessive water shortages in Hollywood.

Response: The water use forecasts in this study used IWR-MAIN (Version 6.1), a PC-based software developed by researchers at Johns Hopkins University and improved upon by the U.S. Army Corps of Engineers Institute for Water Resources. The software program is based on observed relationships between water use and causal factors or determinants of urban demand for water. Two projections of future water consumption for the year 2050 were made for the Lower East Coast study area. The two scenarios differ in terms of the assumed level of water use conservation. The higher estimate is based upon the same percentage distribution and usage of conservation flow devices and irrigation restrictions in effect in 2050 as in 1990. The lower estimate is based upon full implementation of existing SFWMD mandatory regulations and programs. The higher projection estimate for the year 2050 is about 1450 MGD. The lower estimated usage for the year 2050 is about 1200 MGD, approximately 18 per cent less than the higher projection. The 2050 Base condition (without project condition) assumes a more moderate application of conservation practices and effectiveness representing a level of consumption about 12 per cent below the higher year 2050 estimate. A full discussion of the water consumption projections and conservation may be found in

Appendix E. The projections were most assuredly not selected simply because they eliminated excessive water shortage declarations in southeast Broward County.

114. The draft report does not specify the portions of the L-28 and L-28 Tieback levees will be removed. Clarification is required.

Response: Concur. Water Conservation Area 3A Decompartmentalization and Sheetflow Enhancement should also specify component QQ in addition to AA and SS. This will be corrected in the final plan. Component QQ in Appendix A indicates that the levees and canals will be removed from the L-28 Tieback south to L-29.

115. Rehydration of the northwest corner of WCA-3A may be insufficient to restore this area and relocating pump station S-140 may impact flood protection for the eastern portion of the Big Cypress Reservation.

Response: More accurate modeling will occur during the detailed design phases of the components to further ensure the accuracy of component performance. The success of the Restudy in achieving restoration is also heavily dependent on future adaptive assessment. Should the more detailed engineering analyses and adaptive assessment reflect the need for changes, such changes will be made.

116. As component CCC6 provides flood protection for the majority of the Big Cypress Reservation, remove only the portion of the L-28 Interceptor south of the Big Cypress Reservation.

Response: Concur. The complete description of CCC in Appendix A (p. A4-45) indicates that the L-28 Interceptor Canal shall be backfilled at a point south of the Big Cypress Reservation boundary with the Big Cypress National Preserve Addition. This point was added after previous coordination with Tribal representatives.

117. What is the operation and maintenance cost of the Comprehensive Plan?

Response: The current estimated annual operations and maintenance cost for the Comprehensive Plan is $165,000,000. It should be noted that this cost is not realized until all features are fully implemented, which is not expected until 2037. Further, the estimate includes the two wastewater reuse projects which make up more than 50 percent of the annual operating costs. If these projects do not become necessary due to less costly alternatives, then the annual operations and maintenance cost would be considerably less.

118. How will the Restudy affect the ownership and management of our local water utility?

Response: The Comprehensive Plan will not affect the ownership or management of local water utilities. The implementation of the Comprehensive Plan will assure that there will be an adequate quantity of water to meet future demands.

119. There does not appear to be any direct economic benefit to Cypress Grove Community Development District.

Response: All localized impacts are important. It is anticipated that the implementation of the Comprehensive Plan will have positive effects to local economies. The resolution of the economic impact estimating model and methodology is not at a level of detail that would explicitly include this specific concern.

120. Critical Projects that fail to be implemented under the WRDA 96 authority should be included in the Restudy. Further, implementation of these projects should not be delayed until the associated feasibility study is completed.

Response: Funded Critical Projects by definition follow a different, expedited schedule than the Restudy. Critical Projects that have not been approved and funded have been added as Other Project Elements (OPEs). The OPEs will be phased as outlined in the Implementation Plan, which provides a logical sequencing of project features to maximize benefits and reduce disruptions.
Feasibility studies do precede components in the areas under study. The feasibility studies are early in the sequencing process for that reason.

121. Maintain compatibility between the restoration plan and agriculture.

Response: The purpose of the Restudy is to reexamine the C&SF Project to determine the feasibility of structural or operational modifications to the project essential to restoration of the Everglades and south Florida ecosystems while providing for the other water-related needs of the project. Water supply for agricultural uses falls within the other water-related needs of the project. Section 5 of the Report indicates that increasing the availability of fresh water to meet agriculture, urban and environmental needs is an objective of the Restudy.

122. The Restudy should support local efforts toward implementation of Eastward Ho.

Response: Although zoning, growth management and land utilization remain the responsibility of local governmental authorities, nothing in the Restudy precludes or impedes implementation of the program.

123. For environmental restoration, some of the 400,000 acres of sugar cane land is needed while insuring that agricultural runoff is treated to strict water quality standards.

Response: Best Management Practices by land owners and stormwater treatment areas constructed under the Everglades Construction Program, a separate program funded primarily by the SFWMD from agricultural privilege and a special ad valorem tax assessments, will ensure that runoff is treated to required water quality standards. Over 44,000 acres of farmland has been purchased to accommodate the stormwater treatment areas. The Restudy designates another 60,000 acres of Everglades Agricultural Area land for use as surface water storage areas. Thus, nearly 100,000 acres of agricultural land will be purchased to meet water quality cleanup and water storage requirements.

124. Improve the ecological conditions of Water Conservation Area 2B.

Response: The Restudy Team is committed through the implementation process to improve the operation of all the conservation areas.

125. D13R should move forward as the recommended plan. Make diversions of water from the urban areas as a contingency and possible design refinement during the implementation. The Miami-Dade Reuse component should be less specific in location and schedule so that it would remain as a contingency to be used as needed.

Response: The recommended plan is D13R plus the Other Project Elements. Further refinement to the recommended plan will take place during the Project Implementation Reports, which are the next phase of the project.

126. Suggest watershed based approach to solving Biscayne Bay and Florida Bay starting with the Analytical Tools necessary.

Response: Next generation models are being developed for the Miami-Dade County area.

127. Ensure that a process will be funded to identify alternative sources of water for Biscayne Bay and if another source of water is found, re-diverting water from the reuse to this source will not require reauthorization. Costs associated the construction, operation and maintenance, and monitoring for the South Miami-Dade County Reuse component should be eligible for 50/50 cost sharing.

Response: The Draft Implementation Plan released 25 January 1999 identified a Reuse Technology Pilot Project which included studies to address the ecological effects of reuse, design the pilot, construct the pilot and monitor the pilot. It has been the intention of the Restudy to cost share the reuse facility 50/50.

128. Ensure that new facilities are reliable, before switching the supply.

Response: For each major component or series of components that is developed, a Project Implementation Report and supplemental EA or EIS will be prepared. The EIS will contain the operational rules and the impacts on water supply. The process of component development, as well as developing the EIS, will be open to public involvement. Thus, the various stakeholders in the region can actively participate throughout the transition period. Section 10, Implementation Plan contains assurances to water users.

129. Ensure a minimum of 1 in 10-year flood protection.

Response: The Comprehensive Plan provides good performance for agriculture in south Miami-Dade; this view is borne out by evaluations done by the Florida Department of Agriculture and Consumer Services. There exists apprehension by local agricultural concerns about how the conditions may change between current conditions and implementation of the recommended plan. The 2050 Base Case (without the Restudy), unless altered favorably for flood control, will cause worse conditions than today. The Restudy modeling demonstrated favorable groundwater management guidelines.

130. Lower East Coast Utility Water conservation should be broad enough to allow for alternative means to reduce urban water demands and be Federally cost shared.

Response: Concur; water conservation is an important element of the Comprehensive Plan and is best implemented at the state, county, and local levels.

131. The report should be modified to identify a process to resolve areas of deficiency in the performance of the Comprehensive Plan.

Response: The Implementation Plan, Section 10, has been revised to include a process to modify the Comprehensive Plan in the future to affirm, reformulate or modify a component, or group of components, address uncertainties, knowledge learned from pilot projects, and further design the components. This process is the development of Project Implementation Reports (PIR). As the Comprehensive Plan is being formulated in the PIR, significant changes will be evaluated by the Restoration, Coordination and Verification Team (RECOVER). The RECOVER Team will be established to provide system-wide evaluation and analyses and perform program tasks. This team will be similar in function to the Restudy's Alternative Evaluation Team (AET) and the other ad hoc Everglades teams used to formulate and refine the Comprehensive Plan.

132. The components, C-111 North Spreader and the Biscayne Bay Wetlands should not be considered for authorization, until the land is sited.

Response: The Restudy is not seeking authorization on the Biscayne Bay Coastal Wetlands at this time. Authorization is being sought on the C-111 North Spreader Canal to accomplish as part of the C-111 project construction. This canal will provide water to the Model Lands area. More detailed modeling will be accomplished during the design phase of its construction and if warranted, a supplemental NEPA document will be prepared.

133. The Restudy does not provide adequate cost/benefit analysis.

Response: The cost/benefit analysis is contained in Section 7 of this report.

134. Protect coral reefs and public health from sewage.

Response: Although the scopes of the studies have not yet been developed, it is envisioned that the Florida Bay feasibility study and Comprehensive Integrated Water Quality feasibility study contained in the recommended plan will address in detail the issues of nutrient sources and loads, impacts to reef ecosystems, appropriate restoration targets, and remediation programs (including wastewater treatment) to protect and restore reef ecosystems.

135. The results of the Sensitivity Analysis indicate only limited benefits are produced by the North Lake Belt Storage Area. Do the benefits of this component justify its cost?

Response: To the contrary, the sensitivity analysis conducted by the Restudy revealed that eliminating the North Lake Belt Storage Area from the Comprehensive Plan would cause adverse conditions throughout south Florida. Namely, it would result in a significant increase in water deliveries for Lake Okeechobee and Water Conservation Area 3A to the Lower East Coast Service Area 3 to maintain water levels in the canals. As a result lake stages were lower, and there were increases in water restrictions in Lower East Coast Service Area 2 with reduced ability to maintain coastal canals, and a redistribution of flows to Biscayne Bay.

136. How much can a component be changed after the plan goes to Congress?

Response: Subsequent to the submittal for approval of the Comprehensive Plan to Congress, a detailed planning effort in the form of Project Implementation Reports (PIRs) will be developed for each component or a logical group of components. Each PIR will then be submitted to Congress for project authorization. Upon project authorization, the detailed design and real estate activities would commence followed by construction and operation of the component.

137. Additional formulation of the best configuration of the in-ground reservoirs is needed during the subsequent phase of this project.

Response: During pilot projects, the Water Preserve Areas Feasibility Study and future design work for the recommended plan, both groundwater modeling and technical evaluations will be conducted to further explore the feasibility of the underground barriers associated with the Lake Belt storage areas. The Restudy presented the initial design, but a lot of additional studies are required. Technical evaluations will include core-boring studies that will clarify the depths and spatial extents of the clay layers underlying the areas. These layers are critical elements of the in-ground reservoirs. Technical reviews of existing barrier technologies will be completed. Technical evaluations will include discussions with experts familiar with the substrate and the barrier techniques. Modeling evaluations will be conducted at a greater resolution to ensure the reservoirs would not adversely impact groundwater flows in the region. Although years of evaluations will proceed possible implementation of the component, the recommended plan has demonstrated the importance of pursuing in-ground lakes for several reasons: hydrologic restoration of NESRS, water management flexibility, water supply, and prevention of saltwater intrusion.

138. The Restudy is not consistent with the Dade County Lake Belt Plan Committee.

Response: Recommendations of the Lake Belt Committee were considered during the formulation of the Comprehensive Plan. Implementation of this component will require continued communication with the Lake Belt Committee and landowners. It has been the intent of the Restudy to build these components, after mining in the area is through. The Restudy presented the conceptual design, but a lot of additional studies and pilot projects are required, including the timing and construction schedule.

139. Ensure that the Pennsuco wetlands are preserved and enhanced.

Response: The Miami-Dade County Lake Belt Plan Implementation Committee is currently developing a detailed master plan for the northwest portion of the county that includes public ownership and restoration of the Pennsuco wetlands. A draft Programmatic Environmental Impact Statement was released by the U.S. Army Corps of Engineers, Jacksonville District in February 1999, which discusses rock mining and its effects on the region, including the Pennsuco wetlands. The draft Programmatic Environmental Impact Statement includes a proposed funding source and process for the acquisition and restoration of the Pennsuco wetlands.

140. Ensure that maximum ecological, not maximum mining potential is incorporated into the Lake Belt/C&SF Restudy process.

Response: The Comprehensive Plan includes features that would utilize existing and future rock mining lakes as in-ground storage reservoirs. A pilot test of this component will be conducted prior to final design to determine construction technologies, storage efficiencies, impacts on local hydrology, and water quality effects. The purpose of these features is to store damaging excess water from Water Conservation Areas 2 and 3 and then provide environmental releases to Northeast Shark River Slough, Water Conservation Area 3B and Biscayne Bay as needed. The utilization of existing mining lakes will maximize the ecological benefits of this resource with the resources of the Everglades ecosystem as a whole.

141. An expanded discussion on the issue of the Restudy including separable compensatory mitigation features for adverse impacts to existing compensatory mitigation sites established by wetland regulatory permits is recommended. In addition, it is suggested that the Corps commit to promptly identify the location and acreage of existing regulatory compensatory mitigation sites located within the currently sited components of the recommended Comprehensive Plan.

Response: The editorial comment is noted; the section will be rewritten for easier comprehension and an expanded discussion on Restudy impacts to regulatory derived compensatory mitigation sites. As the Project Implementation Report process is initiated for each component, or set of components, the identification of regulatory derived mitigation sites as well as unique and critical habitats will be an early action.

142. Only the Critical Projects that have been approved by HQUSACE and are expected to be funded through the Critical Projects program should be in the Without Project Condition.

Response: Concur. In the Final Report, the approach to Critical Projects will change so the Without Project Condition will only include the Critical Projects that have been approved by Headquarters and are anticipated to be funded through the Critical Projects program. All the remaining Critical Projects will be accounted for in the recommended Comprehensive Plan.

143. The evaluation of the Other Project Elements (OPE) by the interagency team was not in-depth.

Response: Concur. Many of the proposed OPEs were very conceptual in nature and the interagency evaluation team was tasked with the evaluation responsibility with very little time remaining in the plan formulation process. In the final report the conceptual nature of the OPEs will be emphasized.

144. Regarding the OPE evaluation matrix. The “significance” criterion should be eliminated and the factoring of the “geographic extent” criterion should be modified.

Response: There has been no time to reassemble the interagency team to "reevaluate" the OPEs. Even so, reevaluation will occur during the detailed design phases for the OPEs included in the recommended plan. Most of the other OPEs are recommended for additional study through one of the recommended feasibility studies.

145. The OPE evaluation matrix used by the interagency team has the potential for bias due to the ranking method developed by the Corps.

Response: Concur. The ranking method described in the draft report was not used as a basis for selection of the OPEs recommended for inclusion in the Comprehensive Plan. In the final report, the evaluation matrix will not be used to comparatively rank the OPEs.

146. How will the OPEs recommended for inclusion in the Comprehensive Plan be implemented?

Response: The Implementation Plan (Section 10), which will be included in the final report, includes scheduling for the recommended OPEs.

147. Evaluation of the effects of the Restudy were limited to the Caloosahatchee Estuary when the entire Charlotte Harbor Estuary Complex should have been evaluated.

Response: The Restudy's major strategy to improve the ecological health of south Florida's coastal estuaries is to modify both the timing and quantities of freshwater deliveries to the coast in order to produce conditions favorable to aquatic life. Development of the recommended Comprehensive Plan involved evaluation of an array of "alternatives" using a variety of tools. The South Florida Water Management Model (SFWMM) provides the best tool currently available for evaluating the effect of a given alternative on the entire ecosystem influenced by the C&SF Project, including the estuaries.

The Restudy's effect on the Charlotte Harbor Estuary is dependent upon flows down the Caloosahatchee River. The most relevant output from SFWMM simulations is river flow at the Franklin Lock and Dam (S-79). A multi-agency, multi-disciplinary Alternative Evaluation Team (AET) evaluated the various alternative plans using a set of performance measures. The performance measures for the Caloosahatchee Estuary are based on known relationships of various flow rates, and the response of estuarine organisms to those flows. Desirable average monthly flows for S-79 were first developed by SFWMD scientists and then reviewed and approved by the AET. Average monthly flows were determined to be the most appropriate "time slice" for measuring the performance of an alternative because the hydraulic residence time of the Caloosahatchee Estuary averages about one month.

Moderate variation in salinity is one characteristic of a healthy estuary. To account for this desirable variation, both low and high average monthly flows were selected to form a favorable "salinity envelope". Selection of these flows was based on a recent study that estimated the optimum freshwater flows to the estuary for the area from S-79 downstream to Shell Point. The AET evaluated the performance of a given alternative by counting the number of times during the 31-year period of the SFWMM simulation that the desirable average monthly flows were either; not met on the low side, or were exceeded on the high side. The recommended Comprehensive Plan does extremely well at staying within the desirable monthly flows for the Caloosahatchee Estuary. Even so, the Restudy recognizes that the domain of the model used to develop the estuary salinity envelope does not encompass the total Charlotte Harbor Estuary complex. Additional study is needed to confirm that improvements to the Caloosahatchee Estuary will not have unintended adverse effects on the greater Charlotte Harbor Estuary. A coupled circulation and water quality model for the greater Charlotte Harbor Estuary is currently being developed by the SFWMD with completion expected in December 2000. This model of the entire Charlotte Harbor Estuary will allow the Restudy to refine, in consultation with the CHNEP, the desirable average monthly flows for the Caloosahatchee.

The Restudy Implementation Plan includes several pathways to update the Comprehensive Plan as new and better information becomes available. The Implementation Plan (Section 10) also includes many opportunities for continued public review and input. The implementation schedule for the project features proposed for the Caloosahatchee Basin (i.e. Surface Reservoir(s), Aquifer Storage and Recovery systems, and Lake Okeechobee Backpumping facilities) contains ample time to include results from more refined modeling and public input, prior to final design and construction. Construction of Restudy features will provide the management capabilities necessary to attain many of the CHNEP hydrologic objectives related to the Caloosahatchee.

N.2.2 Water Quantity and Modeling

148. What assurances are there concerning the reliability of water supply (for urban, agriculture, and the natural system) during the transition period?

Response: For each major component or group of components that are developed, a supplemental EA or EIS and a project implementation report will be prepared. The EIS will contain operational rules and the impacts on water supply. The process of component development, as well as preparation of the EIS, will be open to public involvement. Thus, the various stakeholders in the region can actively participate throughout the transition period. Study planners will strive to meet or exceed current water supply. Language on assurances to water users can be found in Section 10 of this report.

149. What assurance is there that backpumping Caloosahatchee River water will not degrade the water resources within the Caloosahatchee Basin or estuary?

Response: According to current water allocation rules, the Caloosahatchee Basin receives water supply from Lake Okeechobee without any backpumping to the lake. However, the river will back-flow to the lake when the lake stage is below about 11.2 feet, which happens only rarely. The only new concept in the Restudy is that water only when it is “in excess” of the basin needs would be backpumped to the lake. The only time water is considered to be “in excess” is when (1) water amounts are greater than what is required by the estuary, (2) storage is not available within the basin, and (3) it would otherwise be lost to tide. Once the water is backpumped into Lake Okeechobee, it would be available to the Caloosahatchee Basin if it later needs the water. Under the D13R plan, about 50 percent of the backpumped water is returned to the basin, the rest goes to environmental improvements. Because backpumping only occurs during the events that would send the excess water to tide, it does not cause additional drainage from the basin. During low flow periods of the river, about half of the backpumped water is returned to the basin for water supply and minimum flows to the estuary; the other half of the water is used to support Everglades restoration.

150. Does the Alligator Alley Turnpike cause a hydraulic/hydrologic impediment the flow of water in Water Conservation Area 3A?

Response: A review of headwater and tailwater data shows that Alligator Alley does not impede the flow of water in WCA 3A. There are two reasons why this is likely: (1) there are extensive borrow canals along the road, both north and south, that act like collection ditches; and (2) there are numerous bridges that allows the water to pass from the north side to the south side.

151. Will additional refinements in hydrologic models be done to reduce uncertainty?

Response: Improvements in the NSM and SFWMM (the primary models used to develop targets and alternatives) are expected to continue in the future. One source of uncertainty comes from a lack of precision in land elevations in both the historical and current landscape. Studies and data collection, leading to improved land elevations, are being conducted at this time. Additionally, other models with higher resolution and more suitable for developing detailed information will be used for the design and implementation of components.

152. Does the storage area north of Lake Okeechobee have significant environmental benefits and will it have water quality problems if agricultural lands are used?

Response: The storage area, identified as being north of Lake Okeechobee (about 200,000 acre-feet of capacity), serves to reduce the flood flows coming into the lake. This reduces both the damaging high stages of the lake and the destructive releases to the estuaries. As the lake levels lower, the water is released from the storage area to the lake where the water has several benefits: water quality improvement, environmental releases, water supply, and in-lake low level improvements. Numerous flood reduction features in the Kissimmee Chain of Lakes area have resulted in higher and more rapid flood peaks in the Kissimmee River. The storage feature will be used to ameliorate that effect as well as reduce water that would otherwise be lost to tide.

153. Are the flows to Florida Bay substantially increased by D13R, if not what modifications can be done to increase the flows?

Response: The flow pattern to Florida Bay was not increased by D13R so much as improved. The timing and distribution was improved in the recommended plan, however subsequent scenario modeling that substantially increased the flow to the ENP was successful at increasing the flows to Florida Bay as well.

154. Why were flowways not included in the recommended plan?

Response: A flowway is generally described as a broad, shallow marsh area that is used to freely-flow water from Lake Okeechobee to one or more of the WCAs. The evaluation of the concept shows a number of problems concerning its feasibility, including soil subsidence, evapotranspiration, seepage management, vegetation, timing of flows, and lack of flow events. Additional EAA issues include numerous roads, bridges, and railroad relocations would be required if a flowway cuts through and divides the entire area.

Soil subsidence in the EAA has substantially reduced the hydraulic head that would drive the southward flow of water; hence, velocities and flow rates would be greatly reduced. By spreading the water over shallower areas (as opposed to reservoirs) and because a marsh habitat would have to be kept hydrated, the evapotranspiration loss could easily be doubled. A long, rectangular configuration would have a 75 percent longer levee than a more square area, thus increasing seepage management features. Because nutrient-laden soil would be flooded for the flowway, the vegetation most likely to dominate would be cattails and not desirable Everglades habitat. Flowways would not “hold back” water going the WCAs and the delivery of that water would exacerbate the already high stages in the northern parts of the WCAs. Thus, the timing of flows from flowways would not be manageable or beneficial for the remaining Everglades. Perhaps the most crucial element, water flowing from the lake to the WCAs, is not present in dry or even normal years! For example, during long periods from 1970-1982 or 1985-1994, no significant excess lake water was available for the flowway. Only demand releases to the Everglades were made from the lake during those periods. Water delivered to the Everglades on a demand basis, through a flowway, would not be effective with increased travel times and increased evapotranspiration losses. The only years where water could flow for long duration are wet periods like 1969-1970, 1982-1983, and 1994-1995. In those years, the stages in the WCAs are already too high and additional flow from flowways would be damaging, not beneficial.

155. Can ASR replace the function of surface reservoirs and eliminate the need for large tracts of land?

Response: Reservoirs provide two basic functions: flood storage and subsequent water supply. ASR wells can provide the water supply function, but they cannot provide significant flood storage. ASR wells have a relatively small pumping rate – about 5mdg or 7cfs. Structures designed to handle flood flows have the capacity to pump several thousand cfs. A surface storage area can receive up to 10,000-acre feet per day (at the S-5A capacity) whereas an ASR well can only pump about 14-acre feet per day. Because flood flows require high flow rates on a daily basis, ASR wells – even when clustered – cannot catch flood surges. However, when ASR wells are used in conjunction with reservoirs, the wells can free up reservoir storage over time, which allows the reservoir to catch additional flood surges. Although ASR wells have some loss to the aquifer (assumed to be 30 percent in the Restudy), there are no evapotranspiration losses as in surface storage. Therefore the ASR wells have a superior long-term drought management ability. In the recommended plan, most of the ASR wells are associated with reservoirs so that both flood control and water supply is maximized. In the case of the in-ground storage areas (in the Lake Belt area) no additional evapotranspiration would occur since the area already has open-surface losses. Hence there is no additional water supply benefit with ASR wells used with those storage areas. The land covered by reservoirs may lose natural hydrology, plant communities and wildlife habitat values; judicial placement of reservoirs should be considered as well as the overall benefit to the system.

156. Has the “saturation point” been reached in the LEC with regard to water supply?

Response: No. Under the current conditions, any additional water supply required in dry years by the LEC comes from the WCAs, which reduces water in the natural system. Under the recommended plan, a 50 percent increase in LEC demands can be met while lowering the withdrawals from the natural system. Using water that is currently lost to tide along the LEC allows not only more water to be available for water supply, but also can increase the water to the natural system by about 300,000 acre-feet on average each year.

157. Can the current drainage system furnish restoration flows to the Everglades?

Response: The current drainage system was designed primarily to remove floodwaters from the system while supporting water supply deliveries from the lake. In order to furnish water to the Everglades for restoration, the current system requires extensive changes. Simply routing floodwaters to the Water Conservation Areas does not enhance ecological values because the timing of the flows would not be ecologically beneficial.

158. Will the water levels in the WCAs have the proper fluctuations for restoration?

Response: With the exception of WCA 2B and the southern part of WCA 1, the water levels in the WCAs will be fluctuated to mimic natural system patterns. The damaging over-drainage and ponding effects currently experienced in WCA 2A, 3A, and 3B will be nearly eliminated by the recommended plan. In WCA 1, hydropattern restoration could be accomplished, but it would require using water of a different quality that could adversely alter the landscape in WCA 1. Improvements to hydropatterns in WCA 1 were limited to the northern end (reduced over-drainage). Although several configurations were attempted to return WCA 2B to natural fluctuations, additional efforts are needed to improve performance in the area.

159. Will the westward movement of wellfields in Broward County adversely effect wells in the tribal reservation?

Response: Modeling shows that the groundwater along the LEC will be maintained by the recommended plan, thus protecting against saltwater intrusion. The westward movement of wells does not put other wells at risk as long as more water is delivered to the area. Broward County is the only LEC area that receives greater deliveries from the regional system in the recommended plan. Then too, some well fields will receive water from additional canal works. To ensure the plan is sound, groundwater modeling at a high resolution will be accomplished during the continuing Water Preserver Areas Study.

160. Will site specific ASR pilot tests and aquifer modeling be conducted prior to implementation of the ASR components? How will the amount of recoverable water be determined in ASR wells? Have contingencies been identified if the ASR component is not as effective as modeled?

Response: ASR wells will be evaluated in several ways. Aquifer studies will be conducted that will include data collection and groundwater modeling of regional and local effects. Test wells will be constructed and used to develop feasibility and design information. Operational criteria will be developed based on aquifer performance and water quality data. A multi-agency committee addressed the major unresolved issues in a report to the Working Group in January 1999.

ASR wells were included in the recommended plan because they can provide a water supply function that is superior to reservoirs in long-term drought management. If ASR wells will not function to the level envisioned in the recommended plan, then several contingencies will be explored. The most likely contingency will be to make existing storage areas more hydrologically effective by making the areas deeper. The overall performance of the recommended plan may be reduced if ASR does not perform as well as expected. However, the loss of water resources would be relatively small (less than 5 percent), but without ASR, Lake Okeechobee stages would exceed target levels more often.

161. What are the water supply benefits/impacts of the recommended Lake Okeechobee regulation schedule (component F3)?

Response: The change in Lake Okeechobee regulation schedule, as noted in component F3, was used in the recommended plan D13R. Essentially, the new regulation schedule eliminates all regulatory release schedules except Zone A releases (that are required for levee protection). Zones for operation of the ASR wells around the lake and operation of the storage area north of Lake Okeechobee were identified. Additionally, a zone for passing water to the EAA storage area was defined.

162. Is the amount of storage in the EAA (360,000 acre-feet) sufficient and will the Holey Land and Rotenberger areas be used for storage?

Response: The amount of storage in the EAA is considered sufficient. In most years, 120,000 acre-feet of storage could handle any excess runoff from the EAA without adversely impacting water levels in the WCAs. In wetter years, an additional 120,000 acre-feet of storage is needed to catch the excess runoff plus some releases from Lake Okeechobee. In all but 2 of the 31 years modeled in the Restudy, a third 120,000 acre-feet of storage was needed to capture all excess runoff and releases from the lake. Additional increases in storage size results in some loss of water to the Everglades as modeling results demonstrate. Modeling of 480,000 acre-feet shows a clear reduction of flow to the Everglades although there is an improved ability to handle the two extreme flood events over the period of record. Both Holey Land and Rotenberger are areas to be restored and are not used as storage areas. As Holey Land and Rotenberger represent the last significant portion of the sawgrass plains that historically covered most of the EAA, water levels in those areas will be managed in a way to promote the sawgrass landscape while discouraging cattail dominance.

163. Will the storage area in the Caloosahatchee River Basin be used to improve water supplies to other areas?

Response: No. Water stored in the Caloosahatchee River Basin would be released back to the basin to help meet water supply and estuary demands. In many years, the releases from the storage area will be sufficient to meet the needs of the basin; however, in drier years, there will still be releases from Lake Okeechobee needed to help meet basin demands. Overall, the water supply in the Caloosahatchee River Basin will improve by about 40 percent in addition to meeting most estuary minimum flow needs.

164. The urban water supply need from the Caloosahatchee River Basin (about 50cfs) for Lee County and the City of Ft. Myers was not mentioned in the recommended plan; was this need identified and included in the Restudy?

Response: A 40 percent increase in total water supply demand was assumed by the Restudy. In the recommended plan, that increase would be more reliably met in the year 2050 than current demands are met. Because water allocation is a state responsibility, the federal plan does not reallocate or permit water resources, but rather increases the available water supply. The request for an additional 50 cfs for water supply to Lee County and Ft. Myers was noted, but it cannot be permitted by the Restudy. The permit for the 50 cfs should be considered under state law by the SFWMD.

165. Can pumping be minimized through water management options?

Response: If excess water is to be captured in the Caloosahatchee Basin, it can be either put into storage areas that allow for early dry season deliveries (by gravity feed) or held in smaller retention areas throughout the region. If water is held in the smaller retention areas (such as existing marshes), there is a flood control benefit but the water supply benefit would be greatly reduced (when compared to a single, deeper reservoir). Whenever water is transferred across hydrologic regions, the pumping requirements tend to be high. However, in the case of backpumping excess water into Lake Okeechobee, deliveries can be made to the Everglades or back to the Caloosahatchee River with the same pumping requirement that would be required for reservoir storage within the basin.

166. Does the recommended plan send sufficient water to Biscayne Bay? Furthermore, could another source of water be identified to replace the reuse water?

Response: In the southern Biscayne Bay region, the recommended plan exceeds target flows. In the central regions, flows to Biscayne Bay are below the target; however the excess in the southern region could be used to meet the needs in the central region. In the recommended plan, reuse water was identified as a source of water to augment the flows from the south Miami-Dade drainage basin. At the time alternative plans were formulated, this was the only source readily available for meeting target flows. Alternative sources are being investigated and may be used to replace reuse water if feasible. In modeling conducted in January 1999, modeling scenarios were able to increase the flow to the ENP by about 245,000 acre-feet per year while replacing the need for reuse water in Biscayne Bay. About 75,000 acre-feet per year increase in deliveries to the bay was achieved through the capture of excess water from both Broward and Palm Beach counties.

167. Will all research conducted on hydrology, modeling, and water quality be peer reviewed by experts outside the agency?

Response: The hydrologic models used in the Restudy were peer reviewed. There are extensive peer review efforts associated with water quality (especially as related to the Everglades Forever Act). The Restudy process has been open and available for review throughout the entire study process. The study team included experts from all agencies (state and Federal). Presently, the South Florida Ecosystem Restoration Task Force is proceeding to select a peer review panel to perform ongoing review as part of the implementation process.

168. Does the recommended plan provide an adequate quantity of water to the natural system including Shark River Slough, Taylor Slough, Model Lands, and Florida Bay to ensure a sustainable and diverse ecology within the Everglades ecosystem? Can the recommended plan be modified to increase the amount of flow to the ENP in order to improve various flow targets?

Response: The performance measures for the Shark River Slough, Taylor Slough, Model Lands and Florida Bay all indicated a great improvement over existing conditions, but also showed targets based on NSM were only about 75 percent successful. As a result of a desire to be closer to NSM flow and stage characteristics, additional modeling of the recommended plan was conducted in January of 1999. The modeling effort sought ways to increase the flows to those areas as well as Biscayne Bay. The water identified as excess to tide from C-51 (from West Palm Beach) and southward was captured and routed for that purpose. Water quality issues will require additional evaluations. The modeling effort demonstrated the flexibility of the recommended plan with minor modifications to D13R facilities. As a result, an additional 77,000 acre-feet per year was identified for Biscayne Bay (which could eliminate the need for reuse water) and an additional 245,000 acre-feet per year was delivered to the ENP. There was a dramatic improvement to the Shark River Slough, Taylor Slough, and Florida Bay. Almost 90 percent of NSM flows were delivered to Shark River Slough and essentially 100 percent was delivered to Taylor Slough and southward to Florida Bay. The most extreme deviation for the NESRS stage duration curve showed less than 0.2 foot from the NSM duration curve. There were “pros” and “cons” through the rest of the system that requires additional modeling, but the effort clearly demonstrated the flexibility and robustness of the recommended plan. Improvements to all areas are still possible with more data collection, more modeling, and newer operational scenarios. The recommended plan creates the features necessary to capture and use resources currently lost to tide and therefore remains the basis for restoration of the Everglades while meeting other project purposes.

169. Was the water budget for the recommended plan identified and did it consider the need for groundwater recharge?

Response: The water budgets for all areas have been available on the Restudy web site for public review of the recommended plan as well as for all other alternative plans evaluated. The surficial groundwater component was modeled both in the NSM and SFWMM (the models used for alternative development and evaluation). Groundwater recharge was evaluated along the LEC because of the critical nature of both water supply and prevention of saltwater intrusion.

170. How was the amount of water considered to be “excess to tide” in the Caloosahatchee Estuary determined and were the greater needs of the Charlotte Harbor area considered?

Response: The flow regime necessary for a suitable salinity in the Caloosahatchee Estuary was modeled and evaluated in the mid-1990s and was published by the Charlotte Harbor National Estuary Program in 1997. The evaluation considered the estuarine environment from the mouth (at Shell Point) to just downstream of the Franklin Locks. The Restudy used the available information to determine the amount of “excess flow to tide” for the recommended plan. A modeling study of potential influences of changes in the Caloosahatchee River on the entire Charlotte Harbor was proposed by the SFWMD in the summer of 1998. Modeling results should be available prior to the design and implementation of any components of the recommended plan in the Caloosahatchee Basin. In the recommended plan, dry conditions are improved (not degraded) by the delivery of a minimum flow of 300 cfs; currently there is zero flow to the estuary during dry conditions.

171. Does the recommended plan propose to keep the Caloosahatchee storage area full during the wet season and are the reductions in flow to the Caloosahatchee River from Lake Okeechobee detrimental to the health of the river?

Response: The operation of the storage reservoir in the Caloosahatchee Basin does not include a rule that is designed “to keep” the reservoir full. Under the recommended plan, the reservoir fills upon availability of “excess water”. If sufficient water is available, the reservoir will fill. In years when excess water is less plentiful, the reservoir does not fill. If the water in the river is needed for either water supply or estuarine health, it is not put into storage. Regardless of how much water is in the reservoir, if there is a water supply need in the Caloosahatchee Basin, water would be released from storage. The reductions of flood flows from Lake Okeechobee are highly desirable for the health of the Caloosahatchee River and Estuary, especially because they are not annual events but rather are occasional and destructive.

172. Are the long-term average flow needs of the Caloosahatchee River met and can the water that is identified in the recommended plan for backpumping into Lake Okeechobee be kept in the Caloosahatchee Basin instead?

Response: In the Restudy, 31 years of daily flows were used to determine how much water could be held in storage that would be consistent with the health of the river and estuary. There are only three options for capturing the excess Caloosahatchee River water: in one or two large storage reservoirs, many small and shallow retention areas, or in Lake Okeechobee (via backpumping). Many small and shallow retention areas will not have the water supply benefits (because of large increases in evapotranspiration) of one or two large reservoirs. There are no additional evapotranspiration losses associated with backpumping to Lake Okeechobee. In the recommended plan, backpumping to the lake was preferred over a large increase in surface storage. Half of the water backpumped to the lake is returned to the Caloosahatchee Basin either for water supply or estuary minimum flows. The rest is associated with environmental benefits of the lake and the Everglades.

173. Can the proposed 110mgd ASR capacity in the Caloosahatchee Basin reduce the destructive high flows to levels below 2800 cfs without storage in the basin? Further, if the average river flow is greater than the 300 cfs low target, is river diversion needed?

Response: ASR by itself cannot substantially reduce the destructive flood flows of the Caloosahatchee River. While ASR can store large amounts of water, it can only do so at a slow rate (e.g. 110 mgd). Flood flows are typically short term and large quantities (several thousand mgd). The only way for ASR to capture a flood is by first catching it in a reservoir with suitable inflow capacity and then pumping it into ASR wells. Even if the average flow target is met, flow can be excess at times or deficient at times. Daily averages must be used in determining the flow requirements of the river and whether or not flow is available for capture.

174. How were future changes in basin flows from Fisheating Creek accounted for in the recommended plan?

Response: In absence of definitive changes in the water that flows from Fisheating Creek to Lake Okeechobee, the same flow pattern was assumed. Before substantial changes to the pattern (new water demands or basin development resulting in changes) would occur, the changes would be reviewed and permitted by the SFWMD. Future changes from any watershed, including Fisheating Creek, would be incorporated into the design and implementation of the recommended plan.

175. What is the functional value of the attenuation ponds in the recommended plan?

Response: Flood attenuation ponds can serve three functions: reducing flooding in developed or natural areas, reducing water lost to tide, and providing some water supply benefits. The various reservoirs, located throughout the study area, provide these basic functions. In the recommended plan, there are no flood attenuation “ponds” recommended, only reservoirs.

176. What is the extent of capturing water currently lost to tide (water conservation) in the recommended plan, who gets it, and is it adequate?

Response: In the Caloosahatchee Basin, the amount of water captured is considered to be equal to, or possibly greater than what is identified as “excess”. More refined studies are needed to determine if more or less is available. In the UEC area, additional sources of water may be available for capture and use. Modeling continues in the area to more clearly define the water needs. Currently, there are no excess flows to tide in Miami-Dade County, along the Biscayne Bay inflow area. Only along Service Area 1 and 2, were flows to tide still considered to be “excess to tide.” In modeling conducted in January 1999, almost 350,000 acre-feet of water on an average annual basis was captured and rerouted to both Biscayne Bay and ENP. That represented the most aggressive plan for the capture of water currently identified to be excess. Minor modifications to the recommended plan were necessary to capture and deliver the water. In the design and implementation phase of the Restudy, the plan can be modified as necessary to incorporate new information with regard to capturing and using all excess flows to tide.

177. How was the Everglades Screening Model used in the Restudy?

Response: In the initial stages of modeling, water budget models were used to identify potential sources of water and the features that could be used to catch and distribute the available water. In addition to the Everglades Screening Model, the Object-Oriented Screening Model, and the Prescriptive Reservoir Model were used for the evaluations. Information from the screening phase was helpful in starting the alternative development phase; however, the SFWMM was used in the formulation and evaluation of alternative plans and in the evaluation of environmental impacts. The use of ESM was both proper and valuable in the Restudy.

178. Are high water events eliminated in the WCAs?

Response: While the high stages in the WCAs are improved by the recommended plan, they were not eliminated. The reasons why high stages persist in some areas vary across the region. In some cases the reduction in the spatial extent causes the original flow lines to be severed, especially in WCA 2A and 2B, and along the eastern protective levee in WCA 3A and 3B. Simply putting the original amounts of flow back into the northern borders of the WCAs does not always recreate the desired stages. In some cases, subsidence has caused water to flow more slowly with higher stages for historical flow rates. As the detailed design and implementation of the recommended plan occurs, additional modeling will be conducted to further improve the high stage characteristics of the WCAs.

179. Will Biscayne Bay models (hydrodynamic and ground water) be completed in time for use in the recommended plan design and implementation?

Response: The Biscayne Bay Feasibility Study is currently underway. As part of that effort, a model of the bay, which will include hydrodynamics and water quality is being developed. Findings from that Feasibility Study will be included into the future design and implementation of the Restudy recommended Comprehensive Plan.

180. Do all the major features of the recommended plan have significant environmental benefits?

Response: Yes – either directly or indirectly. For example, storage and use of water to meet environmental targets has a direct benefit, such as in the majority of the EAA storage component. Features that capture and release water that is then used to meet urban and agricultural dry season demands provide an indirect benefit to the environment by reducing high discharges to estuaries as well as reducing the dry season demands on the Water Conservation Areas and Lake Okeechobee.

181. Will computer models be used to simulate "next steps" during the construction of the recommended plan?

Response: Computer modeling has been used extensively throughout the Restudy in the reconnaissance phase, initial screening and alternative selection and refinement phase, and will continue to be used during adaptive assessment and when modeling can assist and support proper decision making. For each major component or series of components, a supplemental EA or EIS and a project implementation report will be prepared that includes the quantified impacts of the component. Modeling will be conducted for each component in order to quantify the impacts. The modeling will not only include the component itself, but will also include the interactions of all existing features.

182. Does the recommended plan protect Miami-Dade County from saltwater intrusion and reduction of flows?

Response: The recommended plan provides protection of the aquifer water levels and there are clear improvements over the 2050 Base Case. Both water supply and prevention of saltwater intrusion are enhanced by the plan. The principal components in the recommended plan that sustains groundwater levels in Miami-Dade County are the North Lake Belt storage area and wastewater reuse facilities.

183. Does the recommended plan provide appropriate flood control for the Miami-Dade agricultural areas?

Response: The recommended plan provides good performance for agriculture in south Miami-Dade County, this view is borne out by evaluations performed by the Florida Department of Agriculture and Consumer Services. There does exist apprehension by local agricultural concerns about how the conditions may change between current conditions and implementation of the recommended plan. The 2050 Base Case (without the Restudy), unless altered favorably for flood control, will cause worse conditions than today. The Restudy modeling demonstrated favorable groundwater management guidelines. The concern is not that the recommended plan will not be better, but that the plan will not be implemented in time. Additional ground/surface water modeling will be conducted at a higher resolution to better define the flood protection issue.

184. Can flood control discharges from Lake Okeechobee, when absolutely necessary, be proportioned according to potential damages throughout the system?

Response: The C&SF project has flexibility, but was not designed to operate in this fashion. Typically, the system operated to minimize damages, not to proportion the damages across the system. The information needed to proportion damages would require that everything (property, businesses, lives, natural habitat, endangered species, etc.) be valued on the same scale. For example, an estuary harmed by large freshwater releases will recover over time and the business losses can be quantified. If an endangered species is lost, there can be no recovery and the economic losses are difficult to identify. Since many impacts are not monetary, this type of analysis was not considered or included in the recommended plan.

185. Can the C-44 Basin flows for stages up to 15.5 feet (instead of 14.5 feet) be returned to Lake Okeechobee until WPAs are constructed in the basin? Additionally, can the stored water be returned to the basin for low flows?

Response: Potentially, making the 15.5 feet rule for backflows would result in more water being sent to Lake Okeechobee. The additional flow to the lake would have to be treated to reduce nutrient loads, probably through a STA, and therefore could not simply backflow. The recommended plan includes storage in the C-44 basin that could be altered to catch the additional flow and use it for water supply in the C-44 basin. Additional modeling, in conjunction with the Indian River Lagoon Study, is ongoing and will address this and other possibilities. If the 15.5 foot rule could be implemented without water quality problems, it could be done separately from the Restudy.

186. Can water supply continue if the destruction of the Everglades is imminent?

Response: Under current state allocation rules, water can be taken from the WCAs and Lake Okeechobee as long as minimum stages are met. If the water levels are at or below minimum levels in those areas, water cannot be taken out for water supply. Water supply is not taken directly from ENP

187. Does the recommended plan meet the timing, delivery, quantity, and quality requirements of the natural system through passive system management?

Response: The recommended plan has included a number of passive management features. WCA 3A was decompartmentalized to allow sheetflow into ENP. To protect the high-quality habitat of WCA 3B, L-67 was degraded to include weirs, considered to be passive structures, so that sheetflow will pass from WCA 3A to 3B and ENP without damage. Most of the natural areas have boundaries with agriculture and urban areas, and many features are necessary that are not passive (e.g. pumps). To the extent possible and for protection and enhancement of habitat within the natural areas, passive features such as weirs and sheetflow features were considered.

188. Why does the recommended plan include the relocation of the S-140 pump to a more southern location?

Response: Water delivered to the WCAs is greatly increased by the recommended plan. In order to deliver water at the right time and place, the S-140 pump was relocated southward. This was done to reduce high damaging stages in the northern boundary of WCA 3A as well as supply water to a high-quality habitat in the central part of WCA 3A. Decompartmentalization of WCA 3A would have adverse low water effects without relocating the S-140 pump. Exact location of the S-140 pump will be evaluated during the implementation phase.

189. Why wasn't full decompartmentalization for all WCAs included in the recommended plan?

Response: Decompartmentalization was the single most-modeled feature of the Restudy alternative development and evaluation process. The evaluation included full decompartmentalization as well as many lesser configurations. Ultimately, the reason full decompartmentalization was not selected was because of the unintended adverse consequences of decompartmentalization. The reduced size of the remaining Everglades does not allow water to flow through the system in its historic way. The eastern protective levee causes those historic flow lines to be severed. The best example can be seen in WCA 2A and 2B where water once flowed southeastward; water must currently flow southwestward to leave the areas, nearly 90 degrees from the original flowlines. That water, when combined with the southeasternly flow of WCA 3A, causes extreme high stages inside the WCAs along the eastern protective levee. The high stages also result in faster flow velocities. The net effect is that higher wet season stages occurred, which are damaging to tree islands, and lower dry season stages occurred, in which flow passed through the system too quickly. Most of the ecologists involved in the evaluations were not willing to cause significant damage to existing high-quality habitat for the sake of full decompartmentalization. Ultimately, a more balanced approach was determined which allowed all of WCA 3A and 3B to be decompartmentalized, including filling in the Miami River Canal through the area. The lower end of the L-67 canal was filled in, but the upper part was needed to help prevent high stages in the northeast part of WCA 3A. The L-67 levee was degraded in places to allow passive flow into WCA 3B without causing high stages and environmental damage to WCA 3B. The hydrologic boundary of the ENP was essentially moved to the northernmost reach of WCA 3A with the resulting sheetflow. The problem in creating sheetflow across WCA 1 was related to water quality concerns. Currently, the center part of WCA 1 is pristine because it is hydrated by relatively pure rainwater. Under a sheetflow scenario, water of a different nature would cover the pristine areas causing changes to the existing communities and therefore were not included in the recommended plan. The problems associated with the severed flowlines of WCA 2A and 2B were not solved during the alternative development process. If future modeling efforts resolve the issues, the information can be used in the design and implementation of the recommended plan.

190. Why didn't the recommended plan restore (raise) Lake Okeechobee to historical levels and create a new littoral northwest of the lake?

Response: One of the major hydrologic characteristics of a littoral zone is that it is underwater most of the time. Zones that are over-flooded for a long period will die because of diminished light penetration. Zones that become dry are in danger of burning as well as converting to more terrestrial species. In order to support a littoral zone in the northwest corner where land elevations are high, the lake would have to be relatively stable (about 3 feet of fluctuation) at around 20 feet above sea level. For the lake to remain stable there can be no water supply taken from it and floodwaters would have to be moved through a smaller system. In the Everglades, the constrained floodwaters would result in depths that are too deep for the remaining natural system. If the lake is to continue providing both flood control and water supply, the lake fluctuation will be about 6 or more feet. Under that scenario (the most likely case), a littoral zone at 18 to 20 feet in the northwest corner would be underwater about once out of every 4 or 5 years. The function of a littoral zone cannot be met in an area that is dry most of the time.

191. Have the flows to the Model Lands, Card Sound, Barnes Sound, and Manatee Bay been addressed in the recommended plan?

Response: Yes. A number of features intended to increase the connectivity and sheetflow in the south Miami-Dade area were included as component WW in the recommended plan. The features include backfilling the lower part of C-111 and creating a spreader canal in the Model Lands. Groundwater models of a higher resolution are being developed that will guide the future design and implementation of the features in that area.

192. Why wasn't the NOAA meteorological modeling work being incorporated into the recommended plan and the hydrodynamic modeling of the Florida Bay?

Response: A hydrodynamic model of the bay is currently being developed. The results of that modeling effort will be incorporated into the Florida Bay and Florida Keys feasibility study recommended in the Comprehensive Plan. The meteorological modeling work conducted by NOAA can be included, if applicable, into the hydrodynamic modeling of Florida Bay.

193. Can existing hydrologic models be refined to provide more reliable predictions of flows into Florida Bay, Biscayne Bay, and across the southwest Florida coast?

Response: The existing models can be refined by the inclusion of more detailed topography, an ongoing activity. Newer ground/surface water models that have higher resolution are needed to not only improve the predictions of flows but to improve the target flows and patterns necessary to restore these areas. The ground/surface modeling of the area upstream of Biscayne Bay is underway. An extension of the Everglades Landscape Model may be possible to increase the resolution of the hydrology associated with flows into Florida Bay on the south of the ENP. The modeling requirements of the southwest coast of Florida will be identified in the Southwest Florida Feasibility Study.

194. What basis, other than using the P33 gage, was used to determine hydrologic improvements to Florida Bay?

Response: The statistical relationships associated with P33 were helpful in the development of performance targets for Florida Bay, but in addition other targets for improvements of flows to Florida Bay were included. Flow lines were developed to evaluated the flow patterns to Florida Bay as the water flowed southward through ENP. NSM patterns were used as the target pattern for the flow lines. Because there are only a few water management features within the ENP, restoration of flow into the ENP dominates the flow patterns into Florida Bay.

195. Is it possible to quantify the amount of flow adjustments to Florida Bay that can be achieved through flexible operation of the C&SF system?

Response: Some model runs could be evaluated to determine the amount of flexibility the C&SF Project has on the flows to Florida Bay. There are, however, only a few water management features within the ENP that can affect deliveries to the bay. To the extent that the flexible flow patterns are acceptable within the ENP, the evaluations could be made.

196. What is the effect of public water supply on the natural system?

Response: In the 1995 Base condition, the LEC receives about 173,000 acre-feet per year from the WCAs and Lake Okeechobee, in addition to rainfall and seepage. Without the Restudy, the amount increases to 252,000 acre-feet from the natural areas by the year 2050 unless some water allocation rule (e.g. minimum flows and levels) prevents it. In the recommended plan, the LEC <u>reduces</u> its dependence on the natural system to 135,000 acre-feet while receiving more water supplies from increased local resources identified in the plan.

197. How is the S-316 structure affected by the recommended plan?

Response: The S-316 structure acts as the hydrologic divide in the L-8 basin. The operation of the structure was not changed by the recommended plan. More flood protection capability downstream of the structure is anticipated as the result of several components of the recommended plan. As part of the ongoing modeling for the Water Preserve Areas, the flood protection benefit will be quantified.

198. Will additional modeling having more accurate predictions be included in the design and development of the LEC areas?

Response: As part of the Water Preserve Areas Feasibility Study, ground/surface water models are being developed at a higher resolution than the SFWMM used in the Restudy. Additional modeling, if necessary, to support the design and implementation of the components identified in the LEC will be done.

199. How will reservoirs be sized and will they have associated “surge tank” areas?

Response: The reservoirs identified in the recommended plan have the basic purposes of flood control and water supply, for natural areas as well as urban and agriculture. Accordingly, the reservoirs will be designed to enhance the capture and distribution of water. The most efficient water supply reservoir would be deep with a small footprint; however, in South Florida, seepage issues tend to limit the depth to which water can be stored effectively. As potential storage sites are identified, data collection and evaluation will be used to determine the maximum depth. The Restudy identified the total amount of storage needed at each site. Once the maximum depth is determined, the actual footprint, or acreage, can be determined. The reservoirs are not expected to require surge tanks. If site inspection and detailed modeling reveal the need for associated surge tanks, they will be included.

200. Will the excessive flood releases from Lake Okeechobee to the estuaries be reduced by the recommended plan?

Response: One of the most dramatic improvements by the recommended plan is the reduction of flood releases from Lake Okeechobee to the estuaries. All but one release was eliminated in the Caloosahatchee Basin and all but two releases were eliminated to the St. Lucie Estuary. The remaining releases would only be about one-tenth the magnitude of the past regulatory releases. As detailed planning and implementation proceeds, there is a chance that all releases can be eliminated. Not only are the damaging releases from the lake nearly eliminated but also damaging local flows are also greatly reduced. Local basin improvements come from reservoirs located within the basin that catch flood waters and then release the stored water to improve low flows to the estuary.

201. Will the excessive flood releases from Lake Okeechobee, as well as some LEC areas such as C-6 and C-9, to the various estuaries be reduced by the recommended plan?

Response: Both the C-6 and C-9 flows to tide are reduced by the recommended plan. Additional modeling of D13R modifications shows that a further reduction in the C-9 basin is possible. The North Lake Belt storage area is instrumental in the capture of the excess water in those basins. In the recommended plan, the water is released to support groundwater levels for the preventing of saltwater intrusion as well as water supply.

202. What evaluations will be conducted to determine the necessary depths of seepage barriers around the Lake Belt storage areas?

Response: During the Pilot Projects, Water Preserve Areas Feasibility Study and future design work for the recommended plan, both groundwater modeling and technical evaluations will be conducted to further explore the feasibility of the underground barriers associated with the Lakebelt storage areas. Technical evaluations will include core-boring studies that will clarify the depths and spatial extents of the clay layers underlying the areas. These layers are critical elements of the in-ground reservoirs. Technical reviews of existing barrier technologies will be completed. Technical evaluations will include discussions with experts familiar with the substrate and the barrier techniques. Modeling evaluations will be conducted at a greater resolution to ensure the reservoirs would not adversely impact groundwater flows in the region.

203. Were discharges from C-23, C-24, and C-25 modeled for the recommended plan?

Response: Yes. As part of the Indian River Lagoon Feasibility Study, C-23, C-24, C-25, and other tributaries to the St. Lucie Estuary were modeled. The C-44 Basin was modeled in the SFWMM, but that model treated all other tributaries to the St. Lucie Estuary as a lumped sum. To ensure the best answers possible, the tributaries were modeled with a higher resolution model and then the results were included into the SFWMM for alternative development and performance evaluations.

204. The 2050 Base Case condition for the C-111 area shows ground water levels that are considered too high; should the base case be corrected by the Restudy?

Response: The base case conditions used in the Restudy represented the best available information. The future operation of the C-111 area was not clearly defined in existing documents and was open to some interpretation. The ongoing C-111 Project will be developing operational rules for that project.

205. How was the role of the permitting process included in the recommended plan? Should the comprehensive plan allow for a watershed-based approach for water allocation?

Response: Water allocation is a State of Florida responsibility. The recommended plan assumed no changes in the way water is allocated in south Florida. The SFWMD, as a Restudy partner, has access to all data and modeling results that could be used in future permitting or in the development of new guidelines; it would not be a Federal activity. If modifications in Florida law change the way water is allocated, any such changes could be incorporated into the recommended plan during the design and implementation phase. It is the responsibility of water management district regional water supply plans to permit for water supply.

206. Should the recommended plan ensure that the 1-in-10 drought criteria are met for all water supply regions?

Response: Florida law requires Water Management Districts to plan for the 1-in-10 year drought. The 1-in-10 drought criteria were accepted as a goal in the Restudy. In some areas of south Florida the 1-in-10 goal was met. In other areas the goal was not quite met although there is clear indication that the recommended plan greatly improves the amount and reliability of water supply while providing for the environment.

207. Because surface storage areas will not supply water throughout long-term droughts, should they be relied upon?

Response: In the recommended plan, surface storage has three basic functions: to capture flows currently lost to tide, provide flood control, and to help meet water supply needs. If the natural areas are full, a reservoir is the only feature that can catch large flood flows to reduce the floodwater that is lost to tide. Because of evapotranspiration and seepage issues, the surface reservoirs are not expected to provide water throughout droughts. By supplying water in the early part of dry seasons, water can be retained in Lake Okeechobee for the longer drought periods. Thus, even short term storage can have significant water supply benefits.

208. Are there any unintended consequences on natural system water demands in the urbanized areas of Broward County – especially related to the capturing of wet season flows?

Response: Under the recommended plan, there is no significant increase in capturing excess water, that is water lost to tide, in Broward County. Some changes in the way seepage and floods are managed in the western part of the county would be changed. Some additional modeling investigations during January 1999 did evaluate the possibility of catching water currently being lost to tide in the county during wet seasons. As part of all modeling efforts, both the groundwater levels and water supply levels are improved and “natural system” demands in the county are dependent upon the groundwater levels. Under the recommended plan, the urbanized area of Broward County is the only LEC area that receives more water from the WCA and Lake Okeechobee rather than less.

209. Was storage provided in the recommended plan for the C-44 Basin?

Response: In the recommended plan, a storage area of about 10,000 acres was included for the purposes of flood attenuation to the estuary, water supply including environmental releases to the estuary, and water quality benefits from reduced nutrient and better salinity control. The maximum storage was set at 4 feet deep so that marsh conditions can exist in the facility. If farmland is ultimately used for storage, deeper depths may be considered.

210. Currently, the western side of WCA 3A is too dry; will it be improved?

Response: In the recommended plan, natural stages and fluctuations will be restored to the northwest side of WCA 3A. On the west-central side of WCA 3A, the S-140 structure will be relocated southward to improve the flows from the west to the central part of WCA 3A. Although some improvements can be expected from the Everglades Forever Act, the recommended plan delivers enough water to restore natural stages.

211. Does the recommended plan include elimination of the diking effect, if any, within Everglades National Park along Flamingo Road?

Response: According to ENP, the Flamingo Road does not create a hydrologic barrier although there are clearly impacts to vegetation. According to ENP, recent flow studies show there to be no hydrologic diking effects. The Restudy Team did not evaluate Flamingo Road and the recommended plan did not include any changes to Flamingo Road.

212. What was proposed for the Southern Golden Gates Estates area in the recommended plan?

Response: As part of the recommended plan, restoration of part of the Southern Golden Gates Estates area was included as an Other Project Element. The details of the OPE were developed as part of a feasibility study conducted by the SFWMD.

213. What modifications were included for the Big Cypress National Preserve?

Response: Changes in the Big Cypress National Preserve identified in the recommended plan primarily affect the eastern side of that Preserve. In the northeast, the L-28 Interceptor will be partially degraded to increase the flows directly into Mullet Slough. Stormwater treatment areas upstream of the interceptor will improve water quality as well. North of Tamiami Trial, the L-28 levee and the L-29 levee will be degraded allowing for natural sheetflow across those areas.

214. Did the recommended plan address conveyance and connectivity along US Route 1 and in the Model Lands areas?

Response: The recommended plan contains a component to extend the C-111 spreader canal east of Card Sound Road. If the conveyance problems are not solved by some other project prior to implementation of the recommended plan, for instance through a mitigation project, then the issue will be addressed as part of the recommended plan.

215. Were underwater structures in the canal along the western edge of Card Sound Road evaluated for the recommended plan?

Response: The regional extent of the models used in the development of the alternatives (NSM and SFWMM) does not accurately predict hydrologic characteristics of the areas near the coastline. This effect, as many other existing drainage features, was not modeled. However, an OPE was included in the recommended plan to incorporate several features to improve the flows to southern Biscayne Bay. As part of the future design work, many existing ditches in the area will be evaluated to see if filling or blocking is warranted.

216. Should S-197 be removed for ecological/hydrological purposes?

Response: S-197 would be removed and the lower end of the C-111 Canal will be back-filled (component WW) as part of the recommended Comprehensive Plan.

217. Can the 8.5 Square Mile Area be used in restoring flows to Northeast Shark River Slough?

Response: In the current system, flood concerns within the 8.5 Square Mile Area (as well as other private lands to the north of the area) tend to restrict the flows to Northeast Shark River Slough. As part of the Modified Water Deliveries Project, the stage restriction due to the 8.5 Square Mile Area will be removed so that natural stages can be restored to the slough. The recommended plan assumes that stage restrictions currently imposed by the 8.5 Square Mile Area will be resolved (either through levee construction or buyouts) prior to the implementation of the plan.

218. Should the flows through L-5 be increased in the recommended plan?

Response: Some flow improvements can be expected from the Everglades Forever Act; however the recommended plan delivers enough water with the correct timing to restore natural stages. There is some speculation that too much water is added to the northern part of WCA 3A. Because the recommended plan sends so much more than the Act, most of the flows have to be routed around the northern part to the western side of WCA 3A to prevent too high stages. Additionally, flows added along L-5 tend to “stack up” along the eastern side of WCA 3A. To help reduce this effect, the recommended plan removes some of the flows along the eastern side of WCA 3A and routes them down to NESRS via the Central Lakebelt storage area.

219. Did the recommended plan adversely effect the water flowing to tribal lands?

Response: Flows to tribal lands were altered slightly as part of the operation of two new stormwater treatment areas included in the recommended plan for water quality improvements. The flow changes are likely to include some flood benefits for the tribal lands, but more refined modeling will be conducted to quantify the benefits. No adverse impacts are known or anticipated.

220. Were the connections between Florida Bay and the Atlantic Ocean addressed in the recommended plan?

Response: A hydrodynamic model of the bay is currently being developed. The issues of connectivity between Florida Bay and the Atlantic Ocean will be investigated as part of the Florida Bay and Florida Keys feasibility study.

221. Did the recommended plan have specific water conservation program suggestions for the LEC?

Response: The 2050 Base in the Restudy assumed the current SFWMD water conservation rules would remain in place, but the success of the program would be similar to the success in UEC areas. That resulted in about a 12 percent reduction in future water demands, as compared to no specific water conservation program. In the recommended plan, full compliance with the rules was assumed, which lead to an additional 6 percent reduction.

222. This number was inadvertently skipped and therefore not used for a comment.

223. Should flow predictions from models be used as restoration targets?

Response: According to the USGS and others, the accuracy of flow predictions by the NSM and SFWMM is one of the least accurate parameters – stages are far more predictable. Stages are often a more important indicator of ecological health. When the aerial extent of the natural system is considered, a modeling error in stage of 0.1 feet can result in large changes in flow-rates and flow-volumes.

N.2.3 Ecological (Including Targets and Fish and Wildlife)

224. The question is since estuarine systems exist because of fresh water and saltwater mixing, are their target salinity ranges that are currently not being met?

Response: Salinity targets were developed based on how much fresh water would be required to achieve the target salinity range, based on the salinity preferences of selected estuarine plant and animal communities. During plan development, each estuary was evaluated as to how well its fresh water needs were met. For existing conditions, many of the targets are frequently violated. The recommended plan makes marked improvements in achieving many of the targets. The Caloosahatchee and St. Lucie estuaries salinity targets were met over 90% of the time.

225. Due to uncertainty of modeling results the Corps should verify modeling limitations for the PEIS. The Corps should also consider further model review / verification / refinement, and field monitoring results as needed.

Response: Concur. In an attempt to acknowledge the uncertainties and develop strategies to resolve them, the final report includes an Uncertainty Appendix (Appendix O) and a more detailed Implementation Plan.

226. There is concern that optimal fresh water be delivered to Florida Bay, particularly the Taylor Slough/panhandle area. Additional concern is that regression equations used to predict salinity at coastal locations based on inland stations (P33 gage) are not adequate. It is recommended that due to uncertainties in the reliability of this method that the recommended plan remain flexible to accommodate these uncertainties in flows as well as water quality requirements.

Response: The Florida Bay sub-team of the Alternatives Evaluation Team developed the regression equation used to evaluate salinity in this area of Florida Bay. It was critiqued, revised, and accepted by the Alternative Evaluation Team as being an acceptable method to evaluate project alternatives effect on the bay. Members of the Florida Bay subteam also participated on the Marl Prairie (Taylor

Slough) subteam of the Alternative Evaluation Team. This was valuable due to the relationship of rehydration of the marl prairie to flows entering Florida Bay. Plan implementation will include developing and using more accurate modeling and evaluation tools. Furthermore, the Florida Bay Program Management Committee has in their response letter dated 1 December 1998, pledged to develop a detailed set of ecological performance measures and restoration targets for Florida Bay in the next twelve months (see below).

227. The regression equations for relating salinity at coastal locations to water levels at P33 should not be relied on for detailed planning. The PMC will develop a detailed set of ecological performance measures and restoration targets for Florida Bay in the next twelve months.

Response: Concur. Development of performance measures and targets by the PMC would be of great benefit to planners involved with developing restoration plans for Florida Bay during the implementation phase.

228. The relationship between water levels in P33 and salinity in Florida Bay are based on the hypothesis that water flows and levels in Shark Slough influence the entire hydrological conditions in the entire region including Florida Bay. There is uncertainty in this assumption. The evaluations of the alternative D13R should take into account these uncertainties in the salinity predictions, in particular the benefits to Florida Bay suggested in Tables 7-12 and 7-13.

Response: There is uncertainty associated with the models used in the analysis. An uncertainty analysis, Appendix O, has been added to the final Report/PEIS to acknowledge the magnitude of uncertainty of the models and evaluation tools used to develop the Comprehensive Plan.

229. There is disagreement with the Restudy response to #13a of the draft Fish and Wildlife Coordination Act Report Recommendations on using a variety of different hydrologic targets rather than on using the single parameter flow volume. The ecological restoration of Florida Bay depends most directly on restoring freshwater flow volumes. The use of hydroperiod and stages at inland locations are only indirectly and imperfectly related to flow in Florida Bay.

Response: Concur that the performance measures used for Florida Bay are imperfect. However, the approach used to evaluate different plans was successful in identifying improved hydrologic conditions for Everglades National Park and Florida Bay.

230. Biscayne Bay performance targets are based on providing a slight increase over current flow rather than based on research of what flow is best for the bay. This research is needed to more appropriately determine benefits to the bay.

Response: Concur. The Implementation Plan includes a strategy that will allow research findings to be incorporated in project planning and implementation as they become available.

231. The “river of grass” image and focus of the Restudy needs to be replaced with a perspective that recognizes the diverse ecological complex of pre-drainage southern Florida, including uplands. The Restudy does not or inadequately addresses the restoration of all biologically significant community types, including pine and cypress forests, the pond apple forest located south of Lake Okeechobee, and high sawgrass plains.

Response: The Restudy attempted to consolidate as much scientific information as was available on the communities that comprised the historic wetland system of central and southern Florida. Concur that the major focus of the Restudy is on wetlands impacted by the C&SF Project in accordance with the authorization for the study. Although the Corps has jurisdiction over activities which effect wetlands, rather than uplands, the Corps does consider the impact of its activities on upland areas, usually with assistance of other agencies such as U.S. Fish and Wildlife Service and the Florida Game and Fresh Water Fish Commission. Concur that not all historic communities, such as the pond apple forest historically located along the southern boundary of Lake Okeechobee, are recreated in the recommended plan. The forms and functions of these historic communities were analyzed to the extent possible, based on existing information, and appropriately included in the plan. As more information on these communities becomes available and as these systems become better understood and documented in the Conceptual Ecological Models, then actions can be taken to include these additional areas into subsequent planning, as appropriate. The Implementation Plan explains this process.

232. More natural patterns of water flow should be provided to western cypress forests, through mangrove forests and other coastal areas.

Response: Concur. Plan D13R includes the removal of L-28 Interceptor and increasing flows through Tamiami Trail in order to achieve more natural water flows in these areas.

233. Containing the natural process of ground water flow through curtain walls or other barriers may have unintended adverse ecological impacts.

Response: Concur. A seepage management pilot project is one of the pilot projects that are recommended. The effect of seepage control on coastal resources, including such areas as Biscayne Bay, was evaluated in the plans. An important aspect of subsequent studies and the pilot projects will be to address these concerns.

234. The Restudy does not guarantee or assure biologically based water allocation for Florida’s natural systems.

Response: Biologists and ecologists, when asked how much water is needed for the natural system could not answer definitively. The Restudy Team agreed early in the study, based on the draft Ecological Conceptual Models, that the best available tool to help evaluate the water needs of the natural environment was the Natural System Model. The Restudy Team also acknowledges that the water needs of the natural system may change as more is understood about the needs of the biological systems. An Adaptive Assessment approach to the study will be used as discussed in Section 10: Implementation Plan for the Restudy.

The Restudy's Comprehensive Plan attempts to capture, store, and deliver water to natural, agricultural and urban areas as efficiently as possible. The goal was to provide the target amounts of water specified by the performance measures. The idea behind this has been to eliminate to the extent possible water shortages for both the natural and built communities. Water allocation in the State of Florida is governed by Florida water law, Chapter 373, F.S.

235. The NSM targets should not be used where there is compelling ecological reasons why these targets should not be met.

Response: Concur. The draft Ecological Conceptual Models and the special needs of some species were used to identify targets other than NSM where appropriate.

236. The final EIS and preferred alternative need to describe the hydrologic regime in sufficient detail for Congress to approve the Restudy.

Response: The final PEIS will contain sufficient detail for Congressional approval. The final PEIS contains an Implementation Plan (Section 10) that specifies details about the project development process, future detailed studies and other pertinent information that was not addressed in the draft report.

237. What are the existing and proposed canal operations of the L-31N and C-111?

Response: The current operating rules for L-31N and C-111 were used to model the 1995 Base, referred to as the existing condition. The 2050 Base or future without project condition was based on information taken from the current C-111 Project. The C-111 Project is an on-going project which will define the operating rules of the South Dade Conveyance System. Component OO4 provides linkage between the C-111 Project and the Restudy.

238. Restoration ecological performance measures should be developed that are flexible enough to incorporate ecological responses to hydrology, should be enforceable, and encompass long-term operations.

Response: Concur. The Implementation Plan addresses these recommendations.

239. The Restudy must address the four main requirements of the Everglades ecosystem: timing, delivery, quantity, and quality of water.

Response: Concur. These were the premises upon which the Restudy was carried out.

240. The St. Lucie Estuary and Indian River Lagoon have permanent problems with shoaling and flocculent organic sediments which must be reduced in order for recovery to begin.

Response: Concur. The Indian River Lagoon Feasibility Study is investigating these problems.

241. The evolution and use of the salinity envelope deserves accolades and deserves more serious consideration in regulatory matters. The approach toward managing salinity should be included in regulatory matters at state and federal levels.

Response: Concur.

242. Regarding the Programmatic Section 404 (b)(1) Evaluation (Annex C), it is suggested that the details of the analysis that quantifies the potential impacts of construction features be presented in the report.

Response: The discussion of the analysis has been revised accordingly. As the Service is aware, the siting of the construction features is only conceptual at this point in time. However, not withstanding the current uncertainty, the Corps attempted to analyze the approximate extent of potential impacts. This analysis supports the need to conduct land suitability analysis during the Project Implementation Report process to avoid or minimize the potential effects on native habitat types in favor of disturbed sites.

243. Water quality warrants close consideration in Big Cypress, particularly since the Restudy will restore natural sheetflow in the northeast portion of the Preserve.

Response: Concur that the impacts on water quality from increased water deliveries to Big Cypress must be carefully evaluated. The potential to degrade water quality by bringing in “outside” water was identified during the study and is being carefully considered by the water quality team.

244. Discharges to estuaries should be based on their ecological requirements and salinity levels managed to restore benthic habitat. Water reservoirs should be managed to accept regulatory discharges from Lake Okeechobee in a way that will minimize the harmful effects of regulatory discharges to coastal waters.

Response: Concur. The salinity envelopes used to identify target discharges to the estuaries are based on their ecological requirements.

245. The Restudy goals and objectives have been diluted from what was presented in the Science Sub-Group Report and replaced with schematics to enhance economic growth. The Restudy should refocus on restoration goals and objectives rather than on ecosystem enhancement.

Response: The goals and objectives presented in the Science Sub-group report were used to develop and to evaluate Restudy plans. An important aspect of the study was to better understand the importance and reason behind each of the goals and objectives. Many of the authors of the Science Sub-Group Report participated on the Restudy. The theories and ideas presented in the book The Everglades: the Ecosystem and its Restoration (Davis and Ogden, 1994) were heavily relied on to understand the form and how the historic Everglades functioned. The Restudy Team worked together to try to solve critical issues such as how areas could be added to increase the spatial extent of natural areas so they could be restored, and how to restore hydrologic structure and function for the system. The Restudy meets the objectives and goals necessary to provide for a sustainable Everglades and sustainable south Florida ecosystem.

246. Restudy biological and hydrological science follows engineering regimes and scenarios that have questionable relevance with the science and biology or needs of a passive ecosystem.

Response: The Restudy looked at a more natural "less managed" plan to restore the form and function of the Everglades. A number of scenarios to decompartmentalize more of the WCAs were modeled and showed some benefits to Everglades National Park but indicated severe adverse effects on the Water Conservation Areas and Loxahatchee National Wildlife Refuge. The recommended plan removes as many impediments to flows as was possible to result in favorable conditions for the entire natural system.

247. The Restudy doesn't meet all the hydrologic targets for the Everglades.

Response: Concur, not all targets were totally met (100%) for all areas. It is anticipated that in more detailed planning and modeling, performance will continue to be enhanced.

248. In LEC areas the Restudy should use urban run-off to maintain canal stages rather than water from natural areas. There are conflicts between providing water to natural areas and to urbanized areas that are tied to the lack of needed land for spatial expanse recommended in scientific studies.

Response: The Water Preserve Areas study will further refine sources of water needed to maintain canal stages and prevent saltwater intrusion. Some urban runoff has been utilized; recent case studies have shown the potential to add more.

249. Water levels in Lake Okeechobee should be regulated to protect the lake's littoral zone.

Response: The recommended plan protects the resources of Lake Okeechobee through a regulation plan which eliminates damaging high and low water levels.

250. Ensure sheetflow in the Water Conservation Areas while protecting ecosystem diversity.

Response: Concur. The recommended plan includes a number of passive management features to enhance sheetflow. WCA 3A was decompartmentalized to allow sheetflow into ENP. To protect the high-quality habitat of WCA 3B, L-67 was degraded to include weirs, considered to be passive structures, so that sheetflow will pass from WCA 3A to 3B and ENP without damage.

251. Maintain water levels in WCA 1 to provide for optimal wildlife management and habitat diversity.

Response: The water levels requested by Loxahatchee National Wildlife Refuge (WCA 1) managers were used as the restoration target for this area.

252. For Florida Bay and the estuaries of Shark River Slough (SRS), the differences between D13R and the restoration target defined by NSM are significant. Alternative D13R proposes to provide 70% of NSM flow volumes to Shark Slough estuaries, which is not adequate to restore or sustain keystone species in Shark Slough estuaries. Water in Shark River Slough is not as deep for as long a period of time under D13R as the target suggests it should be. While Alternative D13R can be described as moving in the right direction, it still appears to fall short of restoration.

Response: The findings of the Alternative Evaluation Team are that D13R would provide hydrologic conditions for a sustainable ecosystem in these areas. Although the targets were not completely achieved it was believed by the Alternatives Evaluation Team that substantial improvements would result from the plan, capable of resulting in sustainable ecosystems. The 70% flow volumes used by ENP was a different performance measure for the Shark Slough Estuary (flow-volume) then was used by the AET. The merits of the different performance measures will be reviewed in future workshops, and improved measures developed and used during detail designs.

253. Greater water depths will be needed in SRS, beyond those predicted by D13R, to encourage development of deep water, water lily-dominated communities that were part of the historic southern Everglades.

Response: Work will continue on the recommended plan to further improve conditions within Shark River Slough. However, the only sure way to determine what effects the plan will have on Shark River Slough vegetation is through monitoring activities within the slough.

254. Alternative D13R may not provide needed conditions for the alligator. An appropriate simulation model for alligators in the southern Everglades is not currently available. An alligator model will be available in 1999 that will provide better information for the alligator.

Response: Concur that additional ecological models are needed. Development and use of additional ecological models is discussed in Section 10: Implementation Plan.

255. D13R predicts higher frequencies of dry downs in the Rocky Glades than the targets warrant and will result in negative consequences for vegetation. D13R falls short of targets in Rocky Glades.

Response: While targets were not completely met, the recommended plan greatly improves conditions within this area. Continued work on restoration plans and evaluation tools, including the conceptual ecological models will be conducted and ultimately should result in further improvements for the natural resources occurring within this area. Subsequent to implementation of any restoration activities, monitoring will be required to determine vegetative responses to such activities.

256. Hydrological conditions for aquatic communities are not adequately improved under D13R.

Response: The findings of the Alternative Evaluation Team for D13R are that hydrologic conditions are greatly improved but that additional improvements may be desirable. Additional work will be accomplished on the conceptual ecological models which should better define and reveal the linkages and relationships between hydrologic conditions and ecological responses. Until this work is completed and the project is implemented no one will really understand the effects of partial or even full achievement of target hydrologic conditions on the natural communities of the Everglades.

257. D-13R does not represent a restoration scenario for the southern, central and northern Everglades.

Response: There is considerable evidence to the contrary, including that of a broad cross-section of scientists, planners, resource managers, and concerned individuals who participated fully during a lengthy inter-agency planning effort. In detailed comments, there is repeated reference to the plans' inability to attain 100% of NSM predicted values. There is a certain degree of uncertainty in conditions predicted under any model, including NSM, and uncertainty as to the precise optimal hydrologic and ecological targets for ENP. It is of dubious value to insist on attaining 100% of a target (in this case NSM) that is constantly being revised, for which there is not an equal degree of certainty that the target will result in optimal ecological conditions.

While the accuracy of NSM may be questionable, it is not the reference by which the Corps evaluates the environmental impacts of its proposed projects. The Corps civil works planning guidance requires the Corps to compare a reasonable array of alternatives to the future without project condition that is predicted to exist should the proposed plan not be implemented (2050 Base in this case). The Corps assesses the ecological "lift" of conditions under the Comprehensive Plan relative to those conditions predicted under the 2050 Base, not the attainment of an as yet undefined and still unclear hydrologic target predicted under the NSM and not compared to existing conditions.

Modeling results have shown very similar hydroperiods predicted by D13R and that of NSM throughout much, but not all, of Everglades National Park and without creating conditions that may jeopardize listed species such as the Cape Sable seaside sparrow.

Scenario $D13R_4$ largely corrects all the shortcomings of previous model output with respect to hydroperiod in the Rocky Glades. Nearly every measure of water depth and duration match NSM for that area. The development of scenarios $D13R_{1-4}$ demonstrate the robust nature of the Comprehensive Plan and the ability to manipulate water flows to different regions of the system to meet demands based on information expected to arise during detailed planning and design.

258. D13R provides a relative improvement of about 10% over the 2050 Base for flows into the Everglades' estuaries. D13R delivers about 70% of the target flows, as compared to about 60% under the 2050 Base no-action alternative.

Response: For a discussion of targets, see response above. Under D13R, and more so under $D13R_4$, for the Florida Bay estuaries, mean salinity, the range of salinity variation and frequency, magnitude and duration of hypersaline conditions would decrease compared with the 1995 or 2050 base. D13R conditions could stabilize conditions and allow the development of a significant vegetative community. $D13R_4$ demonstrated an even better probability of producing a sustainable submerged aquatic vegetation community within the estuaries. This conclusion was reached during the preparation of the inter-agency Alternative Evaluation Team's

Everglades Issue paper, which is reproduced, in part, in the Final Fish and Wildlife Coordination Act Report (see Annex A). Lorenze (1997) has correlated increased flow with increased productivity of prey fish. D13R and $D13R_4$ have greater flows than either 1995 or 2050 bases. $D13R_4$ flows are approximately 80-85% of NSM estimated flow. The Corps has committed to investigating features of $D13R_{1-4}$ which may, in the future, be incorporated into the Comprehensive Plan in order to convey additional flows to ENP and Biscayne National Park, assuming outstanding environmental issues (notably in the WCAs) can be satisfactorily resolved.

259. The reason for the shortfall (in target flows) is that wet season water level targets in Shark Slough are not met.

Response: When compared to D13R and the 1995 and 2050 bases, $D13R_4$ has greater possibility for increased peat accretion and restoration of the historically dominant slough communities. Compared with the base conditions, D13R should improve overall aquatic productivity in Shark River Slough, benefiting the American alligator. The number of drying events, although fewer than predicted historically, are probably within the uncertainty of the model. The mean number of weeks of a drying event is decreased from D13R to $D13R_4$ further improving conditions for aquatic prey production in Shark River Slough. It must be noted that the Restudy AET/ADT process has largely shown the difficulty in implementing incremental project features into the Comprehensive Plan without incurring some negative consequences elsewhere in the system. These issues need to be further investigated and resolved through the inter-agency coordination and planning process before the incorporation of the project features proposed in $D13R_{1-4}$.

260. D13R does not show improvements in ponding depth and duration adequate to sustain fish populations in the southern Everglades.

Response: The above comment refers to attainment of ponding depths as predicted by NSM relative to those by D13R. As mentioned above, the reviewer assumes there would be detrimental environmental impacts incurred due to the implementation of the Comprehensive Plan relative to NSM. The NSM should be used as a reference point, and not as a tool to assess environmental impacts. Attainment of 80% of NSM flows for instance, does not result in a net negative environmental impact when compared to future conditions, it is quite simply 80% attainment of a reference point. Hydroperiods and flow predicted under D13R and $D13R_4$ are an improvement in the environmental conditions as they exist today and as they are predicted to exist in the year 2050. One result of the scenario development process resulting in $D13R_{1-4}$ is that the Comprehensive Plan has demonstrated a robustness and flexibility that would allow for further improvement.

261. D13R largely retains the fragmented management and compartmentalization characterizing today's Everglades.

Response: D13R proposes the removal of a number of levees, canals and structures, particularly in and around the Big Cypress National Preserve, Everglades National Park and within WCA-3. Specifically D13R proposes total removal (including all associated water conveyance structures) of the southern L-28, L-29, L-68, significant parts of the L-67 and nearly all of the Miami Canal within the Everglades Protection Area. Also, the L-67 Extension is assumed to be removed as a part of the future without project condition. These levees and canals are mostly within the central and southern Everglades and directly effect flows to and within the Park. Although restoration of more natural sheet-flow is a priority of the Restudy, this must be balanced against other performance indicators such as hydropattern and ponding depths.

262. On page 7-12, Item 2 asks what was the basis for prioritizing hydrologic targets. Details on how they were prioritized are not presented in Appendix D. Because the models are conceptual the process is subjective. The basis for choosing one hydrologic characteristic over another should be described.

Response: Each subteam on the AET was asked to prioritize the measures and document why one measure was considered more important than another. In many cases the subteams did this; some were unable to. In these instances, the teams were requested to continue work on their appropriate conceptual models with the intent that the linkages that the teams intuitively believed to be valid would become better understood and documented as a result of this continued investigation. The scientific team that developed the slough model agreed that hydroperiod equaled duration of uninterrupted surface flooding and represented the highest priority hydrological target for addressing the major ecological problems of the region.

263. On page 7-12, the Everglades Protection Area should be evaluated on a system level. A conceptual model for the natural system should be developed.

Response: Concur that a total system conceptual model would greatly benefit the evaluation. A Total System Conceptual model will be developed in subsequent phases of the study as described in Section 10: Implementation Plan.

264. On page 7-26, the ENP disagrees with the assessments on how well D13R does in the Everglades Protection Area. The final evaluation matrix is only a small subset of the total set of performance measures used during the model evaluations.

Response: Concur that the final evaluation matrix was a subset of the performance measures used. Each subteam of the AET was requested to conduct a final evaluation of how well each of the plans performed to achieve sustainable ecosystems and provide supporting documentation for the evaluations. The subteams' final evaluations are included in Appendix D.

265. The citation referring to the number of miles of canals and levees removed is incorrect and misleading.

Response: The Alternative Evaluation Team focused its attention on reducing the number of canals and levees in the natural areas. The Total System Performance Measure for Fragmentation: Miles of Canals and Levees uses only the number of miles of canals and levees within the Everglades Protection Area, Big Cypress National Preserve, Holey Land, and Rotenberger Wildlife Management Areas. The list of which structures were included can be found on the web site under “View Maps and Tables”, “Individual Maps and Tables” and the last category “Model Inputs”. The above comment mixes figures from within this selected area with figures from the entire system.

The lengths used in the Fragmentation performance measure are as they are modeled by the SFWMM. Model miles are useful for comparative purposes but are unlikely to exactly match the number of miles actually implemented.

Within the “natural” area, the 1995 Base condition had 330 miles of canals and 400 miles of levees. The 2050 Base condition had 311 miles of canals and 400 miles of levees. Alternative D13 and the D13R scenario have 184 miles of canals and 318 miles of levees. There were 146 fewer miles of canals and 82 fewer miles of levees in D13R. New canals and levees were outside this area so were not counted. The correct number of miles of canals and levees removed in Alternative D13R (and D13R4) within the natural areas is: 146 + 82 = 228.

266. The development of targets for Biscayne Bay is critical in determining the desired flow quantities to be delivered from the C&SF Project and in the future design and implementation of the Restudy's Comprehensive Plan. The feasibility report should identify the process for developing the targets as an early action item. Costs should also be identified.

Response: The Corps and Miami-Dade County are presently conducting a feasibility study for Biscayne Bay. At this point, the study involves development of an hydrodynamic model and related water quality inputs. This model as well as other ongoing efforts are essential to the development of these targets. The Implementation Plan shows "Establishing Biscayne Bay Performance Targets and Alternative Sources” to begin July 1, 1999 and continue through June 26, 2002. Required funds identified for this task are $100,000.

267. Referring to page D-127, this page states that there is a discrepancy between assessments conducted by a Corps contractor and that of Everglades National Park regarding the effect of the southern L-28 levee on NSM-like hydroperiods within the Big Cypress. The sub-team conducting the assessment was unable to comment on how this information may effect the outcome of Restudy modeling of the L-28, since sub-team members had not seen the information. Discrepancies such as this should be eliminated by obtaining and assessing pertinent information from ENP, a cooperating agency.

Response: Concur. Note that Everglades National Park (ENP) was not a Cooperating Agency at the time the Corps contractor was conducting the initial L-28 modifications study. The U.S. Park Service, including ENP, was a Cooperating Federal Agency for the Restudy. The Corps as lead agency regularly requested information, data, technical assistance, and staff expertise of ENP as well as the other Cooperating state and Federal agencies. Due to other exigencies on staff time and resources, these requests, at times, met with mixed results.

268. In reference to the Summary, page viii, how will water level stabilization of Lake Okeechobee make it a healthy, productive lake? Stabilization is the one activity that is most damaging to lake ecosystems in Highlands County.

Response: It is unclear where this information originated from, because the cited information is not present in the summary. The Restudy recommended plan does not propose to stabilize lake levels, rather to restore them to a more natural hydrologic regime with more, not less moderation facilitated through the retention of high water events in storage facilities north of the lake. See Section K.4.4 in Appendix K.

269. Include and provide for invasive / nuisance plant control for, but not limited to, air potato, Japanese climbing vine, melaleuca, Brazilian pepper and cattail.

Response: The recommended Comprehensive Plan does not include measures to *directly* combat exotic plant infestation. Direct measures to control exotic and nuisance plants, such as field treatment with herbicides, mechanical removal, and biological controls are managed by operational elements within the responsible agency (e.g., Army Corps of Engineers, Water Management District, or Everglades National Park). Three Critical Projects involving biological control of Melaleuca were nominated by the Working Group. These include the following: constructing a new quarantine facility, upgrading and retrofitting the current quarantine facility in Gainesville, Florida, and large-scale rearing of approved biological control organisms (e.g., *Oxyops vitiosa*) with release and monitoring at multiple sites in the South Florida Ecosystem. The new quarantine facility is expected to be implemented through the Critical Projects program. The other two projects are included in the Comprehensive Plan as Other Project Elements.

The South Florida Ecosystem Restoration Task Force and Working Group established the Exotic Pest Plant Task Team to develop a statewide strategic plan for managing exotic pest plants. This group recently renamed the Noxious Exotic Weed Task Team (i.e., NEWTT) is composed of scientists and plant management experts from Federal, State, and local government agencies who will deal with current invasive and future invasive plant species. The plan would improve conditions for native plant communities by restoring more natural sheet flow and hydroperiods throughout much of the system, improving water quality, and restoring more natural timing and distribution of flows, hydrologic and ecological conditions. However, care most be taken so that the new structures associated with the restoration (i.e., new canal systems and water retention areas with their associated levees) would not become new areas for invasive plant colonization. While increased hydrology may help control some of the currently known invasive plant species, increased hydrology will have little effect on certain life stages of others. Although the plan would improve hydrologic conditions in the area, invasive plant management would be a challenging problem. Management strategies are being developed by the NEWTT for current invasive plants and it would be the task of the operational elements to develop plans to execute these strategies.

270. The Restudy has not succeeded in advancing the goal of increasing spatial extent of natural areas as described in the report. In reference to Table 7-21, top row, DOI does not agree that Alternative D-13R and the OPEs will increase the total spatial extent of natural areas by 2,370,000 acres. The explanation of this entry in the table was based on the total number of acres judged to be “green” by the AET subteams. Speaking strictly of the spatial extent of natural areas, it is inappropriate to count the acreage of areas classified as “green” as equating to a corresponding increase in spatial extent.

Response: Concur in part. It is true the recommended Comprehensive Plan makes little significant progress in increasing the spatial footprint of the historic Everglades to the degree that would have been (ideally) preferred. The Restudy plan focuses on restoration of existing natural areas that are degraded, usually as a result of a lack of proper volume, timing, distribution and quality of fresh water flows. The Restudy Comprehensive Plan ensures that the functions and values of these degraded areas will be restored providing sustainable habitat for native plant and animal populations. The recommended Comprehensive Plan is expected to restore conditions that provide for a numerous and diverse array of quality habitat “options” that allow necessary habitat to be available during an extreme or catastrophic event such as a hurricane, extreme drought or freeze. This, in a sense, may be viewed as increasing the spatial extent of functional natural areas, although as acknowledged in the comment, the definition of “natural area” is debatable. A broad definition of the term “natural area”, it may be argued, may include those areas within the Water Preserve Areas, some of which will be restored as natural marsh, others converted to impoundments. In either scenario, they will prevent urban sprawl westward from the Lower East Coast, thus, increasing the spatial extent of natural areas relative to the 2050 Base. These areas will certainly provide some wetlands function and value within their footprint, as well as ensuring hydroperiods are maintained west of the protective levee during dry cycles.

271. Effects of the recommended Comprehensive Plan are less clear for Biscayne Bay and the Florida Keys National Marine Sanctuary than for Florida Bay.

Response: Modeling results, and empirical studies have shown there to be no conclusive effects on the Keys National Marine Sanctuary due to freshwater flows from the C&SF Project. Therefore, it was not unexpected when modeling conducted during the feasibility phase of the Restudy, showed that none of the alternatives studied showed substantive impacts (positive or negative) to the Keys. Effects on Biscayne Bay were addressed in the Draft PEIS, although there may be further beneficial impacts which require further study, given the presence of two Other Project Elements expected to benefit Biscayne Bay that are outside of the model domain.

272. Given the uncertainties of the method used to assess the impacts on Florida Bay, the report may overstate the differences among the various restoration alternatives with respect to their expected effects on Florida Bay.

Response: Concur, in part, although in using this line of reasoning the report may have equally understated differences among the alternatives. The current best science was employed in developing and using meaningful performance measures by an inter-agency sub-team during the alternative development and evaluation process. The performance measures that the PMC expects to provide in the upcoming year will be helpful.

273. The proposed restoration plan must be sufficiently flexible to accommodate the remaining uncertainty in the freshwater flow and water quality requirements of the marine ecosystems of south Florida.

Response: Agreed. A process actually occurred beginning in November 1998 and extending through January 1999, which explored several alternative scenarios ($D13R_{1-4}$) which identified possible new flows to the southern Everglades and marine ecosystems of south Florida in addition to those in D13R. An initial assessment of $D13R_{1-4}$ by the Alternative Evaluation Team demonstrated some promising results, however, not without negative effects to other parts of the system. The Corps is committed to exploring elements of these scenarios during detailed planning and design assuming they do not result in unacceptable trade-offs elsewhere in the natural system.

274. The draft fails to provide a flow-way to Loxahatchee National Wildlife Refuge (Water Conservation Area #1).

Response: The assumption is that the comment refers to the lack of a flow-way project feature in the recommended Comprehensive Plan. A flow-way component was evaluated by the interagency study team during the alternatives screening process. The proposed component was intended to divert excess treated water south through the J.W. Corbett Wildlife Management Area, to the Everglades Construction Project and ultimately into WCA-1. The inter-agency team set a condition that there be no adverse impact to Corbett Wildlife Management Area by the backpumped water. The study team determined that a flow-way would result in unacceptable negative impacts to existing high quality wetlands and cause further fragmentation of the regional ecosystem. Furthermore, a flow-way regains little of the water storage that is required to deliver adequate quantities of water to the remaining Everglades. It was also found that the flow-way greatly exacerbates evapotransporation water losses, seepage losses, and dry-season water demands of the flow-way to maintain it as a viable wetland system. Reference Appendix A, Table 5, page A1-42 for a summary of the screening results.

275. Urban natural areas, especially lands set aside for conservation, natural parks/reserves and mitigation are not addressed in the draft document. Urban natural areas should be specifically listed in the Executive Summary as a “Major Feature of the Recommended Plan”.

Response: Under the current system of management, water from urban natural areas does not contribute a significant amount of flow back to the natural system. The focus of the ecosystem restoration component of the Restudy is to address those resources, which are part of and contribute to the natural system of protected wetlands and the Everglades. The C&SF Project Restudy is therefore a regional study with a broad perspective on larger scale water resource issues. Urban natural areas, while valuable in and of themselves, are not specifically targeted within the Restudy for restoration, although they should not be adversely affected by the Restudy. Urban water supply under the Comprehensive Plan is expected to greatly benefit, in many instances surpassing 2050 Base demand targets. This water, though targeted mainly for consumption, protection of well fields, and prevention of saltwater intrusion, may also benefit local urban wetlands and natural areas. Under the Comprehensive Plan, the system will have greater capability to maintain higher canal stages, which may have beneficial effects to localized wetlands, ponds, lakes and natural areas.

276. The increasing hyperinsularity of the remnant Everglades wetland mosaic, if not addressed, will further erode the already declining species richness, biodiversity and vitality of these remaining wetlands.

Response: Concur. Although this is more of a rhetorical statement, it provides the very foundation and justification for the Restudy. It is debatable that the remnant Everglades are “hyperinsular”, surely there are significant problems associated with the many drainage canals and levees which obstruct sheet-flow, thus impacting the natural timing, volume and distribution of flow to large areas. A large number of these canals and levees within the Everglades Protection Area are targeted to be removed from the system under the recommended plan which, it is predicted, will restore more natural hydroperiods to the natural system. All of the

L-29, L-68, the southern portion of L-28, significant parts of the L-67, and the Miami Canal within the Everglades Protection Area will all be removed or filled in. The L-67 Extension is assumed to be removed as a part of the future without project condition. This, in concert with other related project features, will restore more natural hydroperiod conditions to the natural system and allow for a more dynamic system, which should support a sustainable and diverse assemblage of plants and animals and of greater abundance. It will further remove physical barriers for native plants and animals, allowing greater freedom of movement and migration around the system from which they had been heretofore largely restricted.

277. Federal and State Threatened and Endangered fish and other species, as well as their recovery, need to be addressed in the report.

Response: There are no Federally listed threatened or endangered fish species within the project area. Any state listed species or species of special concern present in the study area will be coordinated with the Florida Game and Fresh Water Fish Commission (GFC) under authority of the Fish and Wildlife Coordination Act, of 1959 as amended. This Act requires the Federal agency taking action to coordinate project plans with the U.S. Fish and Wildlife Service, as well as the state agency responsible for management of fish and wildlife. The Endangered Species Act requires action agencies to consider only Federally listed species, although the Corps routinely considers state listed species before proceeding to construction of a project.

278. Project component sequencing as it relates to fish and wildlife, including federal and state threatened and endangered and species of special concern and watchlist species as listed on the Audubon web site must be included in the report. Precautionary measures should be taken to ensure that hydrologic alterations occur at a rate that will not adversely effect fish and wildlife diversity or abundance.

Response: The Restudy Implementation Team is coordinating closely with state and Federal wildlife agencies to ensure that project sequencing will minimize adverse affects to all fish and wildlife species during the implementation phase. Watchlist species do not necessarily have protection under the ESA, so including a list of these species within that portion of the report that discusses Threatened and Endangered species is not appropriate. In an effort to maintain a brief and concise document for an immense study area, with minimal redundancy, and avoid reproducing long lists of plant and animal species which may or may not be affected by the project, the Corps decided to include detailed information in the appendices. All plant and animal species considered, particularly those considered threatened, endangered, of special concern or sensitive, whether protected under the ESA or not will receive consideration and evaluation by an inter-agency study team throughout the detailed planning and design, as well as through the monitoring and adaptive assessment process.

279. ATLSS models, which are used heavily in the document, should not be used as a surrogate for actual field collected data.

Response: The Comprehensive Plan includes substantial monitoring and adaptive assessment components that will collect and interpret field collected data and ensure that those data are used to improve project implementation. These data will also be used to continuously update and improve modeling tools, including the ATLSS models, which will continue to be an important part of detailed design and planning.

280. The effects of predicted hydrologic changes should be assessed with respect to how they affect threatened and endangered species and fish and wildlife throughout their entire life cycle.

Response: The U.S. Fish and Wildlife Service's Preliminary Biological Opinion on the Restudy includes an analysis of the Comprehensive Plan's expected effects on all aspects of affected threatened and endangered species' life cycles. This document is included in the report as Annex B.

281. The implementation of the C&SF Restudy should not adversely affect critical and/or endangered habitat, the health and/or quantity of listed threatened or endangered species, nor shall individual listed species or their habitat be irretrievably lost.

Response: The U.S. Fish and Wildlife Service's Preliminary Biological Opinion on the Restudy includes an analysis of the Comprehensive Plan's expected effects on all aspects of affected threatened and endangered species' life cycles and designated critical habitats. The Biological Opinion recognizes that while many listed species are expected to benefit from implementation of the Comprehensive Plan, some other listed species and some individual animals and specific portions of their habitat may be adversely affected. In most cases, these relatively minor adverse effects are necessary in order to provide a greater overall benefit to listed species and their habitats.

282. In reference to the Summary, page viii, animal populations "should markedly increase" but not as a function of restoration, rather as a function of increased surface water storage for water supply.

Response. Do not concur. A marked increase in animal population numbers is a key objective of the Restudy and will be accomplished largely through restoration of the remaining natural wetland features and characteristics which comprise the Everglades, including more natural volumes, timing, distribution and quality of freshwater flows. The water storage features included in the recommended plan are a means to an end, not an objective in themselves to create more available wetlands in the form of a reservoir.

283. The Integrated report leaves out a number of Federally and state-listed species that fall within the project area, and provides little or no information as to which species may be expected to occur within each region.

Response: It was the intent of the Corps to provide in the draft report, those listed species which were determined to be present within the study area and “likely to be affected” by the Restudy alternatives. This determination was made in consultation with USFWS under Section 7 of the ESA. Listed species expected to be present and likely to be affected were identified for each physiographic region in Appendix J. In following guidance under NEPA, the Corps has endeavored to prepare a report that is complete, yet brief and concise, focusing on those issues which are most applicable. This input will be considered and used in future evaluations. It does not, however, appreciably alter the description of the existing environment. Nonetheless, the information presented is incorporated into Appendix J.

284. In reference to page ii, Major Conclusions, is the sentence describing declining fisheries true for recreational fishing in fresh water, or is this more true of saltwater fisheries?

Response: Since there is no citation next to the statement, it is difficult to know the source of the information. It is reasonable to assume though, that it may equally apply to fresh water, near shore marine and estuarine fisheries. All three fisheries have been documented to have experienced some negative effects of man including Lake Istokpoga, Lake Okeechobee, Florida Bay, the St. Lucie Estuary and other fisheries receiving pollutants or excess freshwater flows from the C&SF Project. Offshore salt water fisheries may have received less of an environmental impact to their fisheries due to the limited effect of the C&SF Project offshore.

285. Implementation of D-13R will result in better deer foraging conditions in WCA 3A, south of I-75, but not necessarily for WCA 2B or WCA 3B.

Response: The final report has been edited accordingly. Reference Appendix K, Section K-101-104. The Corps acknowledges and agrees with GFC assessment that not all areas of the WCA system will benefit by improved deer habitat. This information will be used in future assessments of localized impacts where ecological lift in one part of the ecosystem may result in ecological damage to another.

286. The Table J-1.6.4-1 “List of Common Resident and Migratory Avifauna of South Florida (After USACE Wildlife Survey of Lake Okeechobee 1998”, page J-33 may be more suitable for the section describing the resources of Lake Okeechobee.

Response: Undoubtedly there are more complete lists of avifauna for south Florida. The intention here was to provide a flavor for the types of avifauna typically observed and indicative of the south Florida ecosystem. The table provides recent field collected data and, while certainly not a complete list of all avifauna, is representative of south Florida avifauna.

287. Given the aim (restoration) and scope (south Florida ecosystem) of the Restudy, the GFC feels it appropriate that state listed fish and wildlife species be included in the description of existing conditions.

Response: For this final report State listed fish and wildlife species were included in Appendix J (Existing Conditions) in a table as requested. This table is provided in the Regional Overview, section J.1.7 as this was the organizational system used for listed species in the report, not on a physiographic regional basis.

288. To ensure that the Restudy projects protect, conserve, and enhance habitat for native species, WWF urges the Corps to coordinate closely with the Multi-Species Recovery Team of the USFWS and with the multi-species recovery implementation working group which is being established by the Fish and Wildlife Service.

Response: Close coordination with the U.S. Fish and Wildlife Service throughout the alternatives design and review phase ensured that the Comprehensive Plan was consistent with the Draft Multi-Species Recovery Plan for the Threatened and Endangered Species of South Florida (MSRP). The U.S Fish and Wildlife Service's, Preliminary Programmatic Biological Opinion on the Restudy included an exhaustive list of conservation recommendations taken directly from the MSRP, and the Corps will work to implement as many of these recommendations as possible during the Restudy's detailed design and implementation phases.

289. The Corps must also incorporate biological indicators into its adaptive implementation and management strategy for the Restudy.

Response: The Comprehensive Plan includes substantial monitoring and adaptive assessment components that will collect and interpret field collected data and ensure that those data are used to improve project implementation. These data will also be used to continuously update and improve modeling tools, including the ATLSS models, which will continue to be an important part of detailed design and planning. ATLSS is a complex series of ecological modeling tools, which collectively incorporate biological indicator type data into species models. Several of these models were used for the feasibility study and others, including models for wood storks, crocodile, and Cape Sable seaside sparrow will be utilized during detailed planning and design. The Corps will continue to coordinate with USFWS under the F&W Coordination Act and Section 7 of the ESA, and with the GFC under the Fish and Wildlife Coordination Act to ensure that each Project Implementation Report expected to be tiered from the recommended Comprehensive Plan will receive appropriate consideration for fish and wildlife and threatened and endangered species.

290. The Seminole Tribe of Florida is concerned that the description of its Big Cypress Water Conservation Plan in the Draft Restudy Coordination Act Report (CAR) reflects some confusion about the purpose, benefits and implementation of this project. The Seminole Tribe recommends several changes to the CAR and has submitted extensive edited text which they request be incorporated into the Final CAR.

Response: The Corps coordinates its project planning with the U.S. Fish and Wildlife Service under the Fish and Wildlife Coordination Act of 1959, as amended. Under the Act, the USFWS is obligated (usually with funding provided from the Corps) to prepare a Fish and Wildlife Coordination Act Report (CAR). The USFWS, and not the Corps, is therefore responsible for preparation of the CAR. The Corps forwarded the Tribe's comments, unedited, to the USFWS and suggested the comments be considered for incorporation into the appropriate section of the Final CAR which is included in the Final Integrated Feasibility Report and Programmatic EIS as Annex A.

291. The Restudy is currently inadequate in providing for the recovery of dangerously threatened populations. The Cape Sable seaside sparrow requires 80 days without disruptive water flows for breeding. In 1999 the Restudy only provides 45 days and 60 days in 2003.

Response: This comment seems to confuse information published in the current draft of Reasonable and Prudent Alternatives (USFWS) for the Experimental Program of Water Deliveries to Everglades National Park project. These results do not apply to modeling done for the Restudy. According to the USFWS staff member on the Restudy Team responsible for endangered species coordination, the recommended plan does not endanger the continued survival of the Cape Sable seaside sparrow and *will* provide sufficient nesting habitat to significantly improve the sparrow's chances for survival and recovery. Furthermore, the Cape Sable seaside sparrow nesting cycle is not 80 days but rather is 40-50 days.

N.2.4 NEPA / Compliance with WRDA

292. The main report includes insufficient information regarding Lake Istokpoga, environmental issues on the lake, and current restoration efforts. Maps of the project area do not include approximately 300 square miles of the Kissimmee River watershed in Highlands and Polk Counties that is on the Highlands Ridge.

Response: Due to the desire to explain the existing conditions of the study area in a brief and concise manner, and concentrate on those resources "ripe" for discussion, many details were remanded to the appendices. During the preparation of the draft report, there were no project features proposed for the Lake Istokpoga, Lake Wales Ridge area, therefore under NEPA there was no need to discuss existing conditions for an area not expected to be affected. The draft Fish and Wildlife Coordination Act Report, part of the overall draft Integrated Feasibility Report and Programmatic EIS, and required as a part of the coordination process under the Fish and Wildlife Coordination Act of 1959, describes in detail the Lake Istokpoga existing conditions (reference Annex A).

293. The draft report failed to include the Lake Wales Ridge in project maps.

Response: There were no project features proposed for this area in the draft report. The Lake Istokpoga Regulation Schedule, incorporated in the recommended plan as an Other Project Element since coordination of the draft, is addressed in the comment/response above. The resource issues mentioned in this comment will be considered as a part of this report, and future individual project implementation reports, although not reproduced in the main report.

294. The Upper St. Johns River was specifically excluded from the study.

Response: Yes. The St. Johns River is outside of the Central and Southern Florida project boundary, is part of a separate watershed, and is hence, outside of the Restudy study area. Moreover, issues associated with the Upper St. Johns River are currently being addressed in a separate feasibility study.

295. Localized adverse effects are all north of Lake Okeechobee, while the "overall benefit to the regional system" occurs south and east of the lake. Were cumulative effects quantified? Or merely discounted?

Response: Not all localized adverse effects occur north of Lake Okeechobee. The report cites that there are expected to be localized adverse effects throughout the system in order to achieve an overall, system-wide restoration. Most of the benefits of the proposed plan do occur from Lake Okeechobee southwards and east of the lake. Benefits are also expected to occur west of Lake Okeechobee, within the Caloosahatchee River Basin and estuary and within the northern Big Cypress Basin. The Kissimmee River watershed is currently being addressed by the Kissimmee River Restoration project that is ongoing. A Lake Istokpoga Regulation Schedule study has recently been included within the Restudy as an OPE. An assessment of cumulative impacts to the study area is required in the draft EIS by NEPA, and was not "discounted". The total area expected to be impacted by construction of reservoirs and STAs was quantified and is cited in the report. A qualitative assessment of cumulative impacts was done for each of the physiographic sub-regions, although no quantitative cumulative impact assessment was done, nor any reliable methodology known to be available at this time for a study area of this magnitude.

296. It is recommended that location specific NEPA review be conducted prior to land acquisition and Restudy component installation.

Response: Given the size and complexity of the Comprehensive Plan, by necessity the plan will be divided into smaller projects for implementation. Refer to the Implementation Plan, Section 10 of the Final Integrated Feasibility Report and Programmatic Environmental Impact Study for details on the plan and need for location specific NEPA review as the components are implemented.

297. EPA believes that it is imperative that water quality be fully (if not equally) addressed in the Restudy together with water quantity. EPA is pleased that inputs (Appendix H, pg. H-2) were wholly incorporated into the Draft PEIS as follows:

Water quality concerns have been identified for several of these (water quality) parameters (listed in Draft PEIS). Accordingly, both water quantity and water quality actions will be fully considered in the hydrologic restoration of south Florida via the Restudy PEIS.

EPA requests that the above paragraph be included in the main document of the Final PEIS for emphasis.

Response: Concur. The paragraph has been added to the Final PEIS.

Note: The Corps, as lead agency, for the preparation, editing and publication of the Draft and Final PEIS, is charged with decision making over the data, information, and written text submitted by Cooperating Agencies, including EPA. In editing the report, the Corps tries to determine what information is most relevant, adds substantive information and value to the decision maker. In addition, NEPA guidance is explicit in instructing the preparer to write clearly, concisely, and in terms the average reader can understand. In that light, the Corps judiciously edited inputs to the main report received from its partner agencies, in an attempt to make the document easy to read and understand, while providing a complete comprehensive “story” of the project planning process to date.

298. Because the air quality section in the main volume is very brief, a reference to appended detailed information (Appendix I) is critical and should be added in the Final PEIS.

Response: In reference to Section 3.0, paragraph 5 of Draft PEIS, there are references to both Appendix H (water quality) and Appendix I (air quality) in the main report. A further reference to Appendix I was added to Section 3.3, air quality existing conditions for emphasis.

299. For the environmental effects information submitted, it appears that the air quality section was drastically reduced to a one-paragraph summary in the main document. Again, the summary in the main document did not reference that detailed information was appended as Attachment D of Appendix I.

Response: It was generally agreed in coordination between the Corps and EPA, that there would be no effects to existing air quality due to the array of alternatives presented in the C&SF Restudy. According to NEPA guidelines, preparation of an EIS should address issues at a level of detail commensurate with the anticipated significance of the impact on the human and natural environment. Therefore, the detailed information regarding air quality received from EPA was edited and reduced for the main document to reflect the anticipated lack of significant impacts, and incorporated by reference the air quality appendix. In Section 8.0, paragraph 2, Appendix I is so referenced in the Draft PEIS. Reference has also been incorporated in Section 8.4, air quality for the Final PEIS.

300. A point of contact for NEPA comments should have been provided on page i. For an extensive document such as the Restudy Draft PEIS (nine volumes), EPA concurs with the extension of the public review time to well beyond the NEPA set minimum of 45 days. Greater use of conventional NEPA language in the draft PEIS would have been preferred.

Response: A point of contact was provided on page i. of the draft report. It is generally the Corps policy not to include two points of contact for one document, as it tends to confuse the public. Comment noted regarding review period. This is not a “conventional” study, therefore extraordinary language, outside of the traditional NEPA framework was appropriate.

301. The C&SF Project Comprehensive Review Study, Feasibility Report and draft Programmatic Environmental Impact Statement does not consider the “unconstrained alternative” as required under the National Environmental Policy Act (NEPA). This alternative would provide the basis for evaluating restoration system integrity for comparison to other alternatives and enhancement. Include an analysis of secondary and cumulative impacts of the recommended plan.

Response: The National Environmental Policy Act does not require the consideration or evaluation of an “unconstrained alternative”. However, NEPA does require an evaluation of alternatives that fulfill the objectives and goals of the study, plus the “no action alternative” or the without plan condition. The “no action alternative” for this study is defined as the 2050 condition, the condition one would assume to be in place if none of the Restudy’s alternative plans are implemented. Refer to Section 4, Future Without Plan Condition, of this Final Integrated Feasibility Report and Programmatic Environmental Impact Statement for a description of this condition. The without plan condition provides the basis for evaluating other alternative plans. The difference between the without plan condition and an alternative plan’s condition are the effects or impacts resulting from that plan. The formulation of alternative plans is described fully in Section 7, Formulation and Evaluation of Alternatives. Secondary and cumulative effects were assessed for each physiographic region throughout the study area and were presented in Appendix K, as well as Section 8 of the main report.

302. There is unequal consideration given to upland wildlife as opposed to wetland-dependent species in the Draft PEIS. Section 8 should be revised to include more upland wildlife issues, particularly as they relate to impacts associated with construction of water storage reservoirs.

Response: Section 8 of the draft report was revised with a view to providing more balance to upland and wetlands issues and addressing more fully those upland habitat issues of concern. Note: The C&SF Restudy is by and large a proposed plan for restoring wetland ecosystems and the native plant and animal life that once thrived there. The Restudy also proposes to provide a sustainable water supply to agriculture and urban users, flood protection, and water based recreation within natural areas. Although upland species are important components of these ecosystems, and potential impacts to upland habitat were discussed in the draft report, most discussion in the draft report focused on water resources and restoration of desirable volume, timing, distribution, and quality of fresh water flows.

303. In reference to page 3-1, the statement “the Big Cypress region is less impacted by human activities and is in relatively good condition as an ecosystem”, does not adequately account for major man caused disturbances such as logging, oil and gas exploration, residential development, recreational uses, and agriculture.

Response: The above statement, as presented, is somewhat out of context. It actually read as “In contrast (to the Everglades), the Big Cypress regions is less impacted”. This statement is true and not misleading. The point regarding long-term impacts of human activities, and growth and associated development increasingly impacting the region is well taken. The referenced statement has been enhanced to include these concerns.

304. NEPA requires the Corps to fully analyze and disclose in the Final PEIS how the proposed action would result in increases in criteria and hazardous air pollutants. In addition, the Corps should disclose alternatives to the proposed action that would address restoration goals without increasing air pollutants that would result from the doubling of human population.

Response: Air quality concerns related to the recommended Comprehensive Plan were fully and appropriately assessed by the U.S. Environmental Protection Agency, Air Quality Division, a Cooperating Federal Agency under NEPA on the Restudy. The Environmental Protection Agency determined, with Corps concurrence, that there were no significant impacts to air quality as a result of the implementation of the recommended Comprehensive Plan relative to the without plan (2050 Base) condition, which is our basis of comparison of alternatives. The results of the air quality assessment are available in detail in Appendix I.

305. The Comprehensive Plan facilitates future population growth, therefore the Final Integrated Feasibility Report and Programmatic Environmental Impact Statement should consider the direct, indirect and cumulative effects of such growth, as required under the National Environmental Policy Act.

Response: The Comprehensive Plan does not facilitate future population growth within the 16 county area covered by the Restudy. Future population estimates were projected by the Bureau of Economic and Business Research, University of Florida, State of Florida (BEBR) and the U.S. Department of Commerce for use in establishing the “Future Without” condition (refer to Section 4 of the Final Integrated Feasibility Report and Programmatic Environmental Impact Statement for a detailed description of this condition). The future population estimates are then used to project future urban and agricultural water supply demands. Knowing these demands it would be irresponsible if the Comprehensive Plan did not moderate the projected impacts on this resource.

306. Extend the comment period for the Restudy due to the voluminous text and the holiday season.

Response: Although the concern is understandable, the comment period is longer than required under the NEPA process. The expedited schedule imposed by WRDA 96 to submit the report to Congress by July 1, 1999 did not allow an extension beyond December 31, 1998.

307. The Restudy is not consistent with the intent of the Water Resources Development Act of 1992 and 1996 which authorized the Restudy and appears to have changed its course since the Reconnaissance Study.

Response: The purpose of the Restudy is to review how well the C&SF Project is functioning and determine what modifications may be needed to achieve a new set of objectives. The precursor to the feasibility phase of the Restudy -- the reconnaissance study -- identified a set of regional-scale planning objectives based on the work conducted by the Science Sub-Group of the South Florida Ecosystem Restoration Working Group as well as input form the public. The Governor’s Commission for a Sustainable South Florida also developed a set of regional-scale objectives for the Restudy. A synthesis of these has resulted in an inclusive set of objectives to achieve two general goals for south Florida’s ecosystem: enhance ecological and economic values and social well being.

The Restudy planning objectives were developed as the result of public participation and scientific knowledge of south Florida. Through workshops conducted during the reconnaissance phase of the Restudy, it is evident that the C&SF Project must continue to provide valuable services to developed areas as originally intended. Therefore, many of the economic and social objectives are similar to those of the original C&SF Project. However, unlike the original project purposes of the C&SF Project, the Restudy includes objectives that recognize the importance of the natural system in achieving sustainability of the region.

308. The definition of the South Florida Ecosystem should be consistent with that in WRDA 96 and that used by the South Florida Ecosystem Restoration Task Force.

Response: The south Florida ecosystem as discussed in the Restudy coincides with the 16 county region of the South Florida Water Management District. These 16 counties contain the most significant structures of the 18 county region identified by the original C&SF Flood Control Project.

309. Ecosystem enhancement is not Everglades restoration and does not meet the stated goals of restoration required under WRDA.

Response: Recognizably, the Restudy is not a perfect plan and will not please every concerned individual and stakeholder. The Restudy is a solid, feasible plan that meets the objectives established by WRDA 96. The plan process fully involved state, local and Federal governmental representatives; concerned individuals; citizen groups and stakeholders in the component development and evaluation and preferred alternative selection. Widespread distribution of developmental information and continued public involvement in the Restudy process are objectives that have far exceeded statutory requirements for a study of this nature. The Restudy is fully committed to achieving the best plan possible within the constraints imposed and will continue to improve the plan as it moves forward through the authorization, feasibility study, pilot project and design and construction phases.

N.2.5 Socio-Economics

310. It is not accurate to state that agricultural encroachment has taken place in the floodplain in the areas east of the levee (pg. E-117). The area is flat, sits on top of an extremely porous aquifer and water management in the area is ground water driven. The area has not received a floodplain designation from any governmental entity.

Response: A floodplain designation has not been established for the area. Although the area is flat and sits on top of an extremely porous aquifer, ground water hydrology does affect the types and locations of agricultural production. The primary project purpose of the South Dade Conveyance System is to provide flood protection to the south Miami-Dade County area. One effect of project implementation was to reduce flood risk to the agricultural area by channel improvements and establishing authorized water levels in the canal system. Shortly after implementation of the project, authorized stages were reduced in the canal system to benefit the farming community. During this period, increased agricultural production has occurred in the area due to the reasons sited in the Economic Appendix. Agriculture has not *encroached* upon wetlands in a traditional sense. Nevertheless, additional agricultural development is damage-susceptible given that the current canal water levels are now higher because of increased deliveries to Everglades National Park. The higher stages during the winter months can adversely affect truck crops, and root zones of fruit trees can be affected year around. It is this increased agricultural production with its consequent resulting damage susceptibility that is referred to as encroachment in the report. Section E.6.5.2.2.6 will be revised to generally substitute the phrase “increased agricultural production” for “agricultural encroachment”. This should clarify the fact that agriculture has not encroached upon wetlands in a traditional sense.

311. The original design of the C&SF System was such that the northern (approximately) third of the EAA discharged into Lake Okeechobee. When the Interim Action Plan (IAP) went into effect, the stormwater that was designed to go to the lake was diverted south, affecting the ability of the EAA canals to protect the adjacent farmland. Section E.6.5.2.2.13 (pp. E-119-120) should state that the IAP reduced the original flood protection level of service provided by the original C&SF design. It is not possible to determine with the SFWMM if the recommended plan components have improved this situation.

Response: The recommended plan will reduce flooding problems in the EAA relative to what they would be without the plan. The SFWMM is not the appropriate tool to analyze these effects in detail.

312. The derivation of the tables in the “Beneficially Affected Areas” section is unclear. According to the text, the same information as the “adversely affected areas” was used to generate a list of beneficially affected areas. In many cases, the same nodes show up as both adversely affected and beneficially affected. More information, in general, about how the flood control benefits and adverse impacts were calculated is essential.

Response: The methodology for determining which areas are adversely impacted is discussed on page E-124 of the appendix and illustrated in the tables that follow. The methodology for determining which areas are beneficially affected is discussed on page E-157 but the tables that describe the process are abbreviated. The determination of problem areas that might be beneficially affected use the same methodology as the determination of problem areas that might be adversely impacted. Tables 6.6.2.1-2, 6.6.2.1-3, 6.6.2.1-4, and 6.6.2.1-5 in Appendix E display increases and decreases in depth expected with alternatives A, B, C, D, and D13R for May and October compared to the 1995 and 2050 bases. Flood depth increases recorded in these tables indicate potentially adversely affected areas; flood depth decreases indicate potential beneficial affected areas.

Table 6.6.2.1-6 and Table 6.6.2.1-7 are also used to determine possible adverse affects that could occur during months other than May and October of the year. As stated in the appendix, a potential adversely affected area was defined as an area where the peak stage difference was at least 0.25 feet higher for an alternative than the appropriate base condition for more than 0.0% of the years. Beneficial affects were attributed to an area where the peak stage difference for an alternative was at least 0.50 feet less than the appropriate base condition for more than 0.0% of the years. Using this approach, many of the same nodes show up as both adversely affected and beneficially affected. This is to be expected since there are beneficial and adverse affects that occur under the recommended plan to the same areas at different times of the year or in different years of the period of analysis (1995, 2050).

As noted above, the discussion of beneficial and adverse affects is limited to the areas designated as problem areas. It should also be noted that additional areas that do not have existing problems may also be beneficially or adversely affected by alternatives to the extent flood problems may be created or alleviated. The identification of these areas, though, is beyond the scope of the models used for the Restudy.

313. Encourage appropriate development, and discourage western sprawl, but with care to address minority concerns of gentrification, displacement, and contamination.

Response: Land use planning is largely a matter of local government planning, and wise planning is encouraged in support of, and consistent with, a healthy Everglades south Florida ecosystem. Such planning should include concerns about particular impacts on any one group, especially minorities.

314. A more accurate depiction of where future populations will be located is desirable. A table should be included in the report with details for all of the study area counties concerning county comprehensive plan dates of adoption and revisions and the exact year land use data stems from.

Response: Concur that details concerning population location will be important as plan implementation takes place gradually through time. Such details are beyond the scope of the Restudy. The Comprehensive Plan's focus is on developing and recommending a framework for improving the ecosystem and other water resource needs in south Florida. Such a table would provide interesting information, but is more pertinent to a land use planning document.

315. Worker retraining should be part of the plan for dislocated workers. There must be a preferential hiring program for dislocated workers via clauses in all publicly awarded contracts. The socio-economic part of the report must include provisions to minimize impacts on working families.

Response: Populations at risk have been profiled in Section 12 of Appendix E, “Other Social Effects”. During detailed implementation of the recommended plan, facilities will be sited with care regarding low income, minority and other at-risk populations. Undue impacts on any particular group or individual will be minimized, as a part of compliance with laws and regulations, to include Executive Order 12898 (Environmental Justice).

316. Hendry County population estimates are too low, and should be revised upward.

Response: Population estimates for larger areas tend to be more reliable than for smaller parts of the total; the Restudy is no exception. These observations about Hendry County represent perhaps a case in point. The main purpose of the population projection estimates is to generally describe the economy and demography of the study area, and to assist in estimating municipal and industrial water use in the service areas covered by the South Florida Water Management Model. For purposes of evaluation of large scale planning concepts in this study, adjusting Hendry County estimates due to the cited observations will not likely materially affect regional water demand results enough to alter conclusions and recommendations. Reasonable consistency in estimating study area population 50 years into the future required adherence for the most part to the comprehensive statewide Bureau of Business and Economic Research and U.S. Department of Commerce projections. It will be necessary to adjust this plan as more improved and detailed knowledge during the implementation process, expected to take place over many years, becomes known. Adjustments to relevant planning parameters to the extent affected by departures from the report’s estimates of population can and should be made as necessary in the future. This will be acknowledged in the final report, to include the point that Hendry County’s population estimates could be understated.

317. Water supply needs for Southwest Florida agriculture should be examined.

Response: Caloosahatchee Basin agricultural water demands have been accounted for. Water needs outside the current C&SF project area will be considered in a separate study for Southwest Florida. This will be the proper place to comprehensively address the rest of these Southwest Florida water supply issues.

318. Local economic impacts are callously disregarded in Restudy, and payment-in-lieu-of taxes programs should be addressed to assist Hendry County in counteracting the detrimental impact of taking productive agricultural lands from the tax roll.

Response: Local economic impacts are important, and can be significant for some communities. Economic impact evaluation was limited to the study area on a region-wide scale, about which more could be said with certainty than for individual small areas such as counties. Nevertheless, the recommended plan does acknowledge the potential for significant impacts, especially in the case of small rural communities that are dependent on agriculture for their prosperity, when large amounts of farm land are converted to a reservoir (Section E.12.2). The complexity and uncertainty involved in calculating detailed effects on a county by county basis is such at this level of analysis that it fell outside the scope of this study. Consideration of specific programs such as payment-in-lieu-of taxes has not been a part of this aspect of the Restudy's planning process, but can be incorporated into detailed implementation of specific plan features and components when that activity takes place.

319. Why must livelihoods and daily lives be utterly destroyed for this project? No amount of money can buy lives and homes.

Response: Adverse impacts will be minimized wherever possible.

320. Why don't we deal with the number one reason why things got this way in the first place – i.e., the ultimate exotic invasive species, humankind? We must begin the dialogue of how to control the growth of our human population.

Response: Growth management is not a Restudy issue. The impact of humans on the natural system is important. There is a linkage between anthropogenic stressors and ecological values. A major responsibility and authority of the Corps is with regard to the control and movement of water in the C&SF Project, not population control. The goal of the Comprehensive Plan is to find ways to adjust the functioning of that system to satisfy the public's desire for water for the Everglades ecosystem and for urban and agricultural activities.

321. There's not enough detail to make an informed decision. The plan is too conceptual.

Response: This is a regional scale study, and there is enough detail to make informed decisions at this level.

322. Population projections are too low, and there should be more focus on regulatory approaches, rather than just conservation effects on demand. Users should operate within their own resources, rather than importing additional hydrological resources from elsewhere.

Response: The population projections are adequate for purposes of the regional system issues that the Restudy addresses. Restudy population projections represent a middle ground approach. A number of alternative scenarios for future population and future water consumption were considered, and the future scenario for the Restudy rests in the middle. Unrealistically high or low projections can encourage inappropriately sized project feature recommendations. There is not a one to one proportional correspondence between projected population and recommended project components. The region wide management of water resources has been in place for many years and helps to dampen what would otherwise be significant impacts of too much water in one locality and not enough in another at different points in time. This has been an efficient system; the recommended plan continues this approach. The new water that will be made available for future users would in the absence of this plan be lost to tide, as it is now. The alternative of no action would result in an Everglades ecosystem that would be inferior and not likely sustainable. Part of the monitoring of the system's performance over time will include a monitoring of actual growth in population and its consequent use of water, which will account for any significant departure that may be necessary from the comprehensive plan.

323. It is particularly curious that Glades and Hendry Counties have such low projected populations, and are the locations of large storage lakes are to be built.

Response: These two counties were not singled out and targeted for low growth in the Restudy. Their projections are part of a regional scale estimate of future growth trends. One of the reasons for Corps policy and practice of using a large area (State BEBR, US Department of Commerce) system of internally consistent projections is to avoid bias. Departure from such area wide projections would be ignoring official estimates that take into account state and national control totals. It is important to recognize that the large scale conceptual plan, even though it includes suggestions for specific detailed components, will certainly of necessity be subject to changes over the many years during which implementation is expected to take place.

324. The economic impact of reservoirs proposed for Glades, Hendry, Lee, and Collier Counties is discounted as a local problem (p.E-329).

Response: The discussion in Section E.13.4., titled "Regional Economic Effects," states that these features, if constructed, could eliminate jobs and have adverse effects on local communities and economies. It also states that the detailed locations of such features are not known yet, and that a more detailed assessment of the vulnerability of such communities to the project would be possible when such details become known. While it is true that such effects would likely be localized, this acknowledgment does not equate to discounting such effects as being insignificant.

325. There is a startling lack of empathy for localized collateral community economic and social impact damage, and that there is no component to help the local economy recover or even be stable during the construction effort.

Response: Impacts to the local economies are important, and there is great empathy for those who might feel they will be negatively affected. Such impacts could in certain areas be significant, but they may not be. Negative impacts will be avoided as much as possible.

326. The Restudy report doesn't include specific details regarding Seminole Tribe expectations for economic development in the Fisheating Creek Basin.

Response: All localized negative impacts are important and will be either avoided or minimized. The resolution of the economic impact estimating model and methodology is not at a level of detail that would explicitly include this specific concern.

327. A socioeconomic impact study of the local, regional, and State levels must be conducted by a consortium of State university faculty.

Response: Concur that such a study would be a valuable contribution to the body of knowledge about this issue.

328. We are willing to work with you for the betterment of all concerned, but we are very concerned about the potentially significant economic and physical impact to our citizens and our government.

Response: The impacts to Glades County's people, government, and economy are important. Any negative effects will be minimized to the greatest possible extent.

329. The Restudy plan is heavily weighed in favor of environmental restoration, and should be more balanced, as directed by the original authorization and as restated in WRDA 96. The Corps' economic analysis estimated only 6% of the benefits are attributable to M&I water supply and only 1% to agricultural water supply, and that the remaining 93% are undefined.

Response: The Comprehensive Plan is a balanced plan. Almost if not virtually all water using sectors will have more water with the plan than without the plan. Disagree with the comment about the percentage figures cited; they are incorrect, or at the least misleading. The estimated annual costs in the draft report are $402 million, and the estimated annual M&I water supply benefits are $27.2 million, or about 6.8% of the costs, not 6% of the total benefits, as the comment states. Similarly, the annual agricultural water supply benefit estimate is about $1.9 million, or about ½ % of the costs, not of the total benefits. The total benefits are not all quantified, for reasons discussed in the report. There are likely to be significant other "non-environmental" benefits, especially for fishing and recreation. There has been no attempt to express the natural system environmental benefits per se in economic dollar values.

Disagree with the premise that this project favors the environment vs. the economy in a way that is out of balance. There can be no meaningful separation of the intrinsic value of environmental restoration from benefits associated with other water management needs. A healthy and functioning natural system is the very infrastructure upon which the economic system is built, within which it functions, and upon which it absolutely depends. The economic system and all of its water management needs do not exist separate from the environmental system whose health the Restudy will improve with this plan; they exist *in* the environment. Spending on fishing and recreation activity (including tourism and eco-tourism) in the region is in the hundreds of millions of dollars per year. Agricultural production exceeds $4 billion annually. Total sales in the study area exceed $200 billion per year. All participants in this economic and social environment deserve a clean, healthy natural environment, without which the qualitative and quantitative aspects of the economy and society of south Florida would be endangered.

330. Acceptance of future growth and development should be conditional on the sustainability of environmental systems to accommodate such growth. Just because a current rate equates to some future figure does not mean that is the smartest number to plan for or that it is inevitable.

Response: Growth has an important bearing on ecosystem sustainability. Planning for the most likely future growth is a realistic position that the Restudy has taken. The future projection figures do not equate to current growth rates. Study area population growth projections are characterized by significantly declining growth rates throughout the period of analysis used in the Restudy.

331. Water conservation is an extremely important component of a successfully implemented Restudy plan. Serving unlimited water supplies to unlimited growth must not be a guarantee. It should be the firm resolve of the Corps and the SFWMD to not divert water from the natural system in the future, to the detriment of that natural system, to serve whatever needs arise in the future. Otherwise we will wind up right back where we are, and all this planning will have been for naught.

Response: Concur. All stakeholders have to work together to achieve a sustainable partnership between the needs of a sustainable natural system and the needs of the economy which ultimately depends on the natural system for its very survival.

332. Economic development and water supply will not survive the continued destruction of the Everglades.

Response: Concur. The Restudy plans to reverse the destructive decline in the ecological values of the Everglades system, which will benefit the health of the natural system itself, as well as the health of the economy and its water supply.

333. Population projections should be done in concert with land use analysis, considering zoning and alternative future buildout scenarios. The construction of ASR facilities could wind up being the fuel to fire further future population growth. There should be an entire section devoted to the interrelation of population, landuse, and ecosystem functions. Such information and analysis would be critical for guiding land use acquisition, and for mitigating the effects of population growth.

Response: The Restudy has not followed the analytical procedures suggested with regard to population analysis. The Restudy recommended plan is designed to allow for shifts as implementation proceeds over the many years necessary. One of the issues of ongoing review and adjustment will be population growth – where and how it will in fact be taking place, compared with the general growth scenario used in the Restudy. A most likely middle ground future growth scenario has been considered, based on a state and national control total growth concept. With such a process, the danger of basing regional projections on detailed micro-area analysis is avoided, which can result in the individual parts adding up to more than the total could realistically be. Detailed small area resolution of future growth estimates would have been inconsistent with the regional scale of the hydrologic modeling tool (the South Florida Water Management Model) whose outputs provided the basis for most of the Restudy recommendations. Population projections used in the Restudy are generally characterized by a continued decline in growth rates over time.

334. Population figures should include a projection of where the populations are locating, to aid in appropriate siting and sizing of water storage areas.

Response: The Restudy has chosen to keep the officially reported projection estimates general at the region wide level. Appropriate sizing and siting of storage areas are some of the many implementation details that will necessarily take place throughout the many years of project implementation. Population location is one consideration that will be considered; others will include site suitability, willing sellers of available land and its price.

335. Using the most current local government comprehensive plans, vested development approvals, and future buildout plans, would help to provide a more accurate depiction of where populations are moving.

Response: At this level of detail, the Restudy did not make micro-area-specific projections. Such considerations will be important in the decisions to be made during project implementation. Local government comprehensive plans are generally consistent with the State of Florida Bureau of Economic and Business Research projections, which were used.

336. Were any water supply uses not included in the IWR-Main modeling? If so, how do they affect the findings?

Response: Yes, there were some water uses not covered by IWR-MAIN. IWR-MAIN was used to estimate municipal and industrial water use. This covers commercial, residential, industrial, public, etc., both through utilities and self-supplied by user wells. It covers all of this but the estimates do not identify supply source (user-owned wells vs. utility supplied); they only focus on demand (consumption/use). IWR-MAIN estimated use was by service area, which was disaggregated into well-specific withdrawals, necessary for input into the SFWMM. As a part of this process, there were some adjustments to account for water estimated to be withdrawn from the Floridan aquifer for reverse osmosis (RO) treatment. There were some other similar minor adjustments, in order to make the input for the SFWMM make sense.

IWR-MAIN does not include agricultural use or environmental deliveries. IWR-MAIN estimates were developed to be used as one of the inputs necessary for running the SFWMM. It represents part of the water use "pie."

337. The Restudy report should mention some of the state-managed lands that are used for recreation that are managed by the FGFWFC.

Response: This concern was addressed by adding mention of the Lake Harbor Waterfowl Area and Terrytown (both in the EAA), Rocky Glades WEA, and the Everglades Management Area to Section E.8.2, Recreation Resources, in Appendix E, including the recognition that they also comprise significant recreational resources. Text was also added to direct the reader to seek additional information in the F&W Coordination Act Report, which can be found in the Restudy document in Section A2 of Annex A.

338. The Restudy geographic scope includes the entire SFWMD managed watershed, but the report discussion (Section E.8.2) seems to focus only on Everglades-related recreation.

Response: The study area includes areas that are not part of the Everglades, such as the Kissimmee River basin. The focus, though, tended to concentrate on the areas that most likely will be affected by the ecosystem restoration actions of the Restudy.

339. The Restudy (Section E.8.2) focuses on five main areas for Everglades-related recreation. Why wasn’t the Everglades WMA (WCAs 2 and 3) included?

Response: The five principal areas were selected on the basis of geographic area, designation as nationally significant (i.e., National Park), and available information on visitation. Based upon what could be determined, the Everglades Wildlife Management Area is relatively difficult to access and is not a magnet for state, national, and international visitors to the extent of the five selected areas. Mention of this resource was added to the discussion.

340. Catfish should not be considered by-catch since it is commercially fished in Lake Okeechobee. Bullhead, shad, and gar are technically not by-catch either (in the sense that they are thrown away) since they are sold as crab bait.

Response: In Section E.9.2.1.1 of the report, it is stated that the haul seiners are trying to catch bream when they catch the by-catch. It is recognized that the catfish have some commercial value and could therefore be included with target species. The use of the word “by-catch” is from a 1990 GFWFC paper entitled “Use of a Subsidy to Compensate Commercial Haul Seine Fishermen for By-Catch of Nongame Species in Lake Okeechobee”. The term “incidental” will be used instead of “by-catch.” This sentence will be followed by: “Some of the incidental catch is sold as crab bait and some is given away.”

341. It is hard to believe that only 27% of the visitors that were engaged in recreation on Lake Okeechobee were involved in fishing. This seems inconsistent with our Okeechobee Division of Fisheries staff.

Response: The 27% figure is cited in the document as having come from the Corps’ Natural Resource Management System (NRMS). Since the NRMS information is collected for the entire project, which includes visitation to the St. Lucie and Caloosahatchee rivers, the percentage of fishermen may seem small. But the absolute number of fishermen identified by the NRMS (27% x total visitors) still suggests a significant recreational fishery.

342. Recreational fishing, unlike commercial fishing, is very sensitive to hydrologic changes due to the structural complexity of the vegetation of the spawning grounds.

Response: According to personnel in the GFWFC Division of Fisheries field office in Okeechobee, recreational fishing is also not extraordinarily sensitive to low water, and fishermen can wade from shore rather than fish from their boats, the changes in vegetation of the spawning grounds notwithstanding.

343. Not enough emphasis on snorkeling and diving as economic impact activities.

Response: As discussed on page E-185 of the draft report (Section E.8.1) in the paragraph beginning with “This chapter is concerned with…”, this section focuses on landside Everglades-related recreation, which includes recreation on Lake Okeechobee. However, the subject of snorkeling and diving is also mentioned as part of the description of Biscayne National Park in Section E-8.2. Snorkeling and diving are addressed in Section 9 (Recreational and Commercial Fishing). The prominence of these subjects was expanded in the final report.

344. It is confusing in the discussion on p. E-185 of the draft report that the chapter supposedly deals with land-based recreation, but then goes on to include fishing, swimming, and boating, and defines Lake Okeechobee as a principal recreation area.

Response: Most of the visitors to the lake engage in passive recreational activities (e.g., sightseeing, picnicking, etc), which are often related to visiting the Everglades. For this reason, lake-related recreation was split between Section 8 (Recreation) and Section 9 (Recreational and Commercial Fishing).

345. Florida Keys National Marine Sanctuary should be included as one of the principal south Florida recreation areas.

Response: The FKNMS was not included as a "principal recreation area" because its visitation levels and relationship to the Everglades does not push it into the top category of "principal".

N.2.6 Real Estate

346. Should condemnation procedures be necessary, federal rather than state condemnation processes should be used.

Response: Acquisition of lands required for the implementation of the C&SF Restudy will be based on further study. The lands required will be identified as future Project Implementation Reports are completed. The C&SF Project is a cost shared local cooperation project and as such it is the responsibility of the non-Federal Project sponsor, the South Florida Water Management District, to acquire all lands, and interests in land required for the Project. While it is the intention of both the U.S. Army Corps of Engineers and the South Florida Water Management District to acquire lands from willing sellers, if condemnation of lands becomes necessary, the condemnation action would normally be handled by the non-Federal sponsor.

347. Acquire all lands in the park expansion boundary and all land within the 8.5 Square Mile Area to ensure full ecological and hydrologic restoration of the ENP and Florida Bay. The C&SF Restudy should maximize the utilization of the 8.5 Square Mile Area in restoring flows to ENP.

Response: For purposes of the Restudy Comprehensive Plan, it has been assumed that acquisition of all lands within the Everglades National Park Expansion boundary had been accomplished prior to implementation of plan components. The acquisition of lands within the Everglades National Park Expansion boundary is the responsibility of the National Park Service, Department of Interior. Acquisition of all lands within the 8.5 Square Mile Area was approved by the Governing Board of the South Florida Water Management District in November 1998. The 8.5 Square Mile Area will become a part of the Modified Water Deliveries to the Everglades National Park Project as the locally preferred option, after approval of a Post Authorization Change. The South Florida Water Management District has begun acquisition of portions of the 8.5 Square Mile Area. The Governing Board approved this project subject to a firm financial commitment from the Federal government and Miami-Dade County to cost share this project.

348. Acquire the Model lands and other southern lands designated under EEL and other acquisition programs (i.e.: areas between Everglades and Biscayne National Parks) for conservation purposes.

Response: Acquisition of the Model Lands and other southern lands designated under EEL and other acquisition programs is ongoing by the South Florida Water Management District and Miami-Dade County under state and local land acquisition programs. Portions of these lands may be required for the C&SF Restudy.

349. Accelerate the acquisition of all lands within the WPA footprint to restore hydrologic functions in the Everglades system.

Response: Acquisition of lands from willing sellers within portions of the lands required for the Water Preserve Areas by the South Florida Water Management District has been ongoing for some time and will continue as state or other funding is available. However, under current Corps procedures, until the Comprehensive Plan is approved by Congress, a separate Project Implementation Report is completed and approved, and a Project Cooperation Agreement executed, land acquisition will continue under state land acquisition programs or with funding provided through other sources.

350. Ensure that quarry pits, as they are mined-out, become public property at no additional cost to the public.

Response: Until the Comprehensive Plan is approved by Congress, and a Project Implementation Report is completed and approved, and a Project Cooperation Agreement is executed, land acquisition will accomplished under state land acquisition programs. Acquisition of these mined out quarry pits would be at appraised fair market value as required by law.

351. Acquisition of the lands within the north and central lake belt storage areas involved difficult issues and may delay implementation if issues related to acquisition of these lands cannot be resolved.

Response: Lands required for the North Lake Belt Storage Area and Central Lake Belt Storage Area will be among the last project lands required and these will be among the last components constructed. As described in the Implementation Plan, it is proposed that Phase I lands would be required in 2015 and Phase II lands in 2031. This would allow private landowners a sufficient period to mine and remove the minerals, limestone, rock, sand, etc. The period of time for the removal of the materials will be dependent on when the lands are required for construction of the storage areas.

352. Approval of the plan will cause a loss of private property rights and bypasses elected officials.

Response: Private property will be required to complete construction of Restudy project; however, it is the intent, where practicable to purchase required lands from willing sellers. Approval of the plan will be by Congress and the Florida Legislature. Affected residents, businesses and landowners will continue to be informed of project developments, and provided opportunities to provide input to project design and implementation. The Corps and the SFWMD will continue to evaluate project designs to minimize real estate needs, and work with affected residents and land owners to arrive at mutually acceptable solutions. In any event, Federal laws and regulations require that property owners be paid fair market value, any severance damages, and allowable relocation assistance payments. Further, mitigation of effects on real estate will be developed in accordance with the requirements of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as Amended.

353. The Real Estate acquisition cost for Component FF4 (construction of S-356 A&B structures in Miami-Dade County) seriously underestimated the worth of the land with three miles of major highway frontage and does not account for land and building improvements or equipment.

Response: Land acquisition costs were estimated based on available information and data obtained from various sources. A gross appraisal of the land was not completed, but will be accomplished at the time a Project Implementation Report is processed. At that time, more detailed information would be obtained regarding the building improvements, equipment, and land values in the area. Lands required for the construction of the S-356 A&B structures in Miami-Dade County are projected to be acquired by 2005. On only a portion (approximately 1,082 acres) would the landowner be allowed to retain the rights to extract the minerals and limestone. However, the landowner would be given a specified period of time after the lands were acquired and the component constructed in which to mine and remove the minerals, limestone, rock, sand, etc. This period of time for extraction of the minerals and limestone has not been determined and would be factored into the ultimate land valuation.

354. All land purchases must be justified based on engineering, science, and socioeconomic impact for each specific project. The 3.2 million acres of public lands should be utilized as the first alternative in any project or part of a project before private lands are considered, which would bring down the costs of project implementation. The acquisition of 248,000 acre of private land should be a last resort alternative.

Response: All land purchases will be justified based on engineering, science, and socioeconomic impact for each specific project occurring during preparation of the Project Implementation Reports. The use of the public lands was considered during the planning process and use of these lands was determined not to be feasible, and inconsistent with study goals.

355. Undertake land acquisition efforts on a willing seller basis and only using Florida's state eminent domain procedures, if necessary. Projects should be completed on a whole as funds are available.

Response: The C&SF Project is a cost shared local cooperation project and as such it is normally the responsibility of the non-Federal project sponsor, the South Florida Water Management District, to acquire all lands, and interests in land required for the project. While it is the intention of both the U.S. Army Corps of Engineers and the South Florida Water Management District to acquire lands from willing sellers, if condemnation of lands becomes necessary, the condemnation action would normally be handled by the non-Federal sponsor. Lands purchased for the project will required an independent fair market appraisal prior to purchase.

356. Ensure that Florida Power & Light (FP&L) is adequately compensated for all costs of relocation of electrical lines.

Response: FP&L would be compensated for modifications to existing electric facilities or utility rights-of-way.

357. Component A6 provides for a regional storage reservoir north of Lake Okeechobee. The Tribe supports increased regional storage in this basin, but does not support the use of Tribal lands for storage of water for others.

Response: The location of this storage reservoir has not been determined. It could be located in any of three counties (Glades, Highlands, or Okeechobee). The use of Tribal lands for the storage reservoir has not been considered.

358. Local governments should deny land use amendments that increase the intensity or density of land uses within the WPAs.

Response: Neither the U.S. Army Corps of Engineers nor the South Florida Water Management District can control the actions of local governments on land use amendments. Restudy Team members have been working with local governments during the planning phases of the study and will continue to work with local governments during plan implementation.

359. Immediately acquire all lands necessary for the C&SF Restudy.

Response: It is not feasible to acquire all lands necessary for the C&SF Restudy immediately. Until the Restudy Comprehensive Plan is approved by Congress, a Project Implementation Report is completed and approved, and a Project Cooperation Agreement executed, land acquisition will continue under state land acquisition programs or with funding provided through other sources.

N.2.7 Water Quality

360. A comprehensive, systematic pollution prevention program is needed in urban areas of south Florida. The program should include enhanced emphasis on best management practices (BMPs) and greater participation in the National Pollutant Discharge Elimination System (NPDES) program for urban stormwater facilities.

Response: The recommended Comprehensive Plan includes a Comprehensive Integrated Water Quality Plan feasibility study to ensure that water quality restoration in south Florida is achieved. Although the scope of the feasibility study has not yet been developed, the feasibility of BMPs in specific urban areas should be investigated as well as identifying those urban areas where participation in the NPDES municipal stormwater program is needed.

361. Recent studies indicate that water in quarry lakes is of good quality. Lake Belt water could be pumped directly underground for aquifer storage without additional treatment. ASR should be evaluated as an element of the Lake Belt storage components.

Response: Present regulations require that underground (aquifer) injection of water which meet primary and secondary drinking water standards. If future planning and detailed design work indicates that ASR is viable and necessary as an element of the Lake Belt storage components, and the water to be injected is of adequate quality, ASR could be incorporated into the overall design of those components.

362. The recommended plan should identify strategies to reduce phosphorus and nitrogen loading to coastal waters to assure protection of reef tracts.

Response: Although the scopes of the studies have not yet been developed, it is envisioned that the Florida Bay feasibility study and the Comprehensive Integrated Water Quality feasibility study included in the Comprehensive Plan will address in detail the issues of nutrient sources and loads, impacts to reef ecosystems, appropriate restoration targets, and remediation programs (including wastewater treatment) to protect and restore reef ecosystems.

363. There are water quality issues such as potential treatment system failures, contaminants in the sanitary sewer system, and pollution loads to Biscayne Bay associated with discharging treated reclaimed wastewater into Biscayne Bay/Biscayne National Park as proposed in the South Miami-Dade Wastewater Reuse component.

Response: Future planning and detailed design work necessary to construct and operate the South Miami-Dade Wastewater Reuse component would involve a comprehensive evaluation of potential treatment train methodologies, reliability and dependability of treatment methodologies (including the extent of and controlling and minimizing contaminant inputs to the sanitary sewer system), and designated uses and water quality criteria of receiving water bodies necessary to assure compliance with water quality standards.

364. The Report/PEIS indicates that urban water quality is degraded and not expected to improve. These statements should be reconsidered to reflect the results expected from the federal NPDES Program and local water quality improvement initiatives. Urban stormwater which is returned to the Everglades should continue to be improved.

Response: Statements about future water quality conditions in the Report/PEIS are based on current conditions and trends as summarized in FDEP's 1996 Section 305(b) Report to USEPA and predicted population increases during the planning period for the Restudy (through 2050). While many water quality remediation programs are expected to be planned and implemented during the planning period, for planning purposes, the increase in population is expected to result in a net increase of (legal) point and non-point sources of pollution, delivering a net increase in pollution loads to urban water bodies in the Lower East Coast. Water quality conditions in some secondary and tertiary drainage systems are expected to remain “degraded” compared to designated uses (particularly for Class III water bodies) contained in state water quality standards. Urban stormwater that is returned to the Everglades through operation of recommended plan components will be improved to meet the water quality standards for the Everglades Protection Area. The recommended plan results in a significant decrease in urban stormwater returned to the Everglades, particularly at the S-9 pumping station in Broward County.

365. The draft "Reuse Issue Paper" discussing water quality concerns associated with the wastewater reuse components inappropriately concludes that adverse environmental impacts will occur. There are several benefits that result from incorporating reuse into the recommended plan, including perpetual fresh water supply and a net water quality improvement compared to urban runoff.

Response: The issue papers were prepared by subteams of the Alternative Evaluation Team to resolve issues raised by U. S. Department of Interior agencies prior to finalizing the Fish and Wildlife Coordination Act report for the Final Report/PEIS. Water quality concerns raised by environmental resource management agencies, including BCDNRP, will be addressed in detail during future planning and design work.

366. At present, there is a great deal of uncertainty about the concept of injecting raw (untreated) surface water into aquifers (surficial, Biscayne, Floridan). Issues of concern which have not been clearly resolved include the chemical make-up of potential source water (Lake Okeechobee Basin, Caloosahatchee River Basin, etc), chemical and biological effects of aquifer storage, and the quality of recovered water and its subsequent long-term effects on receiving surface waters. Specific constituents of concern in waters to be potentially injected into ASR facilities in the draft recommended plan include coliform bacteria, several pesticide compounds, mercury and nitrates.

Nearly all surface waters in the greater Everglades ecosystem are contaminated with pesticides, herbicides, and coliform bacteria. To meet federal Safe Drinking Water Act standards, surface waters would have to be treated with chlorine prior to injection into an aquifer at ASR facilities. Treating surface water with chlorine prior to injection may increase the potential for formation of tri-halomethane compounds (THMs).

Other forms of pretreatment should be employed to prevent the injection of bacteria, viruses, and other microbial contaminants into the underground reservoir. Moreover, the effectiveness of treatments under consideration (e.g., microfiltration, reverse osmosis) should be proven to be effective prior to pilot testing.

Response: Current regulatory standards require that any substance to be injected into potential underground sources of drinking water (USDWs) must meet primary and secondary drinking water standards. In addition, FDEP has developed guidance concentrations for many substances for which there are no primary or secondary standards. With regard to aquifer injection of surface waters containing coliform bacteria, USEPA has agreed to adopt a flexible, risk-based approach for ASR components of the recommended Comprehensive Plan. USEPA has oversight authority over FDEP's implementation of the federal Safe Drinking Water Act. This flexible, risk-based approach would allow aquifer injection of water without chlorine treatment, provided that coliform bacteria is the only problematic parameter in the water to be injected, and further providing that there is a demonstration that USDWs will not be endangered in any way that could adversely affect the health of humans.

Full implementation of the ASR facilities contained in the recommended plan depends upon pilot projects, including water quality monitoring work and follow-up assessments, to determine the effect of the injectate on the USDW. The cost for chlorination at ASR facilities, if required to prevent bacteriological contamination of USDWs, is included in the estimated costs for the recommended plan. If future monitoring work indicates that chlorination causes or contributes to the formation of THMs, alternative remediation methods or alternative water storage methodologies will be considered to provide the necessary storage. Technical information about the effectiveness of various treatment technologies for ASR facilities is presently available and will be reviewed during future detailed planning and design work. Pilot testing, possibly including different treatment technologies, is necessary to determine the best combination of technologies for full-scale implementation of the proposed ASR facilities.

367. Water stored in the Floridan aquifer may be contaminated by existing levels of radioactivity.

Response: Levels of radioactivity and the potential for contaminating aquifer stored water will be further evaluated during future detailed planning work. The ASR pilot projects described in the Implementation Plan are key to determining the long term water quality effects on aquifer stored water. Radiation levels would be monitored routinely as part of future operation and maintenance activities, if determined to be necessary as a result of the proposed pilot projects.

368. The protocol for injecting and withdrawing water into confining layers of the aquifer should be better defined to maximize the efficiency of ASR facilities. ASR wells should be designed to compliment surface storage reservoirs and canals. An issue team should be established to evaluate design and operations options. Pilot test results should be peer-reviewed.

Response: The South Florida Ecosystem Restoration Working Group has established an interagency ASR issue team to work through these and other issues associated with ASR. Future detailed planning and design work will address issues of optimal configuration and operation to maximize efficiencies at ASR facilities during the implementation phase of the Restudy. The interagency process will continue to be utilized during implementation of the recommended plan. Peer review of ASR pilot test results will be considered if necessary for objective interpretation.

369. There is a lack of reliable and verifiable water quality data in south Florida. A non-biased, reliable water quality data base should be compiled and continually updated and reviewed.

Response: A number of Federal, state, regional, tribal and local entities collect samples and use water quality data for research recommendations and management decisions in the study area. Although the scope of the feasibility study has not yet been developed, it is envisioned that the Comprehensive Integrated Water Quality Plan feasibility study contained in the recommended plan would address the issues of fragmented sampling, data quality, and climatological effects and trends.

370. Ultimate sources of water and receiving water bodies are not yet known. Future detailed design work to meet regulatory water quality criteria may necessitate design changes. Construction of plan components without the necessary permits could result in the inability to operate those facilities. Plan components requiring water quality treatment facilities should not be authorized until more detailed design is completed.

Response: Future detailed design work will take into account water quality conditions of source waters and designated uses of receiving water bodies, and will include appropriate treatment facilities to assure that designated uses and water quality standards are achieved. Water quality certifications from the State of Florida and the Miccosukee and Seminole Tribes will be obtained as required by federal law. By involving those entities in the planning and design process, it is intended that instances where additional detailed design necessary to assure compliance with water quality standards are completed at the appropriate time and water quality certification is obtained. The project implementation process contained in the Implementation Plan includes additional planning, engineering, and design to assure that water quality problems and permitability issues which could preclude future construction and operation are avoided or dealt with appropriately.

371. Water quality costs have not been included in the project cost estimates. The draft Report/PEIS contains no explanation as to how compliance with the Clean Water Act is to be achieved. Water to be supplied to fruit and vegetable growers must be of adequate quality. A comprehensive water quality feasibility study is necessary. The study should identify costs and cost-sharing.

Response: The estimated costs for the recommended plan include costs for construction, operation, and maintenance of water quality treatment features included in the recommended plan. Compliance with the Clean Water Act is a without project condition (State, Tribal, and local responsibility), except in the case that the recommended plan creates new discharges that potentially conflict with designated uses of receiving water bodies established under water quality standards. In that case, water quality treatment features will be included in future detailed design to assure that designated uses are maintained. Water quality features included in the recommended plan, together with ongoing (without project) programs to improve and maintain water quality, assures that water to be supplied for agricultural purposes will be of adequate quality to meet that designated use.

The recommended plan does include a feasibility study to develop a comprehensive integrated water quality plan to assure that water quality restoration targets in south Florida are achieved. Although the scope of feasibility study has not yet been developed, it is envisioned that the water quality feasibility study would include cost estimates for monitoring and data evaluation, construction and implementation and operation of treatment facilities and other remediation programs, and recommendations for cost sharing.

372. The draft Comprehensive Plan does not address water quality issues in Florida Bay and the Florida Keys. The Florida Keys Water Quality Protection Plan, including wastewater elements, should be included within the Restudy.

Response: The recommended plan includes a feasibility study to evaluate environmental restoration issues, including water quality, in Florida Bay and the Florida Keys. Although the scope of that study has not yet been developed, it is envisioned that the plan which would result from the study will include the Florida Keys Water Quality Protection Plan. The Florida Keys Water Quality Protection Plan includes measures for improving wastewater and stormwater treatment within the within the Keys. Implementation of this plan is critical for ecosystem restoration in the Keys.

373. A discharge standard of 10 ppb total phosphorus should be established and implemented for the EAA. Backpumping of EAA runoff into Lake Okeechobee should be eliminated. Water quality in the Holey Land and Rotenberger Tracts should be restored by the Restudy.

Response: The Florida Department of Environmental Protection has responsibility under state law (the Everglades Forever Act; "EFA") to develop a numeric phosphorus criterion for the Everglades Protection Area. The default concentration in the EFA is 10 ppb; however, a final numeric criterion is not required to be set by FDEP until December 31, 2003. Discharges from the EAA will be treated by the Everglades Construction Project (ECP), including supplemental treatment technologies, if necessary, to achieve compliance with the numeric phosphorus criterion. The ECP significantly reduces, but does not completely eliminate, backpumping of EAA runoff to Lake Okeechobee. Hydrologic modeling results for the recommended plan indicate that, on average, backpumped volumes are slightly increased with the recommended Comprehensive Plan. The hydropattern restoration features of the ECP, continuation of BMPs in the EAA, acquisition of additional lands for storage in the EAA (Component G), and the revised regulation schedules for the Holey Land and Rotenberger Tracts should result in water quality restoration in those areas.

374. There is significant uncertainty about the ability of STA technology to treat urban stormwater runoff to meet restoration water quality goals. It is imperative that the recommended plan seek to eliminate the regulatory flood control function of the S-9 pumping facility.

Response: On average, the recommended plan reduces the volume of water discharged via the S-9 pump station to WCA 3A from 193.6 k ac. ft. per year in the 2050 Base condition to 7.8 k ac. ft. per year with the recommended plan (see Appendix H, p. H-F-27). Most of the remaining 7.8 k ac. ft. is seepage return flow; flood control discharges are virtually eliminated with implementation of the recommended plan. The Non-ECP requirements of the EFA require that all discharges from S-9 to WCA 3A comply with all water quality standards, including the phosphorus criterion, by December 31, 2006.

375. Martin County requests that the Final Report/PEIS contain language assuring that water quality criteria will be included in design scopes for all Restudy projects.

Response: The Implementation Plan (Section 10) describes how existing and yet-to-be-developed water quality criteria (TMDLs, PLRGs,) will be integrated into future detailed planning and design activities as part of the Project Implementation Report process.

376. Estimated costs for treating water prior to aquifer injection may make other alternatives to ASR such as recycling and desalination more economically and environmentally attractive. Once an aquifer is contaminated, it will remain contaminated. This is a concern, in terms of future treatment costs, for those municipalities withdrawing water supplies from contaminated aquifers.

Response: Contamination of underground drinking water supplies is prohibited by underground injection control (UIC) regulations. Routine monitoring associated with ASR operations will be performed to continuously evaluate waters to be injected and the response of the aquifer into which water is injected to prevent aquifer contamination. Local initiatives to develop alternative water supplies will supplement the regional system.

377. The Restudy must address the four main requirements of the Everglades ecosystem: timing, delivery, quantity, and quality of water.

Response: The recommended plan should significantly improve water quality in the study area through optimal design and operation of the components to achieve water quality restoration targets. The recommended plan also includes a feasibility study to develop a comprehensive integrated water quality plan for south Florida. Although the scope of the feasibility study has not yet been developed, it is envisioned that the comprehensive integrated water quality plan will involve the development of additional water quality restoration targets where needed, recommendations for remediation programs to achieve those targets, and recommendations for synchronizing water quality restoration programs with the implementation schedule for the components of the recommended plan.

378. Reductions in Caloosahatchee River flow volumes resulting from the recommended plan should be recognized as part of the reduction in pollutant loads required by FDEP total maximum pollutant load (TMDL) limits.

Response: Establishment of total maximum daily loads (TMDLs) of pollutants for impaired water bodies is a responsibility of FDEP for state waters. FDEP is represented on the interagency Restudy Team, and will continue to be represented during plan implementation and other subsequent studies in south Florida. The TMDL process takes into account the assimilative capacity of water bodies and ongoing and planned water management and environmental restoration projects.

379. Construction and operation of the Caloosahatchee Backpumping with Stormwater Treatment component (Component DDD5) requires treating water discharged from Lake Okeechobee into the Caloosahatchee River before it is returned to Lake Okeechobee. The same water quality requirements should apply for water discharged from the lake to the river as those which apply for water to be pumped from the river back to the lake. The stormwater treatment area for this component should be reconsidered based on this criterion.

Response: Component DDD5 is designed to treat runoff from the C-43 basin and return treated water to Lake Okeechobee, providing a net increase in fresh water captured and stored within the regional system. The stormwater treatment area is included in the conceptual design and cost estimate for this component to assure that designated uses of Lake Okeechobee (Class I – potable water supply) continues to be met as a result of hydrologic changes contemplated by the Comprehensive Plan. The recommended plan also includes several components specifically included to improve water quality in Lake Okeechobee; however, fully restoring water quality in Lake Okeechobee depends on actions outside of the recommended Comprehensive Plan (e.g., establishment of total maximum daily pollutant loads (TMDLs) and development of pollutant load reduction programs to meet Lake Okeechobee water quality targets). The recommended feasibility study to develop a comprehensive integrated water quality plan for south Florida will investigate water quality issues associated with implementing recommended Comprehensive Plan components, including ecological effects of Lake Okeechobee releases on downstream waterbodies.

380. The Comprehensive Plan does not address how the huge volumes of water that will be stored and diverted to the Everglades will meet the soon-to-be-established stringent numeric phosphorus criterion. The costs associated with the necessary treatment should be included in the estimated costs for the Comprehensive Plan.

Response: The increased volume of water delivered to the Everglades from areas to the north (EAA, Lake Okeechobee) will be routed through the Everglades Construction Project (ECP) stormwater treatment areas (STAs). The ECP STAs are a without project condition for the Restudy. An evaluation of the effect of the recommended plan on the ECP STAs was performed by William Walker, Ph.D., for the Corps of Engineers and the Department of Interior during the plan formulation and evaluation phase of the Restudy. Dr. Walker's evaluation indicated that the recommended plan was not expected to adversely affect the projected overall performance of the STAs. This was due primarily to the beneficial effect of the EAA storage reservoir (Component G6) on STA 3/4. A summary of Dr. Walker's results is included in Appendix H.

However, that evaluation was performed without any assumptions about future (Phase 2) treatment requirements necessary to meet the final phosphorus criterion. Once the technology or technologies have been determined which will supplement the ECP STAs, a subsequent evaluation of the effect of the recommended plan on the performance of the ECP will be performed during future detailed design activities.

The Water Quality Subteam of the AET also evaluated other new discharges to the Everglades contemplated in the recommended plan. The most significant new discharges identified were: the increase in flows through the modified S-140 pump station (Component RR4) and the new discharge into the L-31N Canal through the proposed S-356 pumps. Using water budget data, the Water Quality Team determined that the increased flows through the S-140 pump originated in ECP STAs (STAs 3/4 and 6), natural areas (Holey Land and Rotenberger WMAs), and the L-28 Interceptor Canal basin, runoff from which is to be treated by whatever strategy/facility is developed for that basin as part of the Non-ECP requirements of the EFA (also a without project condition for the Restudy). The source of the increased flows through the proposed S-356 pumps is seepage water from WCAs 2 and 3 stored in the Central Lakebelt storage area and is assumed to meet the water quality criteria for the Everglades.

381. The Water Quality Sub-team of the AET's evaluation of the alternative plans for the Caloosahatchee watershed does not include the effects of ASR.

Response: Average volumes of water discharged from ASR facilities to the Caloosahatchee watershed and Lake Okeechobee was considered by the Water Quality Subteam as a potential performance indicator. The performance indicator was rejected because of uncertainties about the quality of the stored water withdrawn from the aquifer and the effects, if any, of aquifer stored water on receiving water bodies. Discharges from ASR facilities to surface waters will be required to meet applicable surface water quality standards.

382. Routing of water around the northern portion of WCA 3A is likely to lead to water quality problems. The recommended plan proposes a 285,000 acre-feet per year increase through the modified S-140A pump station. This creates a new point discharge into the Everglades. Adequate water quality treatment is not provided. This operation could neutralize the hydropattern restoration and water quality objectives of the Everglades Construction Project.

Response: Structural flows into northwestern WCA 3A were increased specifically to achieve preferred hydroperiods and hydropatterns in northwest WCA 3A. Component RR4 includes a spreader canal in the initial design and cost estimate to re-establish sheetflow into WCA 3A. It is not intended that discharges from the modified S-140A pump station would create a new point source discharge into WCA 3A.

According to water budget data from the SFWMM, the upstream sources of the flows through S-140A in the Comprehensive Plan break down as follows:

	2050 Base	Draft Comp. Plan
Holey Land	0.0	20.0
Rotenberger	77.0	99.0
STA 3\4	5.0	228.0
STA 6	0.0	11.0
S140A	93.0	102.0*
SUBTOTAL	175.0	460.0
Difference:		285.0 increase

Note: All flow volumes indicated are 31-year averages, in k ac. ft.

Thirty-one year average flow volumes were compared to the projected future (2050) Base condition flow volume for S-140A. During plan formulation and selection, it was concluded by the Water Quality Subteam (which included Everglades National Park) that increased flows through S-140A would not adversely affect water quality conditions in WCA 3A. This conclusion is based on the future without plan condition for the Restudy, i.e. full implementation of the State of Florida's Everglades Program contained in the Everglades Forever Act (F.S. 373.4592) by December 31, 2006. This condition includes construction and operation of the Everglades Construction Project (ECP) STAs and any supplemental treatment technologies necessary to achieve compliance with the yet-to-be-determined numeric phosphorus criterion, and implementation of the Non-ECP discharge structures requirements of the EFA (Section 373.4592(9), F.S.).

Non-ECP structures are those water control structures within the control of the SFWMD, which are not associated with the Everglades Construction Project discharging "into, within, or from the Everglades Protection Area." The S-140 pump station was specifically identified as a water control structure discharging into the Everglades Protection Area in the Non-ECP discharge structures permit issued by FDEP to the SFWMD. The EFA requires that schedules and strategies be identified and implemented for all Non-ECP structures to achieve compliance with all water quality standards in the Everglades Protection Area by December 31, 2006.

From the table above, it can be seen that all flows delivered through the modified S-140A pump station as contemplated in the Restudy Comprehensive Plan originate from STA 3\4, STA 5, STA 6, the Rotenberger and Holey Land WMAs, or via whatever water quality treatment strategy is developed for the S-140 basin. It should be noted that the average annual volume of runoff originating from the S-140A basin directed to WCA 3A increases approximately 9.0 k ac. ft. (from 93.0 k ac. ft. to 102.0 k ac. ft; see "*" in above table). If it is determined in future detailed planning and design work that the increased volume and proposed operation would adversely affect whatever treatment strategy is developed for the S-140 basin in accordance with the Non-ECP requirements of the EFA, modifications necessary to assure that the water quality requirements of the EFA are achieved would be incorporated into the final design and operation of Component RR4.

383. Reducing water levels in northwest WCA 3A will likely cause soil oxidation and more subsidence and will degrade downstream water quality.

Response: Water depth and duration of flooding performance indicators were established for specific grid cells in WCA 3A. The recommended plan was formulated to meet those targets to the maximum possible extent consistent with all of the other performance measures developed / approved by the AET. Projecting with certainty the ecological responses to alternative water management scenarios was not possible during plan formulation and evaluation due to the scale of the models used (two mile by two mile grid cells), uncertainties about final locations, and uncertainties about antecedent conditions in the vicinity of water control structures and appurtenant features to be constructed. Ecological responses, including potential releases of phosphorus from enriched soils, will be further evaluated in future detailed planning and design actions as described in the Implementation Plan (Section 10). It is anticipated that future improved versions of the Everglades Landscape and Everglades Water Quality (phosphorus) Models will simulate soil phosphorus releases and affects on water column phosphorus concentrations.

384. Restoration of sheet flow in the northern Everglades will create a water quality benefit by reducing the rapid, long-distance transport of aquatic pollutants into wetlands.

Response: Concur. To evaluate the alternative plans, the Water Quality Sub-Team of the AET utilized structural flows into the Everglades Protection Area (including the northern Everglades) as an indicator of potential pollution loads. High structural flows (loads) received low scores in the team's ranking matrix for the Everglades Protection Area.

385. Lake Okeechobee Water Quality Model results indicate that phosphorus enriched sediments provide a high rate of internal loading to the lake. Dredging of phosphorus enriched sediments is necessary to fully restore the lake and decrease phosphorus loads discharged to downstream ecosystems.

Response: The final recommended plan now includes all of the reservoir assisted stormwater treatment areas (RASTAs) recommended by the Lake Okeechobee Issue Team to reduce external phosphorus loading to the lake to target levels. A discrete task already identified to be performed as part of the recommended feasibility study to develop a comprehensive integrated water quality plan for south Florida involves evaluating the environmental and economic costs and benefits of dredging phosphorus enriched sediments in Lake Okeechobee.

386. Isolating deep storage reservoirs (e.g., North and Central Lake Belt storage areas) from ground water flows by constructing curtain walls may cause water quality problems in those reservoirs. The potential for poor water quality in these lakes must be thoroughly investigated.

Response: Future detailed planning and design work for the Lake Belt storage components would include evaluating the effects of the proposed designs on water quality, including thermal stratification and the migration of pollutants.

387. Two twenty thousand-acre storage reservoirs are insufficient to cleanse runoff from an area of 550,000 acres (the EAA). The proposed areas for the six STAs in the Everglades Construction Project are insufficient. Acreages of Storage (sic) Treatment Areas (STAs) must be expanded to fully address water quality.

Response: The initial design of Component G6 includes three 20,000-acre storage reservoirs, totaling 60,000 acres of storage in the EAA. Evaluation and modeling of the six stormwater treatment areas (STAs) presently included in the design of the Everglades Construction Project during Restudy plan formulation and evaluation work indicated that the interim performance target for the STAs was not likely to be adversely affected by the recommended plan (see Appendix H). In particular, the performance of STA 3/4 improved due to the upstream storage and attenuation provided by the EAA reservoir (Component G).

388. The interim (Phase 1) water quality target (50 ppb of phosphorus) for the STAs does not assure adequate protection of Everglades marshes. The Phase 2 target will become a “Herculean” task without providing vastly expanded STA acreage. Failure to provide guaranteed clean water with a maximum of 10 ppb of phosphorus will further impact the ecosystem and the costs of cleanup. Other pollutants such as mercury and pesticides need further review.

Response: The water quality treatment requirements of the Everglades Forever Act (EFA), including potential supplemental treatment (Phase 2) technologies are a without project condition for the Restudy. Modifications to those facilities necessary to accommodate recommended plan components will be evaluated during future detailed planning and design work, included as appropriate, and are eligible for federal cost-sharing. Due to the many uncertainties about potential Phase 2 treatment technologies, assumptions about the sizes, locations, and costs of Phase 2 technologies were not incorporated into the evaluation of the alternative plans and the selection of the recommended plan. Modeling work performed during plan formulation and evaluation indicated that increasing the area of storage proposed for the EAA greater than the 60,000 acres proposed did not significantly improve overall plan performance. Impacts of pollutants other than phosphorus will be evaluated during future detailed planning and design work to the extent that pollution load reduction targets and total maximum daily loads (TMDLs) for pollutants causing impairment of receiving water bodies are established by USEPA, FDEP, Tribal, and local water quality regulatory agencies.

389. The Corps should insure that all Restudy components are designed so that water outflows meet restoration standards for water quality. The federal share for water quality features of the recommended plan should be fifty percent, provided that state, regional, and local interests have done all they can to implement BMPs and appropriate water quality regulations.

Response: The Implementation Plan (Section 10) contains steps to assure that water quality restoration targets developed by state and tribal agencies (e.g., total maximum daily loads (TMDLs) and pollution load reduction goals (PLRGs)) are considered during future detailed planning and design work. The Water Resources Development Act of 1996 contains provisions authorizing fifty- percent federal cost sharing for water quality features determined to be essential to Everglades restoration. All of the water quality features of the recommended plan are recommended for fifty- percent federal cost sharing.

390. Sewage treatment in the Florida Keys should be improved to protect public health and coral reefs.

Response: Improved sewage treatment is a part of the Florida Keys Water Quality Protection Plan developed as part of the Florida Keys National Marine Sanctuary

Program. The final Report/PEIS (Sections 5, 8, and 9) has been revised to acknowledge the need for water quality improvements, including improved sewage protection, in the Florida Keys.

391. Water quality issues associated with aquifer storage should be addressed to protect and preserve the quality of underground drinking water sources.

Response: Regulatory criteria are in place to assure that water to be injected by future ASR facilities would meet drinking water standards. Underground injection regulations prohibit the injection of substances (including raw surface water) which could potentially adversely impact underground sources of drinking water.

392. Restoration of the Everglades is critical to improving the ecological health of coral reefs in the Florida Keys. Strategies for reducing agricultural runoff containing pesticides, herbicides, and fertilizers (including phosphorus and nitrogen) should be identified in the Restudy restoration plan.

Response: The State of Florida's Everglades Program contained in the Everglades Forever Act is the primary strategy for reducing agricultural pollution, including phosphorus and nitrogen compounds, entering the Everglades Protection Area. State and tribal agencies are also responsible under the federal Clean Water Act for developing total maximum daily loads (TMDLs) and pollution load reduction goals (PLRGs) for phosphorus and nitrogen where those pollutants are impairing water bodies other than the Everglades. Achieving water quality restoration targets in the Everglades and other water bodies will benefit downstream water bodies (Florida Bay, Florida Keys). In addition, the Florida Bay/Florida Keys feasibility study included in the recommended plan will address ecological and water quality restoration targets and remediation programs in Florida Bay and the Florida Keys.

393. The quality of water in canals that discharge into Biscayne Bay needs to be drastically improved to ensure ecological restoration in the bay. Cleanup priority should be given to highly contaminated canals, such as the Miami River, Military and Mowry Canals. Reduce nutrient loading.

Response: Under the federal Clean Water Act, the State of Florida is responsible for identifying impaired water bodies (not meeting water quality standards), including canals flowing into Biscayne Bay. For pollutants (including nutrients) causing Biscayne Bay canals to not meet water quality standards, total maximum daily loads (TMDLs) will be developed, along with remediation programs (including canal cleanup, if appropriate) to achieve TMDLs and compliance with water quality standards. It is envisioned that the Restudy Comprehensive Integrated Water Quality Plan feasibility study included in the recommended plan will contribute to expedited development of TMDLs for south Florida impaired water bodies by FDEP as well as expedited remediation programs for water bodies where TMDLs are implemented. The Restudy Implementation Plan (Section 10) assures that plan features (where located in or adjacent to impaired water bodies) will be designed and located to improve water quality conditions to the maximum extent possible.

394. The recommended Comprehensive Plan should ensure that all water entering Biscayne Bay meets or exceeds applicable water quality standards.

Response: The State of Florida, through its statewide, regional, and local agencies is responsible for assuring compliance with applicable water quality standards for existing discharges and sources of pollution. The Restudy Implementation Plan assures that plan features (where located in or adjacent to impaired water bodies) will be designed and located to improve water quality conditions to the maximum extent possible. It is expected that implementation of those components of the Restudy affecting Biscayne Bay will be located and designed to improve water quality conditions in the bay.

395. Establish numeric water quality standards for Outstanding Florida Waters (OFWs) as soon as possible.

Response: Numeric criteria already exist for many specific water quality parameters listed in the State of Florida's water quality standards. In addition, an anti-degradation provision, based on conditions at the time of OFW designation, applies to all OFWs designated by the State of Florida. Numeric interpretations of the OFW anti-degradation requirement for specific water quality parameters are the responsibility of the state or tribal agency having jurisdiction over the water bodies to which the OFW and anti-degradation provisions apply. Under the federal Clean Water Act, USEPA has an oversight and approval authority when states and tribes undertake such actions.

396. Rigorously enforce state and federal water quality standards. Moreover, establish and enforce standards that address both concentration and cumulative loading. All standards must be established to meet restoration objectives and maintain the integrity of the ecosystem.

Response: Enforcement of water quality standards is the responsibility of USEPA and state and tribal agencies. The establishment of new or additional water quality standards and criteria is the responsibility of states and tribes, over which USEPA has oversight and approval authority under the federal Clean Water Act. Existing, new or additional water quality standards and total maximum daily pollution loads (TMDLs) for impaired water bodies will be considered during future detailed planning and design work undertaken to implement components of the recommended Comprehensive Plan with the goal of maintaining or restoring ecosystem integrity.

397. Water from non-natural sources (e.g., urban, agricultural, industrial sources) should be treated to meet the most stringent of federal and state water quality standards prior to being discharged to the Kissimmee River and Lake Okeechobee.

Response: Existing and future discharges from urban, agricultural, and industrial sources are required to meet water quality standards established by state and tribal agencies regulating water quality, over which USEPA has oversight authority. The stringency of water quality standards depends upon the designated use of receiving water bodies and other special designations to which additional criteria apply. At present, several water bodies within the Kissimmee River watershed are designated "Outstanding Florida Waters" (OFWs) by the State of Florida, affording the most stringent water quality protection; however, most of the Kissimmee River watershed is not designated as OFW. Such designations, if appropriate, are the responsibility of the State of Florida through the Department of Environmental Protection, and are subject to review by USEPA. The designated use for most of the Kissimmee River watershed is Class III (recreation and propagation and maintenance of a healthy, well-balanced population of fish and wildlife), to which general and specific criteria particular to that classification apply. Lake Okeechobee is classified by the State of Florida as a Class I water body (potable water supply). The criteria for Class I water bodies are the most stringent for surface waters. Lake Okeechobee is not designated an OFW. Water quality remediation goals and targets for Lake Okeechobee have been set through the Lake Okeechobee Surface Water Improvement and Management (SWIM) Plan process developed by the SFWMD and approved by FDEP.

398. A maximum total phosphorus concentration of 10 ppb should be established for all water that is discharged into the environment from developed and or cultivated sources to help ensure the chemical, physical, and biological integrity of Florida's interior and coastal waters. An EAA maximum total phosphorus discharge criterion of 10 ppb or less should be established. Monitor changes in WCA 3B and ensure that discharges into WCA 3B meet all applicable water quality criteria.

Response: The State of Florida has responsibilities for enforcing water quality standards within its jurisdiction. Under the Everglades Forever Act, the State of Florida is presently engaged in research to numerically interpret the phosphorus concentration for the Everglades Protection Area. The default phosphorus concentration is 10 ppb in the event that no alternative numeric criterion is adopted through administrative rule making by December 31, 2003. USEPA must approve the numeric interpretation of the phosphorus criterion for the Everglades Protection Area. For other water bodies not meeting designated uses, the State of Florida or the Seminole and Miccosukee Tribes, as appropriate, are required under the federal Clean Water Act to develop total maximum daily loads (TMDLs) for pollutants, including phosphorus, causing impairment of water bodies. The recommended Comprehensive Plan's Comprehensive Integrated Water Quality Plan feasibility study will address accelerating FDEP's efforts to numerically interpret the total phosphorus and other water quality criteria for other south Florida waterbodies outside of the Everglades Protection Area.

For Restudy planning purposes, it was assumed that the State would enforce applicable water quality standards through BMPs and other regulatory and non-regulatory programs governing point and non-point sources of pollution. To compliment regulatory and non-regulatory water quality programs by the state and local governments, the Implementation Plan (Section 10) provides that plan components will be planned and designed to the maximum extent practicable to augment basin pollutant load reduction and total maximum daily loading targets. Under the Everglades Forever Act, flows to WCA 3B will be treated to meet all applicable State water quality standards.

399. Alternative methods of water treatment, such as periphyton-based STAs (PSTA) should be investigated. To the extent possible, “natural” methods of stormwater treatment (i.e. PSTA) should be used in the C&SF Restudy. Chemical dosing, if utilized, should not adversely affect the environment.

Response: The Corps and the SFWMD are presently investigating PSTAs as possible supplemental treatment technologies. Other natural technologies (e.g., submerged aquatic vegetation and limerock) are also being investigated by the SFWMD. The most appropriate technology for achieving low phosphorus concentrations has not yet been determined. Future modifications of Restudy water storage and water quality treatment components, including PSTAs, necessary to accommodate plan components and operations will be included in future detailed planning and design efforts.

400. Committees such as ETAC and TOC should continue their efforts to develop methods for effectively monitoring water quality.

Response: The Everglades Technical Advisory Committee (ETAC) was formed by FDEP to assist the Department in future decisions regarding research, monitoring, and the establishment of the numeric phosphorus criterion for the Everglades Protection Area. The Technical Oversight Committee (TOC) was formed pursuant to the settlement agreement for the federal lawsuit regarding pollution of Loxahatchee National Wildlife Refuge and Everglades National Park. The Corps of Engineers and SFWMD participate on both of those committees. Although the functions of those committees is outside the scope of and the authority for the Restudy, it is expected that those committees will continue to meet and make recommendations regarding water quality, including monitoring, during implementation of the recommended plan.

401. Agencies involved in best management practices (BMPs) for agricultural activities should monitor international BMP developments, particularly those

BMPs which increase nutrient and mercury uptake. Such practices should be evaluated for applications in south Florida, where feasible.

Response: The development of agricultural BMPs is the responsibility of those state, tribal, and local agencies responsible for protecting water quality and regulating agricultural and water management activities. USEPA provides financial assistance to state and tribal governments through the Clean Water Act's Section 319 grant program to develop and implement agricultural BMPs which result in reducing non-point source pollutant loading to receiving waters. Improved BMPs are expected to be implemented in south Florida, where feasible. The effects of BMPs will be incorporated into future detailed planning and design work undertaken to implement components of the recommended plan. The Restudy's recommended feasibility study for developing a Comprehensive Integrated Water Quality Plan will assist in development/implementation of agricultural and urban BMPs designed to reduce pollutant loading into south Florida receiving waters.

402. Existing water quality monitoring programs should remain in place. However, adaptive assessment should be used to reexamine existing water quality monitoring programs on a regular basis and/or when development/construction is about to occur.

Response: Although the scope of the study has not yet been developed, it is envisioned that the Comprehensive Integrated Water Quality Plan feasibility study, which is included in the recommended Comprehensive Plan, will include evaluating existing monitoring programs in order to make recommendations for modifying and integrating those programs to more effectively monitor water quality changes and ecological responses to water quality conditions. The adaptive assessment process contained in the Implementation Plan assures that monitoring is adjusted throughout the implementation process to provide meaningful information regarding the water quality and ecological effects of implementing the recommended plan.

403. To date, water quality monitoring in the Everglades has focused on phosphorus and the development of a phosphorus water quality standard. Water quality standards should be developed for other chemicals that are commonly used at industrial and agricultural facilities (e.g., nutrients, pesticides, herbicides, and metals). Furthermore, numerical Outstanding Florida Water standards should be developed and used as applicable standards for all waters that are discharged to designated natural areas and/or sensitive ecosystems.

Response: The Everglades Forever Act requires FDEP to evaluate all existing water quality standards (including non-phosphorus parameters) applicable to the Everglades Protection Area. Establishing and/or revising water quality standards is the responsibility of the state or tribal entity having jurisdiction over those water bodies where such actions are proposed. The USEPA has authority to approve or disapprove proposed water quality standards or revisions to water quality standards pursuant to the federal Clean Water Act. The recommended Comprehensive Plan includes a recommended feasibility study to develop a comprehensive integrated water quality plan that will assist with the expedited development of numeric water quality criteria for other, non-phosphorus water quality constituents. Also see response #402.

404. Provide increased flow through the L-5 canal and ensure water quality improvements.

Response: The recommended Comprehensive Plan increases the volume of water routed through the L-5 canal into WCA 3A. Water quality improvements to EAA runoff are a without project condition for the Restudy (i.e., full implementation of Everglades Forever Act requirements by December 31, 2006). Any Restudy related flows to WCA 3A via the L-5 canal above and beyond future without project flows will be treated to meet all applicable state and tribal water quality standards.

405. Ensure that water discharged from the C-11/S-9 system meets all water quality standards.

Response: The recommended plan diverts urban runoff from the C-11 west basin presently discharged via the S-9 pump station to WCA 3A to storage and water quality treatment facilities in Broward and Miami-Dade counties. Remaining discharges from the S-9 to WCA 3A are required to meet water quality standards, including the phosphorus criterion, by December 31, 2006, pursuant to the Non-ECP requirements of the Everglades Forever Act.

406. Site-specific investigations of potential ASR sites, including chemical analysis of the geologic formations of aquifers proposed for storage, water contained within those aquifers, potential contaminant plumes, and simulated leaching and dissolution rates to characterize the quality of water recovered from storage aquifers should be undertaken to aid future design and monitoring activities.

Response: The suggested investigations will be undertaken as part of the ASR pilot projects included in the recommended Comprehensive Plan and initial authorization request.

407. Existing (and proposed future) injection facilities in the vicinity of proposed ASR sites should be subjected to in-depth evaluation, including the confining geologic formations, to determine the long-term risks of locating ASR facilities in the vicinity of potential sources of aquifer contamination.

Response: Inventories of existing and known-proposed injection facilities will be developed during future detailed planning work undertaken for implementation of ASR components. Monitoring data and technical information, including information describing confining geologic formations, will be reviewed. Part of the ASR Pilot projects proposed in the Restudy initial authorization package is an extensive literature review of existing Florida ASR operations, including chemical composition of ASR injectate and Floridan aquifer chemical composition at the ASR well. It will be completed prior to detailed design of any Restudy ASR facilities.

408. After suitable sites for ASR facilities are identified, pilot tests should be undertaken to obtain additional hydraulic and aquifer chemistry data. Actual data should be compared to previously modeled results. Adaptive assessment principles should be applied to subsequently determine appropriate locations for ASR facilities. Laboratory analytical results from all Florida wells and exploratory borings into the Floridan Aquifer should be obtained to assess the chemical properties of the aquifer at the well location. These data should be used to look for potential contaminant plumes that might affect ASR reservoirs.

Response: The process suggested is generally that which is described in the Restudy Implementation Plan. Pilot testing of ASR facilities is included in the recommended initial authorization package.

409. Are there water quality data describing pre-drainage conditions for WCAs 2B and 3B?

Response: In describing pre-drainage water quality conditions for the Everglades, Section 2.5.4 erroneously referred specifically to Water Conservation Areas 2A and 3A; the statement has been corrected in the final report to refer more broadly to WCAs 2 and 3.

410. DOI supports the proposed modifications to the L-28 Interceptor Canal and levees (Component CCC). However, DOI is concerned with the quality of the proposed sheetflow entering Big Cypress National Preserve as a result of implementation of this component. It is unclear whether proposed treatment techniques included in the plan will adequately reduce this contamination risk.

Response: Flows directed into Big Cypress National Preserve through modifications to the L-28 Interceptor Canal would be required to meet applicable water quality standards. The Preserve is designated an Outstanding Florida Water by the State of Florida, to which more stringent water quality requirements apply. The initial design of this component included STAs designed consistent with the criteria used to size the STAs for the Everglades Construction Project. Future detailed planning and design work for that component will involve reviewing current water quality conditions, applicable water quality standards and criteria, and designing appropriate treatment technologies.

411. Water quality performance (of the recommended plan) was not ranked for Big Cypress National Preserve. The Preserve is increasingly affected by degradation of water quality to the north. Existing and future water quality of flows entering the Preserve warrants closer consideration.

Response: The Water Quality Subteam of the Alternative Evaluation Team determined that water quality performance of the recommended plan could not be ranked for the Big Cypress area, due to a lack of quantitative tools (e.g., modeling results) and performance measures with which to perform a comparative evaluation. Water quality models are under development which will augment future detailed planning and design work of components affecting hydrologic the Preserve. Under the State of Florida's Everglades Program, flows from the C-139 and Annex Basins which could adversely affect ecological conditions in the Preserve will be directed to STAs 5 and 6 of the Everglades Construction Project. A BMP program is also under development for those basins. The Seminole Tribe's Water Conservation Plan, when implemented, should also improve water quality in the northeastern area of the Preserve. The Seminole Water Conservation Plan is included in the recommended plan as an OPE.

412. The Restudy should provide adequate quality of water throughout central and southern Florida's natural areas.

Response: The State of Florida and the Miccosukee and Seminole Tribes, through their appropriate agencies, have responsibilities for enforcing water quality standards within their jurisdictions. For Restudy planning purposes, it was assumed that those entities would enforce applicable water quality standards through BMPs and other regulatory and non-regulatory programs governing point and non-point sources of pollution. All flows from Restudy facilities will meet applicable state and tribal water quality standards. To compliment regulatory and non-regulatory water quality programs by state, tribal, and local governments, the Implementation Plan for the Restudy provides that plan components will be planned and designed to the maximum extent practicable to augment basin pollutant load reduction and total maximum daily loading targets. The recommended plan also includes a feasibility study to develop a Comprehensive Integrated Water Quality Plan for south Florida.

413. Water that is lost to tide via the C&SF project as a result of urban stormwater runoff should be captured, treated to meet the most stringent of federal and state water quality standards, and stored in reservoirs.

Response: The recommended Comprehensive Plan includes numerous components that capture freshwater flows currently "lost to tide" and utilizes these water resources for ecosystem restoration and improved urban and agricultural water supply. Approximately 1.9 million acre feet per year (31 year average) of freshwater currently lost to tide is captured by over 180,000 acres of surface water storage facilities and extensive ASR facilities. Additionally, the Restudy proposes approximately 36,600 acres of water treatment facilities to reduce pollutant loading of Restudy flows entering surface water bodies throughout south Florida. Restudy water flows to surface and ground water receiving bodies will be treated to meet existing and future state and tribal water quality standards.

414. Efforts to identify "control areas" characteristic of historical Everglades water quality should continue. Once defined, the characteristic of the water quality "control area" should be defined for use as a restoration standard.

Response: Research to characteristic "pristine" Everglades water quality conditions is an ongoing requirement of the Everglades Forever Act. Field sampling sites remote from surface water pollution sources are being monitored in an effort to assist the State of Florida with establishing numeric water quality criteria for the central Everglades region. Restudy water quality monitoring programs will be designed utilizing existing unimpacted areas of the Everglades to assist with establishment of ecological restoration standards.

415. Phosphorus laden sediments in lakes, canals, and the Kissimmee River should be mitigated by removal and/or through the use of drawdowns wherever possible.

Response: The existing headwater revitalization program of the Kissimmee River Restoration project includes lake draw-down activities to improve water quality and habitat conditions in the Kissimmee Chain of Lakes area. These activities are not operational components of the Restudy but they are considered in the future without project planning analysis. In the lower Kissimmee River basin, the recommended Comprehensive Plan includes the Lake Okeechobee Tributary Sediment Dredging Other Project Element (OPE) component. This OPE includes dredging of sediments from 10 miles of primary canals within an 8-basin area to remove phosphorus from canal sediments and reduce nutrient loading to downstream receiving waters in an effort to improve water quality conditions in the primary canals and in the downstream Lake Okeechobee.

416. Restoration efforts should protect the river corridor and associated prairies from nutrient rich runoff generated by adjacent agriculture and pasturelands.

Response: In the lower Kissimmee River area, the Restudy final recommended plan now includes several OPEs that will result in water quality improvements via construction and operation of reservoir assisted stormwater treatment areas (RASTAs) to reduce nutrient loading to the downstream Lake Okeechobee. Additionally the North of Lake Okeechobee reservoir (Component A) has been modified to include a 2,500-acre STA. Cumulatively, these lower Kissimmee River RASTAs total approximately 6,900 acres. Additional RASTAs in the recommended Comprehensive Plan in the Fisheating Creek and C-41 Basins totaling approximately 14,600 acres will be subject to further evaluation in the next phase of the Restudy. All of these facilities will significantly reduce nutrient loading to their respective river corridors.

417. Provide proper quality of water to the St. Lucie River/Estuary and the Caloosahatchee River/Estuary.

Response: The State of Florida has responsibilities for enforcing water quality standards within its jurisdiction. For Restudy planning purposes, it was assumed that the State would enforce applicable water quality standards through BMPs and other regulatory and non-regulatory programs governing point and non-point sources of pollution. All flows from Restudy facilities will meet applicable state and tribal water quality standards. To compliment regulatory and non-regulatory water quality programs by the state and local governments, the Implementation Plan for the Restudy provides that plan components will be planned and designed to the maximum extent practicable to augment basin pollutant load reduction and total maximum daily loading targets.

Within the St. Lucie River/Estuary watershed the recommended Comprehensive Plan proposes approximately 45,500 acres of water storage areas, with additional acreage for storage areas and reservoir assisted stormwater treatment areas (RASTAs) in tributaries of Lake Okeechobee. These Restudy water storage/ treatment facilities should substantially reduce non-point source pollutant loading to the St. Lucie River/Estuary.

Within the Caloosahatchee River/Estuary watershed the Restudy proposes approximately 20,000 acres of water storage areas and a 5,000-acre stormwater treatment area (STA), with additional acreage of storage areas and RASTAs in tributaries of Lake Okeechobee. These Restudy water storage/ treatment facilities should substantially reduce non-point source pollutant loading to the Caloosahatchee River/Estuary. The recommended plan also includes a feasibility study to develop a comprehensive integrated water quality plan for south Florida.

418. Eliminate/minimize sediment loading to the St. Lucie Estuary and the Caloosahatchee Estuary from all sources to ensure ecological restoration of estuary ecosystems.

Response: Restudy water storage/treatment facilities should substantially reduce sediment loads being delivered to the lower St. Lucie River and Estuary and to the Caloosahatchee Estuary. The recommended water quality feasibility study is expected to address reduction of sediment loading to the Caloosahatchee Estuary and the St. Lucie River/Estuary systems.

419. As part of the C&SF Restudy, all of the Holey Land and Rotenberger areas should be designated as OFW.

Response: The Rotenberger Wildlife Management Area is currently designated as an Outstanding Florida Water (OFW) by the Florida Department of Environmental Protection (FDEP). Designation of the Holey Land Wildlife Management Area as an OFW is not an action that the Restudy has statutory authority to accomplish, however, implementation of the Restudy Comprehensive Integrated Water Quality Plan may result in FDEP designating the Holey Land as an OFW.

420. Restore proper water quality to the Holey Land and Rotenberger. Enforce and strengthen water quality standards for water sent to these areas.

Response: The State of Florida has responsibilities for enforcing water quality standards within its jurisdiction. For Restudy planning purposes, it was assumed that the State would enforce applicable water quality standards through BMPs and other regulatory and non-regulatory programs governing point and non-point sources of pollution. To compliment regulatory and non-regulatory water quality programs by the state and local governments, the Implementation Plan provides that recommended plan components will be planned and designed to the maximum extent practicable to augment basin pollutant load reduction and total maximum daily loading targets. Under the Everglades Forever Act's Everglades Construction Program (ECP), future Phase 2 water flows to Rotenberger will be routed through STA 5 as part of the ECP's hydroperiod restoration activities. Operation of STA 5 will also result in reduced pollutant loading in flows directed to the Holey Land. The recommended Comprehensive Plan includes a recommended feasibility study to develop a comprehensive integrated water quality plan that will address water quality issues relating to the Holey Land and Rotenberger.

421. Restoration of pre-drainage water quality should be restored to the southern BCNP by modification or, where feasible, elimination of the L-28, S-343, and the S-344 structures.

Response: The recommended plan would result in the removal of the L-28 and L-28 Tieback levees and borrow canals. Existing structures S-343/S-344 would also be eliminated with removal of the L-28 levee/borrow canal. Water quality conditions in this region should be restored to pre-drainage conditions with the Big Cypress/L-28 Interceptor modification, which would treat water in the L-28I basin via two STAs totaling 1900 acres, and would degrade the lower portion of the L-28I levee and backfill this portion of the L-28I canal. These activities would reestablish surface water sheetflow across the eastern portion of the BCNP, with pollutant loads from the L-28I system being adequately treated to meet applicable state and tribal water quality standards.

422. The C&SF Restudy should not adversely alter the quality of water flowing into tribal lands. Moreover, efforts by tribal, federal, state, and local governments to monitor water quality should continue.

Response: The primary strategy for improving water quality in the Everglades is the activities undertaken by the State of Florida pursuant to the requirements of the Everglades Forever Act (EFA). All structural discharges to the Everglades are required to meet applicable water quality criteria, including the yet-to-be-determined State phosphorus criterion, by December 31, 2006 (see Section 4.8.5 of the Final Report/PEIS). Restudy features that discharge into or alter discharges into the Everglades will include appropriate treatment facilities to meet applicable water quality criteria. Future detailed planning and design activities undertaken during implementation of specific components will consider all applicable state and tribal water quality standards, and will be designed to achieve maximum water quality performance consistent with those standards and the overall performance objectives of the Restudy. The Restudy Team is aware of and acknowledges the Miccosukee and Seminole Tribe's adopted water quality standards, including the phosphorus criterion. The recommended plan features discharging into Tribal waters (e.g. the proposed modifications to the S-140 pump station and the L-28 interceptor modifications) will include appropriate treatment necessary to comply with applicable water quality standards. Water quality certification from the Miccosukee Tribe and Seminole Tribe will be sought when appropriate as required by federal law.

423. Provide the proper quality of water entering Everglades National Park to ensure a sustainable and diverse ecology within the Everglades ecosystem.

Response: The State of Florida has responsibilities for enforcing water quality standards within its jurisdiction. For Restudy planning purposes, it was assumed that the State would enforce applicable water quality standards through BMPs and other regulatory and non-regulatory programs governing point and non-point sources of pollution. To compliment regulatory and non-regulatory water quality programs by the state and local governments, the Implementation Plan for the Restudy provides that components will be planned and designed to the maximum extent practicable to augment basin pollutant load reduction and total maximum daily loading targets. Under the Everglades Forever Act flows to Everglades National Park (ENP) will be treated to meet all applicable State water quality standards. Additionally, water quality of freshwater flows to ENP is subject to the Everglades lawsuit settlement agreement, which ensures that waters of adequate quality to fully protect the ecology of ENP are delivered to the park.

424. The C&SF Restudy should provide the proper quality of fresh water to Biscayne National Park while making every effort to reduce or eliminate reliance on wastewater reuse.

Response: Biscayne National Park (BNP) is currently designated as an Outstanding Florida Water (OFW) by the Florida Department of Environmental Protection (FDEP). An anti-degradation provision applies to all OFWs designated by the State of Florida. For Restudy planning purposes, it was assumed that the

State would enforce applicable water quality standards. Several Restudy components would result in reduction of pollutant loads currently being delivered to BNP via the C&SF primary canal system. Relative to wastewater reuse concerns, the recommended Comprehensive Plan includes a pilot project to evaluate the feasibility of treating wastewater to sufficient quality to be discharged to BNP. Due to the anticipated high costs of potential wastewater reuse treatment technology, a thorough evaluation of alternative, less costly, potential supplies of freshwater to BNP will be completed prior to any detailed design initiated relative to directing wastewater reuse flows to BNP.

425. What are the regulatory and monitoring requirements for agricultural runoff to be relatively free of pollution?

Response: Agricultural runoff is exempt from National Pollutant Discharge Elimination System (NPDES) permitting requirements administered by USEPA and FDEP. However, discharges from agricultural facilities can not cause violations of applicable water quality standards. Ambient monitoring programs are in place to assess pollutants in water bodies, including those contributed by agricultural runoff. Where necessary (based on ambient monitoring data), best management practices (BMPs) and other regulatory and non-regulatory programs are in place or will be instituted to minimize the contribution of pollutants in agricultural runoff to receiving water bodies.

426. There are water quality issues associated with directing wastewater reuse flows to Biscayne Bay as proposed in the recommended plan.

Response: The Implementation Plan for the Restudy includes pilot testing of wastewater reuse facilities prior to full-scale implementation. Pilot testing will include detailed investigation of water quality issues, including applicable water quality standards and criteria, treatment requirements, and the ecological suitability of wastewater reuse discharges to Biscayne Bay. It should be noted that the cost estimates for wastewater reuse components included in the recommended plan include treatment facilities necessary for discharges to comply with water quality standards.

427. The preferred alternative (recommended plan) contains insufficient measures to ensure that the water quality needs of the Everglades system are met.

Response: The principal measure for achieving the water quality needs of the Everglades is the Everglades Construction Project and the Non-ECP elements of the Everglades Forever Act. Full implementation of the requirements of the EFA is a without project condition for the Restudy. An evaluation of the effect of the recommended plan on the ECP indicates that the performance of the ECP will not be adversely affected by the Restudy.

Other areas of the greater Everglades ecosystem lack specific water quality restoration targets at this time. State and tribal agencies are responsible under the federal Clean Water Act for developing total maximum daily loads (TMDLs) and pollution load reduction goals (PLRGs) for impaired water bodies within their jurisdictions. The Implementation Plan ensures that components of the recommended plan will be designed and operated to achieve TMDLs and PLRGs consistent with the overall Restudy performance objectives.

428. The Restudy preferred alternative does not meet water quality requirements with flows to the St. Lucie estuary.

Response: The recommended Comprehensive Plan had the best performance, from a water quality perspective, of all the alternatives evaluated in terms of beneficial water quality effects on the St. Lucie River estuarine system. This determination was based primarily on salinity targets for the estuary, but also included a consideration of the effect of the proposed water storage areas on pollutant settling and load reduction. Future detailed planning and design work currently underway as part of the Indian River Lagoon feasibility study will lead to further refinements in plan components located in the St. Lucie Estuary watershed.

429. EPA recommends that water quality considerations be made more explicit in the Final Report/PEIS.

Response: Several sections of the Report/PEIS were revised to more specifically describe water quality problems and opportunities in the study area (Section 5), water quality effects of the recommended plan (Section 8), water quality elements of the recommended plan (Section 9), and water quality considerations during future implementation actions (Section 10). The Summary section prefacing the Report/PEIS and the water quality portion of Appendix H was also revised to more explicitly address water quality. As a cooperating agency under NEPA, EPA was involved in the drafting of those revisions.

430. EPA proposes a multi-agency south Florida "water quality initiative" under the auspices of the South Florida Ecosystem Restoration Task Force to review water quality features of the recommended Comprehensive Plan, consider water quality standards, criteria, and restoration targets, and to address areas of south Florida (e.g., Florida Keys) not addressed by the recommended plans.

Response: The recommended plan includes a feasibility study to create a "Comprehensive Integrated Water Quality Plan" which would address all of the above issues. As an element of the recommended Comprehensive Plan, the feasibility study and future recommendations would involve consultation with the federal Task Force and Working Group, and the Florida Governor's Commission for a Sustainable South Florida.

431. As basin-specific total maximum daily loads (TMDLs) are developed, Restudy facilities should be designed to maximize reduction of pollutant loads to downstream receiving water bodies.

Response: The Implementation Plan describes how water quality considerations will be integrated into future detailed planning studies. TMDLs will be considered in future detailed planning and design work for specific components/projects. It should be noted that TMDLs have not yet been developed for any of the impaired water bodies identified in south Florida, with the exception of the ongoing process to determine the numeric phosphorus criterion in the Everglades. Development of TMDLs is the responsibility of the State of Florida and tribal entities having jurisdiction over impaired water bodies. Development of TMDLs is a “critical path” item necessary to design and operate Restudy components to achieve maximum water quality benefits.

432. EPA recommends that the interagency Restudy Water Quality Subteam focus efforts on the development of basin-specific TMDLs, re-evaluation of existing water quality criteria, and set priorities and schedules as well as funding strategies for accelerating water quality improvements in south Florida. Efforts should be integrated with the regulatory and enforcement responsibilities of federal, state, and local agencies.

Response: Although the scope of the study has not yet been developed, it is envisioned that the feasibility study included in the recommended plan to create an Integrated Comprehensive Water Quality Plan will address all of the above issues including continuing involvement by the interagency Restudy Water Quality Subteam. It is expected that EPA will play a key role in the development and preparation of the feasibility study and subsequent recommendations.

433. EPA wishes to emphasize that the Future “Without Plan” condition alternative assumes full compliance with the Everglades Forever Act, including timely implementation of a numeric phosphorus criterion to be proposed by FDEP and approved by USEPA or the default criterion of 10 ppb in the Everglades Forever Act.

Response: The above-described condition is the without project or without plan condition for the Restudy; that is, full implementation of the requirements of the Everglades Forever Act by December 31, 2006.

434. The Restudy does not provide reasonable assurances that water quality will ensure the health of natural systems and meet water quality standards.

Response: The State of Florida and the Miccosukee and Seminole Tribes, through their appropriate agencies, have responsibilities for enforcing water quality standards within their jurisdictions. For Restudy planning purposes, it was assumed that those entities would enforce applicable water quality standards through BMPs and other regulatory and non-regulatory programs governing point and non-point sources of pollution. To compliment regulatory and non-regulatory water quality programs by state, tribal, and local governments, the Implementation Plan for the Restudy provides that plan components will be planned and designed to the maximum extent practicable to augment basin pollutant load reduction and total maximum daily loading targets. The recommended plan also includes a feasibility study to develop a Comprehensive Integrated Water Quality Plan for south Florida.

435. Planning for water quality improvements in south Florida should not be limited to nutrients; a variety of other pollutants should also be addressed (e.g. pesticides and mercury).

Response: The State of Florida and the Miccosukee and Seminole Tribes are required under the federal Clean Water Act to identify impaired water bodies within their respective jurisdictions, identify the pollutants causing impairment, develop total maximum daily loads (TMDLs) for those pollutants, and develop remediation programs to improve impaired water bodies. Although excessive nutrient loading is the primary cause of impairment in many such water bodies, other contaminants are known to be contributing to impairment. TMDLs and remediation program will be developed to address all pollutants causing impairment.

436. Regarding the proposed wastewater reuse components, it is not clear in the draft Report/PEIS whether it will be effective, much less cost effective, to treat the proposed level of sewage to acceptably low phosphorus and coliform bacteria levels for discharges to National Park Service waters.

Response: The wastewater reuse components were included in the overall plan because they provided a ready source of additional water to areas where additional flows were needed. Wastewater reuse is also consistent with the State of Florida's water management planning efforts required under Chapter 373, F.S. The technology to treat to low phosphorus and coliform bacteria levels presently exists, and is included in the estimated cost of those components (see Appendix C, Section 3.5.3.2; and, pages C-A-51 and 58). Cost effectiveness will be re-evaluated during future detailed planning and design work undertaken during the implementation phase of the recommended plan.

437. How will the explosive growth projected for south Florida affect water quality? The projected increase in population will increase the amount of hazardous and toxic chemical releases into groundwater and sewage systems to the detriment of the ecological health of south Florida.

Response: Federal planning regulations require a 50-year planning horizon for water resource development projects. Future population projections were based on current trends and growth management plans for south Florida. Recommended plan components will be designed and located to provide maximum water quality protection benefits consistent with the overall performance objectives for the recommended plan. As such, it is expected that without the Restudy, water quality conditions in the study area will decline, particularly in those areas expected to experience a significant increase in population. A notable exception to this prediction is the Everglades. Water quality in the Everglades is expected to improve between now and 2007 as the requirements of the Everglades Forever Act are completed.

438. Everglades restoration plans should include steps to ensure that agricultural runoff containing harmful contaminants is not discharged to Florida Bay and the downstream coral reefs of the Florida Keys. The recommended plan should identify strategies for reducing both phosphorus and nitrogen loading to waters of Florida Bay and the Florida Keys in recognition of the fact that the nutrient thresholds for coral reefs are lower than previously acknowledged.

Response: The State of Florida's Everglades Forever Act (EFA) is a comprehensive plan for water quality improvements in the Everglades. The EFA includes the Everglades Construction Project (designed to clean-up agricultural runoff from the EAA) and a requirement that all other discharges into the Everglades meet all water quality standards by December 31, 2006 (the so-called Non-ECP requirements of the EFA; see Sections 373.4592(9) and (10), F.S.). The Non-ECP element of the EFA addresses agricultural non-point source runoff entering the Everglades from areas other than the EAA. Full implementation of the EFA is a without project condition for the Restudy. Restudy components that alter or increase discharges to the Everglades will be designed to meet applicable Everglades water quality standards, regardless of the source of the water stored and discharged by those components.

State and tribal agencies are also responsible under the federal Clean Water Act for developing total maximum daily loads (TMDLs) and pollution load reduction goals (PLRGs) for phosphorus and nitrogen where those pollutants are impairing water bodies other than the Everglades. Achieving water quality restoration targets in the Everglades and other water bodies will benefit downstream water bodies (Florida Bay, Florida Keys). In addition, the Florida Bay/Florida Keys feasibility study included in the recommended plan will address ecological and water quality restoration targets and remediation programs in Florida Bay and the Florida Keys.

439. The draft Report/PEIS falls short of identifying those features which will result in improved water quality in the Everglades. It should be noted that the EAA Storage Reservoirs were not designed with improved water quality in mind. By "stacking" water to maximize storage depth, storage components of the recommended plan fail to take advantage of additional wetland treatment benefits that would be available.

Response: The primary strategy for improving water quality in the Everglades is the activities to be undertaken by the State of Florida pursuant to the requirements of the Everglades Forever Act (EFA). All structural discharges to the Everglades are required to meet applicable water quality criteria, including the yet-to-be-determined phosphorus criterion, by December 31, 2006 (see Section 4.8.5 of the Draft Report/PEIS). Recommended plan features that discharge into or alter discharges into the Everglades will include appropriate treatment facilities to meet applicable water quality criteria. Future detailed planning and design activities undertaken during implementation of specific components will consider all applicable water quality standards, and will be designed to achieve maximum water quality performance consistent with those standards and the overall performance objectives of the Restudy.

440. The Restudy fails to recognize that a more stringent (than the State of Florida's current interim criterion) for phosphorus already exists. The water quality criterion for total phosphorus in surface waters on the Miccosukee Reservation is 10 ppb.

Response: The Restudy Team is aware of and acknowledges the Miccosukee Tribe's adopted water quality standards, including the phosphorus criterion. Plan features discharging into Tribal waters (e.g. the proposed modifications to the S-140 pump station) will include appropriate treatment necessary to comply with applicable water quality standards. Water quality certification from the Miccosukee Tribe will be sought when appropriate as required by federal law.

441. The Restudy calls for an annual increase of 285,000 acre-feet of water (above the 2050 Base condition) to be routed through the S-140 pump station. This additional water has no water quality treatment component to ensure that the water is treated to Tribal water quality standards prior to discharge. The Miccosukee Water Management Plan will treat Tribal waters to 10 ppb total phosphorus, but is not designed to treat the additional 285,000 acre-feet of water from upstream areas. Previous assurances that elements of the Everglades Forever Act (assumed to be in place in the 2050 Base condition) will adequately address this issue are unsatisfactory to the Tribe.

Response: Planning assumptions for the Restudy include full implementation of the requirements of the Everglades Forever Act, including those facilities/strategies necessary to achieve compliance with the State of Florida's phosphorus criterion in the Everglades for discharges from the S-140 pump station. The sources of the proposed increase in the average annual volume of water discharged through the S-140 are upstream treatment areas designed to achieve compliance with State of

Florida water quality standards, including the yet-to-be-determined phosphorus criterion for the Everglades. Also, see response #382.

442. The draft Restudy Report/PEIS falls short of meeting water quality requirements of the Water Resources Development Act of 1996 because it fails to mention NPDES Permit requirements. At a minimum, the final Report/PEIS should include a discussion of the federal Clean Water Act (CWA) as it applies to discharges into the Everglades in general and the S-9 pump station in particular, designated uses of the Everglades, CWA 305(b) requirements, CWA 303(d) (total maximum daily load) requirements, the permitability of the Restudy, and applicable State and Tribal Water Quality Standards.

Response: The Report/PEIS was revised to more specifically address water quality issues in several sections. NPDES, 305(b), and 303(d) requirements of the federal Clean Water Act are addressed in Section 5.3 (Water Quality Problems and Opportunities), Section 8.10 (Water Quality), Section 9.1 (Construction Features), and Section 9.7.3 (Comprehensive Integrated Water Quality Plan). Permitability (sic) is addressed in the revised Implementation Plan (Section 10). State and Tribal water quality standards are discussed in Appendix H.

443. The Florida Department of Environmental Protection (FDEP) is aware that a significant risk to aquifers exists with ASR as proposed in the Restudy but has asked the U. S. Environmental Protection Agency (EPA) to relax the requirements of the federal Safe Drinking Water Act to allow contamination of aquifers.

Response: FDEP has not asked USEPA to relax the requirements of the Safe Drinking Water Act. In a letter dated October 1, 1998, the Chairman of the Governor's Commission for a Sustainable South Florida, the Secretary of the Florida Department of Environmental Protection, the Executive Director of the South Florida Water Management District, and the Commander of the Jacksonville District Army Corps of Engineers requested the Administrator of the U. S. Environmental Protection Agency to consider a "risk-based" approach for allowing injection of water containing coliform bacteria into saline aquifers in the implementation of Restudy ASR facilities. Current EPA and FDEP underground injection control (UIC) regulations require primary drinking water standards must be met prior to injection into an underground source of drinking water. The primary drinking water standard for coliform bacteria is zero; none can be present. The request to use a risk-based approach when reviewing future UIC permit applications was based on the assumption that "microorganisms do not present a public health threat when stored underground in a saline aquifer." USEPA responded to the request to use a risk-based approach in a letter dated February 9, 1999. EPA agreed that a flexible, risk-based approach was appropriate to consider, provided that coliform bacteria is the only problematic parameter in the water to be injected, and further providing that there is a demonstration that underground sources of drinking water (USDWs) will not be endangered in any way that could adversely affect the health of humans. Copies of the letters were provided to the Miccosukee Tribe.

444. The recommended plan includes a 2,600 acre water quality treatment facility in the S-65D sub-basin (Pool D) of the Kissimmee River in Highlands and Okeechobee Counties. Is this of the same scope and location of current Kissimmee River Restoration projects in that basin, or is this additional water storage derived from channel restoration?

Response: Completion of the Kissimmee River Restoration Project is a without project condition for the Restudy; that is, it is assumed that Kissimmee River Restoration will be completed as authorized. The proposed Pool D water quality treatment area is not part of the Kissimmee River restoration project. Future planning and design work for the proposed treatment facility would consider hydrologic conditions created by the completed Kissimmee River Restoration Project.

445. It is possible that additional water quality problems may potentially be created through implementation of the draft recommended Comprehensive Plan. There should be an explicit recognition in the Restudy report/PEIS of the critical need to deal with all remaining water quality issues at the most appropriate stages of project planning, design development, permitting, and construction of the recommended plan components.

Response: Several sections of the Report/PEIS were revised to more specifically describe water quality problems and opportunities in the study area (Section 5), water quality effects of the recommended plan (Section 8), water quality elements of the recommended plan (Section 9), and water quality considerations during future implementation actions (Section 10). The Summary section prefacing the Report/PEIS and the water quality portion of Appendix H were also revised to more explicitly address water quality. The recommended Comprehensive Plan facilities will be designed to meet applicable state and tribal water quality standards. To compliment regulatory and non-regulatory water quality programs by state, tribal, and local governments, the Implementation Plan provides that plan components will be planned and designed to the maximum extent practicable to augment basin pollutant load reduction and total maximum daily loading targets. The Comprehensive Plan includes a recommendation for a feasibility study to develop a comprehensive integrated water quality plan for south Florida.

446. According to Florida environmental rules, water discharges to OFWs cannot cause water quality conditions to be degraded and must be clearly in the public interest. The proposed restudy wastewater reuse projects must also comply with the requirements of chapter 62-610, F.A.C., which governs the reuse of reclaimed water, and Chapter 62-611, F.A.C. which contains the provisions for discharges of reclaimed water to wetlands.

Response: Biscayne National Park (BNP) and Everglades National park (ENP) are currently designated as an Outstanding Florida Waters (OFWs). An anti-degradation at the time of OFW designation provision applies to all OFWs designated by the State of Florida. Relative to wastewater reuse concerns, the Restudy includes a pilot project to evaluate the feasibility of treating wastewater to sufficient quality to be discharged to BNP and ENP. Due to the anticipated high costs of potential wastewater reuse treatment technology, a thorough evaluation of alternative, less costly, potential supplies of freshwater to BNP and ENP will be undertaken in future planning and design efforts prior to beginning detailed design work relative to directing wastewater reuse flows to BNP and ENP.

447. The Department understands that the cost for treating raw surface waters to be injected into aquifers has been included in the overall estimated cost for the recommended plan. While the Department supports consideration of revised underground injection regulations to allow underground injection of raw surface water in some cases to achieve ecological restoration and water supply objectives, protection of ground water resources and drinking water supplies is of paramount importance to the Department. Aquifer stored water must be treatable to meet designated uses upon recovery.

Response: In a letter dated October 1, 1998, the Chairman of the Governor's Commission for a Sustainable South Florida, the Secretary of the Florida Department of Environmental Protection (FDEP), the Executive Director of the South Florida Water Management District (SFWMD), and the Commander of the Jacksonville District Army Corps of Engineers requested the Administrator of the U. S. Environmental Protection Agency (USEPA) to consider a "risk-based" approach for allowing injection of water containing coliform bacteria into saline aquifers in the implementation of Restudy ASR facilities. Current EPA and FDEP underground injection control (UIC) regulations require primary drinking water standards must be met prior to injection into an underground source of drinking water. The primary drinking water standard for coliform bacteria is zero; none can be present. The request to use a risk-based approach when reviewing future UIC permit applications was based on the assumption that "microorganisms do not present a public health threat when stored underground in a saline aquifer." USEPA responded by letter dated February 9, 1999, indicating that it will work with the Corps, FDEP and SFWMD to develop a risk-based flexible approach to constructing and permitting ASR wells proposed by the Restudy provided that the risk-based analyses of Restudy ASR projects "demonstrate that the USDW will not be endangered in a way that could adversely effect the health of humans" or the environment.

448. An additional concern regarding ASR is the quality of the recovered water to be reintroduced into the natural system to achieve ecological objectives. Aquifer-stored water is likely to be low in temperature, low in dissolved oxygen, and have a different pH than receiving waters. Other chemical changes may occur which have not been identified. Recovered water would have to be treated to meet surface water quality standards prior to discharge if it were subsequently determined that aquifer storage water created water of unacceptable quality for surface discharges.

Response: Full implementation of the ASR facilities contained in the Restudy depends upon pilot projects, including water quality monitoring work and follow-up assessments, to determine the effect of the injectate on the USDW as well as the potential effect of the recovered ASR waters on the receiving surface water bodies. The recommended Comprehensive Plan includes aeration treatment of recovered ASR waters. If ASR pilot projects indicate that other water quality treatment is required to treat ASR recovered waters in order to be in compliance with applicable state and tribal water quality standards, then modifications will be made to the appropriate ASR components prior to initiation of detailed design and construction.

449. Modeling performed during plan formulation and evaluation indicates that already planned diversion of 80% of the drainage discharge from the four 298 Drainage Districts and Closter Farms identified in the Everglades Forever Act to the Everglades Construction Project does not fully occur in the draft recommended plan. Instead, only about 40% of the discharge is diverted and 60% continues to be pumped to Lake Okeechobee. An explanation should be provided for this modification of a major and expensive pollution reduction component required by the Everglades Forever Act.

Response: The comment is accurate; however, no deliberate effort was made to increase backpumping to Lake Okeechobee. Water budget data from the SFWMM for the EAA/298 Districts and Lake Okeechobee in the recommended plan are summarized below (in k as. ft.):

298s to Lake Okeechobee:	23.80
S-236 to Lake Okeechobee:	10.90
298s to STA 2:	10.79
298s to STA 3\4:	5.94
S-236 RO South:	7.37
TOTAL, 298s + S-236:	58.80 (Total flows for 298s)

The percentage of runoff from the 298 Districts/Closter Farms diverted for treatment by the ECP is calculated as follows:

298s to STA2:	10.79
298s to STA 3\4:	5.94
S-236 RO South:	7.37
SUBTOTAL:	24.10 (Combined 298s RO to STAs)

(Combined 298s RO to STAs) ÷ (Total flows for 298s) x 100% = (Percentage of RO Treated)

(24.10) ÷ (58.80) x 100% = 41.0%

The modeling results indicating that the diversion of runoff from the 298 Districts and Closter Farms is reduced in the Restudy compared to the target in the Everglades Forever Act are likely to be an artifact of the overall operational triggers and routing mechanisms in the model. There was no deliberate effort made to increase backpumping to Lake Okeechobee. There is sufficient conveyance and storage capacity provided in the plan, particularly with the inclusion of the EAA storage area (Component G), to manage the target volume of 80 percent, if not more. This apparent operational and routing problem will be more fully investigated in future detailed planning and design work undertaken for the construction and operation of the EAA storage area.

450. The recommended plan significantly increases flows at several existing Non-ECP structures, including the proposed modified S-140 structure (Component RR). Although it is understood that most of the increased flow through the proposed S-140A pump station is to be diverted from the STAs, approximately 9,000 acre feet (average annual volume) of additional runoff (greater than future base conditions) from Seminole and Miccosukee tribal lands is to be directed through the structure into WCA 3A. If it is determined that this increased volume were to cause whatever treatment strategy/facility is to be developed for that basin to fail to perform adequately, the recommended plan should assure that additional modifications to assure that water quality standards would continue to be met will be implemented as part of the overall design, construction, and operation of the applicable recommended plan components.

Response: The planning assumptions for the Restudy include full implementation of the requirements of the Everglades Forever Act, including those facilities/strategies necessary to achieve compliance with the State of Florida's phosphorus criterion in the Everglades for discharges from the proposed S-140A pump station. The sources of the proposed increase in the average annual volume of water discharged through the proposed S-140A pump station are upstream treatment areas designed to achieve compliance with State of Florida water quality standards, including the yet-to-be-determined phosphorus criterion for the Everglades. If it was determined in future detailed planning and design work that the increased volume and proposed operation would adversely affect whatever treatment strategy is developed for the S-140 basin in accordance with the Non-ECP requirements of the EFA, modifications necessary to assure that the water quality requirements of the EFA are achieved would be incorporated into the final design and operation of Component RR4.

451. The draft recommended plan includes at least two new structures (S-356 A&B, Component FF) which would be considered new discharges into the Everglades Protection Area (EPA). If future investigations indicate that water to be directed through the new structures would not meet water quality criteria for the EPA (including the yet-to-be-established numeric phosphorus criterion an the phosphorus concentration targets mandated by the federal Settlement Agreement), additional treatment measures would have to be incorporated into the overall design and operation of this component by the Corps and the SFWMD to assure that water quality standards are met

Response: The planning assumptions for the Restudy include full implementation of the requirements of the Everglades Forever Act, including those facilities/strategies necessary to achieve compliance with the State of Florida’s phosphorus criterion in the Everglades. The source of water to be discharged by the S-356 A & B structures is the WCAs 2 and 3. Seepage and surface waters from WCAs 2 and 3 will be directed to the Central Lake Belt storage area. Under certain conditions, the stored water is returned to the L-31 N canal bordering Everglades National Park. It has not yet been determined that water quality treatment facilities will be necessary to operate Component FF as conceptually planned. However, water quality treatment facilities, if necessary, associated with the proposed Central Lake Belt storage area and discharges from the S-356 A&B structures will designed to achieve compliance with State of Florida water quality standards, including the yet-to-be-determined phosphorus criterion for the Everglades.

N.2.8 Public Outreach

452. Counties north of the lake did not participate in the Restudy process.

Response: The Restudy is committed to an open public process and the participation of all 16 counties within the study area. The Restudy Team highly encourages participation by county and local governments and will actively seek enhanced involvement in the future as the Restudy moves into more detailed design and planning.

453. The USEPA wishes to continue its involvement in the Restudy and requests to be advised of Restudy progress.

Response: Concur. USEPA’s continued involvement in the Restudy is seen as being crucial. Restudy progress will be reported regularly.

454. There was not adequate exposure of different alternatives and inadequate time for public input.

Response: The Restudy process has been ongoing in South Florida since the beginning of the Reconnaissance phase in 1993. As described in Section 11: Public Involvement, the Restudy Team has held numerous public meetings throughout the study area to apprise the public on the study's progress and to solicit input. As the study moves into the more detailed stages, continued public involvement will be sought.

455. The comment centered around increased efforts to educate and work with the public regarding local, regional, state, and Federal issues.

Response: The Restudy Team, since its beginning, has been committed to understanding the issues within the study area and at larger scales. This commitment will continue as more detailed study and planning progresses.

456. There should be full coordination between partnering agencies and different levels of government.

Response: Concur. The Restudy Team is made up of individuals from a wide variety of Federal, state, local, and tribal governments and the study has been carried out in a spirit of cooperation and collaborative problem-solving.

457. The concern regards project impacts on minority communities.

Response: Concur. As the study moves into more detailed design, the Restudy Team will actively work within the communities where project works will be sited.

458. The Department expects to continue to be fully involved in the Restudy.

Response: Concur. The Department's continued involvement in the Restudy is seen as crucial.

459. The public comment period for the Comprehensive Plan was inadequate and additional review time is necessary.

Response: The Restudy Team appreciates the fact that the Comprehensive Plan contains a great deal of information. However, the entire plan formulation process of the Restudy was posted on a public web site over the formulation period of September 1997 through August 1998. The comment period for the draft programmatic environmental impact statement was one month longer than that required under NEPA.

460. The comment regarded the technical feasibility of ASR and whether it would be practical to go to Manatee County to visit ASR facilities there.

Response: Pilot projects to test the technical feasibility of ASR are slated for early authorization; indeed, the SFWMD is drilling monitoring wells at the Site 1 location (Hillsboro Canal) at the present time. Information gleaned from operating ASR wells is helpful, however, the more site-specific data gathered from the Restudy pilot projects will be the most valuable to the Restudy.

461. It was recommended that education be one of the features of the recommended plan.

Response: Education is typically is not a formal activity of the Corps of Engineers, although it is concurred that pollution prevention and water conservation are important items for the public to understand. In conjunction with the November 1998 public meetings, however, an environmental education component was developed for grade school and high school levels. Public outreach activities, which by their nature include education, will be ongoing in all future Restudy planning.

462. The comment was a commendation on the interagency efforts of the Restudy and the commitment to work collaboratively in the future.

Response: Concur. All efforts will be needed to further the goals of the study.

463. Environmental needs were an afterthought in the study.

Response: The Restudy is about restoration of the south Florida and Everglades ecosystems while continuing to provide for the other water-related needs of the region. Restoration goals have always been at the forefront of the study.

464. The Restudy seems to favor a management approach that will shortchange the ecosystem.

Response: Current operation of the C&SF Project has had adverse effects on the natural system. The philosophy of the Restudy is that in addition to structural changes to the project, operations must also change such that degradation does not continue to occur.

465. Stakeholders need to have a better understanding of the PIR process and their points of entry.

Response: Five public workshops were held during the development of the Implementation Plan, which was released January 25 for a review period of ten days. The entire PIR process is explained in the Implementation Plan.

466. The level of detail available in the Comprehensive Plan is not sufficient to answer specific questions. When such detail becomes available, will there be sufficient time for the commission to respond?

Response: The more detailed or site specific resolution of issues will come in this next phase of Restudy planning, the Project Implementation Report process. The Implementation Plan explains this process and points of entry for comment / public input. There will be continuing opportunities for stakeholders and the public to be involved in the implementation process.

467. There was a lack of straightforward information presented at public meetings.

Response: Information presented at the public meetings was consistent with the level of detail of the Comprehensive Plan. There was an open house at each of the meetings so that the public could have questions answered by team members. The more detailed or site specific resolution of issues will come in this next phase of Restudy planning, the Project Implementation Report process. The Implementation Plan for the Restudy explains this process and points of entry for comment / public input.

468. The Corps is applauded for the initiation of a minority outreach program. The effort should involve the multi-agency working group.

Response: Concur.

469. NOAA recommends that Restudy implementation plans include multi-agency education and outreach efforts.

Response: As the Restudy continues on through its successive phases, the commitment has been made to continue the multi-agency approach. Public outreach will be an integral part of all future work.

470. The same level of public participation that occurred throughout the Restudy should continue.

Response: Concur. Public outreach will be an integral part of all future work.

471. There has been no real effort to inform the public about the Restudy.

Response: The Restudy public outreach program actively sought ways and means of informing the public about the study and will continue to do so. Section 11: Public Involvement describes all of the public outreach activities conducted during the study.

N.2.9 Implementation Plan and Monitoring

472. What guarantees are there that the project will be operated to achieve hydrologic regimes for the entire remaining Everglades?

Response: The Comprehensive Plan was formulated to address issues and problems currently facing the south Florida ecosystem. The plan attempts to strike an important balance in the system's needs. Hydrologically, initial assessments indicate that all areas and users reap benefit from implementation of the plan. Formulation of operational criteria will include coordination with involved stakeholders and agencies.

473. How will operational changes affecting Everglades National Park be handled?

Response: Interim operation criteria will be developed as part of the next phase of component development. Formulation of any interim operational schemes stemming from the Restudy will include coordination with involved stakeholders and agencies.

474. NRDC recommends the immediate acquisition of the Model Lands.

Response: The C-111N Spreader Canal component will enhance connectivity and sheetflow in the Model Lands area. This feature, which includes acquisition of the Model Lands, is one of the features recommended for initial authorization.

475. What is the status of South Miami-Dade Agricultural and Rural Land Use and Water Management Plan and Biscayne Bay Coastal Wetlands Critical Projects?

Response: In an effort to advance this work, these projects will be addressed in the ongoing Biscayne Bay Feasibility Report.

476. Why is the L-28 Interceptor Canal Backfill component not implemented earlier?

Response: The Implementation Plan schedule was developed to implement each component as soon as possible under reasonable and prudent constraints. The L-28 Interceptor Canal Backfill component must be implemented in conjunction with the decompartmentalization of WCA-3 and has been scheduled accordingly.

477. How can the WCA-3A Decompartmentalization and raising Tamiami Trail components be implemented faster?

Response: It is currently anticipated that certain features could be advanced under the authority of the Modified Water Deliveries to Everglades National Park Project.

The first phase of decompartmentalization, which includes raising the eastern portion of Tamiami Trail, is recommended for initial authorization.

478. How is surface water storage maximized and what assurances do water users have?

Response: The formulation of the Comprehensive Plan included analyses of the use of surface water storage. The recommended Comprehensive Plan attempts to balance known and existing sources with new sources and sources that may be contributed through the implementation of high technology. Assurances to water users are addressed in the Implementation Plan, Section 10 of this report.

479. What commitment exists in this report to address water quality needs and how will water quality features be included in future component design?

Response: The Implementation Plan schedule, Section 10 of this report, provides a level of detail consistent with the Comprehensive Plan. General design that includes water quality needs will be accomplished during the project implementation process. Water quality considerations will be included during this process, as described in the Implementation Plan. Additionally, a feasibility study to develop a comprehensive integrated water quality plan for south Florida is being recommended.

480. Why are expensive reuse facilities being considered?

Response: The Implementation Plan recognizes the high cost of constructing and operating reuse facilities along with the potential issues involving the operation of such facilities. For that reason, components involving reuse have been scheduled as last orders of work, so that alternatives can be considered that may preclude the need to rely on this source of water.

481. When and how will optimization of design, sizing, and siting be accomplished to maximize water quality benefits?

Response: General design will be accomplished during project implementation studies and reports. Detailed design will follow authorization of each component. These considerations can be included as design considerations and the development for construction. Optimization for each component's designs, performance, and operation will be considered as part of future component development.

482. The EAA Storage component should be phased.

Response: Concur. The Implementation Plan reflects a phased approach.

483. What level of management of the system will be required?

Response: The Comprehensive Plan was formulated to address issues and problems currently facing the south Florida ecosystem. The plan attempts to strike an important balance in the system's needs. Hydrologically, initial assessments indicate that all areas and users reap benefit from the implementation of the plan. During the implementation process, formulation of operational criteria will include coordination with involved stakeholders and agencies. The level of system management will be in accordance with the efficient and effective functioning of the system.

484. Why is the schedule for implementation of the Comprehensive Plan biased towards building water supply and flood control components.

Response: The scheduling of components have been made in such a manner as to attempt to achieve project goals in the most efficient way possible. It is inappropriate to attribute or assign the function of an individual component to urban, agricultural, or environmental water supply. The premise of the plan is that restoration can only be achieved through the full implementation of the recommended Comprehensive Plan with each component contributing to the overall goal of ecosystem restoration. Initial authorization recommendations clearly recognize the need to provide ecological benefit as soon as possible, while maintaining a broad range of water supply sources until additional studies are performed.

485. The Restudy should recognize the need for peer review, evaluation of pilot projects prior to construction, distribution of research funds, a Florida Bay Feasibility Study, accurate and comprehensive topographic data, monitoring program provided should provide the procedure of how monitoring data will be disseminated to interested parties, and avoidance of single species management.

Response: The Implementation Plan schedule, Section 10 of this report, provides a level of detail consistent with the Comprehensive Plan. The Restudy Team recognizes the importance of peer review, which has been addressed in Section 10. Pilot projects have been identified and the current schedule reflects the dependencies of certain components on the completion of the pilots and analysis of performance. The recommended plan includes a Florida Bay and Florida Keys Feasibility Study. Ongoing efforts will be integrated into this study. The recommended plan does include obtaining the necessary data to complete design of project components. The dissemination of adaptive assessment data and analysis will be part of the commitment to continue to do business in an open and public manner. Use of the internet and other publicly accessible outlets will be used for all project information to the maximum extent possible. As additional formulation is performed, and as details for the design of each component progresses, the Project

Team will coordinate the refined plan with the necessary agencies to insure appropriate implementation occurs in regards to environmental concerns.

486. How does the plan address the issue of future funding uncertainties?

Response: The Implementation Plan has been constructed to provide a “technical solution” for execution of work. Applying funding constraints (such as the $400 million annual guideline) reflects a prudent and reasonable expectation for Federal and local sponsor annual appropriations and capability. The Comprehensive Plan must be completely implemented to achieve project goals. The schedule has been built to allow for changes in the implementation of the components due to funding shortfalls or accelerated funding.

487. How can the St. Lucie and Martin County (Indian River Lagoon and St. Lucie River) components be expedited? What is the ability of local governments to participate? The implementation schedule should assure that all Lake Okeechobee storage will be completed to stop damaging freshwater discharges into the St. Lucie Estuary.

Response: The Implementation Plan schedule was developed to implement each component as soon as possible. The feasibility report for the Indian River Lagoon is ongoing and in recognition of the opportunity for immediate benefit, the component for the C-44 Storage Reservoir will be recommended for initial authorization. Additionally, as a result of recent discussions, the Implementation Plan will be revised to reflect a phased approach that will allow the Indian River Lagoon components to be initiated sooner.

488. What interim improvements will be made in St. Lucie and Martin Counties and what impacts will there be to the St. Lucie Estuary?

Response: The St. Lucie River Issue Team of the Working Group identified four main project types that could be made in the interim before Restudy projects are implemented. The four categories of interim projects include stormwater retrofits, water storage areas, restoration, and programs.

489. What assurance is there that backpumping of Caloosahatchee River water will not degrade the water resources within the St. Lucie Basin or estuary?

Response: The backpumping facility includes a 5,000-acre stormwater treatment area for water quality treatment prior to discharge into Lake Okeechobee.

490. Why is the implementation and funding scheduled so late, how were priorities of individual components determined, and what has been done to expedite the implementation of the Comprehensive Plan?

Response: The schedule was developed using the "best professional judgement" of a broad multi-disciplinary team to identify the linkages between components. In this way, each component is implemented as soon as possible using reasonable and prudent constraints. Prior to implementing any component of the Restudy (except for the WPA's and IRL feasibility studies which are on-going), agreements outlining the roles and responsibilities for the Federal government and the local sponsor during pre-construction engineering and design phase. No Federal funds may be expended on the construction prior to congressional authorization and execution of terms for local cooperation.

491. How does project component sequencing relate to threatened and endangered species?

Response: General design will be accomplished during the project implementation phase. Detailed design will follow authorization of each component. Implementation of projects will include endangered species considerations to prevent negative impacts.

492. The WPA Feasibility Study should be expedited.

Response: The WPA Feasibility report is currently underway and scheduled to be completed in 2001.

493. Hydrological transitions should be staged and timed to encourage fish and wildlife to move toward safe habitat.

Response: General design will be accomplished during the project implementation phase. Detailed design will follow authorization of each component and can include the stated design considerations. Refer to the adaptive assessment strategy in the Implementation Plan.

494. Sensitive periods for aquatic life should be identified, and changes in hydrological conditions and other disruptive activity timed to avoid negative impacts.

Response: Component design and system-wide analyses can include these considerations during future planning and design efforts.

495. How was the Phase A analysis [2010 Scenario] used and how will the concerns contained in the National Park Service's conclusions on Phase A be addressed?

Response: As part of the development of the Implementation Plan schedule, a list of Comprehensive Plan components that could be expected to be operational by the year 2010 was developed. This scenario represents approximately the first 10 years of implemented projects using an estimated capital expenditure of approximately $400 million per year. The components were then modeled using the South Florida Water Management Model to simulate the performance of the C&SF Project at this point in time. The Alternative Evaluation Team, to help understand and determine the ecological and water supply effects that would occur, evaluated the output as a result of incrementally implementing the Comprehensive Plan. The goal of this analysis was to improve conditions over the base cases and at a minimum not to have performance inferior when compared to the base cases. No attempt was made during the analysis to optimize operations. It was not expected that modeling the 2010 components would attain the hydrologic or ecological performance of the Comprehensive Plan. The focus was to identify any areas where performance was worse than the 1995 Base Case or 2050 future without project condition. Sub-groups looked for and suggested corrections for sequencing. These types of scenario-based analyses will be used during future component development to refine the Implementation Plan.

496. The details of the Implementation Plan need to be completed and go through a process of peer review and public input prior to the submission to the Chief of Engineers. Funding sources, methods, and justifications must be included in the Implementation Plan. Federal matching funds must be guaranteed annually before commitment and expenditure of state and local funds. Florida legislative support for the plan is critical and must include public hearing at the local level.

Response: The level of detail contained in the Implementation Plan is consistent with that contained in the Comprehensive Plan. The current Implementation Plan addresses the lack of detail by identifying processes that will be used for future project development. A revised Implementation Plan was released for public review on 25 January 1999, and addressed the guidelines for implementation and schedule development. Appropriate peer review will be addressed during advanced formulation portion of the Project Implementation study and report. Financial analyses are contained in Appendix G. The Federal funding of water resource projects are subject to development by the administration and review and modification by Congress annually. Historically, Congress has chosen not to provide full funding on these types of projects. It is expected that local cost sharing will be handled programmatically with the SFWMD using a combination of District, state, and local government funds. The details of this effort are being formulated and will be solidified as detailed information is developed during the Project Implementation Report period. The Corps and the SFWMD have continually worked with the state and local governments to provide an understanding of the proposed project. This process will continue throughout the implementation period.

497. Why does the plan not schedule early acquisition of land? It is recommended that the Restudy's land acquisition program be a top priority during the first implementation phase. The Restudy should maximize the spatial extent of functional wetlands by prioritizing land acquisition since lands continue to be lost to development. The Implementation Plan is weighted towards building expensive water supply components early which may leave funding shortfalls for future land acquisition. Adaptive management should be used to determine if a more passive surface storage system responds better that "high tech" components [contained in the Comprehensive Plan].

Response: The scheduling of components has been in such a manner as to attempt to achieve project goals in the most efficient way possible. The Implementation Plan has been structured to address land acquisition concerns using current policy and law. The schedule has been constructed with flexibility that would allow for any changes that would advance work in any area, like real estate acquisition (once authorized). The Implementation Plan was developed with the input of Federal, state, local, and tribal input; as well as stakeholders and the public. It is inappropriate to attribute or assign the function of an individual component to urban, agricultural, or environmental water supply. The premise of the plan is that restoration can only be achieve through the full implementation of the recommended plan with each component contributing to the overall goal of ecosystem restoration. Initial authorization recommendations clearly recognize the need to provide ecological benefit as soon as possible, while maintaining a broad range of water supply sources until additional studies are performed. Federal funding will be subject to Congressional review on an annual basis and would be exposed to their appropriation equally in any one budget year. The use of Adaptive Assessment is an inherent part of the implementation of the Comprehensive Plan.

498. Provisions should be included in the Restudy plan to ensure that secondary impacts are considered and addressed.

Response: The next phase of the project development includes more detailed planning, engineering and design. These efforts will be contained in a Project Implementation Report for each component or groups of components. The studies conducted in preparation of this report will include advanced formulation, general engineering and design, real estate analysis, and socio-economics analysis. It is expected that coordination with adjacent and impacted users will occur through this process as well as through the public involvement process that will be conducted prior to the approval of the Project Implementation Report.

499. Provisions should be included in the Restudy plan to ensure that future co-location of electrical facilities with the Restudy's components are made as compatible as possible.

Response: See response # 498 above. Coordination with FPL and other entities is expected to occur during the Project Implementation Report and Detailed Design phases.

500. It is essential that the Implementation Plan provide a process that ensures that water quality or any other requirement that could prevent implementation of a component, be identified, fully addressed, and equitably funded by both the Federal government and the local sponsor before the components are authorized and public resources are irrevocably committed. The period of review for the revised Implementation Plan (25 January 1999 release) is too short.

Response: The Implementation Plan is consistent with the level of detail contained in the Comprehensive Plan. Project development process discussion has been included in the Implementation Plan. The next phase of project development includes detailed planning, engineering and design. These efforts will be contained in a “Project Implementation Report” for each component or groups of components. The studies conducted in preparation of these reports would address most issues contained in the comment. The Federal funding of water resource projects are subject to development by the administration and review and modification by Congress annually. Historically, Congress has chosen not to provide full funding on these types of projects. The comment period and public meeting was held after a series of public workshops conducted to improve the Implementation Plan for release for public review on 25 January 1999. In order to meet the legislatively directed submission date for the Comprehensive Plan, adequate time is required for the processing of comments received as part of the latest public input of the Implementation Plan. The maximum allowable time for further review was made available that would allow for completion of the report. A final state and agency review will occur as part of the Corps approval process prior to the submission of this report to Congress on 1 July 1999.

501. What provisions have been made for future public input to decision making? There has not been enough time allotted for adequate review of the Comprehensive Plan. Components should be subjected to an appropriate level of technical analysis prior to congressional action.

Response: One of the guidelines for the development of the Implementation Plan (see Section 10 of this report) is the continuation of outreach and public involvement. In addition, public review and input has been ongoing even prior to the October 1998 release of the draft Comprehensive Plan. The next phase of the project development includes detailed planning, engineering and design. These efforts will be contained in a “Project Implementation Report” for each component or groups of components. The studies conducted in preparation of these reports will address technical issues contained in the comment, including the agency and public review prior to preparation of detailed design.

502. The Implementation Plan should address: integration of other ongoing efforts (Federal, state, regional, and local planning efforts), adaptive management, assurances for the natural system, expediting feasibility studies, integration with parallel planning processes and restoration projects, and contingency planning.

Response: Integration of other ongoing efforts has been occurring throughout the Restudy. The Implementation Plan contains an explanation of the integration of the recommended components of the Restudy with ongoing projects and programs (Section 10) and provides an explanation of how adaptive assessment will be used throughout the project development lifecycle. The Implementation Plan contains language dealing with assurances. The schedule and recommended initial authorization include both pilot projects and additional feasibility studies as part of the first order of work. The next phase of each component's development would include detailing the features in preparation for detailed design. This process will include specific integration with on-going projects and programs. In addition, public and stakeholder review and input will occur. The level of detail contained in the Comprehensive Plan required that the cost estimate for the recommended features contain contingency funding. If the analysis of the performance of pilot projects should reveal a significantly less reliability than is expected in the Comprehensive Plan, then the plan will be modified.

503. Revisions to the Implementation Plan contained in the October draft report should have some mechanism for review and comment. Additional work is required to determine how the Comprehensive Plan will be implemented.

Response: Concur. A revised Implementation Plan containing stakeholder and public input was released for additional public review on 25 January 1999. Additionally, the Implementation Plan will be revised as new and better information becomes available.

504. Given that so much of the report's basis is meeting the speculative growth, why does the Restudy plan not employ more prudent uses of public money by staging certain components.

Response: The revised Implementation Plan, Section 10 of this report, does stage (phase) a number of components over a 37-year implementation period.

505. The report states that the Caloosahatchee Basin and Estuary and the Big Cypress Basin have been under-assessed by the EIS. That being the case, the timing [scheduling] of some of the projects components should be delayed pending the conclusion of the [Southwest Florida] feasibility study. An assessment of the basin's water supply needs and the greater estuarine salinity level needs must be completed and accepted before the Restudy Plan can be approved.

Response: Due to the recognized need, a feasibility study for Southwest Florida was authorized and is currently being pursued. This study will investigate the water resources of this portion of the south Florida ecosystem. Plans arising from this study will be integrated into, and must be consistent with the plan of improvement of the Restudy. To the extent possible, Restudy components were developed to address system-wide concerns. These components will undergo further formulation and once reviewed and if approved, constructed. Currently, with the exception of an ASR pilot project, facilities proposed for the area are anticipated to begin construction in 2005 and so will be able to incorporate the findings from the feasibility study.

506. It is recommended that a streamlined permitting process be established with the approval of the Governor and Cabinet for features in the Comprehensive Plan.

Response: Concur. The Restudy will continue to identify areas to improve the efficiency of the implementation process. Currently, the Corps meets with state agencies on a quarterly basis to discuss these types of matters.

507. The implementation of the components of this project must include adequate assurance to existing water users that their source of water will not be taken or reduced prior to installation of proven alternative sources. The implementation strategy must include provisions for assurances to existing water users and provisions requiring adequate facilities to be in place before any re-allocations of water that would adversely affect existing users. Costs must be distributed equitably. Restoration and preservation must be undertaken in accordance with state water law and must be balanced with the needs for water supply and flood protection.

Response: The revised Implementation Plan, Section 10 of this report, addresses in greater detail assurances to water users. The plan does recognize the need for a reasonable and prudent implementation in regard to replacing water sources. Details for individual components will be developed and/or refined during the Project Implementation Report process.

508. For those more speculative components of the Comprehensive Plan about which there continues to be much technical debate and concern, the Corps and the SFWMD should undertake detailed, yet accelerated feasibility analyses in order to eliminate uncertainties.

Response: The current plan recommends early authorization of pilot projects and additional studies to address uncertainties as rapidly as possible. Project Implementation Studies and Reports will be conducted and will consider these types of issues. Formulation of operational criteria will include coordination with involved stakeholders and agencies.

509. The Council has serious concerns about the potential for delays or slippage in the implementation plan in light of a 20 year implementation projection. The Council supports the development of a detailed Implementation Plan. The Council is concerned that the revised Implementation Plan will not receive public review.

Response: Revisions to the Implementation Plan provide an aggressive, but more realistic implementation period. The level of detail contained in the Implementation Plan cannot be greater than that contained in the Comprehensive Plan. The current Implementation Plan addresses the lack of detail by identifying processes that will be used for future project development. The revised Implementation Plan was released to the public on 25 January 1999, with a 12 day review period.

510. The Council believes that Federal and state agency review and certification should occur prior to authorization.

Response: Prior to the submission to Congress, the plan will receive a final state and agency review. Each Project Implementation Report will include a supplemental NEPA document and will undergo full public and agency review.

511. The process for prioritizing and packaging elements [components] under the Implementation Plan remains unclear. The Corps should provide information on how the Restudy components are prioritized and packaged for authorization.

Response: The Implementation Plan, Section 10 was revised with input from stakeholders and the public. It addresses the guidelines for implementation and schedule development.

512. The implementation of the Seminole Tribe Water Conservation Plan Other Project Element is critical for full restoration of the south Florida ecosystem. This component should be one of the first funded in the Restudy.

Response: The Seminole Tribe Water Conservation Plan Other Project Element is scheduled for early implementation. It is also included as a component that would be pursued under the recommended Programmatic Authority for the Restudy.

513. The feasibility study did not allow a thorough investigation of Southwest Florida. A feasibility study of this area is recommended as soon as possible. A pilot project for ASR is recommended. When would this pilot project be underway?

Response: The Southwest Florida Feasibility Study is included in the Comprehensive Plan and will be initiated in 1999. Pilot projects have been recommended for initial authorization and will be initiated as soon as possible. The design of the ASR pilot projects is currently scheduled to be initiated in fiscal year 1999 and 2000.

514. The Corps and the SFWMD must commit to providing adequate modeling and monitoring support for the implementation process. Computer models should be used to simulate “the next step” prior to making alterations to the existing infrastructure. There should be a continuous effort to refining and improving models.

Response: Concur. The Implementation Plan, Section 10 of the main report, provides an explanation of how this comment will be addressed through adaptive assessment, future component development, and continuation and improvement to models and tools throughout the implementation lifecycle. The Implementation Plan can be utilized as a model that provides insight to the affects of changes to the implementation schedule.

515. The Implementation Plan should including monitoring, research and performance evaluation. The authorization should be broad enough to accommodate “adaptive management.”

Response: Concur. The current plan addresses the use of an adaptive assessment program throughout the implementation period. The Implementation Plan, Section 10 of this report, provides an explanation of the project’s Adaptive Assessment strategy.

516. It is imperative that the Implementation Plan adequately characterize the benefits of the components so that appropriate funding strategy can be developed and supported by stakeholders.

Response: The formulation process followed by the Restudy precludes a strict use of cost effectiveness and incremental cost analyses in optimizing the recommended plan. The individual components were combined during formulation in recognition of their synergistic effects that extend throughout the ecosystem. The schedule developed for the Implementation Plan reflects a logical sequencing that has been reviewed by a wide sector of stakeholders and the public. This schedule constrained to an annual funding target of $400 million provides a basis for funding the effort over a 37-year program. The schedule has been constructed so that increases or decreases in annual funding can be evaluated and the schedule revised accordingly. Section 7: Plan Formulation and Evaluation describes the benefits of the recommended Comprehensive Plan. SFWMD’s financing plan for the non-Federal share of project costs is contained in Appendix G: Local Cooperation and Financial Analysis in this final report.

517. How are Biscayne Bay Estuary Targets addressed?

Response: The Implementation Plan schedule addresses the need to complete the Biscayne Bay Estuary targets prior to initiation of certain features.

518. The Restudy report should be modified to provide a process for obtaining policy-level review and input throughout the development and implementation of the project.

Response: The Implementation Plan, Section 10 of this report, provides discussion of the guidelines that will be used throughout the implementation of the recommended plan. Included in the guidelines is the commitment to continue interdisciplinary and interagency teams throughout the project's lifecycle. Further project development (project implementation studies and reports) would include formal and informal consultation with stakeholders.

519. What is the process for designing and implementing pilot projects and DERM's role?

Response: The Implementation Plan schedule provides a level of detail consistent with the Comprehensive Plan. It is currently recommended that pilot projects receive early authorization. Upon the execution of appropriate cost sharing agreements, design is expected to be initiated as early as fiscal year 2000. The plan recognizes the commitment to continue interdisciplinary and interagency teams throughout the project's lifecycle, of which, DERM would have a role.

520. The Implementation Plan must include process descriptions for dealing with uncertainties, contingency planning, and assurances to water users, as well as, the ability to assess the effectiveness of these processes.

Response: The Implementation Plan schedule, Section 10 of this report, addresses the issues contained in this comment.

521. There should be utilization of local funding sources in combination with Federal and SFWMD funds to advance the implementation of the project.

Response: Concur. It is expected that throughout the period while the Project Implementation Report is being developed, dialogue will continue with state and local governments to maximize and leverage funding to advance the implementation of the project.

522. How will future land use planning be addressed in the Restudy.

Response: The Implementation Plan schedule has been structured in such a manner that allows for adjustments that will be necessary over the implementation lifecycle. As land use plans are modified and as land use decisions are being analyzed, the Implementation Plan schedule can be used to analyze the effects on the schedule of actual and proposed changes.

523. Will the Restudy plan require immediate acquisition of all required lands.

Response: Expenditure of Federal funds for lands recommended in a pre-authorization decision document is a matter of law. Once a project is authorized, Federal cost sharing may be applied to the acquisition of necessary lands once terms of local cooperation are agreed to. The scheduling of components have been made in such a manner as to attempt to achieve project goals in the most efficient way possible. The Implementation Plan has been structured to address land acquisition concerns using current policy and law. The schedule has been constructed with flexibility that would allow for any changes that would advance work in any area, like real estate acquisition.

524. Model output should be used to eliminate/minimize adverse environmental conditions throughout the implementation of the Conceptual Plan.

Response: General design will be accomplished during the Project Implementation study and report. Detailed design will follow authorization of each component. These considerations can be included as design considerations and the development of construction period and interim water regulation schedules.

525. The Restudy plan should require the establishment of operational standards and minimum operational requirements prior to construction.

Response: General design will be accomplished during the Project Implementation study and report. Detailed design will follow authorization of each component. As part of these design efforts, the details for construction and post-construction interim operations will be developed. A Detailed Design Report requires approval prior to construction.

526. Local outreach programs should be expanded to ensure that qualified local contractors have access to the bidding process. Consideration should be given to establishing local procurement programs, including local preferences where appropriate, to maintain contract dollars locally.

Response: Contracts procured by the Federal government must follow the Federal Acquisition Regulations. Experience has shown that awards made to the large contractors have resulted in the contractor choosing to use local labor and sub-contractors. Additionally, the Corps has several other procurement programs intended to provide opportunities to all sectors of the community. The Corps will develop a comprehensive Small Business and 8a set-aside program. Under the 8a program, local certified contractors would be utilized on a priority basis. As a normal part of establishing a Small Business and 8a plan for a project, the Jacksonville District's Small Business Officer would coordinate the Corps efforts with the project's local sponsor and local community.

527. The importance of establishing a baseline water quality and ecological monitoring program that monitors performance and measures water quantity and water quality improvements should be emphasized and such a program should be developed. The program must include appropriate monitoring to assess performance of the individual project components and impacts/benefits to the overall water resources in south Florida.

Response: Concur. The Corps with its cooperating agencies is in the process of establishing a standing multi-disciplinary, interagency coordination team to oversee the development of a regional monitoring program. The objectives of the monitoring program and monitoring program planning guidelines are contained in Section 9.5 of this Final Integrated Feasibility Report and Programmatic Environmental Impact Statement for the C&SF Project Comprehensive Review Study. These objectives and guidelines will guide the coordination team in developing a regional monitoring program that will have a dual focus on the biological and hydrological restoration objectives in the natural system, and water supply and flood protection objectives in the urban and agricultural regions. The program will be tailored so that it will detect change as a result of the implementation of Comprehensive Plan features. This information, in turn, will guide the adaptive management strategy by becoming the basis for improving the design of the Comprehensive Plan and the next incremental step in the restoration program.

528. The monitoring program should include baseline information on the Floridan Aquifer. The obtained data should serve as a tool to assess the success of the component and the affect of ASR activities on local and regional ground water flow in the Floridan and surficial aquifer systems.

Response: Concur. In addition, see response #527.

529. Regional monitoring should occur throughout the simultaneous testing of all ASR pilot test facilities.

Response: Concur. In addition, see response #527.

530. The comprehensive monitoring program should include methods for effectively monitoring water quality.

Response: Concur. In addition, see response #527.

531. The comprehensive monitoring program should include research on the relationships between native biological species and water quality. Such research should attempt to identify individual and/or communities of species that are sensitive to varying nutrient concentrations. If a relationship can be established the identified biological indicator should be used for regional scale monitoring of nutrient levels within the Everglades.

Response: Concur. In addition, see response #527.

532. The comprehensive monitoring program should utilize as much of the existing water quality monitoring programs as possible. These programs should be reexamined to determine if the matrices and sampling protocols are sufficient to provide the spatial and temporal information necessary to implement an adaptive management strategy on a project component basis as well as at the Everglades regional level.

Response: Concur. In addition, see response #527.

533. The water quality component of the comprehensive monitoring program should sample other water quality constituents in addition to phosphorus.

Response: Concur. In addition, see response #527.

534. Monitor changes in WCA-3B and ensure that discharges into WCA-3B, at minimum, meet all applicable water quality standards.

Response: Concur. In addition, see response #527.

535. Current monitoring of water quantity/quality budgets by tribal, Federal, state, and local governments should continue.

Response: It is not the intent of the proposed monitoring program contained in the Comprehensive Plan to discourage or supplant any tribal or governmental agency from continuing with their current water quality monitoring programs. It is the hope of the Corps and its planning partner, the SFWMD, that the existing programs would serve as a framework from which a base condition could be established for a region wide system that would monitor water quality conditions as individual project components are constructed and operated.

536. The monitoring program should ensure that hydrological alterations occur at a rate that will not negatively affect fish and wildlife species abundance or diversity, or threatened and endangered species.

Response: Concur. In addition, see response #527.

537. The comprehensive monitoring program should include specific Restudy project component monitoring to ensure that hydrological alteration results in the correct biological responses.

Response: Concur. In addition, see response #527.

538. Northeast Shark River Slough, Taylor Slough, and Florida Bay should be used as output indicators of the entire system and continue to be closely monitored for water quality and water flow measurements. As the Comprehensive Plan is implemented these downstream areas need to be monitored to ensure the success of the restoration program.

Response: Concur. See response #527.

N.2.10 Authorization / Funding

539. EPA believes that the potential exists that water quality features proposed in the Restudy may not be fully realized if implementation of the Restudy is in someway abbreviated. Accordingly, EPA recommends that Congress authorize improvement and protection of water quality for natural system protection and restoration as an authorized purpose of the C&SF Project.

Response: The water quality features included in the recommended Comprehensive Plan are an integral part of the Implementation Plan. Congress may consider adding water quality improvement as a purpose of the C&SF Project as part of an upcoming Water Resources Development Act.

540. There is much concern that if funding is cut in the future, the water supply components will be built but the restoration components will be abandoned or will be insufficient.

Response: Implementation of all of the components of the recommended plan is necessary to achieve the full level of benefits of the plan. Water storage is needed to achieve restoration as well as to meet regional water supply needs. The Implementation Plan sequencing recognizes the need to have storage facilities available as soon as possible.

541. Editorial changes in Section 11 of the report.

Response: Concur. Some of the requested changes have been made. While NOAA personnel have been valuable members of the study team, NOAA was not a contributing agency in the preparation of the PEIS.

542. The South Florida Water Management District should work closely with the State of Florida to ensure that the local share of the project (50%) should not be born solely by local residents, property owners, and water users.

Response: South Florida Water Management District's financing plan for the non-Federal share of project costs is contained in Appendix G: Local Cooperation and Financial Analysis in this final report.

543. Will funding to implement the plan be available?

Response: Implementation of the recommended plan will require appropriations by Congress as well as funding from non-Federal sources.

544. Who will pay for cost overruns and at what percentage? How much is this going to cost in new taxes (Federal and local)?

Response: All costs for the recommended Comprehensive Plan will be shared 50-50 between the Federal government and the non-Federal sponsor. Federal funding will be determined by Congress in future Appropriation Acts. The South Florida Water Management District's financing plan for the non-Federal share of project costs is contained in Appendix G: Local Cooperation and Financial Analysis in this final report.

545. The Restudy lacks sufficient funding to complete immediate purchase of East Coast Buffer/Water Preserve Lands.

Response: The initial authorization recommendations include a number of components in the Water Preserve Areas. The remaining components for the Water Preserve Areas will be included in the Water Preserve Areas Project Implementation Report, which is scheduled for completion in 2001.

546. The plan is conceptual and Congress should not be asked to approve any significant element of this plan until detail is provided to judge the costs and benefits of this action.

Response: It will be recommended that the Comprehensive Plan be approved as a framework for modifications to the C&SF Project. Authorization will be sought for pilot projects and for some components of the Comprehensive Plan as described in Section 10: Implementation Plan. If authorized, these components would still undergo more detailed planning and design before construction.

547. The C-111 North Spreader and the Biscayne Bay Wetlands would require purchase of more than 26,000 acres. These components should not be presented to Congress for approval until the land that will be taken and the benefits that will be contained are known.

Response: The C-111 North Spreader component is recommended for initial authorization so that it can be implemented as part of the ongoing C-111 Project. The Biscayne Bay Wetlands component will be developed further in a Project Implementation Report before authorization is sought.

548. A process should be developed whereby the acquisition of critical lands can occur prior to the execution of a Project Cooperation Agreement without jeopardizing the 50% Federal cost share.

Response: Section 528 of the Water Resources Development Act of 1996 provides for crediting of lands acquired for the Comprehensive Plan regardless of the date of acquisition. Some lands needed for the project have already been acquired under various state and Federal programs.

549. Provide more definition on the Federal cost share for operation and maintenance prior to the end of the public comment period.

Response: Concur. Section 9: Recommended Comprehensive Plan has been revised for the final report to describe the rationale for recommending Federal cost sharing of operation and maintenance costs.

550. In light of possible funding shortfalls, there needs to be careful attention paid to the sequencing of projects. Land acquisition must be prioritized and it is important to establish interim restoration targets.

Response: Sequencing of projects was developed based on a number of factors, including utilizing lands already acquired for restoration. The RECOVER team, described in Section 10: Implementation Plan, will establish interim targets as part of the adaptive assessment process.

551. Inclusion is requested in the initial authorization of all Restudy components in the Martin and St. Lucie Counties watershed.

Response: The C-44 Basin reservoir is recommended to be included in the initial authorization package. The remaining components in Martin and St. Lucie Counties are currently being developed in more detail as part of the ongoing Indian River Lagoon study, which is scheduled for completion in 2001. Those components are expected to be authorized after completion of that study.

552. The voters of Martin County agreed to implement an additional 1 cent sales tax for the next three years in order to clean up the estuary. A provision should be added in the final report that when local taxpayers contribute directly to Restudy projects, those projects are assured of priority funding at the Federal and state levels.

Response: Funding decisions for implementing the components of the Comprehensive Plan will be made by Congress and the appropriate non-Federal entities.

553. The Ten-Mile Creek Water Preserve Area must be funded and accelerated.

Response: The Ten Mile Creek project has been approved and is currently awaiting funding under the Critical Projects Program. Should the Ten Mile Creek Project not be funded under that program, it can be implemented under the programmatic authority being requested for the Restudy.

554. The state and Federal government should ensure that Restudy projects are not approved as an unfunded mandate requiring local governments to fund these projects.

Response: A Project Cooperation Agreement, which includes provisions and details about how the local share of project costs will be provided, must be executed by the Corps and the non-Federal sponsor before any project can be implemented.

555. St. Lucie and Palm Beach Counties have passed bond referendums for purposes of purchasing environmentally sensitive lands. There may be ways to use these funds in ways that will benefit specific Restudy projects.

Response: Funding sources for the non-Federal share of project costs will be developed in more detail during the implementation phase of the project.

556. Concern was expressed that emphasis has been placed more heavily on Everglades restoration, not a balance between restoration and water supply. It is recommended that the authorization bill include language to insure the dual purposes.

Response: The components of the recommended Comprehensive Plan provide water for both restoration and regional water supply. Authorization for the recommended plan will be the result of Congressional action.

557. Primary concerns about the Implementation Plan are in regard to the lack of specific information about funding. It is recommended that a detailed funding plan be prepared for public comment.

Response: In response to public comment, a draft Implementation Plan was developed and released for the public to review in January 1999. The South Florida Water Management District's financing plan for the non-Federal share of project costs is contained in Appendix G: Local Cooperation and Financial Analysis in this final report.

558. The Florida Water Council strongly supports the need for a thorough analysis of the technical and economic feasibility of any plan submitted to Congress for authorization. The Council strongly supports Congressional authorization and implementation of only those components for which general consensus exists.

Response: Approval of the Comprehensive Plan as a framework for modifications to the C&SF Project is recommended as well as authorization of pilot projects and an initial set of components. The remaining components of the Comprehensive Plan will be authorized subsequently after completion of Project Implementation Reports. As described in Section 10: Implementation Plan, more detailed analyses will be conducted prior to project implementation.

559. It is imperative that the Governor and Legislature be formally and directly involved as the Comprehensive Plan is developed, in reviewing authorizations of the Comprehensive Plan and in determining how they will be funded.

Response: Implementation of the recommended Comprehensive Plan will require a partnership with the state of Florida. The Governor and Legislature will determine their role in this process.

560. As part of the Corps criteria for a feasibility-level study, the project sponsor must be able to submit assurances that it has the capacity to commit its share of the project funding. It is not understood how this will be possible by the time the comprehensive plan is scheduled to go to Congress.

Response: South Florida Water Management District's financing plan for the non-Federal share of project costs is contained in Appendix G: Local Cooperation and Financial Analysis in this final report.

561. The amount and sources of funding for construction and long term operation of the Restudy improvements need to be established through public debate. Another issue is how big should the authorization be for Restudy implementation. The Restudy results and cost estimates can be adjusted before the full plan is authorized.

Response: South Florida Water Management District's financing plan for the non-Federal share of project costs is contained in Appendix G: Local Cooperation and Financial Analysis in this final report. Approval of the Comprehensive Plan as a framework for modifications to the C&SF Project is recommended as well as authorization of pilot projects and an initial set of components. The remaining components of the Comprehensive Plan will be authorized subsequently after completion of Project Implementation Reports.

562. The Implementation Plan was designed with the assumption that resources will be unlimited. There is encouragement to look for less expensive ways to accomplish the goals of the Restudy plan throughout the process.

Response: The Implementation Plan has been revised with a guideline of $400 million per year funding. Value engineering analyses to optimize components and reduce costs will be conducted as part of Project Implementation Reports.

563. Concern was expressed about how the local sponsor / State of Florida and Florida taxpayers will be able to pay the cost of operation, maintenance, and monitoring.

Response: Section 9: Recommended Comprehensive Plan has been revised for the final report to describe the rationale for recommending Federal cost sharing of operation and maintenance costs.

564. Congress will inquire why water conservation measures are not included in the Plan to reduce project costs. In addition, a more passive system could eliminate the need for expensive components such as ASRs, seepage barriers, and pump stations, and thus save billions.

Response: Water conservation measures are included as part of the recommended plan (Component AAA6). Value engineering analyses to optimize components and reduce costs will be conducted as part of project implementation studies.

565. The Seminole Tribe's interpretation of Section 528(e)(2)(B)(I) of the Water Resources Development Act of 1996 is that water quality aspects of the Restudy should be cost-shared by the Federal government at the rate of 50%.

Response: The water quality components included in the Comprehensive Plan have been found to be essential to Everglades restoration and are recommended for 50-50 cost sharing.

566. The scope of work being authorized is not clear. It is stated that the scope of requested authorization will be provided in the final report. However, this timing does not allow for public comment on the chosen project elements.

Response: In response to public comment, a draft Implementation Plan, which included a list of projects recommended for initial authorization, was developed and released for the public to review in January 1999. Approval of the Comprehensive Plan as a framework for modifications to the C&SF Project is recommended as well as authorization of pilot projects and an initial set of components. The remaining components of the Comprehensive Plan will be authorized subsequently after completion of Project Implementation Reports.

567. The draft report is based on the success of the pilot projects, which are not yet proven to be technically feasible. If the technologies prove infeasible, will further authorizations be necessary?

Response: Authorization for components that depend on the results of the pilot projects is not being sought at this time. Project Implementation Reports will be completed for these components after assessment of the results of the pilot projects.

568. Given the many uncertainties associated with the draft Comprehensive Plan, it cannot be supported either as a final decision-making document or as a blanket authorization in its present form by Congress.

Response: Approval of the Comprehensive Plan as a framework for modifications to the C&SF Project is recommended as well as authorization of pilot projects and an initial set of components. The remaining components of the Comprehensive Plan will be authorized subsequently after completion of Project Implementation Reports.

569. Congressional authorization for those features that were included specifically to enhance the ecological indicator regions should automatically include a 50-50 cost share for water quality treatment features that may be needed in order to redirect the water where it is desired. Currently, operation and maintenance costs for most of the C&SF Project are the responsibility of South Florida Water Management District. It is recommended that the authorization request includes 50-50 cost sharing for operations and maintenance associated with the plan components.

Response: The water quality components included in the Comprehensive Plan have been found to be essential to Everglades restoration and are recommended for 50-50 cost sharing. Section 9: Recommended Comprehensive Plan has been revised for the final report to describe the rationale for recommending Federal cost sharing of operation and maintenance costs.

570. Utilize local funding sources in combination with Federal and SFWMD funds to advance the implementation of the project.

Response: It is expected that throughout the period when Project Implementation Reports are being developed, dialogue will continue with state and local governments to maximize and leverage funding to advance the implementation of the project.

571. The entire Comprehensive Plan should not be authorized.

Response: Careful attention was given to developing an initial authorization recommendation for pilot projects and key specific components. This recommendation is based on the need to expedite project development to ensure consistency with ongoing Federal, state and local programs.

APPENDIX O
UNCERTAINTY ANALYSIS

This Appendix was written by a consultant for the U.S. Army Corps of Engineers as part of a contract to investigate uncertainty issues concerning the Recommended Comprehensive Plan. This Appendix accurately reflects the commitments that the Restudy Team has made to address key uncertainty issues in subsequent planning and design activities and recommends additional studies to help resolve outstanding uncertainty issues including a qualitative risk assessment.

O.1 INTRODUCTION

The Central and Southern Florida Project Comprehensive Review Study (the Restudy) was initiated in the face of gargantuan uncertainty about the future of the Everglades and south Florida. There was uncertainty about complex ecosystems that embodied physics, chemistry, and all the biological sciences. There was uncertainty about engineering systems and their function. There was uncertainty about social and political values large and small. Economic systems and values were also uncertain. There was uncertainty everywhere one looked.

The Restudy marks a watershed event in the investigation of ecosystem restoration projects. The hundreds of people involved in this effort have provided decision makers with an unprecedented quantity and quality of useful information for a study of this scale, complexity, and importance. Unparalleled progress has been made in reducing the uncertainty attending the problems and solutions addressed in this effort. Despite this tremendous progress, study managers recognized there was still much that remained uncertain. Hence, this uncertainty analysis was undertaken.

The study has been extremely successful in generating more and better data than has ever before been available for this kind of study. There is a clear consensus that the quality of the models, databases, and the general information developed for the Restudy are extraordinary for a study of this scale. However, is it enough? No. Do we want more? Yes.

This study has been examining the forest, not the trees. Direction is the forest, details are the trees. The Restudy, to date, has set direction; the details will come in time. Doctors make life and death decisions on a daily basis, while medical research continues to improve the quality of those decisions in the future. That is the situation in which this study finds itself.

Those who do not address resource planning issues on a regular basis, look at the remaining uncertainties they are able to see for the first time and they may feel uncomfortable. Perhaps they have less feel for just how great the uncertainties were before this study began. The uncertainty they see now, great though it may be, is a fraction of what it once was.

To an extent, we have different orientations among some study interests. People who must live and die with the details of their decisions look at the certainty in this study's glass and see it is only half full. Planners and many analysts look at the certainty in the glass and are pleased that it is already half full.

If we're not sure, we're uncertain. This summary of the uncertainty analysis begins with a few facts and opinions.

- Fact: Uncertainty is a fact of life, it cannot be avoided.
- Fact: Uncertainty never disappears, although it can be diminished.
- Fact: Uncertainty describes a range of situations from a complete lack of specific knowledge to knowing everything but the exact outcome of an action.
- Fact: Different uncertainties warrant different responses.
- Opinion: The existence of uncertainty is no excuse to avoid making decisions about Florida's future.
- Opinion: Deciding not to proceed with the Restudy because uncertainty exists is foolish as long as the key uncertainties are recognized, acknowledged and are being addressed in a rational and appropriate manner.
- Opinion: To take no action, to make no decisions because the Restudy is not free of uncertainty may doom central and south Florida to a far more uncertain future than they might face in a well-reasoned and carefully monitored new direction.

O.2 PURPOSE OF THIS UNCERTAINTY ANALYSIS

The primary purpose of this uncertainty analysis was to identify which of the remaining uncertainties are most significant. That is, which uncertainties have the most potential to affect the effectiveness of the project that will eventually be implemented. A secondary purpose of this analysis was to identify broad strategies that can be used to address or reduce the remaining uncertainties. It was not the purpose of this analysis to quantify or resolve the uncertainty that remains.

A few words about significance may help the reader understand why some things are discussed here and others are not. We define three categories of uncertainties: perceived uncertainties, routine uncertainties, and unique uncertainties. Perceived uncertainties are things that some one or more persons might not know but which are known by other people. For example, many people do not know the basic workings of aquifer storage and recovery technology (ASR). To those unfamiliar with this technology, the perceived uncertainties are many. To experts who understand the technology, they are fewer. Perceived uncertainties are not addressed here. The importance of perceived uncertainties should not be overlooked, however. The cure is simply more and better two-way communication. Those who perceive the uncertainties have to ask more questions, and experts need to answer them. This can be handled in the normal planning process.

Much of the uncertainty that attends this study effort is what we call routine uncertainty. Planning is an iterative process. The iterations are distinguished by an increasing quantity and quality of information and a corresponding decrease in uncertainty. In any planning study there are things that are unknown at one point in time that must and will be known before the project can be implemented. That includes such things as specifically where project elements will be located, how much they will cost, and who will pay for them, among many other issues. Planners are well aware of these uncertainties, and they will be resolved. There is a great deal of routine uncertainty attending this stage of the planning study.

All of the routine uncertainties will be answered in due time as the study proceeds and the required information becomes available. Time and more analysis will reduce these important uncertainties. In the meantime, there is sufficient information to begin to make decisions. As important as the answers to the types of questions raised above are, their articulation is the very work of a planning study. For that reason, this analysis did not concentrate on the resolution of questions that we know will be answered in time.

The problem seems to be that experienced planners understand and accept the existence of these routine uncertainties while those who must rely on planners for information are anxious for answers, sometimes wondering if they will ever come. Well established planning, engineering and scientific practices will resolve the routine uncertainty issues at an appropriate time, and these uncertainties are not further addressed in this analysis.

The Restudy effort has been marked by an extensive effort to communicate effectively and in a timely fashion with a broad array of public and private interests. Anxiety about routine uncertainties may be best addressed through the continuation of this communication effort and by focusing some public involvement resources specifically on the task of addressing routine uncertainties of particular concern to the public. For example, compiling the types of questions people are raising and perhaps even publishing them on the Restudy Web site so they become part of the public record, would go some distance in easing anxiety. The list enables concerned parties to see that their concerns have been heard. It also facilitates communication among stakeholders, while simultaneously serving as a "To Do" list for the study team. As answers are found or as investigations to find answers are scheduled, this information can be published as well.

Although much of the uncertainty that remains in the Restudy is routine and will be addressed in time, there are some uncertainties that are too unique to ignore. For example, although the basic workings of ASR technology are a perceived uncertainty, there are some unique uncertainties associated with their application on a magnitude of this scale. These key and unique uncertainties were the focus of this analysis. The remainder of this appendix describes these uncertainties and the manners in which they are being or could be addressed in the future.

O.3 HOW THIS ANALYSIS WAS CONDUCTED

This analysis began in the summer of 1998 in a conversation with the study's managers in order to identify the objectives of this uncertainty analysis. That conversation was followed by an extensive review of the available planning documents related to the Restudy effort. These included the November 1994 Reconnaissance Report and Appendices, as well as numerous reports and memoranda generated as part of the current Restudy effort.

A brief survey of all the Restudy team members (in excess of 150 people) was circulated via e-mail. The survey asked respondents to identify: 1) three things in the study of which they were most sure; 2) three things of which they were least sure; 3) the one thing more time could be spent on to improve the study; 4) the aspect of the study within the respondents' expertise that makes them feel least comfortable; 5) the aspect of the study outside the respondent's expertise that makes them feel least comfortable; and 6) an acceptable level of uncertainty. The purpose of the survey was to explore potential consensus on major uncertainties and to guide the more intensive interviews that would follow. Forty-nine useable responses were obtained from this initial survey effort.

The results of the survey were used to identify both broad areas of general concern and specific examples. A meeting was held with representatives of the U. S. Army Corps of Engineers and the South Florida Water Management District following the survey to identify a subset of study team members who would best be able to provide more detailed information about major areas of uncertainty as identified from the survey. Face-to-face interviews were held during the week of July 6-10, 1998 with 25 study team members identified from a broad cross section of interests and disciplines.

The information gleaned from these meetings, study documents, surveys, telephone conversations and interviews were combined with a little common sense, information from a literature search and the author's experience to produce this analysis.

O.4 KEY UNCERTAINTIES

Four key uncertainties were identified in this analysis that are unique enough to warrant special attention in the future. They are:

- Uncertainties about major Restudy models;
- Uncertainties about the linkage between hydrologic change and ecosystem restoration;
- Uncertainties about new technologies; and,
- Uncertainties about the risks associated with the recommended Comprehensive Plan.

There are other uncertainties that, while not routine, are not considered key uncertainties. For example, some study participants have suggested the evaluation process that relied on performance measures and often subjective judgments was fraught with uncertainty. We draw a distinction between subjectivity in a decision process, which we consider inevitable and appropriate, and uncertainty. Each of the key uncertainties is discussed in turn below.

O.4.1 Models

A large portion of the Restudy's success to this point in time is attributable to the many state-of-the-art models employed in the study's numerous investigations. Models are uncertain by nature because they are simplifications of reality. Some of the uncertainty may reside in the models' basic structures, i.e., are we thinking about this system correctly? Some uncertainty will reside in the values of select decision variables and value parameters used in the models. Other uncertainties can arise because of the quality of the input data and other empirical quantities used in the models.

The Natural System Model (NSM) and the South Florida Water Management Model (SFWMM) are the two most important models used in the Restudy (see Appendix B). The NSM attempts to depict the hydrologic response of the pre-drained system to the rainfall and other hydrologic conditions of the period 1965 through 1995. The resulting hydrologic responses were to serve as approximate targets or goals to be achieved by alternative water management scenarios. There is a widespread and mistaken impression that the NSM is intended to describe the conditions of the pre-drained Everglades system. It is not. The SFWMM was used to characterize the expected hydrologic response of the existing system under various water management scenarios in the future.

Because changes in the hydropattern are viewed as the key to ecosystem restoration, the outputs of the NSM and SFWMM model investigations were used as inputs to numerous calculations and other model runs throughout the Restudy analysis. The results of these various analyses have been used in or have contributed to countless decision processes and subsequent analyses including plan formulation, ecosystem response, project cost estimates and the like. Because of their keystone position in the Restudy, the NSM and SFWMM are the models of primary concern here.

The NSM and SFWMM are state-of-the-art models. The SFWMM has been calibrated and verified. The NSM cannot be. They are the best available models for this analysis. They have been peer reviewed. Their limitations are well understood by their developers and the modelers who use them. A great deal of work has been directed to identifying and addressing uncertainties associated with these models.[1] Nonetheless, there are unique and significant uncertainties that remain with these models and their applications.

O.4.1.1 Topographic Data

There are little if any reliable elevation data for the pre-drained Everglades system. In addition, some of the existing condition topographic data are not as current and accurate as desired. Specifically, there are concerns about topographic data in some parts of the study area. If actual ground elevations differ significantly from the elevations used in the model, outputs could be misleading. Areas might actually be wetter or dryer than model runs indicate. Actual flows could also differ from model predictions. The result could be plan impacts quite different from what is expected. In turn, ecosystem responses to these impacts could be unexpected.

Improved topographic data has been identified as a high priority need for future study efforts, and it will be collected. Improving the quality of key data inputs is an appropriate way to address this uncertainty. Changes would subsequently be made to the Comprehensive Plan as warranted by the improved information. Efforts to gather information about the pre-drained system continue. These efforts represent a

---

Florida Atlantic University, Boca Raton, Florida, August 1995 and Lal, A.M. Wasantha, Jayantha Obeysekera, and Randy Van Zee. A Sensitivity and Uncertainty Analysis of a Regional Simulation Model for the Natural System in South Florida. From *Coping with Scarcity and Abundance, Proceedings of Theme A, Water for a Changing Global Community.* The 27th Congress of the International Association for Hydraulic Research, Water Resources Engineering Division/ASCE. Held August 10-15, 1997, San Francisco, CA.

reasonable and appropriate response to this uncertainty.

O.4.1.2 Resolution of Model

The current versions of the NSM and SFWMM use two-mile square grids. This resolution was based on the available spatially distributed data. A concern has been raised by some that at that level of resolution it is not possible to consider impacts of plans on smaller areas of particular interest to stakeholders. Although the models are more than sufficient for making decisions about regional water management plans, there are uncertainties about plan impacts on smaller areas.

The NSM and SFWMM were never intended to be used to develop specific plans for smaller critical areas of special interest. Uncertainty about the plan's effects on these areas will be reduced through the use of finer resolution grids, as small as 500 feet square. In critical areas, where site specific analyses are desired, other models better suited to local analysis will be used. The finer resolution and specialized models are appropriate means of reducing this uncertainty in the future.

O.4.1.3 Rainfall Sequence

The major data inputs for both the NSM and SFWMM include the daily rainfall data for the most recent 31 years of record. This database represents a phenomenal amount of spatially and temporally distributed data. The 31-year period presents stretches of dry years and wet years and is generally regarded as representative of the region in modern times. The database may not be perfect but it is surely the world's best data for this region, and it is far better than what is available for most studies of this magnitude. Because both the NSM and SFWMM use the same rainfall database for making relative comparisons, the relative rankings of the various plans' performances are considered reliable and reasonably robust.

Despite the unprecedented quantity of data, some uncertainty remains. As good as these data are, they represent only one 31-year sequence of rainfall patterns from among an infinite number of possible 31-year sequences of rainfall. The likelihood that the next 31 years of rainfall will have the same spatial and temporal distribution as the 1965 - 1995 period is effectively zero. The likelihood that the available data will be *representative* of the next 31 years is pretty high.

Ideally, it would be advisable to test the sensitivity of the recommended Comprehensive Plan to significant changes in the rainfall sequence. *Significant* changes could be defined by qualified experts. To illustrate the idea, suppose we took the driest year from the 31-year period of record and assumed it will be the wettest year in the next 31 years.[2] How, if at all, might such a sequence change the

[2] We do not suggest there is any reason to do so other than to illustrate the point we are making. Clearly a better recommendation would be to develop a stochastic model for rainfall and use it to develop synthetic traces.

recommended plan? How would the recommended plan perform under this scenario? If we chose the wettest year and repeated the exercise how might the ranking of plans change? At the current time, we do not know the answers to these or related questions.

Uncertainty concerning the performance of the recommended Comprehensive Plan under rainfall patterns different from that of recent history could be reduced by using alternative sets of rainfall data that depict scenarios of most interest to analysts, such as extremely dry and extremely wet sequences. No one really argues this point, but it is not yet possible to perform this kind of analysis. Hence, the uncertainty remains.

The NSM and SFWMM models are the best in the world for this analysis. They are state-of-the-art. The simple truth is that art has not yet advanced to the point that it can accommodate the kind of sensitivity analysis we might like to see. There is no known, practical method that can be employed with these models to generate meaningful and useful synthetic databases. The data requirements for these models are huge. The spatial and temporal dependencies in hydropatterns are exceedingly complex. The capability does not currently exist to develop alternative databases for sensitivity analysis in a practical manner.

Although some uncertainty remains, the NSM and SFWMM are more than adequate for current decision making purposes. Hydrologists and modelers alike would agree that *the* best 31-year sequence of rainfall data to have for an analysis like this would be the modern historic record, i.e., the most recent 31 years.[3] This is standard engineering practice. The modern historic record is the database that is available and it is an excellent one.

The uncertainty that results from the limited sequence of rainfall patterns can be addressed in several ways as the study proceeds. First, research can be initiated to develop a stochastic model for the space-time rainfall structure in the study area and then use the Monte Carlo technique to simulate future possible realizations of rainfall patterns. In view of the state-of-the-art of stochastic hydrology, this may be a difficult task.

Second, the period of record used by the current model includes droughts and wet periods. The performance of alternatives has been investigated by carefully analyzing the modeling results for these extremes within the period of record. Efforts are also underway to extend the period of record to include earlier years spanning back to the 1920s. This will include even more drought and wet periods. Careful analysis of these will provide further sensitivity analysis of the plan's response to extreme patterns of rainfall.

[3] There is nothing magical about a 31-year period of record. There just happens to be 31 years of data available. As more data become available they will be added to the database and used. The point made here is invariant with respect to the number of years of recorded data.

Third, because the NSM and SFWMM are and will, presumably, remain state-of-the-art models, there is a desire to expand their capability to include the type of sensitivity analysis described above. So, although the capability for such analysis does not yet exist, it may in the future. If and when it does, it will be used to improve the formulation of more refined plans for central and south Florida.

If the capability for such evaluation does not become available in a timely or cost effective manner, it should be noted that the Recommended Comprehensive Plan will not likely be inadequate for any resulting rainfall sequence. Operations may be modified to adjust to future situations in much the way that gates on existing structures are opened and closed to adjust to current hydrologic conditions. The worst case is expected to be that, through hindsight, it may have been possible to have designed a somewhat more efficient and cost effective system. Eliminating hindsight is never going to happen. If the study team continues to do whatever sensitivity analysis it can to explore the Recommended Comprehensive Plan's sensitivity to the assumed rainfall sequence; and if the NSM and SFWMM models take advantage of advances that can produce synthetic databases; and if the water management system is managed effectively; this uncertainty will be properly addressed.

O.4.1.4 Amplification and Dampening of Uncertainty

Another unique model-related uncertainty concerns the manner in which the uncertainty in one model combines with the uncertainty in another model to produce greater cumulative uncertainties (amplification) or to cancel one another out (dampening). This is a reasonably possible impact that has not yet been formally investigated. It should be.

NSM and SFWMM outputs are used in many study activities and analyses. This is important because errors in these models can be amplified as uncertain outputs from one model become inputs to subsequent models that add their own uncertainties and errors in ways that are not yet well understood. There are countless points in the various models in the Restudy where small changes or errors, for example in the NSM or SFWMM, could have potentially large impacts on decisions if those errors are magnified in subsequent analysis.

Some Restudy team members have raised concerns about the NSM's empirical sufficiency, primarily because there were little or no data available to describe natural system conditions.[4] Many of the values had to be approximated or even guessed. An example is the previously mentioned elevation data. Reliable topographic mapping of the pre-drained condition in central and southern Florida does not exist. Hence, the

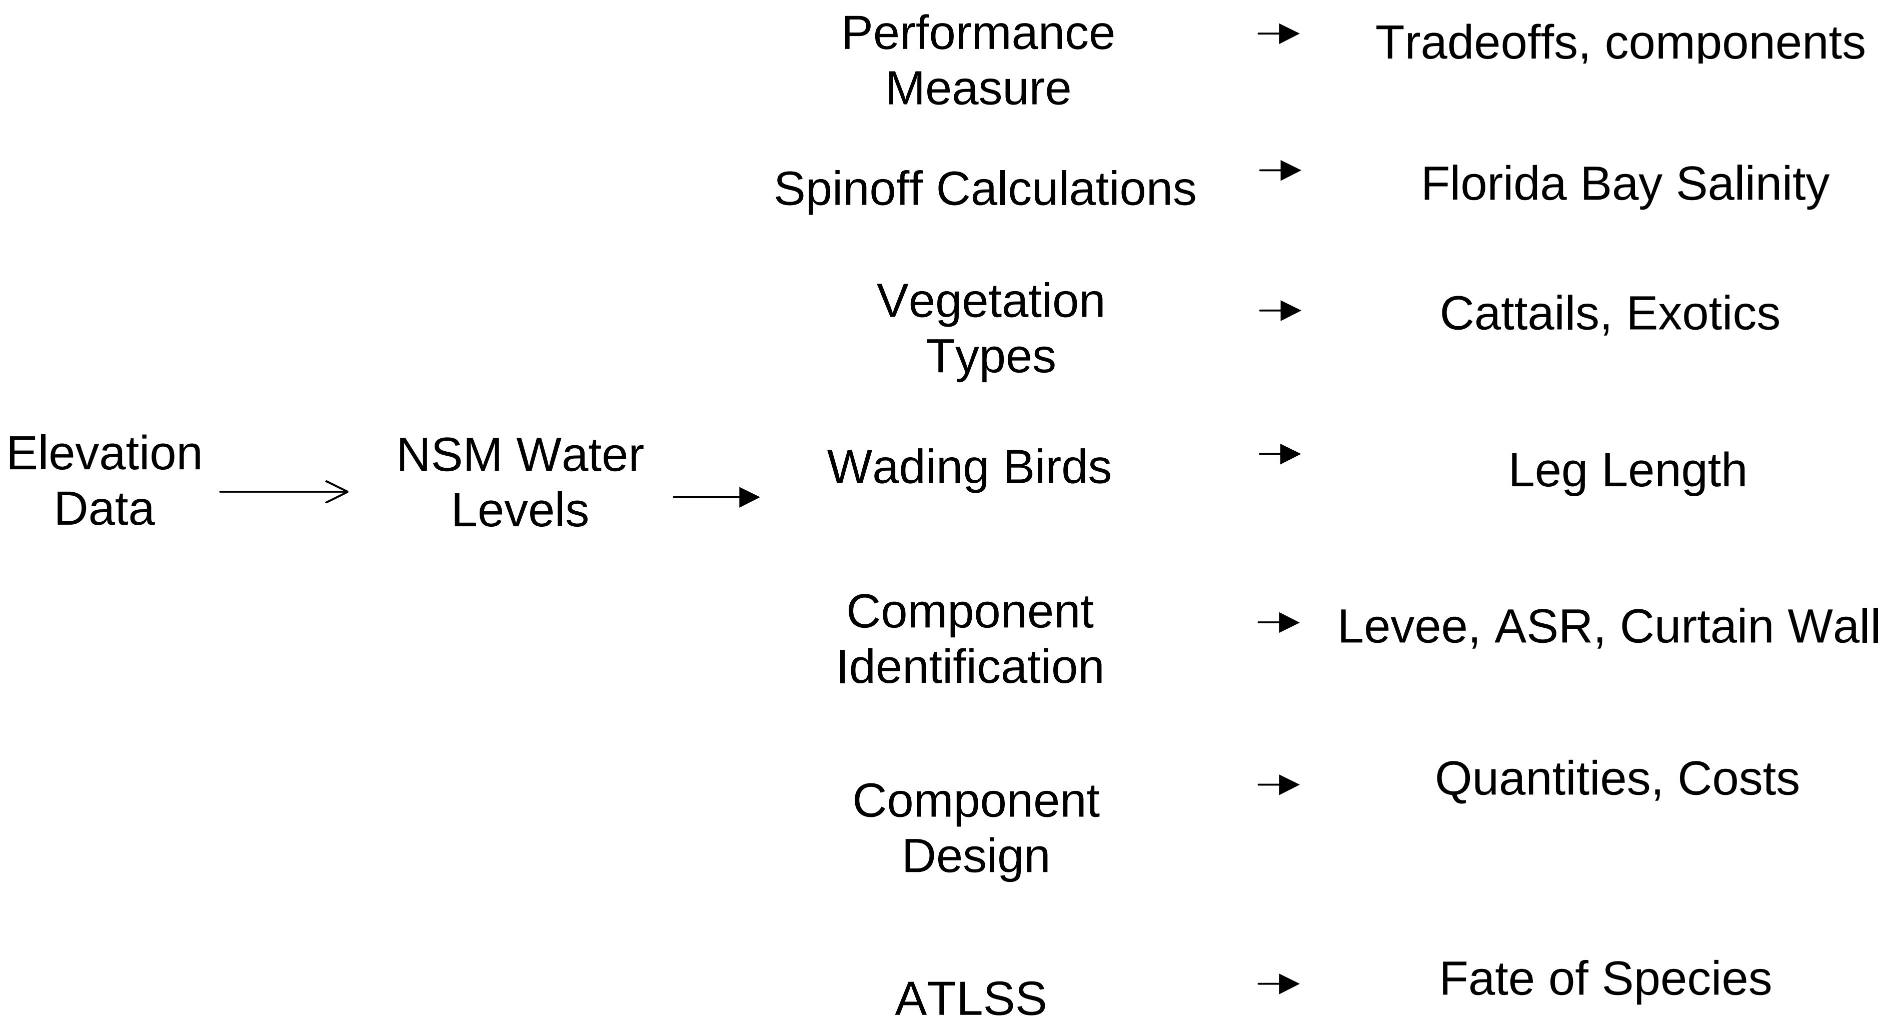
[4] A thorough effort to document historical conditions has been and continues to be undertaken. A draft report entitled, ASoil-Based Estimation of Historic Hydrology of the Everglades, Florida 1840-1880; Comparison with the Natural System Model,≅ by C. W. McVoy, W. A. Park, and J. Obeysekera, dated 1996 is currently being updated and revised.

elevation variable values are uncertain. Figure 1 shows some of the ways elevation data might impact the plan formulation process via the NSM and subsequent models, although the subsequent models are not specifically identified.

Elevation data affect numerous NSM outputs, including water levels, water depths, water flows, and water volumes. Figure 1 addresses only the water levels. Water levels may be used in some areas as performance measure targets. These targets are used to define and make plan trade-offs. For example, if a water target indicates depths that could present a problem for the Cape Sable seaside sparrow (an endangered species), the planning team could decide to lower the depths to aid the sparrow at the cost of some adverse impact to other species. Thus, any uncertainty in the elevation data could ultimately affect trade-offs in plan formulation. There are countless other examples that could be used here as well. There are many calculations that use NSM water levels to estimate other values of interest. For example, salinity levels in Florida Bay have been used with NSM water level estimates at gage P33 in Shark River Slough to develop a simple linear regression relating water levels and salinity. These salinity estimates are critical to the Bay ecosystem. The ecosystem's response to the changes in hydrology depends directly on water levels. Vegetation and animal species that result in the restored ecosystem will depend directly on water depths. Cattails or exotic vegetation could replace sawgrass if depths are more favorable to the former. Whether and which wading birds inhabit an area depend on the depth of water and the length of the birds' legs.

Water levels will help to dictate whether a levee, ASR system, reservoir or other plan component is used to effect the desired hydrologic change. Water levels will have a strong influence on the design of a plan component. For example, the length, top height, width of top and side slopes of a levee depend on the water levels. Levee quantities and costs depend on levee design, which depends on water levels, which depends on elevation data. And so it goes.

Figure 1: Role of Sample NSM Data in Plan



Water levels are inputs to other models. The Across Trophic Level System Simulation (ATLSS) model takes SFWMM water levels and uses them as an input to its own algorithms. When water levels that might be considered indicative and accurate within plus or minus a half foot are used as precise estimates of water levels in another model, the uncertainty attending water levels might be amplified or dampened. Without a more formal and structured investigation of the cumulative effects of uncertainties, we simply do not know. [5]

ATLSS outputs might include a population viability analysis for an endangered species. An analyst might then take the ATLSS outputs, which are very precise in appearance, and offer an opinion about the species' relative risk of extinction. Thus, uncertainty attending the elevation data combines with the model uncertainty of three models (NSM, SFWMM, and ATLSS), all of which are used in a subjective decision process to make a judgment about a species' potential viability in a specific area. These combined uncertainties could, in the worst case, be disastrous for the species. In the best case, they might be negligible or they might cancel one another out. They should not, however, be overlooked.

The cumulative effects of uncertainty are unexamined sources of potentially significant uncertainty in the Restudy. It is reasonable, given study resources, the cutting edge nature of the analysis required, and the existing tight schedule that requires decisions be made at this time while these uncertainties remain. It is equally reasonable to expect that a formal effort to address this remaining source of potentially significant uncertainty be initiated in the Implementation Plan.

One way to begin to address the problem is to conceptually map the potential cumulative uncertainties. As a practical matter, this begins with the NSM and SFWMM. Study team members can identify the ways they have or will use these model outputs in their own work. Thus, this map or flowchart would show the connections among the various models used in the analysis. If ATLSS uses NSM and other model outputs as inputs, these can be simply sketched. Similarly, it should be a straightforward matter to identify the models, analyses and decisions that employ ATLSS outputs. Each analyst and modeler involved in the study should be able to sketch their part of such a map or flowchart.

Armed with the map, the second step would be to rank the potential amplification and dampening from least to most concern, perhaps using a simple criteria-based ranking technique.[6] Step three would be to systematically investigate

[5] A naive example of a sensitivity analysis might be to increase then decrease water levels by one-half foot, as indicated, in coordination with NSM modelers and see if the ATLSS results are significantly different. If not, then we can safely assume the uncertainty in water levels is not a factor worthy of further consideration.

[6] For example as found in Yoe, Charles AUse of Criteria-Based Rankings in Risk-Based Analysis of Ecosystem Restoration Projects,≅ in *Risk-Based Decision Making in Water Resources VIII*, Yacov Haimes, et al eds. American Society of Civil Engineers, Reston, 1998.

the sensitivity of important decisions to these cumulative uncertainties. Step four would be to modify the plan as necessary or, alternatively, to identify potential outcomes for monitoring and assessment during implementation. The last step would be to disseminate the findings of such an effort as widely as appropriate.

This discussion has used the NSM and ATLSS models for example purposes. The potential for cumulative uncertainties exists wherever diverse models have been linked through "outputs as inputs" uses. It should be formally considered, if not investigated, wherever it exists. Although it may not yet be feasible to vary the input data for the NSM and SFWMM, that may be an entirely reasonable expectation for some other models. If varying key inputs changes a decision, then further effort is warranted. That could be reducing the uncertainty in the input by collecting additional data, using better models, or doing more research. Alternatively, it could mean closely monitoring the input sensitive outcome in the adaptive assessment program. In any case, each study team analyst should make a concerted effort to identify and address as appropriate the potential for cumulative uncertainty in their areas of responsibility.

O.4.2 Linkage Between Hydrologic Change And Ecosystem Restoration

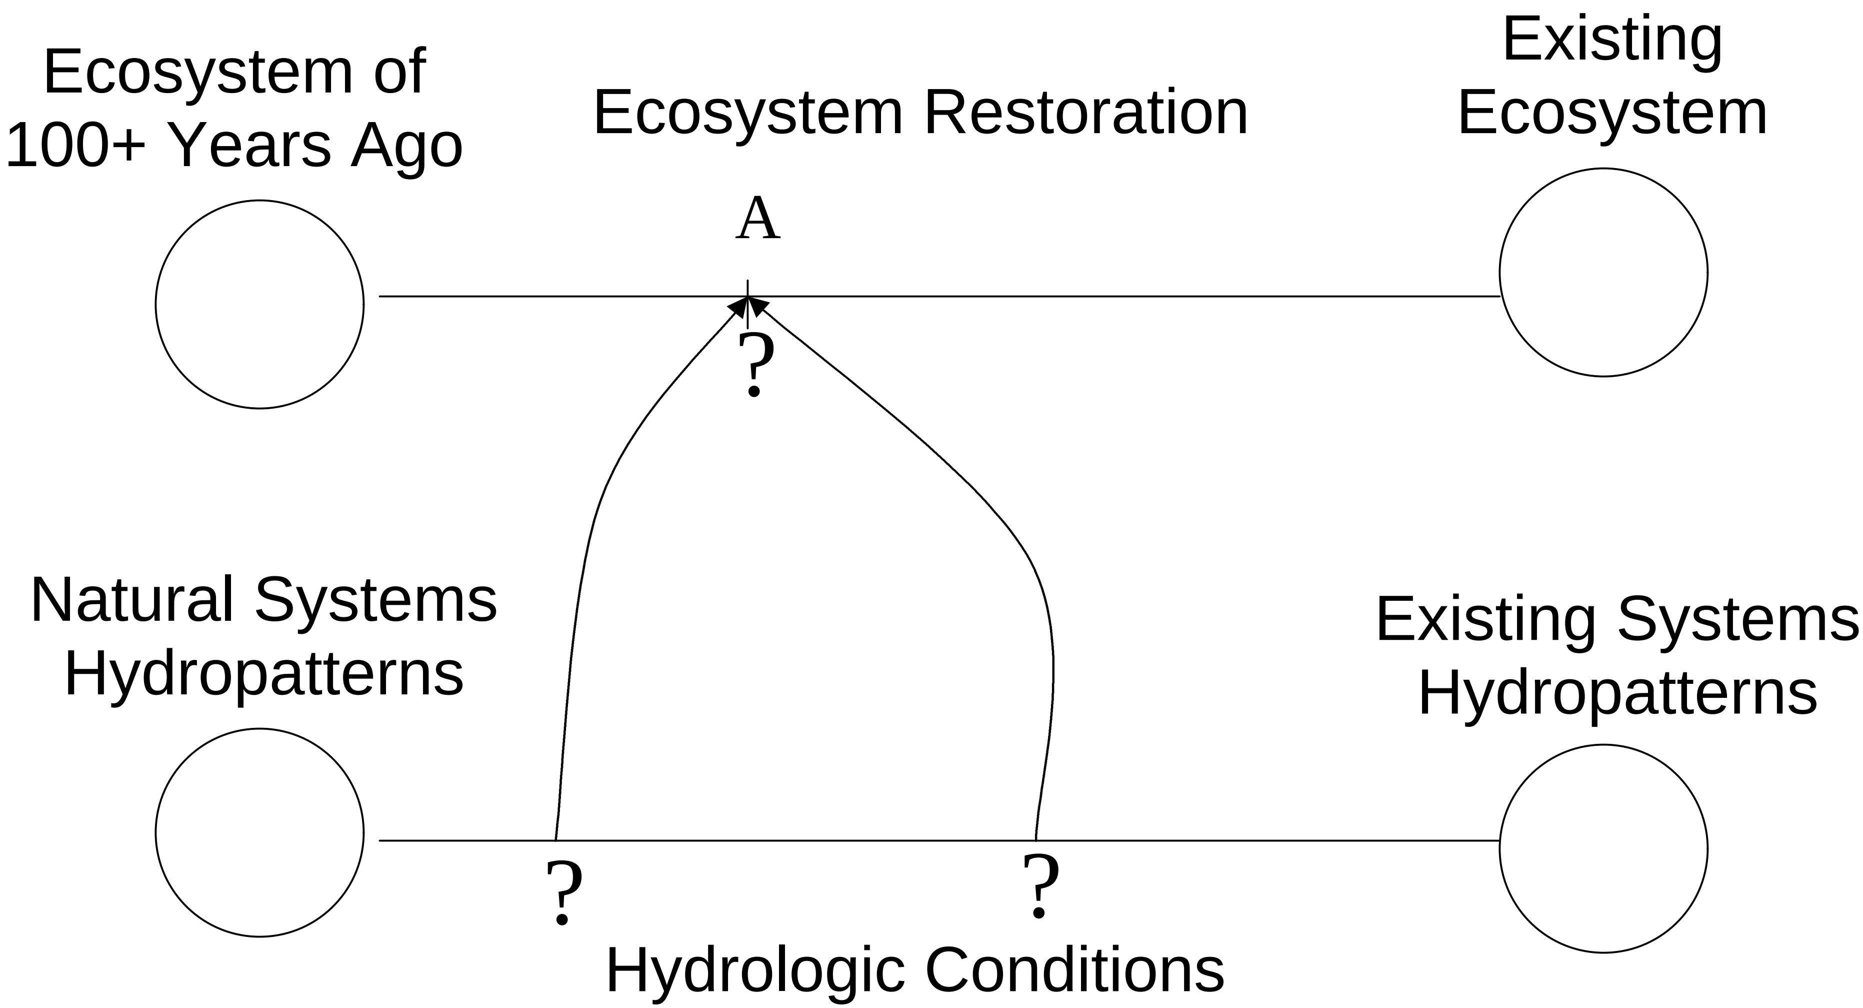
Linkage, as used here, refers to the way that things are connected or united. Perhaps the most important remaining uncertainty is the manner in which the ecosystem of the Everglades will respond to the planned hydrologic changes. It bears noting that most people are well aware of this uncertainty, and it is the principle focus of the adaptive assessment component of the Implementation Plan.

O.4.2.1 Endpoints

There is very real and, to a great extent, unresolvable uncertainty about what the new ecosystem will look like. Because no one knows for sure what the ecosystem will look like, no one knows for sure what the hydropattern required to produce it will look like. This is, in our view, the greatest uncertainty in the entire study. Moreover, we do not know with certainty what the linkages between hydropatterns and the ecosystem are.

Figure 2, an adaptation of an idea offered by a study team member, suggests the conceptual nature of this uncertainty. The bottom line shows that the existing hydrologic system differs from the NSM over a continuum. The top line shows that the existing ecosystem differs from what it was 100 years or more ago, an arbitrarily chosen time frame, also through a continuum.

Figure 2: Hydrology - Restoration



What is known with certainty is that the existing ecosystem is not what we want. We don't even know if the existing ecosystem can be sustained by current hydropatterns. It is important to bear in mind that not all uncertainties are associated with the Recommended Comprehensive Plan. The status quo has its own considerable uncertainties.

Conceptually, we want the ecosystem to move leftward toward a healthier, more predictable and persistent ecosystem. It is certain that we will not achieve the ecosystem conditions of 100 or more years ago. The past is used here to represent a conceptual ecological ideal. The farther to the left on our continuum we move the ecosystem, the more desirable it is. What we don't yet know are the answers to two very important questions. Where do we *want to be* on the line? Where on the line *will we eventually be*? These are major remaining uncertainties.

Now suppose that for argument's sake we decide we want the ecosystem to be at point A. The linkage uncertainty now takes center stage because at large, regional scales we do not know what hydropattern will sustain the ecosystem at point A.[7] We do not know with certainty the water levels, locations, depths and duration that will be needed to get the ecosystem to point A. But that is not even a particular problem yet, because we do not know where point A is or what it will look like.

The desired environmental endpoints have not yet been clearly identified. That does not mean there are not plenty of ideas about what they might be, however. Now that broad consensus on goals and plans has been reached, the study team is working on developing a consensus view on a number of ecological fronts. For example, when this analysis was initiated in the summer of 1998 there was not a consensus definition or understanding of what ecosystem restoration meant in the current context. The Alternative Evaluation Team (AET) has subsequently defined ecosystem restoration as follows: "In its original meaning, and when used with reference to a natural system under anthropogenic stress, 'restoration' means a return to a system that is not under anthropogenic stress. When used in the context of the south Florida wetland system, ‘restoration’ has come to mean the recovery of sustainable wetland systems at some higher level of ecological health than characterizes the current, impacted systems. The broad goal is to recover and sustain the major defining ecological characteristics of the pre-drainage south Florida wetland systems over as large an area of the remaining wetlands as possible."[8]

What this definition means in specific terms for the Everglades still remains a matter of debate and discussion. There are legitimate professional disagreements

[7] Our understanding of linkages between ecological targets and hyrdological patterns at much smaller scales is much sharper. For example, we know fairly well what hydrological patterns are needed to recover healthy alligator ponds.

[8] "Defining Restoration - I, A Restudy Alternative Evaluation Team White Paper,≅ dated 16 November 1998.

about what to emphasize when specifically characterizing a restored ecosystem. Some might prefer nutrient levels, plant community mosaics, food chains, and endangered species or other characteristics. There is broad agreement in qualitative terms, however, about most of the biological and physical characteristics that describe restoration.

The strategy for the coming months and years is to refine the definition of what restoration will look like, i.e., by identifying specific endpoints at finer levels of specificity and detail. Workshops and other consensus building activities are planned for the spring and summer of 1999 to formally begin the process of reducing the uncertainty concerning what restoration *should* look like. Only implementation will reveal what restoration *will* look like.

There is a widespread and robust consensus belief that water is *the* essential ingredient for ecosystem restoration. Each conceptual ecological model, developed to guide restoration planning, identifies hydrologic stressors as primary factors in the ecosystem. So, there exists both popular and science-based support for and agreement with the statement that we are sure that restoration is impossible without changes in the hydropatterns.

Once the ecological endpoints have been identified, the specific water targets required to attain them can be better estimated. Much of this work will be the routine and ongoing work of implementing the plan. Whether these water targets can be achieved via the components of the Recommended Comprehensive Plan is uncertain at this point. If better ways can be found to achieve water targets as they become better defined, they will be pursued. This is an example of a routine uncertainty in a planning process. Whether the water targets once achieved will lead to the desired ecological endpoints is another matter of considerable uncertainty.

The conceptual ecological models represent a set of hypotheses about how the ecosystem functions. Plan implementation is, in some respects, like a scientific experiment. The Implementation Plan's "adaptive assessment" function has been created to oversee this experimental process and to assure the plan's ultimate performance and success. The Implementation Plan says with respect to the uncertainty about the link between hydrology and the ecosystem: "If an unexpected response occurs, it becomes the basis for reviewing and revising the operating set of hypotheses, which results in an ever improving focus on the actions required to meet the ultimate restoration objectives. "

The study team is both aware of and open about the major uncertainties that remain in refining the definition of ecosystem restoration. They are equally aware and open about the uncertainties that accompanies the linkage between hydropatterns and ecosystem response. It is clear that water is essential to every endpoint of importance, but it is not yet clear exactly how the hydropatterns must be changed.

There is an honest awareness of major linkage uncertainties that could not have been reduced at this point by any available means. There is a plan in place and underway for reducing the remaining uncertainty about what restoration should look like, i.e., where on the continuum we want to be. A proactive adaptive assessment program will be developed, in part, to reduce the uncertainty about the link between hydrology and restoration. There is little that can be said at a general level to improve on that strategy. Whether this strategy is adequate for reducing the remaining uncertainty or not will depend on the study team’s ability to reach consensus on the specific details of restoration and the quality of the adaptive assessment process. Both bear close and constant scrutiny in the months and years ahead.

O.4.2.2 It Takes More Than Water

Hydrology is not the only requirement for restoration. The conceptual models reveal that more than water is going to be needed to achieve whatever picture of restoration ultimately emerges. An AET white paper has had the following to say about restoration requirements other than hydropatterns. "Ecological restoration cannot even begin to succeed without the successful maintenance or recovery of a number of other conditions, such as: an appropriate fire regime, exotic control, good water quality, and appropriate human use of different parts of the system. A restored system will also require the physical connections among areas of the system to allow for the completion of all parts of organisms' life cycles and to provide for flexibility in their movements about the system to deal with temporal variations in water levels, fire history, and climatic events. The AET recognizes that there will continue to be uncertainties associated with our current understandings of natural responses, which will continue to influence our ability to reach a final definition of a restored system".[9]

The roles of these other stressors in the attainment of desired endpoints will, ideally, be revealed and assessed through the adaptive assessment process, just as the hydrologic linkage will. So there is a mechanism in place for identifying those factors, in addition to hydropatterns, required for restoration. What is not yet in place or accounted for is a process that will assure that these non-water requirements of restoration will be met.

This restoration project is a complex and multi-faceted, one of a kind, first of its kind effort. It presents coordination challenges of unprecedented magnitude. There are multiple levels of government involved; there is inter-agency baggage to consider; and there are many diverse stakeholders involved. If water quality improvements are required, if a fire regime is needed, if control of exotics becomes necessary, it is not yet clear how, or if, the Restudy can marshal the resources to assure that these essential ingredients of a successful restoration will be provided. This seems too important to leave to chance.

[9] "Defining Restoration - I, A Restudy Alternative Evaluation Team White Paper,≅ dated 16 November 1998.

It may be reasonable to assume that should we get close to restoration, the political willpower will somehow be found to effect the additional changes needed. Given the certainty of changing social values, political objectives, economic situations and the like, it seems explicit attention might profitably be directed toward addressing strategies and decision structures for handling these seemingly inevitable situations. Once again, there is no shortage of thoughts on the subject, but they have not yet crystallized into a strategy. Although a reasonable strategy exists for identifying the non-water factors required for ecosystem restoration, the manner in which those needs will be met remains uncertain. It deserves early and explicit attention in the implementation plan.

O.4.3 Technology

The recommended Comprehensive Plan comprises a complex arrangement of components that employ a vast array of technologies to deliver water to a variety of places at the times and in the quantities required by ecosystems and human systems. Although some of the technologies are relatively new, none of them are untested. Much is known about all of them, although more is known about some than others. What is not known is if some of the newer technologies can succeed in producing the desired quantities of water at the scale envisioned in the recommended Comprehensive Plan.

O.4.3.1 Aquifer Storage and Recovery

ASRs have been used in the U.S. for about 30 years. They were first used in Florida in 1982. There are currently seven ASR facilities operating in Florida and eight more are under construction. ASRs are not an unknown and untested technology. An extensive literature has identified and addressed a host of issues associated with this technology. There is a great deal that is known about ASRs. So let us disavow anyone of the notion that ASRs are a great unknown. There is much perceived uncertainty about ASRs. Most people have never heard of the technology and know nothing about it. They have many questions and much uncertainty. They are largely unaware of what is known about ASRs.

Nonetheless, there are substantial unique uncertainties associated with the use of ASRs. Chief among these is the fact that ASRs have never been used on such a large scale in such a variety of geologic conditions before. In addition, because the technology is only 30 years old it has no long-term track record.

There are questions about water storage. Will ASRs be able to provide the quality and quantity of water required at the times they are needed and wanted? Are there likely to be any unintended consequences of this technology? What will it cost?

In the surveys and interviews conducted for this analysis, team members and stakeholders raised many questions about ASRs. Will the Floridan aquifer be able to handle the volume of water to be injected? Will the injected water simply dissipate in the aquifer? Might the injected water flow to the ocean in underground rivers? What will retrieval rates be like in the many different geologic conditions? Could water injection raise the water table and affect subsurface flows in as yet unknown ways? What effect would the increase in underground storage have on fractures and weak spots in the aquifer's dome? How might untreated water affect the aquifer's waters? How might treated water affect the aquifer's waters? Might retrieval of water from multiple wells result in land subsidence or sinkholes? How long will these technologies last? What are its long-term consequences? How might the ecosystem be affected by this unnatural point source intrusion on the aquifer? Could ASRs throw off natural balances we do not yet understand? Might there not be a tremendous temptation to use the ASRs to remove floodwaters from the land during very wet seasons? In what ways could the ASRs be misused?

An Aquifer Storage and Recovery Issue Team was formed in September 1998 explicitly for the purpose of addressing the surface water, hydrogeological and geochemical uncertainties associated with regional ASR facilities. Thus, there is now a deliberative body in place that will explicitly address the uncertainties that attend the use of this new technology on this unprecedented scale.

In a December 1998 report, the ASR Issue Team produced a Draft Assessment entitled "A Report to the South Florida Ecosystem Restoration Working Group." That report identified the following items as the seven most important issues associated with implementing ASR facilities on a regional scale. Addressing them will reduce much of the remaining uncertainty.

- Characterization of the quality of prospective source waters and spatial and temporal variability.

- Characterization of regional hydrogeology of Upper Floridan Aquifer: hydraulic properties and water quality.

- Analysis of critical pressure for rock fracturing.

- Analysis of site and regional changes in head and patterns flow.

- Analysis of water quality changes during movement and storage in the aquifer.

- Aquifer storage and recovery potential effects on mercury bioaccumulation.

- Relationship between ASR storage interval properties and recovery rates and recharge volume.

Implementation of the ASR facilities is expected to take up to 20 years or more and will begin with a pilot program to test ASR feasibility in specific locations around Lake Okeechobee. As a result of the pilot program and future modeling efforts, a decision will be made whether or not to proceed with the technology to provide the 1.8 billion gallons per day of water requirements proposed in the recommended plan. If ASR technology is to be used, periodic evaluations will continue. If ASR use is to be reduced or eliminated, other features will be substituted for them.

Much is known about ASR technology. ASRs have never been applied at the scale proposed. As a result, there are significant uncertainties remaining. There is an Issue Team in place, formed specifically to address these uncertainties as the study moves ahead. The team has identified the initial set of priorities to investigate. A December 1998 plan outlines the Team's plan of approach. The proposed approach is an exemplary effort to identify and reduce project uncertainties in a formal fashion. In fact, it would be wise to emulate the ASR Issue Team model for seepage management technologies as well.

O.4.3.2 Seepage Management

Seepage management measures invite questions similar to those being asked about ASRs, for many of the same reasons. The scale and geologic diversity are again unprecedented. Unlike ASRs, seepage management measures are not new technology. A great deal is known about seepage management measures, and the techniques presented in the Recommended Comprehensive Plan are based on the findings of the Governor's Commission for a Sustainable South Florida Technical Advisory Committee.

In the Restudy, the "bathtub" concept has been used to describe the concept of lining in-ground reservoirs to control seepage. Curtain walls have been proposed to control seepage of water from the Everglades to adjoining aquifers. Curtain walls are not new ideas, but a so-called curtain wall that is almost 100-feet deep would be quite different. It would be difficult to find trenching equipment that could dig and brace a trench to that depth. That it may not have been done before may suggest some uncertainties. What kinds of head will the curtain be working against? Will the gaskets in the plastic sheeting hold at the required depths? If it does not work, can it be removed? There are also questions about the technology's unintended effects.

If we succeed in blocking off sub-surface flows, do we understand what other things are going to be affected? Seepage management presents us with a situation somewhat analogous to that faced by the builders of the existing project. The levees and canals we see today have had far reaching, unintended consequences. We need to try to anticipate every possible consequence of our actions and avoid irreversible courses of action when the range of consequences cannot be anticipated. These and other questions have not yet been adequately identified and discussed.

The ASR Issue Team provides an ideal model to follow in addressing uncertainty associated with seepage management measures. The surface water, hydrogeological, geochemical and construction uncertainties associated with seepage management are complex and technically sophisticated. They require the on-going attention of experts. Forming a Seepage Management Issue Team to emulate the work of the ASR Issue Team could be an effective way to identify and address uncertainty issues.

O.4.4 Risk Assessment

There are some simple, yet extremely important questions that have not yet been asked and answered about the Recommended Comprehensive Plan. They are: 1) What can go wrong? 2) How likely is it to happen? and, 3) What are the consequences if it does happen? We believe these questions need to be asked and answered, at least qualitatively, about each of the major aspects of the plan. The risks associated with the plan are not as well understood at this point as perhaps they should and could be with some formal risk assessment.

The Restudy has, in part, been made necessary by the inability of people decades ago to foresee how the unintended consequences of their canal and levee system, together with changing social values, could result in serious future consequences for society and the environment. We would be wise to learn from that experience and make the best possible effort to avoid placing a future generation in the position we now find ourselves.

We suggest that can best be done by conducting an initial risk assessment of the Comprehensive Plan's recommendations. Risk assessment can help us make general predictions about the potential outcomes of our decisions. The process of conducting a risk assessment can yield information that might subsequently be useful for risk management. If one or more of the actions below are taken, we suggest using the Corps' without and with plan comparison framework to explore risks. There are substantial risks associated with the status quo as well as with the recommended plan.

The cumulative impact of the uncertainties discussed in this analysis, along with the routine uncertainties we have not addressed, leads us to conclude that we have to think about and ask the right questions about this project. Answers are not necessary at this point, but it is absolutely essential that we pose the questions now. What risks do society and the ecosystem face if we take no action? What risks do they face if we implement the Recommended Comprehensive Plan?

What are the risks associated with new technologies? What are the potential unintended effects of this plan? Consider ASRs. If 200 ASRs are installed, what could happen the first time, 10, or 20 years down the road, when they start injecting water into the ground at the same time? What could go wrong in the short run? In the long run?

It is likely that 50 years ago no one was able to anticipate the unintended consequences of the Central and Southern Florida Project that we are now addressing. Do we really have any reason to believe we are more farsighted with our state-of-the-art technologies than our predecessors were with theirs? Problems that we do not expect will arise. Far fewer of them are likely to become threats to society or the ecosystem if we can anticipate as many of them as possible right now.

At a bare minimum, the study team should undertake an effort to ask and answer the right questions about the recommended plan as soon as possible. Identifying the questions, answering those that can be answered and deciding if and how to answer those that cannot be answered now is an important step in assuring the success of the ecosystem restoration.

The purpose of posing the right questions is to raise issues of potential importance for consideration in plan implementation or its adaptive assessment component. Answering the questions may provide invaluable insight into the study's adaptive assessment strategy. Even if specific questions cannot be authoritatively answered, the process of posing the questions should prove invaluable to future study efforts.

A risk assessment goes beyond the minimalist task of asking the right questions about the plan. It answers as many questions as possible by characterizing the answers by likelihood and magnitude. As noted above, a risk assessment answers the following three questions. 1) What can go wrong? 2) How likely is it to happen? 3) What is the magnitude of the outcome should the unwanted event occur? Or, stated differently, how bad might it get?

These questions can be posed and answered using available information. The answers need not be quantitative. For example, if sinkholes are one of the things that could go wrong with ASRs, the next step is to estimate how likely sinkholes are to occur. Initially, that estimate may be a simple statement, e.g., not very likely or highly likely. Next, we would like to know the magnitude or seriousness of the impact. What are the consequences of sink holes? Once we have identified potential risks and their relative likelihood and consequences, we can decide if the risk is worth worrying about or not.

A risk analysis consists of risk assessment, risk management and risk communication. In a risk analysis, once the nature of the potential risks has been identified in a risk assessment, the next step is to determine what is to be done about the risks. Potential risk management measures can be preliminarily identified by posing and answering the following questions (numbered consecutively after the above questions): 4) What can be done, broadly, about the risks previously identified? 5) What options are available and what are their associated trade-offs? 6) What are the impacts of current decisions on future options?

A third set of questions helps us to communicate with others about the nature of the risks and what can be done to manage them. A simple risk communication exercise would require answering questions like the following: 7) With whom do you communicate about the risks you have identified? 8) How do you convey the information? 9) When do you communicate? 10) What information do you exchange?

A qualitative risk assessment, as outlined earlier, could rely on expert opinions, given the available data. No new analysis is needed to do this initial risk assessment. Many elements of a risk assessment have already been prepared as part of the Restudy analysis. The conceptual models showing the relationships among stressors and ecological endpoints are consistent with the conceptual models suggested in EPA's Ecological Risk Assessment Guidelines. ATLSS outputs on population viability include the relative risks of extinction, the risk that a population falls below some threshold, and the probability a population will grow. Some cost estimates are being prepared using Monte Carlo processes, and there has been limited use of sensitivity analysis by some study members. Posing and answering questions 1 through 3 of this section about new technologies and ecosystem responses to hydrologic changes would be a valuable tool to help guide plan implementation and its adaptive assessment process. There are many knowledgeable professionals working on the Restudy, and there is a great deal of knowledge that has been developed during this study. It would be timely and well-advised to conduct a qualitative, limited scope, risk assessment of the recommended plan as soon as possible.

The next step beyond a qualitative risk assessment might be to conduct an ecological risk assessment. An ecological risk assessment is a flexible process for organizing and analyzing data, information, assumptions, and uncertainties to evaluate the likelihood that adverse ecological effects may occur as a result, in this case, of implementing the recommended plan. The EPA has recently published final Guidelines for Ecological Risk Assessment (EPA/630/R-95/002F April 1998) available at the EPA Home Page on the World Wide Web. Given the significant uncertainties attending this study and the value of the ecosystems at stake, an ecological risk assessment would be an appropriate future step to take, in our opinion.

The existing conceptual models could form the basis for an ecological risk assessment. It could be qualitative or quantitative. The guidelines are flexible and straightforward. Ecological risk assessment is a relatively new field of endeavor. Assessments of simple ecological risks can be difficult. No one has ever attempted an ecological risk assessment of the complexity and magnitude that would be required by this project. A formal ecological risk assessment would be expensive and difficult. It would also be an invaluable decision tool.

An initial risk assessment, qualitative and soon, is essential to identify risks associated with the recommended plan. A risk assessment team could structure an initial risk assessment in a cost effective and efficient manner. That might include a workshop that invites a broad base of study participants to take part in structured exercises aimed at identifying what can go wrong, how likely it is and what its consequences are, in an effort to gather a maximum amount of insight and information in as short a period of time as possible. There is any number of alternative approaches to this task.

Ultimately, it would be advisable to conduct a more detailed ecological risk assessment. This would focus specifically on the more important risks to the ecosystem, and it could be done in accordance with EPA Risk Assessment Guidelines.

O.5 CONCLUSIONS AND RECOMMENDATIONS

This analysis ends with a few conclusions and recommendations. The major conclusions follow.

- Conclusion: The Restudy team leaders are genuinely interested in and committed to identifying and reducing significant uncertainties.
- Conclusion: The Restudy has done an excellent job of reducing much of the massive amounts of uncertainty it faced at its initiation.
- Conclusion: Perceived uncertainties do not present a real problem to the decision process because they can be readily reduced through communication.
- Conclusion: There are numerous important but routine uncertainties that will be addressed in a timely and appropriate fashion during the course of future planning.
- Conclusion: Several significant and unique uncertainties, discussed in this report, remain and need to be addressed.
- Conclusion: Responsible members of the Restudy team are well aware of most of the remaining significant uncertainties.
- Conclusion: Reasonable and appropriate measures for addressing several of the remaining uncertainties have already been identified and initiated.

Each discussion of a unique uncertainty ends with a description of what is being or will be done or a general recommendation of what could be done. These are not all repeated here. The recommendations that follow should be considered by the Restudy team as additional ways to address the uncertainties identified in this Appendix.

- Recommendation: The Restudy team should continue to revise and develop the NSM and SFWMM models with a particular view toward eventually being able to investigate the results of alternative rainfall sequences on plan performance.
- Recommendation: The potential impacts of cumulative model uncertainties on critical decisions should be formally addressed.
- Recommendation: A process or decision structure that can assure that non-

water requirements of restoration will actually be met should be developed.

- Recommendation: A Seepage Management Issue Team should be formed to identify and address uncertainties associated with this technology.
- Recommendation: An initial, qualitative risk assessment of the recommended plan should be completed as soon as is practical.
