CENTRAL AND SOUTHERN FLORIDA PROJECT
COMPREHENSIVE REVIEW STUDY

FINAL
INTEGRATED FEASIBILITY REPORT
AND
PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Responsible Agencies: The responsible lead agency is the U.S. Army Corps of Engineers, Jacksonville District. The responsible cooperating agencies are the South Florida Water Management District, the U.S. Fish and Wildlife Service, the U.S. Environmental Protection Agency, the National Park Service, the Florida Game and Fresh Water Fish Commission, the U.S. Geological Survey, the Natural Resources Conservation Service, and the Florida Department of Environmental Protection.

Abstract: The south Florida ecosystem is a nationally and internationally unique and important natural resource. It is also a resource in peril, having been severely impacted by human activities for over a hundred years. This report recommends a comprehensive plan for the restoration, protection, and preservation of the water resources of central and southern Florida, including the Everglades. This is a final integrated feasibility report and Programmatic Environmental Impact Statement, which identifies and discusses the plan's proposed project features, its beneficial effects and potential impacts on existing resources. The recommended Comprehensive Plan contains over sixty project features. Principal features of the plan are the creation of approximately 217,000 acres of new reservoirs and wetlands based water treatment areas. These features vastly increase storage and water supply for the natural system, as well as for urban and agricultural needs, while maintaining current Central and Southern Florida Project purposes. The recommended Comprehensive Plan achieves the restoration of more natural flows of water, including sheetflow, improved water quality, and more natural hydroperiods in the south Florida ecosystem. Improvements to native flora and fauna, including threatened and endangered species, will occur as a result of the restoration of hydrologic conditions.

THE OFFICIAL CLOSING DATE FOR THE RECEIPT OF COMMENTS IS 30 DAYS FROM THE DATE ON WHICH THE NOTICE OF AVAILABILITY OF THIS FINAL PROGRAMATIC EIS APPEARS IN THE FEDERAL REGISTER.

Telephone: (904) 232-3967

NOTE: This report includes an integrated Programmatic Environmental Impact Statement (PEIS) within the final feasibility report; sections required for compliance with the National Environmental Policy Act (NEPA) are noted by an asterisk in the Table of Contents.

CENTRAL AND SOUTHERN FLORIDA PROJECT COMPREHENSIVE REVIEW STUDY

FINAL INTEGRATED FEASIBILITY REPORT AND PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

SUMMARY

The recommended Comprehensive Plan contained within this report will, when implemented, restore, protect, and preserve a natural resource treasure – the south Florida ecosystem. The greater Everglades ecosystem is nationally significant and unique in the world. If actions are not taken now, irretrievable loss of this extraordinary resource will occur. The Comprehensive Plan affords the opportunity to reverse the course of declining ecosystem health and leave an Everglades legacy for generations to come.

The Central and Southern Florida (C&SF) Project, first authorized by Congress in 1948, is a multi-purpose project that provides flood control, water supply for municipal, industrial, and agricultural uses, prevention of saltwater intrusion, water supply for Everglades National Park, and protection of fish and wildlife resources. The primary system includes about 1,000 miles each of levees and canals, 150 water control structures, and 16 major pump stations.

The C&SF Project Comprehensive Review Study, known as the Restudy, is authorized by Section 309(l) of the Water Resources Development Act of 1992 (P.L.102-580). This study is also authorized by two resolutions of the Committee on Transportation and Infrastructure, United States House of Representatives, dated September 24, 1992. Section 528 of the Water Resources Development Act of 1996 provides specific direction and guidance for the Restudy.

The purpose of this study was to reexamine the C&SF Project to determine the feasibility of modifying the project to restore the south Florida ecosystem and to provide for the other water-related needs of the region. Specifically, as required by the authorizing legislation, the study investigated making structural or operational modifications to the C&SF Project for improving the quality of the environment; protecting water quality in the south Florida ecosystem; improving protection of the aquifer; improving the integrity, capability, and conservation of urban and agricultural water supplies; and improving other water-related purposes.

The following principles guided the development of the recommended Comprehensive Plan:

- The overarching objective of the Comprehensive Plan is the restoration, preservation and protection of the south Florida ecosystem while providing for other water related needs of the region;
- The Comprehensive Plan will be based on the best available science, and independent scientific review will be an integral part of its development and implementation;
- The Comprehensive Plan will be developed through an inclusive and open process that engages all stakeholders;
- All applicable Federal, tribal, state, and local agencies will be full partners and their views will be considered fully; and
- The Comprehensive Plan must be a flexible plan that is based on the concept of adaptive assessment – recognizing that modifications will be made in the future based on new information.

Although this document meets the requirements of Section 404 (r) of the Clean Water Act (Public Law 92-500, as amended), as addressed in Annex C, the Corps will request a Section 401 State water quality certificate during subsequent phases of this project.

The final integrated feasibility report and Programmatic Environmental Impact Statement is being transmitted through the Division Engineer and the Washington-level Federal report review process, which will include reviews by the Chief of Engineers and the Secretary of the Army. The Assistant Secretary of the Army for Civil Works, representing the Secretary of the Army, will coordinate the documents with the Office of Management and Budget, and send them to Congress. The study authority states that the Secretary shall transmit the Comprehensive Plan to Congress not later than July 1, 1999.

MAJOR CONCLUSIONS

The Everglades has molded the regional character of central and southern Florida and sustains the economic and cultural growth of the region. The Everglades has influenced the regional mosaics of space and landscape patterns - urban, agricultural and natural. As such, it epitomizes the region's sense of definition and place. As importantly, the Everglades is unlike any other place in the world.

The remaining Everglades and other natural ecosystems in south Florida no longer exhibit the functions, richness, and spatial extent that defined the pre-drainage systems. There have been substantial and irreversible reductions in the spatial extent of the wetland systems (including an approximately 50 percent reduction in the extent of the true Everglades) and in the total water storage, timing, and flow capacities of these systems. These natural systems will not recover their defining characteristics under current conditions and will not be sustained into the future. Indeed, the health of the ecosystem will continue to decline unless corrective actions are taken. For example, wading birds, whose numbers have already decreased by 85-90 percent, are key indicators of broad, regional patterns of aquatic production. There is a continuing reduction in the total number of birds initiating breeding in south Florida. Fisheries, including economically important recreational and commercial species, continue to decline steadily in many areas of south Florida, affecting the natural and the human environment.

Several of the major unintended impacts to the natural system attributed to the C&SF Project in south Florida include the following:

- extreme fluctuations in high and low water levels in Lake Okeechobee have a major adverse impact on the lake's littoral and pelagic zones and fish and wildlife habitats;
- extreme fluctuations between too much and too little freshwater discharge into the Caloosahatchee and St. Lucie estuaries result in detrimental salinity conditions and physical alterations of fish and wildlife habitat;
- detrimental hydrologic conditions in freshwater wetland habitats cause major adverse impacts on plant and animal communities of the native Everglades; and
- unsuitable freshwater flows to Florida and Biscayne bays and Lake Worth Lagoon adversely impact salinity and physically alter fish and wildlife habitat.

Water quality throughout south Florida has also deteriorated over the past 50 years since construction started on the C&SF Project. Many wetlands that acted as natural filters and retention areas either can no longer serve these purposes or have been lost to drainage or development. Urban and agricultural development and drainage systems result in the rapid discharge of runoff containing pollutants into south Florida's water bodies. As a result, many water bodies throughout south Florida presently do not meet water quality standards. Untreated urban and agricultural storm water that does not meet water quality standards is sometimes sent to natural areas. Excessive nutrients entering the Everglades have led to an overabundance of cattails, a visible sign of unfavorable water quality conditions and a potential decline in ecological productivity. Flood control releases from Lake Okeechobee and runoff discharged via secondary drainage canals in the St. Lucie River Basin have been linked to fish lesions and a decline in estuarine productivity, resulting in substantial ecological and economic impacts.

Adequately and reliably meeting water supply for all sectors is also a problem. Historically, most rainwater soaked into the ground in the region's vast wetlands. As south Florida developed, the canal network worked too effectively and drained too much water off the land too quickly. The result is that not enough water is stored for all uses. Water shortages that occur today are expected to become more frequent without any changes to the water management system. Without the steps outlined in this Comprehensive Plan, conflicts over the allocation of water needed for natural, agricultural, and urban areas will only increase.

Flooding is also a problem. Florida is a low-lying, flat, and wet state. Today, the Project provides flood protection on a regional basis for south Florida, supported by many locally operated canal networks. The Comprehensive Plan will maintain, and in some situations improve, this important protection from flooding.

Altogether, these problems seriously threaten the natural and human environment of the south Florida ecosystem.

What Is Expected to Happen Without the Recommended Comprehensive Plan

Although some level of ecological improvement will occur in the south Florida ecosystem as a result of implementation of projects currently planned outside of the Restudy, the cumulative, regional benefits from these projects would not result in a sustainable south Florida ecosystem. Specifically, based on an evaluation of conditions in the year 2050 without the recommended Comprehensive Plan, it was determined that the overall health of the ecosystem will have substantially deteriorated. This type of assessment was carried out for all planning alternatives evaluated during the course of the Restudy. The analyses show that making modifications to only some portions of the C&SF Project in order to achieve sustainable natural systems will not succeed. Conditions predicted in 2050 fail to meet the basic needs of the south Florida ecosystem.

Demands placed on Lake Okeechobee result in damaging water levels and extreme harm to the littoral zone. Damaging fresh water discharges into the Caloosahatchee and St. Lucie estuaries result in major harm to fisheries. Damaging high flows alter salinity balances in Lake Worth Lagoon. Hydropatterns predicted for the Water Conservation Areas are harmful to tree islands. Everglades National Park does not receive enough freshwater flow to maintain important aquatic habitat in Shark River Slough. Low flows to Florida and Biscayne bays also result in harm to the resources in these areas. These ecological problems would not be corrected solely by implementation of currently planned or ongoing projects.

Relatively greater levels of improvement were identified for water quality conditions in the future compared to existing conditions in south Florida. It is expected that state, tribal, regional, and local programs to improve water quality will be implemented to varying degrees throughout the study area during the next 50 years. Ongoing restoration projects in the Kissimmee River watershed are expected to beneficially affect water quality. Current efforts to reduce inputs of excessive nutrients into the Everglades through the Everglades Construction Project should substantially slow the spread of cattails and other plants with high nutrient tolerances and result in a slow recovery of natural vegetation patterns in some nutrient-stressed parts of the system. Proposed modifications to the Lake Okeechobee regulation schedule and water quality improvement projects suggested by the South Florida Ecosystem Restoration Working Group's Lake Okeechobee, St. Lucie, and Caloosahatchee Issue Teams should improve water quality conditions in those water bodies. Nonetheless, the future without plan condition, while resulting in water quality improvements over existing conditions in certain subregions of the Restudy area, was still determined by the Restudy's water quality team to be unacceptable for sustainable ecosystems.

The future demand for suitable water is expected to exceed the limits of readily available sources. Predictions of water restrictions in the future indicate serious – and probably unacceptable – levels of water supply cutbacks. Modeling of the future "without plan" condition shows that for the Lake Okeechobee Service Area, 24 percent of water supply demands could not be met over a 30-year period. This translates into water supply restrictions every other year. In the Lower East Coast, water restrictions would be expected to occur every other year in Palm Beach, Miami-Dade, and the Florida Keys portion of Monroe County. In Broward County water restrictions would occur on nearly an annual basis. The ability to sustain the region's natural resources, economy, and quality of life depends, to a great extent, on the success of the efforts to enhance, protect, and better manage the region's water resources.

A major advantage of the Comprehensive Review Study is that it has used tools and methods to evaluate the entire C&SF Project area together as an integrated system. Thus, the effects of making modifications in one area on another area were able to be seen and then used to develop a plan that maximized positive system-wide benefits. The South Florida Water Management Model is the tool that demonstrates the hydrologic effects of changes in one region on other regions. The Restudy Team developed measures to evaluate an alternative plan's effect on the entire C&SF Project area. The use of system-wide tools and a science-based analytical approach supports the conclusion, as shown in the following table, that the future without plan condition is not favorable - nor is it sustainable - for the south Florida ecosystem.

PERFORMANCE OF THE COMPREHENSIVE PLAN COMPARED TO THE NO-ACTION ALTERNATIVE

Area	Future Without Plan	Future With Plan
Lake Okeechobee	Y	G
Caloosahatchee Estuary	R	G
St Lucie Estuary	R	G
Lake Worth Lagoon	Y	Y
Holey Land & Rotenberger WMA	Y	G
Loxahatchee National Wildlife Refuge	Y	G
Water Conservation Area 2A		G/Y
Water Conservation Area 2B		R
Northwestern Water Conservation Area 3A		G
Northeastern Water Conservation Area 3A	R	Y
Eastern Water Conservation Area 3A		Y
Central & Southern Water Conservation Area 3A		G/Y
Water Conservation Area 3B		Y
Everglades National Park – Shark River Slough	R	G
Everglades National Park – Rockland Marl Marsh	R	Y
Florida Bay	R	G
Biscayne Bay	Y	G
Model Lands	R	G
Big Cypress National Preserve	Y	G
Lake Okeechobee Service Area	R	G
Urban Lower East Coast	R	G

Green (G) - predicted hydrologic performance will result in recovery and long-term sustainability of ecological or water supply objectives.

Yellow (Y) -marginal or uncertain ability to achieve long-term sustainability of ecological or water supply objectives.

Red (R) -ecological or water supply objectives will not be met.

How the Restudy Team Developed the Recommended Comprehensive Plan

A multi-agency, multidisciplinary team was created to develop plans that addressed the problems within the study area. This team included biologists, ecologists, economists, engineers, geographic information system specialists, hydrologists, planners, public involvement specialists, and real estate specialists from a number of Federal, state, tribal, and local government agencies.

Between September 1997 and June 1998, alternative comprehensive plans were formulated and evaluated. Beginning with a "Starting Point" alternative and continuing until the recommended plan was chosen, each iterative formulation and evaluation cycle built upon the strengths of the previous alternative plan while addressing its shortfalls. The Alternative Evaluation Team, a subgroup of the Restudy Team, evaluated each alternative based on modeling results and comments received from the entire team as well as the general public. The Alternative Development Team, another Restudy subgroup, then used that evaluation to design a better alternative. All modeling results and evaluations were posted on the Restudy web site for the team and general public to review.

Because of its fundamental importance to restoration, much of the emphasis early in the plan formulation process was on increasing regional storage capacity and increasing water management flexibility to meet water quantity objectives. Later iterations addressed the restoration objectives of greater system connectivity (decompartmentalization) and sheetflow. Throughout the formulation and evaluation period, many different decompartmentalization scenarios were modeled. These scenarios gave the team feedback on how the system responded under different conditions. This knowledge was valuable in the effort to improve conditions in the remaining Everglades in the final alternative, which became the basis of the recommended Comprehensive Plan.

The Restudy Team recognized that water quality standards were not being met in many water bodies in the study area. The team recognized the changes in flow patterns, even though beneficial hydrologically, might adversely affect water quality conditions in downstream water bodies. To address this problem, several water quality treatment facilities were included in the recommended Comprehensive Plan to ensure water quality standards would be met. Future implementation of the features of the Comprehensive Plan, including detailed planning and design, will take into account water quality restoration targets as they are developed for specific water bodies in south Florida.

Major Features of the Recommended Comprehensive Plan

The Restudy Team formulated and evaluated 10 alternative comprehensive plans and more than 25 intermediate computer simulations. Alternative D-13R was selected as the Initial Draft Plan. Alternative D-13R along with the series of Other Project Elements, Critical Projects, water quality treatment facilities, and other modifications that further improve performance of the plan, comprise the recommended Comprehensive Plan. The estimated first cost of the recommended Comprehensive Plan is $7.8 billion; and the annual operation and maintenance costs, including adaptive assessment and monitoring, are $182 million. The plan includes the following structural and operational changes to the existing C&SF Project:

Surface Water Storage Reservoirs. A number of water storage facilities are planned north of Lake Okeechobee, in the Caloosahatchee and St. Lucie basins, in the Everglades Agricultural Area, and in the Water Preserve Areas of Palm Beach, Broward and Miami-Dade counties. These areas will encompass approximately 181,300 acres and will have the capacity to store 1.5 million acre-feet of water.

Water Preserve Areas. Multipurpose water management areas are planned in Palm Beach, Broward and Miami-Dade counties between the urban areas and the eastern Everglades. The Water Preserve Areas will have the ability to treat urban runoff, store water, reduce seepage, and improve existing wetland areas.

Manage Lake Okeechobee as an Ecological Resource. Lake Okeechobee is currently managed for many, often conflicting, uses. The lake's regulation schedule will be modified and plan features constructed to reduce the extreme high and low levels that damage the lake and its shoreline. Management of intermediate water levels will be improved, while allowing the lake to continue to serve as an important source for water supply. Several plan components and Other Project Elements are included to improve water quality conditions in the lake. A study is recommended to evaluate in detail the dredging of nutrient-enriched lake sediments to help achieve water quality restoration targets, important not only for the lake, but also for downstream receiving bodies.

Improve Water Deliveries to Estuaries. Excess stormwater that is discharged to the ocean and the gulf through the Caloosahatchee and St. Lucie rivers is very damaging to their respective estuaries. The recommended Comprehensive Plan will greatly reduce these discharges by storing excess runoff in surface and underground water storage areas. During times of low rainfall, the stored water can be used to augment flow to the estuaries. Damaging high flows will also be reduced to the Lake Worth Lagoon.

Underground Water Storage. Wells and associated infrastructure will be built to store water in the upper Floridan aquifer. As much as 1.6 billion gallons a day may be pumped down the wells into underground storage zones. The injected fresh water, which does not mix with the saline aquifer water, is stored in a "bubble" and can be pumped out during dry periods. This approach, known as aquifer storage and recovery, has been used for years on a smaller scale to augment municipal water supplies. Since water does not evaporate when stored underground and less land is required for storage, aquifer storage and recovery has some advantages over surface storage. The recommended Comprehensive Plan includes aquifer storage and recovery wells around Lake Okeechobee, in the Water Preserve Areas, and the Caloosahatchee Basin.

Treatment Wetlands. Approximately 35,600 acres of manmade wetlands, known as stormwater treatment areas, will be built to treat urban and agricultural runoff water before it is discharged to the natural areas throughout the system. Stormwater treatment areas are included in the recommended Comprehensive Plan for basins draining to Lake Okeechobee, the Caloosahatchee River Basin, the St. Lucie Estuary Basin, the Everglades, and the Lower East Coast. These are in addition to the over 44,000 acres of stormwater treatment areas already being constructed pursuant to the Everglades Forever Act to treat water discharged from the Everglades Agricultural Area.

Improve Water Deliveries to the Everglades. The volume, timing, and quality of water delivered to the south Florida ecosystem will be greatly improved. The Comprehensive Plan will deliver an average of 26 percent more water into

Northeast Shark River Slough over current conditions. This translates into nearly a half million acre-feet of additional water reaching the slough, and is especially critical in the dry season. More natural refinements will be made to the rainfall-driven operational plan to enhance the timing of water sent to the Water Conservation Areas, Everglades National Park, and the Holey Land and Rotenberger Wildlife Management Areas.

Remove Barriers to Sheetflow. More than 240 miles of project canals and internal levees within the Everglades will be removed to reestablish the natural sheetflow of water through the Everglades. Most of the Miami Canal in Water Conservation Area 3 will be removed and 20 miles of the Tamiami Trail (U.S. Route 41) will be rebuilt with bridges and culverts, allowing water to flow more naturally into Everglades National Park, as it once did. In the Big Cypress National Preserve, a north-south levee will be removed to restore more natural overland water flow.

Store Water in Existing Quarries. Two limestone quarries in northern Miami-Dade County will be converted to water storage reservoirs to supply Florida Bay, the Everglades, Biscayne Bay, and Miami-Dade County residents with water. The 11,000-acre area will be ringed with an seepage barriers to ensure that stored water does not leak or adjacent groundwater does not seep into the area. A similar facility will be constructed in northern Palm Beach County.

Reuse Wastewater. The recommended Comprehensive Plan includes two advanced wastewater treatment plants in Miami-Dade County capable of making more than 220 million gallons a day of the county's treated wastewater clean enough to discharge into wetlands along Biscayne Bay and for recharging the Biscayne Aquifer. This reuse of water will improve water supplies to south Miami-Dade County as well as reducing seepage from the Northeast Shark River Slough area of the Everglades. Given the high cost associated with using reuse to meet the ecological goals and objectives for Biscayne Bay, other potential sources of water to provide freshwater flows to the central and southern bay will be investigated before pursuing reuse.

Pilot Projects. A number of technologies proposed in the Comprehensive Plan have uncertainties associated with them -- either in the technology itself, its application, or in the scale of implementation. While none of the proposed technologies are untested, what is not known is whether actual performance will measure up to that anticipated in the Comprehensive Plan. The pilot projects, which include wastewater reuse, seepage management, Lake Belt technology, and three aquifer storage and recovery projects are recommended to address uncertainties prior to full implementation of these components.

Improve Fresh Water Flows to Florida Bay. Improved water deliveries to Shark River Slough, Taylor Slough, and wetlands to the east of Everglades National Park will in turn provide improved deliveries of fresh water flows to Florida Bay. A feasibility study is also recommended to evaluate additional environmental restoration needs in Florida Bay and the Florida Keys.

Southwest Florida. There are additional water resources problems and opportunities in southwest Florida requiring studies beyond the scope of the Restudy recommended Comprehensive Plan. In this regard, a feasibility study for Southwest Florida is being recommended to investigate the region's hydrologic and ecological restoration needs.

Comprehensive Integrated Water Quality Plan. The recommended Comprehensive Plan includes a follow-on feasibility study to develop a comprehensive water quality plan to ensure that the Comprehensive Plan leads to ecosystem restoration throughout south Florida. The water quality feasibility study would include evaluating water quality standards and criteria from an ecosystem restoration perspective and recommendations for integrating existing and future water quality restoration targets for south Florida water bodies into future planning, design, and construction activities to facilitate implementation of the recommended Comprehensive Plan. Further, water quality in the Keys is critical to ecosystem restoration. The Florida Keys Water Quality Protection Plan includes measures for improving wastewater and stormwater treatment within the Keys. Implementation of the Keys Water Quality Protection Plan is critical for restoration of the south Florida ecosystem.

Overall, the recommended Comprehensive Plan will capture and store much of the water that is now lost to the ocean and gulf. This will provide enough water in the future for both the ecosystem, as well as urban and agricultural users. It will continue to provide the same level of flood protection as it does at present, if not more, for south Florida. The Comprehensive Plan is a system-wide solution for ecosystem restoration, water supply, and flood damage reduction. It is a necessary step towards a sustainable south Florida.

What the Comprehensive Plan Will Accomplish

Implementation of the recommended Comprehensive Plan will result in the recovery of healthy, sustainable ecosystems throughout south Florida. It is a plan that will lead to a much improved environment, for people and for the plants and animals that depend upon the natural system for their survival. The Comprehensive Plan contains all of the essential components to achieve this goal. There are many reasons for having confidence that it will be successful. No other plan, especially one on a smaller scale or one lacking the appropriate balance between ecosystem restoration and future urban and agricultural water supply objectives, would achieve a similar level of success.

The Comprehensive Plan does not provide all the answers – no plan could. The plan, however, contains an aggressive adaptive assessment strategy that includes independent scientific peer review and a process for identifying and resolving uncertainties. Because it is acknowledged that all the answers cannot be known at this time, and that inaction is not an option, adaptive assessment provides the means to allow restoration to move forward. A major strength of the current plan is that its flexibility allows for efficient and successive opportunities to make further improvements as we refine our plans and obtain new information.

The focus of the recommended Comprehensive Plan has been on recovering the defining ecological features of the original Everglades and other south Florida ecosystems. What made these ecosystems unique was their topographic flatness and expansiveness, and that they formed hydrologically integrated systems from boundary to boundary. What this means in a healthy ecosystem is that water patterns in one part of the system could be used to predict the patterns throughout the system. Animals living in the Everglades would "read" the water patterns, and "know" where to go to find the food and water that they needed for successful reproduction and survival under a range of natural conditions. It was the combination of connectivity and space that created the range of habitats needed for the diversity of plants and animals. The construction of the many levees and dikes designed to compartmentalize the Everglades and separate Lake Okeechobee from its natural overflow, and the canals that drained water to the coast, disrupted these natural patterns, and destroyed the ability of many animals to find the dependable habitat needed for their survival at the right time.

The recommended Comprehensive Plan, by removing over 240 miles of internal levees in the Everglades, and approaching recovery of the natural volume of water in the remaining wetlands, will restore these essential defining features of the pre-drainage wetlands over large portions of the remaining system. The plan also includes water storage and water quality treatment areas that will improve water quality conditions in the south Florida ecosystem. In response to this substantial improvement, the characteristic animals of these ecosystems will show dramatic and positive responses. At all levels in the aquatic food chains, the numbers of such animals as crayfish, minnows, sunfish, frogs, alligators, herons, ibis, and otters, will markedly increase. Equally important, animals will respond to the recovery of more natural water patterns by returning to their traditional distribution patterns.

The recommended Comprehensive Plan will support the return of the large nesting "rookeries" of wading birds to Everglades National Park, and the recovery of several endangered species to more certain and optimistic futures. Wading birds, e.g., herons, egrets, ibis and storks, are symbolic of the overall health of the Everglades. As recently as the 1950s and 1960s, large "super colonies" of nesting waders remained in the park; none have been there since. Wading birds, perhaps more than any other animal, assess the quality of habitats over the entire basin of south Florida wetlands, before making “decisions” about where and when, or even whether, to nest. The recovery of the super colonies will be a sure sign that the entire ecosystem has made substantial progress towards recovery. Of the endangered species, the wood stork, snail kite, Cape Sable seaside sparrow, and American crocodile, among others, will benefit and increase. Undoubtedly, implementation of the recommended Comprehensive Plan will once again allow us to witness what is now only a fading memory of the former abundance of wildlife in the Everglades.

It is important to understand that the “restored” Everglades of the future will be different from any version of the Everglades that has existed in the past. While it certainly will be vastly superior to the current ecosystem, it will not completely match the pre-drainage system. This is not possible, in light of the irreversible physical changes that have made to the ecosystem. It will be an Everglades that is smaller and somewhat differently arranged than the historic ecosystem. But it will be a successfully restored Everglades, because it will have recovered those hydrological and biological patterns which defined the original Everglades, and which made it unique among the world’s wetland systems. It will become a place that kindles the wildness and richness of the former Everglades.

Lake Okeechobee will once again become a healthy lake. The littoral and pelagic zones within the lake, essential to the lake’s commercial and recreational fishery and other aquatic species, will be greatly enhanced by the water levels projected in the recommended Comprehensive Plan. Water quality will also be improved significantly. The lake provides huge regional benefits to wildlife, including waterfowl, other birds, and mammals.

The Comprehensive Plan provides major benefits to the Caloosahatchee and St. Lucie estuaries, and Lake Worth Lagoon. The plan eliminates almost all the damaging fresh water releases to the Caloosahatchee and most detrimental releases to the St. Lucie. The plan makes substantial improvements to Lake Worth Lagoon. As a result, grassbeds and other submerged aquatic vegetation will benefit and thus provide abundant favorable habitat for the many aquatic species that depend on these areas for food, shelter, and breeding grounds, thereby enhancing the productivity and economic viability of estuarine fisheries. The recommended Comprehensive Plan also includes several water storage and treatment areas to improve water quality conditions in the Indian River Lagoon and the St. Lucie and Caloosahatchee estuarine systems.

The recommended Comprehensive Plan makes improvements in fresh water deliveries to Florida and Biscayne bays. These bays will benefit from more natural water deliveries. Appropriate fresh water regimes will result in substantial improvements in aquatic and semi-aquatic habitats; fish and wildlife will respond favorably to these beneficial changes. Mangroves, coastal marshes, and seagrass beds interacting together to produce food, shelter, and breeding and nursery grounds will support more balanced, productive fish, shellfish, and wildlife communities.

South Florida does not have to follow the fate of some states that suffer severe water shortages, creating tension between natural resource protection and water supply. The recommended Comprehensive Plan expands the storage capability of the C&SF Project, enabling the system to better meet ecosystem and urban water supply needs in the future. Frequency of water restrictions expected with the recommended Comprehensive Plan are greatly reduced compared to the Without Plan Condition. This will be accomplished by more effectively providing adequate flows from the regional system to recharge the surficial aquifer. This will help offset withdrawals from public water supply wellfields and other users in the urbanized Lower East Coast Region. Such recharge also protects the surficial aquifer from saltwater intrusion, allowing it to remain a productive source of fresh water in the future.

The recommended Comprehensive Plan will significantly increase the capability to supply water from the regional system to agricultural users. This will provide better protection from economically harmful water supply cutbacks and allow agriculture to remain productive. Storage facilities associated with Lake Okeechobee such as those north of the lake, and Lake Okeechobee aquifer storage and recovery will enable the lake to remain an important source of water supply while keeping lake stages at more ecologically desirable levels. Additional storage facilities built throughout the system will diversify sources of water for many users and enable recycling of water within a basin to meet dry season demands, significantly improving the reliability of agricultural water supply in the future.

The recommended Comprehensive Plan also assures that the quality of south Florida's water bodies will be restored to achieve overall ecosystem restoration. The recommended Comprehensive Plan includes many features to assure that water quality standards will be met and water quality conditions are improved or not degraded. The Comprehensive Plan includes the development of a comprehensive integrated water quality plan, which will lead to recommendations for water quality remediation programs and the integration of water quality restoration targets into future design, construction, and operation activities as features of the recommended Comprehensive Plan are implemented.

How the Comprehensive Plan Will Be Implemented

No plan can anticipate fully the uncertainties that are inherent in predicting how a complex ecosystem will respond during restoration efforts. For example, the remaining Everglades are only one-half as large as the original and current boundaries do not logically follow natural ground elevations or habitat patterns. For these and many other reasons, the ways in which this ecosystem will respond to the recovery of more natural water patterns almost certainly will include some surprises. The recommended Comprehensive Plan anticipates such surprises and is designed to facilitate project modifications that take advantage of what is learned from system responses, both expected and unexpected, and from future restoration targets as those become more refined. For example, future water quality restoration targets will be integrated into the detailed design, construction, and future operation of all recommended Comprehensive Plan features.

A new type of reporting document will be prepared as the implementation process begins. Project Implementation Reports will bridge the gap between the Comprehensive Plan and the detailed design necessary to proceed to construction. In addition to supplemental National Environmental Policy Act documentation, the Project Implementation Report process will allow for continuing public participation on each feature. In this more detailed phase of analysis, Comprehensive Plan components will be further investigated and appropriate actions recommended.

The Comprehensive Plan includes an aggressive adaptive assessment strategy. This strategy ensures that new information about the natural system, learned from continuing research and from measuring responses to implementation of plan components, can be used to increase the ultimate level of success of the overall restoration program. Specifically, adaptive assessment uses a well focused, regional monitoring program to measure how well each component of the plan accomplishes its objectives. This, in turn, sets up opportunities for refinement of succeeding components. Such adaptive assessment and regional monitoring are essential features of the recommended Comprehensive Plan and ensure its overall success. Independent scientific peer review is an integral part of this process.

Pilot projects to demonstrate the effectiveness of technologies such as aquifer storage and recovery, seepage management, and wastewater reuse are a part of the implementation strategy. Three new feasibility studies, Florida Bay and the Florida Keys, Southwest Florida, and a comprehensive integrated water quality plan, will also be undertaken to assure that full implementation of the Comprehensive Plan leads to overall ecosystem restoration in south Florida. The use of the best available science and extensive outreach and public involvement, both of which have been an essential part of the Restudy, will continue during the implementation process.

The recommended Comprehensive Plan described in this report will serve as a framework and guide for modifications to the Central and Southern Florida Project. The pilot projects and a set of specific key components are recommended for initial authorization. The estimated total cost of these initial features are $1,198,000,000 (October 1999 price levels) and an annual cost of $20,000,000 for operation and maintenance. The estimated Federal cost is $599,000,000 with estimated annual operation and maintenance costs of $10,000,000; and the estimated non-Federal cost is $599,000,000 with estimated annual operation and maintenance costs of $10,000,000.

Further, the Water Resources Development Act of 1996 provided authorization for Critical Restoration Projects in order to expedite implementation of the restoration effort. A similar programmatic authority is recommended to help expedite implementation of some components in the recommended Comprehensive Plan. This programmatic authority would be limited to those components of the Comprehensive Plan that have a total project cost of $70,000,000 with a maximum Federal cost of $35,000,000.

Authorization for the remaining components of the Comprehensive Plan will be sought after completion of more detailed planning and submission of Project Implementation Reports to Congress. Each Project Implementation Report will also contain an analysis of the Comprehensive Plan and any recommendations concerning modifications to the plan.

AREAS OF CONTROVERSY AND UNRESOLVED ISSUES

During the course of the Restudy, a number of important issues have emerged. Many have been resolved, but some remain. For example:

Scientific Models. Many scientific and engineering models were used in developing the recommended Comprehensive Plan. The models employed in the Restudy are state-of–the-art, and represent the best understanding of the hydrology of both the pre-drainage and current C&SF system (Natural System Model and South Florida Water Management Model) as well as species responses to hydrology (Across Trophic Landscape System Simulation). But by their very nature, models are uncertain because they are simplifications of reality. The South Florida Water Management Model and the Natural System Model have undergone technical peer review. The conclusions that can be drawn from them are only as good as the basic understandings and information that are the foundations of the models. Most importantly, such conclusions must be understood in the context of model uncertainty and appropriateness of scale, and are best utilized to compare performance among alternative plans. The Natural System Model, for example, depicts the hydrologic response of the pre-drained system to rainfall and other hydrologic conditions of the period from 1965 through 1995. It does not depict the conditions of the pre-drained Everglades system, although there is a misconception that it does; such data does not exist. This model was used to help define performance measures for the natural system and to evaluate the performance of different alternative plans. However, defining acceptable performance of any particular alternative plan by ridged adherence to outs from the Natural System Model is an improper use of such output.

Water Quality Restoration Targets. Many water bodies in south Florida are not currently meeting water quality standards. The State of Florida and the Miccosukee and Seminole Tribes are required under the Federal Clean Water Act to identify those water bodies periodically. Total maximum daily loads for those pollutants causing those water bodies to not meet standards and remediation programs to assure that standards will be met must be developed. The current schedule for developing these standards has the potential to delay implementation of certain features of the recommended Comprehensive Plan until those targets are developed and remediation programs are implemented. In addition to this program, several water bodies have been prioritized by the state's Surface Water Improvement and Management Program, including the development of pollutant load reduction goals. There is some concern as to the degree to which remediation programs have been limited, and that some load reduction goals may not be protective enough to achieve ecosystem restoration. The comprehensive integrated water quality plan feasibility study included in the recommended Comprehensive Plan will include prioritizing the development of both water quality standards and pollution load reduction goals consistent with the Restudy implementation schedule. Recommendations will be made for optimizing the design, construction, and operation of plan features to assure that water quality restoration targets are achieved. Existing water quality criteria will be reviewed, and additional water quality criteria may be developed to complement future detailed planning and design activities undertaken to implement recommended Comprehensive Plan components.

Technology Uncertainties. Most of the recommended Comprehensive Plan's features are tested and proven reliable means to manage water. However some of the facilities proposed such as aquifer storage and recovery and seepage control have not been implemented on such a large scale. A series of pilot projects are proposed in the recommended Comprehensive Plan to address the uncertainties of these technologies. Results from these studies will help direct future detailed planning and design related to implementation of these types of facilities.

This Comprehensive Plan makes no claim that all the questions have been answered, that all the uncertainties have been addressed, or that all the issues have been resolved. No plan could do all these things. We have improved our understanding of this complex system and know that there is much more to learn. The Comprehensive Plan is a roadmap -- and a very important one -- that provides critical direction and organizational structure for restoring and protecting the south Florida ecosystem. The Implementation Plan contained in this Comprehensive Plan recommends a phased approach to project construction that provides for substantial region-wide benefits and a feedback mechanism through adaptive assessment to ensure that implementation of project features continues to achieve desired objectives. The adaptive assessment and monitoring process, including independent scientific peer review, will serve as a system “check” as projects are constructed and operated. Enough flexibility has been built into the Implementation Plan such that project design and sequencing will take into account system responses and new information as it becomes available.

WHY RESTORE THE EVERGLADES?

Why restore the Everglades? The answers to this question are overwhelming. The Everglades is to south Florida what the Rockies are to many western states; the old growth forests are to the Pacific northwest; the Adirondack, White and Green Mountains are to the northeast; and the Mississippi River is to the nation's heartland. The Everglades epitomizes the region's sense of definition and place, both substantially and spiritually (by providing clean water and recreation and by providing a sense of hope for the quality of the region's future). The Everglades is unlike any other place in the world. It attracts the eyes of the world.

We are now at an important crossroad in our efforts to restore this internationally important ecosystem. If we act now with courage and vision to implement this technically sound comprehensive restoration plan, we will be successful and we will leave a proud Everglades legacy. If we fail to act, our legacy will be one of lost opportunities for all future generations. The world is indeed watching as we make this choice.

PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

TABLE OF CONTENTS

***SUMMARY** i

SECTION 1 INTRODUCTION
1.1 Study Authority 1-3
1.2 Study Purpose & Scope 1-7
1.2.1 Study Purpose 1-7
1.2.2 Study Scope 1-8
1.2.3 Report Organization 1-9
1.3 Study Area 1-9
1.3.1 Kissimmee River Basin 1-10
1.3.2 Lake Okeechobee 1-13
1.3.3 Upper East Coast 1-13
1.3.4 Everglades Agricultural Area 1-15
1.3.5 Water Conservation Areas 1-15
1.3.6 Lower East Coast Area 1-17
1.3.7 Biscayne Bay 1-18
1.3.8 Everglades National Park 1-19
1.3.9 Florida Bay, Whitewater Bay, and the Ten Thousand Islands 1-20
1.3.10 Florida Keys 1-20
1.3.11 Florida Reef Tract 1-21
1.3.12 Big Cypress Basin 1-21
1.3.13 Lower West Coast 1-22
1.4 National Environmental Policy Act Requirements 1-22
1.5 Study Process 1-24
1.6 The Central And Southern Florida Project 1-25
1.7 Other Studies, Reports, And Projects 1-28
1.7.1 C&SF Project Authorizations 1-28
1.7.2 Other Studies 1-30

SECTION 2 PRE-DRAINAGE CONDITION
2.1 Introduction 2-1
2.2 Description Of The Natural System 2-2
2.3 Fundamental Characteristics Of The Pre-Drainage System 2-2
2.3.1 Dynamic Storage and Sheet Flow 2-3
2.3.2 Large Spatial Scale 2-3
2.3.3 Heterogeneity in Habitat 2-4
2.4 Relationships With Spatial And Temporal Variation 2-4

2.5 Overview Of Historic Water Quality Conditions.......2-6
2.5.1 Kissimmee River Basin.......2-6
2.5.2 Lake Okeechobee.......2-6
2.5.3 Upper East Coast.......2-7
2.5.4 The Central Everglades.......2-7
2.5.5 Lower East Coast and Biscayne Bay.......2-8
2.5.6 Florida Bay and the Florida Keys.......2-8
2.5.7 Big Cypress Basin.......2-9
2.5.8 Caloosahatchee River Basin.......2-9

SECTION 3 *EXISTING CONDITIONS
3.1 Geology And Soils.......3-2
3.2 Climate.......3-4
3.3 Air Quality.......3-4
3.4 Noise.......3-4
3.5 Vegetation.......3-5
3.6 Fish And Wildlife.......3-8
3.7 Threatened, Endangered And State Listed Species.......3-13
3.8 Water Management.......3-15
3.8.1 Kissimmee River – Istokpoga Basin.......3-15
3.8.2 Lake Okeechobee and Everglades Agricultural Area.......3-16
3.8.3 Water Conservation Areas.......3-17
3.8.4 East Coast Canal Watersheds.......3-18
3.9 Water Quality.......3-19
3.9.1 Regional Overview Of Water Quality Conditions.......3-21
3.9.2 Groundwater Conditions.......3-24
3.10 Water Supply.......3-25
3.11 Socio-Economics.......3-27
3.12 Land Use.......3-28
3.13 Recreation Resources.......3-30
3.14 Aesthetics.......3-32
3.15 Cultural Resources.......3-34
3.16 Hazardous, Toxic And Radioactive Waste.......3-36

SECTION 4 *FUTURE "WITHOUT PLAN" CONDITION
4.1 "With And Without" Comparisons.......4-1
4.2 Planning Horizon.......4-2
4.3 Climate.......4-3
4.4 Sea Level Rise.......4-3
4.5 Population And Socio-Economic Conditions.......4-6
4.6 Land Use And Land Cover.......4-7
4.7 Water Quality.......4-10
4.7.1 Kissimmee River Region.......4-10
4.7.2 Lake Okeechobee.......4-10
4.7.3 Upper East Coast.......4-11
4.7.4 Everglades Agricultural Area.......4-11
4.7.5 Natural Areas.......4-17
4.7.6 Lower East Coast and Biscayne Bay.......4-17
4.7.7 Florida Bay.......4-18
4.7.8 Florida Keys.......4-18

4.7.9 Big Cypress Basin 4-18
4.7.10 Caloosahatchee River Region 4-19
4.8 Urban And Agricultural Water Supply Demands 4-19
4.8.1 Lower East Coast Region 4-19
4.8.2 Everglades Agricultural Area Region 4-22
4.8.3 Upper East Coast Region 4-23
4.8.4 Big Cypress And Caloosahatchee River Regions 4-24
4.9 Physical Facilities And Operations 4-24
4.9.1 C&Sf Project Modifications 4-24
4.9.2 Critical Projects....4-29
4.9.3 Interim Plan For Lower East Coast Regional Water Supply 4-30
4.9.4 Northwest Dade Lake Belt Area....4-33
4.9.5 East Cape And Homestead Canals 4-33
4.10 Land Acquisition Programs 4-33
4.10.1 Save Our Rivers Program, Preservation 2000 and Conservation and Recreation Lands....4-33
4.10.2 Miami-Dade County Environmentally Endangered Lands Program....4-35
4.10.3 Farm Bill 4-35
4.11 Recreation....4-36

SECTION 5 PROBLEMS AND OPPORTUNITIES

5.1 Public Concerns....5-1
5.2 Ecological Problems And Opportunities 5-3
5.3 Water Quality Problems And Opportunities 5-5
5.3.1 Regional Overview....5-5
5.3.2 Kissimmee River Region....5-8
5.3.3 Lake Okeechobee 5-9
5.3.4 Upper East Coast and Indian River Lagoon....5-10
5.3.5 Everglades Agricultural Area 5-11
5.3.6 Natural Areas....5-12
5.3.7 Lower East Coast and Biscayne Bay 5-13
5.3.8 Florida Bay 5-15
5.3.9 Florida Keys....5-16
5.3.10 Big Cypress Basin 5-17
5.3.11 Caloosahatchee River Region 5-18
5.3.12 Mercury 5-18
5.4 Economic And Social Well-Being Problems And Opportunities 5-19
5.5 Planning Goals And Objectives....5-20
5.5.1 Enhance Ecologic Values 5-21
5.5.2 Enhance Economic Values And Social Well Being 5-24
5.6 Ecosystem Restoration 5-26
5.6.1 Why Restore The South Florida Ecosystems?....5-26
5.6.2 Certainties And Uncertainties 5-28
5.6.3 Different Views 5-29
5.6.4 The Recovered Ecosystems....5-30
5.6.5 Role Of Adaptive Assessment 5-32
5.7 South Florida Ecosystem Restoration Vision....5-35

SECTION 6 GOVERNOR'S COMMISSION CONCEPTUAL PLAN FOR THE RESTUDY

6.1. Governor's Commission For A Sustainable South Florida 6-1
6.2. Initial Report 6-1
6.3. Development Of The Conceptual Plan 6-3
6.3.1. Commission's Planning Objectives 6-3
6.3.2. Preferred Alternatives 6-5
6.4. Conceptual Plan Elements 6-8
6.4.1. Concept 1: Regional Storage Within The Everglades Headwaters And Adjacent Areas 6-10
6.4.2. Concept 2: Lake Okeechobee Operational Plan 6-12
6.4.3. Concept 3: Everglades Agricultural Area Storage 6-14
6.4.4. Concept 4: Water Preserve Areas 6-15
6.4.5. Concept 5: Natural Areas Continuity 6-18
6.4.6. Concept 6: Water Supply and Flood Protection for Urban and Agricultural Areas 6-23
6.4.7. Concept 7: Adequate Water Quality for Natural System Functioning 6-24
6.4.8. Concept 8: Increased Spatial Extent and Quality of Wetlands Beyond the Everglades 6-28
6.4.9. Concept 9: Invasive Plant Control 6-30
6.4.10. Concept 10: Aquifer Storage and Recovery 6-31
6.4.11. Concept 11: Protection and Restoration of Coastal, Estuarine, and Marine Ecosystems 6-33
6.4.12. Concept 12: Conservation of Soil 6-36
6.4.13. Concept 13: Operation, Management, and Implementation of the C&SF Project Modifications and Related Lands 6-38

SECTION 7 PLAN FORMULATION AND EVALUATION

7.1 Plan Formulation And Evaluation Methodology 7-1
7.2 Identification And Screening Of Plan Components 7-2
7.2.1 Identification Of Plan Components 7-3
7.2.2 Screening Of Plan Components 7-3
7.2.3 Screening Conclusions 7-6
7.3 Formulation And Evaluation Of Alternative Plans 7-8
7.3.1 Methodology For Formulation And Evaluation Of The Alternative Plans 7-8
7.3.2 Formulation And Evaluation Iterations 7-14
7.3.3 Initial Draft Plan 7-35
7.3.4 Conclusions Of Comprehensive Plan Formulation And Evaluation 7-44
7.4 Other Project Elements 7-45
7.4.1 Evaluation Of Other Project Elements 7-45
7.4.2 Conclusions Of The Evaluation Of The Other Project Elements 7-46
7.5 Final Array Of Alternative Plans 7-46
7.5.1 Economic Evaluation of the Alternative Plans 7-46
7.5.2 Environmental Evaluation of the Alternative Plans 7-51
7.5.3 Cost Effectiveness and Incremental Cost Analyses 7-52
7.5.4 Fish and Wildlife Mitigation Analysis 7-59
7.5.5 Uncertainty Analysis 7-60
7.5.6 Planning Criteria 7-61
7.5.7 Evaluation Accounts 7-61
7.6 Plan Formulation Process Summary 7-67

7.7 Subsequent Iterations Of The Recommended Plan....7-68
7.7.1 Scenario D-13R4 Description....7-70
7.7.2 Evaluation of D-13R4....7-72
7.8 Plan Formulation Conclusions....7-74

SECTION 8 *ENVIRONMENTAL EFFECTS

8.1. Soils....8-1
8.2. Geology....8-2
8.3. Climate....8-2
8.4. Air Quality....8-2
8.5. Noise....8-2
8.6. Vegetation....8-3
8.7. Fish And Wildlife....8-4
8.8. Threatened And Endangered Species....8-6
8.9. Water Management....8-6
8.10. Water Quality....8-9
8.11. Water Supply....8-11
8.12. Socio-Economics....8-12
8.13. Land Use....8-14
8.14. Recreation Resources....8-15
8.15. Aesthetic Resources....8-16
8.16. Cultural Resources....8-17
8.17. Hazardous, Toxic, And Radioactive Wastes....8-17
8.18. Unavoidable Adverse Environmental Effects....8-18
8.19. Relationship Between Short Term Uses And Long Term Productivity....8-19
8.20. Irreversible And Irretrievable Commitments Of Resources....8-20
8.21. Cumulative Effects....8-20

SECTION 9 RECOMMENDED COMPREHENSIVE PLAN

9.1 Construction Features....9-1
9.1.1 Kissimmee River Region....9-2
9.1.2 Lake Okeechobee Region....9-6
9.1.3 Caloosahatchee River Region....9-7
9.1.4 Upper East Coast....9-8
9.1.5 Everglades Agricultural Area....9-9
9.1.6 Big Cypress Region....9-10
9.1.7 Water Conservation Areas....9-11
9.1.8 Lower East Coast Region....9-13
9.1.9 Southwest Florida Region....9-26
9.1.10 Florida Bay and Keys....9-28
9.1.11 System-wide....9-28
9.2 Operational Features....9-29
9.2.1 Lake Okeechobee Region....9-29
9.2.2 Caloosahatchee Region....9-29
9.2.3 Upper East Coast Region....9-30
9.2.4 Water Conservation Areas and Everglades Regions....9-30
9.2.5 Lower East Coast Region....9-31
9.3 Pilot Projects....9-32
9.3.1 Lake Okeechobee Aquifer Storage and Recovery – Pilot Project (GG)....9-32

9.3.2 Caloosahatchee River (C-43) Basin Aquifer Storage and Recovery – Pilot Project (D) 9-32
9.3.3 Site 1 Impoundment and Aquifer Storage and Recovery – Pilot Project (M)....9-33
9.3.4 In-Ground Reservoir Technology – Pilot Project 9-33
9.3.5 L-31N Seepage Management – Pilot Project (V) 9-33
9.3.6 Wastewater Reuse Technology – Pilot Project (HHH, BBB, and OPE) 9-34
9.4 Real Estate 9-34
9.4.1 Land Acquisition 9-35
9.4.2 Relocation Assistance (Public Law 91-646) 9-35
9.5 Adaptive Assessment And Monitoring Program....9-38
9.5.1 Adaptive Assessment Program....9-38
9.5.2 Monitoring Program 9-39
9.5.3 Monitoring Program Planning Guidelines....9-41
9.6 Fish And Wildlife Mitigation 9-50
9.7 New Feasibility Studies 9-51
9.7.1 Florida Bay And The Florida Keys Feasibility Study....9-51
9.7.2 Southwest Florida Feasibility Study 9-52
9.7.3 Comprehensive Integrated Water Quality Plan 9-52
9.8 Future Improvements To The Comprehensive Plan 9-54
9.9 Cost Estimate....9-56
9.9.1 Initial Costs....9-56
9.9.2 Adaptive Assessment and Monitoring Costs....9-56
9.9.3 Operation, Maintenance, Repair, Replacement, and Rehabilitation (OMRR&R) Costs 9-56
9.9.4 Annual Costs 9-61
9.9.5 Cost Estimate Uncertainties....9-61
9.10 Cost Sharing 9-62
9.10.1 Cost Sharing of Water Quality Features....9-62
9.10.2 Cost Sharing of Construction and Land Costs 9-64
9.10.3 Cost Sharing of Adaptive Assessment and Monitoring....9-65
9.10.4 Cost Sharing of Operations and Maintenance....9-65

SECTION 10 IMPLEMENTATION PLAN
10.1. Introduction 10-1
10.2. Guidelines For Implementing The Comprehensive Plan....10-2
10.2.1. Utilize Interdisciplinary and Interagency Teams 10-3
10.2.2. Incorporate Outreach and Public Involvement 10-3
10.2.3. Maintain Regional System Focus....10-3
10.2.4. Integration With Ongoing And Future Projects And Programs 10-4
10.2.5. Integrate Contingency Planning 10-6
10.2.6. Address Water Quality Needs....10-6
10.2.7. Plan Evaluation Through Adaptive Assessment....10-7
10.2.8. Uncertainties....10-11
10.2.9. Assurances To Water Users 10-11
10.2.10.Development And Refinement Of Models And Tools 10-16
10.3. Project Implementation Process....10-17
10.3.1. Project Implementation Reports....10-18
10.3.2. Restoration, Coordination, And Verification Process....10-20
10.3.3. Independent Scientific Peer Review....10-22
10.3.4. Water Quality Considerations 10-25
10.3.5. Flood Protection 10-25

10.3.6. Project Management........10-25
10.4. Schedule Development........10-26
10.4.1. Assumptions And Rules........10-27
10.4.2. Implementation Schedule........10-30
10.4.3. Funding Stream........10-34
10.4.4. Evaluation Of The Project Schedule........10-35
10.5. Implementation Program........10-38
10.5.1. Approval Of The Comprehensive Plan........10-39
10.5.2. Initial Authorization........10-39
10.5.3. Programmatic Authority........10-42
10.5.4. Future Water Resources Development Acts........10-44
10.5.5. Components Not Needing Congressional Authorizations........10-47
10.5.6. Feasibility Studies........10-47
10.6. Recommended Features For Initial Authorization........10-48
10.6.1. Pilot Projects........10-48
10.6.2. Initial Features for Authorization........10-52
10.6.3. Adaptive Assessment and Construction Monitoring Program........10-64
10.6.4. Total Cost for Features Included in this Recommendation........10-65
10.6.5. Cost Sharing........10-66
10.6.6. Financial Analysis........10-66
10.6.7. Local Cooperation........10-66
10.6.8. Sponsor's Views........10-69
10.7. Conclusion........10-70

SECTION 11 *PUBLIC INVOLVEMENT AND COORDINATION
11.1 Public Involvement Program........11-1
11.2 Scoping........11-2
11.3 Other Required Coordination........11-4
11.3.1 U.S. Fish And Wildlife Service........11-4
11.3.2 Florida Game And Fresh Water Fish Commission........11-7
11.3.3 Florida State Historic Officer........11-10
11.4 Reconnaissance Study Public Workshops........11-10
11.5 Focus Groups........11-11
11.6 Stakeholder Involvement And Outreach........11-15
11.6.1 Stakeholder Involvement........11-15
11.6.2 Public Information And Outreach........11-23
11.6.3 Governor's Commission For A Sustainable South Florida........11-29
11.6.4 South Florida Ecosystem Task Force And Working Group........11-31
11.6.5 South Florida Water Management District Governing Board........11-32
11.7 Internet Web Site........11-32
11.8 Review Conferences........11-33
11.9 Coordination........11-34
11.9.1 Cooperating State And Federal Agencies........11-34
11.10 Review Of Draft Integrated Feasibility Report And Programmatic Enviromental Impact Statement........11-35
11.10.1 Report And Peis Recipients........11-35
11.10.2 Comments And Responses........11-39
11.11 Public Meetings........11-40
11.12 Implementation Plan Coordination........11-49

SECTION 12. *COMPLIANCE WITH ENVIRONMENTAL REQUIREMENTS

12.1 National Environmental Policy Act Of 1969 12-1
12.2 Fish And Wildlife Coordination Act Of 1958 12-1
12.2.1 U.S. Fish and Wildlife Service draft Fish and Wildlife Coordination Act Report Recommendations 12-2
12.2.2 U.S. Fish and Wildlife Service final Fish and Wildlife Coordination Act Report Recommendations 12-10
12.2.3 Florida Game and Fresh Water Fish Commission, Fish and Wildlife Coordination Act Report, Part I Recommendations 12-14
12.2.4 Florida Game and Fresh Water Fish Commission, Fish and Wildlife Coordination Act Report, Part II Recommendations 12-18
12.2.5 Florida Game and Fresh Water Fish Commission, Fish and Wildlife Coordination Act Report, Part III Recommendations 12-21
12.3 Endangered Species Act Of 1973 12-22
12.4 National Historic Preservation Act Of 1966 12-23
12.5 Clean Water Act Of 1972 12-23
12.6 Clean Air Act Of 1972 12-23
12.7 Coastal Zone Management Act Of 1972 12-23
12.8 Farmland Protection Policy Act Of 1981 12-23
12.9 Wild And Scenic River Act Of 1968 12-24
12.10 Estuary Protection Act Of 1968 12-24
12.11 Federal Water Project Recreation Act Of 1965 12-24
12.12 Resource Conservation And Recovery Act Of 1976 12-24
12.13 Toxic Substances Control Act Of 1976 12-24
12.14 Marine Protection, Research, And Sanctuaries Act Of 1972 12-25
12.15 Rivers And Harbors Appropriation Act Of 1899 12-25
12.16 Coastal Barrier Resources Act 12-25
12.17 Section 904 Of The 1986 Water Resources Development Act 12-25
12.18 Section 307 Of The 1990 Water Resources Development Act 12-25
12.19 E.O. 11988, Floodplain Management 12-25
12.20 E.O. 11990, Protection Of Wetlands 12-26
12.21 E.O. 12114, Environmental Effects Abroad Of Major Federal Actions 12-26
12.22 E.O. 12898, Environmental Justice 12-26

SECTION 1
INTRODUCTION

The Central & Southern Florida (C&SF) Project extends from south of Orlando to the Florida Keys and is composed of a regional network of canals, levees, storage areas and water control structures. First authorized by Congress in 1948, the project serves multipal purposes. The authorized purposes of the project include flood control, regional water supply for agricultural and urban areas, prevention of salt water intrusion, water supply to Everglades National Park, preservation of fish and wildlife, recreation and navigation. For close to 50 years, the C&SF Project has performed its authorized functions well. However, the project also has had unintended adverse effects on the unique natural environment that constitutes the Everglades and south Florida ecosystem.

In the late 1800s and early 1900s, the principal impediment to development in south Florida was flooding. Flood control works were necessary to realize the economic potential of the state's exceptional natural resources. As a result, major drainage projects were initiated first by the State of Florida and then later in partnership with the federal government, through the Corps of Engineers. This partnership worked to control the hydrologic conditions that were hampering economic development. The emphasis on economic goals clearly focused the design of the C&SF Project towards development of the region with little understanding of or concern for the consequences to the Everglades ecosystem.

To meet project objectives, the C&SF Project impacted a significant portion of the natural system. The Kissimmee River was channelized. Lake Okeechobee was diked to prevent uncontrolled overflows from the lake. The region of the Everglades immediately south of Lake Okeechobee, now called the Everglades Agricultural Area, was drained and ground water levels were managed to reduce flood damages to agricultural production. A drainage system was constructed in the lower east coast to allow for urban, suburban and agricultural development. Central portions of the Everglades were diked to create the Water Conservation Areas, serving the dual purposes of storing water for human needs in the lower east coast and for deliveries to Everglades National Park. While some fish and wildlife value was expected to remain in the Water Conservation Areas, the only area intended for preservation in its natural state was Everglades National Park.

Land use and water management practices over the past 100 years in south Florida have resulted in either the loss or extensive alteration of the defining characteristics of the pre-drainage ecosystem. Loss of spatial extent of natural areas has been most severe in the past 50 years with the construction of the C&SF Project as nearly half of the original Everglades ecosystem has been converted to agricultural and urban uses. The ecological effects of this loss in spatial extent include:

- a substantial reduction in habitat options for wildlife,
- reduction in the system-wide levels of primary and secondary production, and
- changes in the proportions of community types within the remaining system.

The hydrology of the remaining Everglades has also been substantially altered by the operation of the C&SF Project, which has reduced average annual flows and surface water stages and lowered regional ground water in the natural system. Depending on location, annual hydroperiods have either increased or decreased, geographically relocating long- and short-hydroperiod wetlands. Additionally, average salinity levels in estuaries have been raised.

Overall, the construction and operation of the C&SF Project and its subsequent modification of the natural system have:

- contributed to the substantial reduction in spatial extent and system resiliency,
- provided a network of canals and levees that have accelerated the spread of polluted water and exotic species,
- greatly reduced the water storage capacity within the remaining natural system, and
- created an unnatural mosaic of impounded and over-drained marshes throughout the natural system.

The lack of storage in the system, particularly during wet periods, has led to ecological damage of Lake Okeechobee's littoral zone and damaging regulatory releases to the St. Lucie and Caloosahatchee estuaries. Conversely, in dry periods, this lack of storage has led to water supply shortages for both the human and natural environment. The Governor's Commission for a Sustainable South Florida in its October 1995 *Initial Report* (GCSSF, 1995) stated that "*South Florida is not sustainable on its present course.*"

Sustainability, according to the Governor's Commission, requires a balance between the resource requirements of the environment, the economy, and society, which are interdependent. Society is dependent upon the natural system for public health, safety, and welfare as well as an enhanced quality of life. Economic vitality is dependent upon a healthy ecosystem. A self-sustaining natural system is largely dependent upon the wisdom and actions of its human inhabitants. Actions taken by society today should not deplete the resources needed for tomorrow. The ability to restore the health of the remaining Everglades ecosystem and achieve sustainability in water resources for all needs depends on the ability to protect and manage the resource successfully.

Protection and enhancement of the water resources in south Florida is one step towards moving the region in the direction of sustainability. The C&SF Project is the predominant feature that affects this resource. Accordingly, the C&SF Project Comprehensive Review Study, better known as the Restudy, has looked at the existing project, its physical features and operations, with a view towards recommending structural and/or operational changes to better meet the goals of south Florida ecosystem restoration and the continued provision of safe, reliable water supply and flood protection for the people who live there. Ensuring sustainable water resources for the future, or "getting the water right," – the right quantity, quality, timing, and distribution – is what the Restudy is about.

This section describes the study's authority, purpose and scope, and organization of the report; discusses compliance with the National Environmental Policy Act; and provides a brief overview of the study area and a list of prior studies and reports.

1.1 STUDY AUTHORITY

The C&SF Project Comprehensive Review Study, known as the Restudy, is authorized by Section 309(l) of the Water Resources Development Act of 1992 (Public Law 102-580) which states:

> *"(1) CENTRAL AND SOUTHERN FLORIDA. -- The Chief of Engineers shall review the report of the Chief of Engineers on central and southern Florida, published as House Document 643; 80th Congress, 2nd Session, and other pertinent reports, with a view to determining whether modifications to the existing project are advisable at the present time due to significantly changed physical, biological, demographic, or economic conditions, with particular reference to modifying the project or its operation for improving the quality of the environment, improving protection of the aquifer, and improving the integrity, capability, and conservation of urban water supplies affected by the project or its operation."*

This study is also authorized by two resolutions of the Committee on Transportation and Infrastructure, United States House of Representatives, dated September 24, 1992. The first resolution states:

> *"Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Board of Engineers for Rivers and Harbors, is requested to review the report of the Chief of Engineers on Central and Southern Florida, published as House Document 643, Eightieth Congress, Second Session, and other pertinent reports, to determine whether modifications of the recommendations*

contained therein are advisable at the present time, in the interest of environmental quality, water supply and other purposes."

The second resolution states:

"Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Board of Engineers for Rivers and Harbors, is requested to review the report of the Chief of Engineers on Central and Southern Florida, published as House Document 643, Eightieth Congress, Second Session, and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at the present time, in the interest of environmental quality, water supply and other purposes for Florida Bay, including a comprehensive, coordinated ecosystem study with hydrodynamic modeling of Florida Bay and its connections to the Everglades, the Gulf of Mexico, and the Florida Keys Coral Reef ecosystem."

The Water Resources Development Act of 1996 was enacted on October 12, 1996. Section 528 of the Act (Public Law 104-303) entitled "Everglades and South Florida Ecosystem Restoration" authorizes a number of ecosystem restoration activities and also provides specific direction and guidance for the Restudy. The provisions of Section 528 concerning the Restudy are:

"(b) RESTORATION ACTIVITIES-

(1) COMPREHENSIVE PLAN-

(A) DEVELOPMENT-

(i) PURPOSE- The Secretary shall develop, as expeditiously as practicable, a proposed Comprehensive Plan for the purpose of restoring, preserving, and protecting the South Florida ecosystem. The Comprehensive Plan shall provide for the protection of water quality in, and the reduction of the loss of fresh water from, the Everglades. The Comprehensive Plan shall include such features as are necessary to provide for the water-related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the Central and Southern Florida Project.

(ii) CONSIDERATIONS- The Comprehensive Plan shall--

(I) be developed by the Secretary in cooperation with the non-Federal project sponsor and in consultation with the Task Force; and

(II) consider the conceptual framework specified in the report entitled "Conceptual Plan for the Central and Southern Florida Project Restudy", published by the Commission and approved by the Governor.

(B) SUBMISSION- Not later than July 1, 1999, the secretary shall--

(i) complete the feasibility phase of the Central and Southern Florida Project comprehensive review study as authorized by section 309(l) of the Water Resources Development Act of 1992 (106 Stat. 4844), and by 2 resolutions of the Committee on Public Works and Transportation of the House of Representatives, dated September 24, 1992; and

(ii) submit to Congress the plan developed under subparagraph (A)(i) consisting of a feasibility report and a programmatic environmental impact statement covering the proposed Federal action set forth in the plan.

(C) ADDITIONAL STUDIES AND ANALYSES- Notwithstanding the completion of the feasibility report under subparagraph (B), the Secretary shall continue to conduct such studies and analyses as are necessary, consistent with subparagraph (A)(i).

(2) USE OF EXISTING AUTHORITY FOR UNCONSTRUCTED PROJECT FEATURES- The Secretary shall design and construct any features of the Central and Southern Florida Project that are authorized on the date of the enactment of this Act or that may be implemented in accordance with the Secretary's authority to modify an authorized project, including features authorized under sections 315 and 316, with funds that are otherwise available, if the Secretary determines that the design and construction--

(A) will accelerate the restoration, preservation, and protection of the South Florida ecosystem;

(B) will be generally consistent with the conceptual framework described in paragraph (1)(A)(ii)(II); and

(C) will be compatible with the overall authorized purposes of the Central and Southern Florida Project.

(3) CRITICAL RESTORATION PROJECTS-

(A) IN GENERAL- In addition to the activities described in paragraphs (1) and (2), if the Secretary, in cooperation with the non-Federal project sponsor and the Task Force, determines that a restoration project for the South Florida ecosystem will produce independent, immediate, and substantial restoration, preservation, and protection benefits, and will be generally consistent with the conceptual framework described in paragraph (1)(A)(ii)(II), the Secretary shall proceed expeditiously with the implementation of the restoration project.

(B) INITIATION OF PROJECTS- After September 30, 1999, no new projects may be initiated under subparagraph (A).

(C) AUTHORIZATION OF APPROPRIATIONS-

(i) IN GENERAL- There is authorized to be appropriated to the Department of the Army to pay the Federal share of the cost of carrying out projects under subparagraph (A) $75,000,000 for the period consisting of fiscal years 1997 through 1999.

(ii) FEDERAL SHARE- The Federal share of the cost of carrying out any 1 project under subparagraph (A) shall be not more than $25,000,000.

(4) GENERAL PROVISIONS-

(A) WATER QUALITY- In carrying out activities described in this subsection and sections 315 and 316, the Secretary--

(i) shall take into account the protection of water quality by considering applicable State water quality standards; and

(ii) may include in projects such features as are necessary to provide water to restore, preserve, and protect the South Florida ecosystem.

(B) COMPLIANCE WITH APPLICABLE LAW- In carrying out the activities described in this subsection and subsection (c), the Secretary shall comply with any applicable Federal law, including the National Environmental Policy Act of 1969 (42 U.S.C. 4321 et seq.) and the Endangered Species Act of 1973 (16 U.S.C. 1531 et seq.).

(C) PUBLIC PARTICIPATION- In developing the Comprehensive Plan under paragraph (1) and carrying out the activities described in this subsection and

subsection (c), the Secretary shall provide for public review and comment on the activities in accordance with applicable Federal law.

(c) INTEGRATION OF OTHER ACTIVITIES-

(1) IN GENERAL- In carrying out activities described in subsection (b), the Secretary shall integrate such activities with ongoing Federal and State projects and activities, including--

(A) the project for the ecosystem restoration of the Kissimmee River, Florida, authorized by section 101 of the Water Resources Development Act of 1992 (106 Stat. 4802);

(B) the project for modifications to improve water deliveries into Everglades National Park authorized by section 104 of the Everglades National Park Protection and Expansion Act of 1989 (16 U.S.C. 410r-8);

(C) activities under the Florida Keys National Marine Sanctuary and Protection Act (16 U.S.C. 1433 note; 104 Stat. 3089); and

(D) the Everglades Construction Project of the State of Florida.

(2) STATUTORY CONSTRUCTION-

(A) EXISTING AUTHORITY- Except as otherwise expressly provided in this section, nothing in this section affects any authority in effect on the date of the enactment of this Act, or any requirement of the authority, relating to participation in restoration activities in the South Florida ecosystem, including the projects and activities specified in paragraph (1), by--

(i) the Department of the Interior;

(ii) the Department of Commerce;

(iii) the Department of the Army;

(iv) the Environmental Protection Agency;

(v) the Department of Agriculture;

(vi) the State of Florida; and

(vii) the South Florida Water Management District.

(B) NEW AUTHORITY- Nothing in this section confers any new regulatory authority on any Federal or non-Federal entity that carries out any activity authorized by this section.

(d) JUSTIFICATION-

(1) IN GENERAL- Notwithstanding section 209 of the Flood Control Act of 1970 (42 U.S.C. 1962-2) or any other provision of law, in carrying out the activities to restore, preserve, and protect the South Florida ecosystem described in subsection (b), the Secretary may determine that the activities--

(A) are justified by the environmental benefits derived by the South Florida ecosystem in general and the everglades and Florida Bay in particular; and

(B) shall not need further economic justification if the Secretary determines that the activities are cost-effective.

(2) APPLICABILITY- Paragraph (1) shall not apply to any separable element intended to produce benefits that are predominantly unrelated to the restoration, preservation, and protection of the South Florida ecosystem.

(e) COST SHARING-

(1) IN GENERAL- Except as provided in sections 315 and 316 and paragraph (2), the non-Federal share of the cost of activities described in subsection (b) shall be 50 percent.

(2) WATER QUALITY FEATURES-

(A) IN GENERAL- Except as provided in subparagraph (B), the non-Federal share of the cost of project features to improve water quality described in subsection (b) shall be 100 percent.

(B) EXCEPTION-

(i) IN GENERAL- Subject to clause (ii), if the Secretary determines that a project feature to improve water quality is essential to Everglades restoration, the non-Federal share of the cost of the feature shall be 50 percent.

(ii) APPLICABILITY- Clause (I) shall not apply to any feature of the Everglades Construction Project of the State of Florida.

(3) OPERATION AND MAINTENANCE- The operation and maintenance of projects carried out under this section shall be a non-Federal responsibility.

(4) CREDIT- Regardless of the date of acquisition, the value of lands or interests in land acquired by non-Federal interests for any activity described in subsection (b) shall be included in the total cost of the activity and credited against the non-Federal share of the cost of the activity. Such value shall be determined by the Secretary."

1.2 STUDY PURPOSE & SCOPE

1.2.1 Study Purpose

The purpose of the Restudy is to reexamine the C&SF Project to determine the feasibility of structural or operational modifications to the project essential to the restoration of the Everglades and the south Florida ecosystem, while providing for other water-related needs such as urban and agricultural water supply and flood protection in those areas served by the project. The intent of the study is to evaluate conditions within the study area and make recommendations to modify the project to restore important functions and values of the Everglades and south Florida ecosystem and plan for the water resources needs of the people of south Florida for the next 50 years.

Planning by the U.S. Army Corps of Engineers (Corps) for water resources projects is accomplished in two phases: a reconnaissance phase and a feasibility phase. The reconnaissance phase is conducted at full Federal expense, while the cost of the feasibility phase is shared between the Federal government and the non-Federal sponsor. The non-Federal sponsor for this study is the South Florida Water Management District.

The reconnaissance phase defines problems and opportunities, identifies potential solutions, and determines if planning should proceed further into the feasibility phase based on Federal interest and identification of a non-Federal sponsor willing to support further study. The reconnaissance phase of this study was initiated in June 1993 and the reconnaissance report was completed in November 1994. The objective of the reconnaissance study was to identify problems and opportunities, formulate alternative plans, evaluate conceptual alternative plans, and recommend, if feasible, further detailed studies. The reconnaissance study helped to frame issues and set the direction for further detailed studies carried out in partnership with the local sponsor during the feasibility study.

Feasibility studies further develop the most promising alternatives and recommend a plan for authorization by Congress. The feasibility phase for this study was initiated in August 1995 following approval of the Project Study Plan by the Corps' headquarters and the Governing Board of the South Florida Water Management District. As a result of the passage of the Water Resources Development Act of 1996, a revised Project Study Plan was approved in May 1997.

The recommended plan is designed in greater detail during the preconstruction engineering and design phase, necessary real estate is then acquired, and then the project is constructed.

Figure 1-1 outlines the steps necessary to develop and implement a typical Corps project.

FIGURE 1-1
STEPS IN CORPS OF ENGINEERS PROJECT DEVELOPMENT

Reconnaissance Study	Feasibility Study	Preconstruction Engineering and Design	Real Estate Acquisition	Construction	Operation and Maintenance
Define the problems and opportunities in the study area; assess Corps and local roles in solving the problems; and develop and evaluate preliminary concepts to address the problems.	Describe and evaluate alternative plans to address the problems and realize the opportunities and fully describe a recommended project.	Complete all of the detailed technical studies and design needed to begin construction of the project. Usually overlaps the end of the Feasibility Study phase.	The non-federal sponsor acquires the necessary real estate by purchase, donation, or condemnation so that the project can be constructed, operated, and maintained. (Overlaps with construction phase).	Features that have been agreed to by the Corps, the sponsors' and other project interests are built and begin to function as needed.	All of the activities needed to allow the project to solve the problems and realize the opportunities for which the project was built are conducted. Monitoring is also included in this phase.

1.2.2 Study Scope

The purpose of this feasibility study is to develop a Comprehensive Plan for the overall regional C&SF system and the tools necessary to evaluate the Comprehensive Plan as well as separable and incremental portions of the project. This study represents the first thorough, system-wide update since the project's original inception. The Comprehensive Plan will include such features as are necessary to provide for the regional water-related needs of the region; including flood control, the enhancement of water supplies, and other objectives served by the C&SF Project. This feasibility study included hydrologic modeling, environmental modeling, water quality analyses, and water supply studies that refined the information developed in the reconnaissance study. The feasibility study was conducted to identify a Comprehensive Plan for the C&SF Project and an adaptive implementation and operational strategy based on monitoring, evaluation, and modeling.

The Comprehensive Plan presented in this report is similar in scope to that contained in the 1948 Comprehensive Report for the Central and Southern Florida Project (House Document 80-643). This feasibility report does not include the normal level of detail that is expected from much smaller projects, such as the identification of specific sites for proposed project facilities. The Comprehensive Plan identifies components needed to restore the south Florida ecosystem, which includes the needs of all users, and the formulation process that produced them, from the viewpoint of hydrologic impacts of the regional water management system. This report also documents the uncertainties in plan selection and future tasks that will be needed to minimize these uncertainties. Engineering and real estate cost estimates are based on the analyses and assumptions made during the process of formulating and developing the components of the Comprehensive Plan. Uncertainties in design details and uncertainties in the exact location of components could impact future alternative analyses and subsequent design and cost estimates.

1.2.3 Report Organization

This feasibility report consists of a main report with an integrated Programmatic Environmental Impact Statement and appendices. The main report provides an overview of the study effort and summarizes information found in the appendices. The appendices provide detailed supporting information for all of the investigations and tasks conducted for the Restudy. In addition, a separate summary report has also been prepared

1.3 STUDY AREA

The study area encompasses approximately 18,000 square miles from Orlando to the Florida Reef Tract with at least 11 major physiographic provinces: Everglades, Big Cypress, Lake Okeechobee, Florida Bay, Biscayne Bay, Florida Reef Tract, nearshore coastal waters, Atlantic Coastal Ridge, Florida Keys, Immokalee Rise, and the Kissimmee River Valley. The Kissimmee River, Lake Okeechobee and the Everglades are the dominant watersheds that connect a mosaic of wetlands, uplands, coastal areas, and marine areas. The study area includes all or part of the following 16 counties: Monroe, Miami-Dade, Broward, Collier, Palm Beach, Hendry, Martin, St. Lucie, Glades, Lee, Charlotte, Highlands, Okeechobee, Osceola, Orange, and Polk.

The C&SF Project, which was first authorized by Congress in 1948, is a multi-purpose project that provides flood control; water supply for municipal, industrial, and agricultural uses; prevention of saltwater intrusion; water supply for Everglades National Park; and protection of fish and wildlife resources throughout the study area. The primary system includes about 1,000 miles each of levees and canals, 150 water control structures, and 16 major pump stations. The Central and Southern Florida Project is shown on ***Figure 1-2***.

The Upper St. Johns River Basin has been excluded from this study because it is a separate hydrologic basin which is not a part of the Everglades and south Florida ecosystems. C&SF Project works in the Upper St. Johns River Basin which are expected to meet the water resources needs of that basin are nearing completion.

The following sections provide details on each of the regions that comprise this large study area. The study regions are the Kissimmee River Basin, Lake Okeechobee, Upper East Coast, Everglades Agricultural Area, Water Conservation Areas, Lower East Coast, Biscayne Bay, Everglades National Park, Florida Bay, Whitewater Bay and the Ten Thousand Islands, Florida Keys, Big Cypress Basin, and Lower West Coast. A map of the study regions is shown on ***Figure 1-3***.

1.3.1 Kissimmee River Basin

The Kissimmee River Basin is comprised of 3,013 square miles, and extends from Orlando southward to Lake Okeechobee. The watershed, which is the largest source of surface water to the lake, is about 105 miles long and has a maximum width of 35 miles.

Project works in the basin for flood control and navigation were constructed by the Corps as part of the C&SF Project. Upper Basin works consist of channels and structures that control water flows through 18 natural lakes into Lake Kissimmee. The Lower Basin includes the channelized Kissimmee River (C-38) as a 56-mile earthen canal extending from Lake Kissimmee to Lake Okeechobee.

The northern portion of the basin is comprised of many lakes, some of which have been interconnected by canals. This large sub-basin, often termed the “Upper Basin” or “Chain of Lakes”, is bounded on the southern end by State Road 60, where the largest of the lakes, Lake Kissimmee, empties into the Kissimmee River.

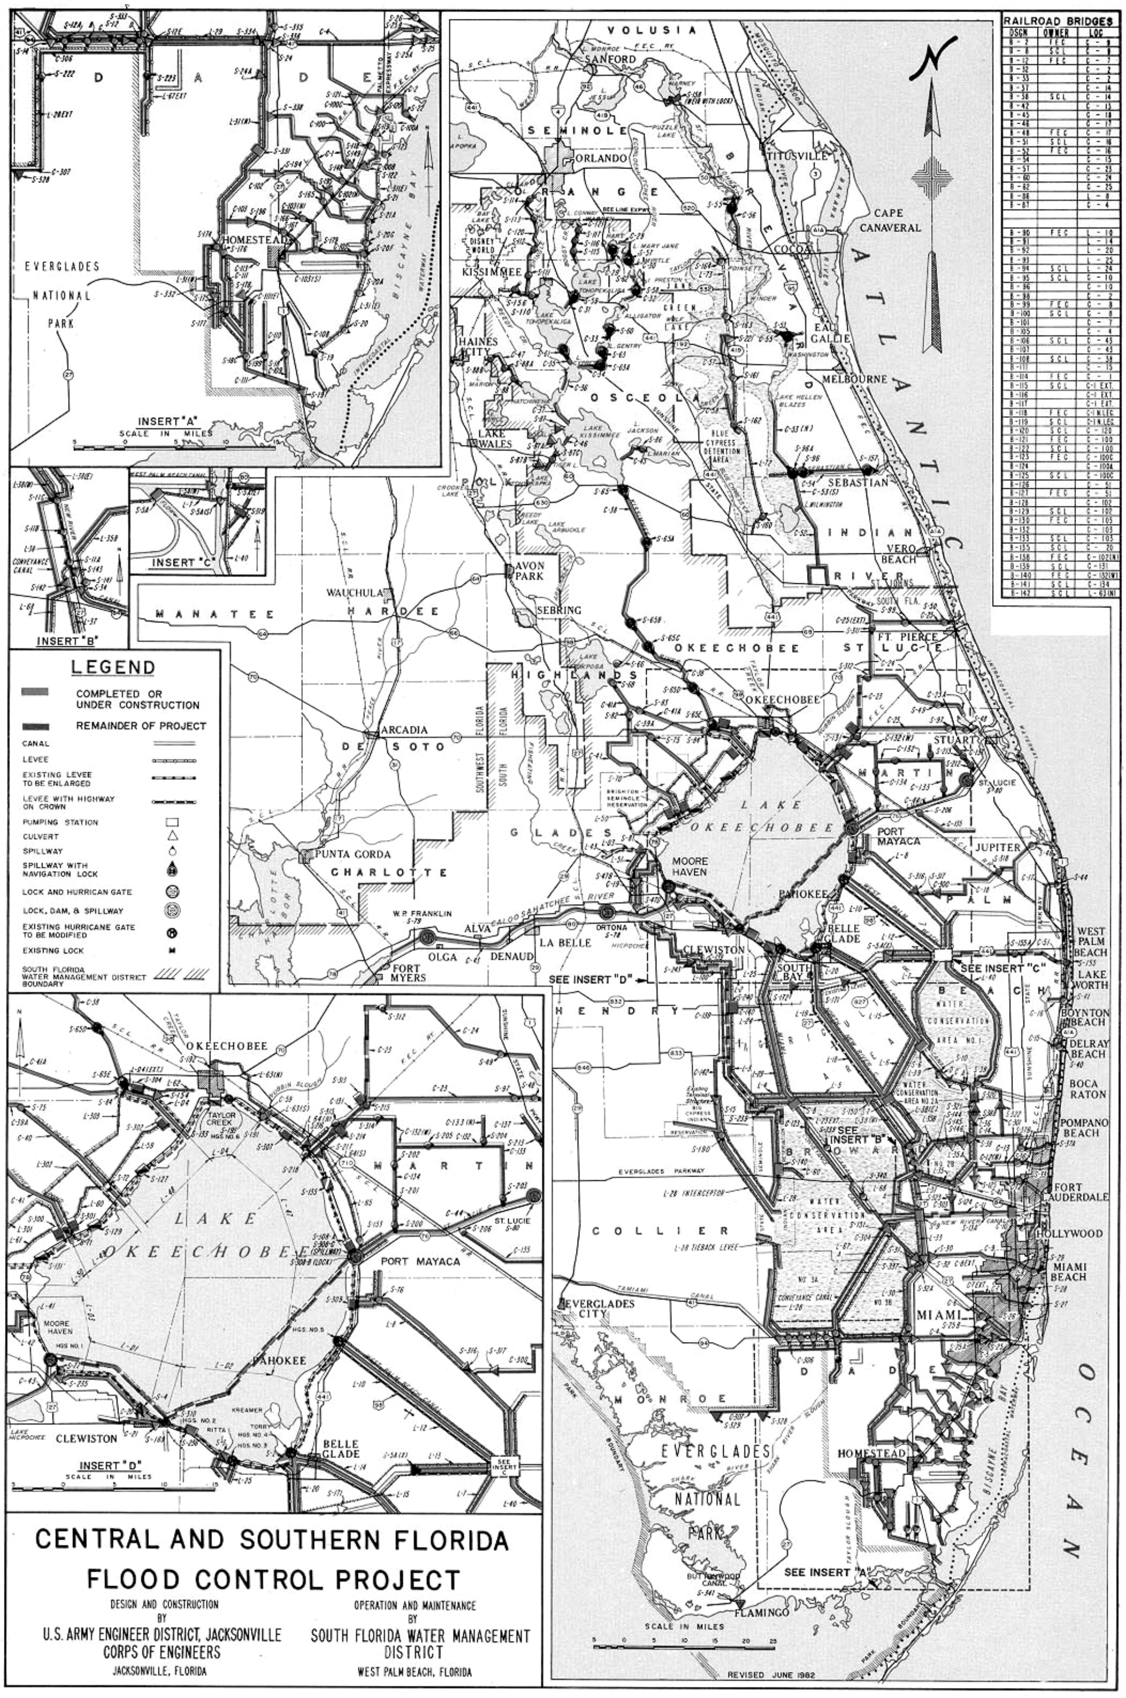

FIGURE 1-2 C&SF PROJECT MAP

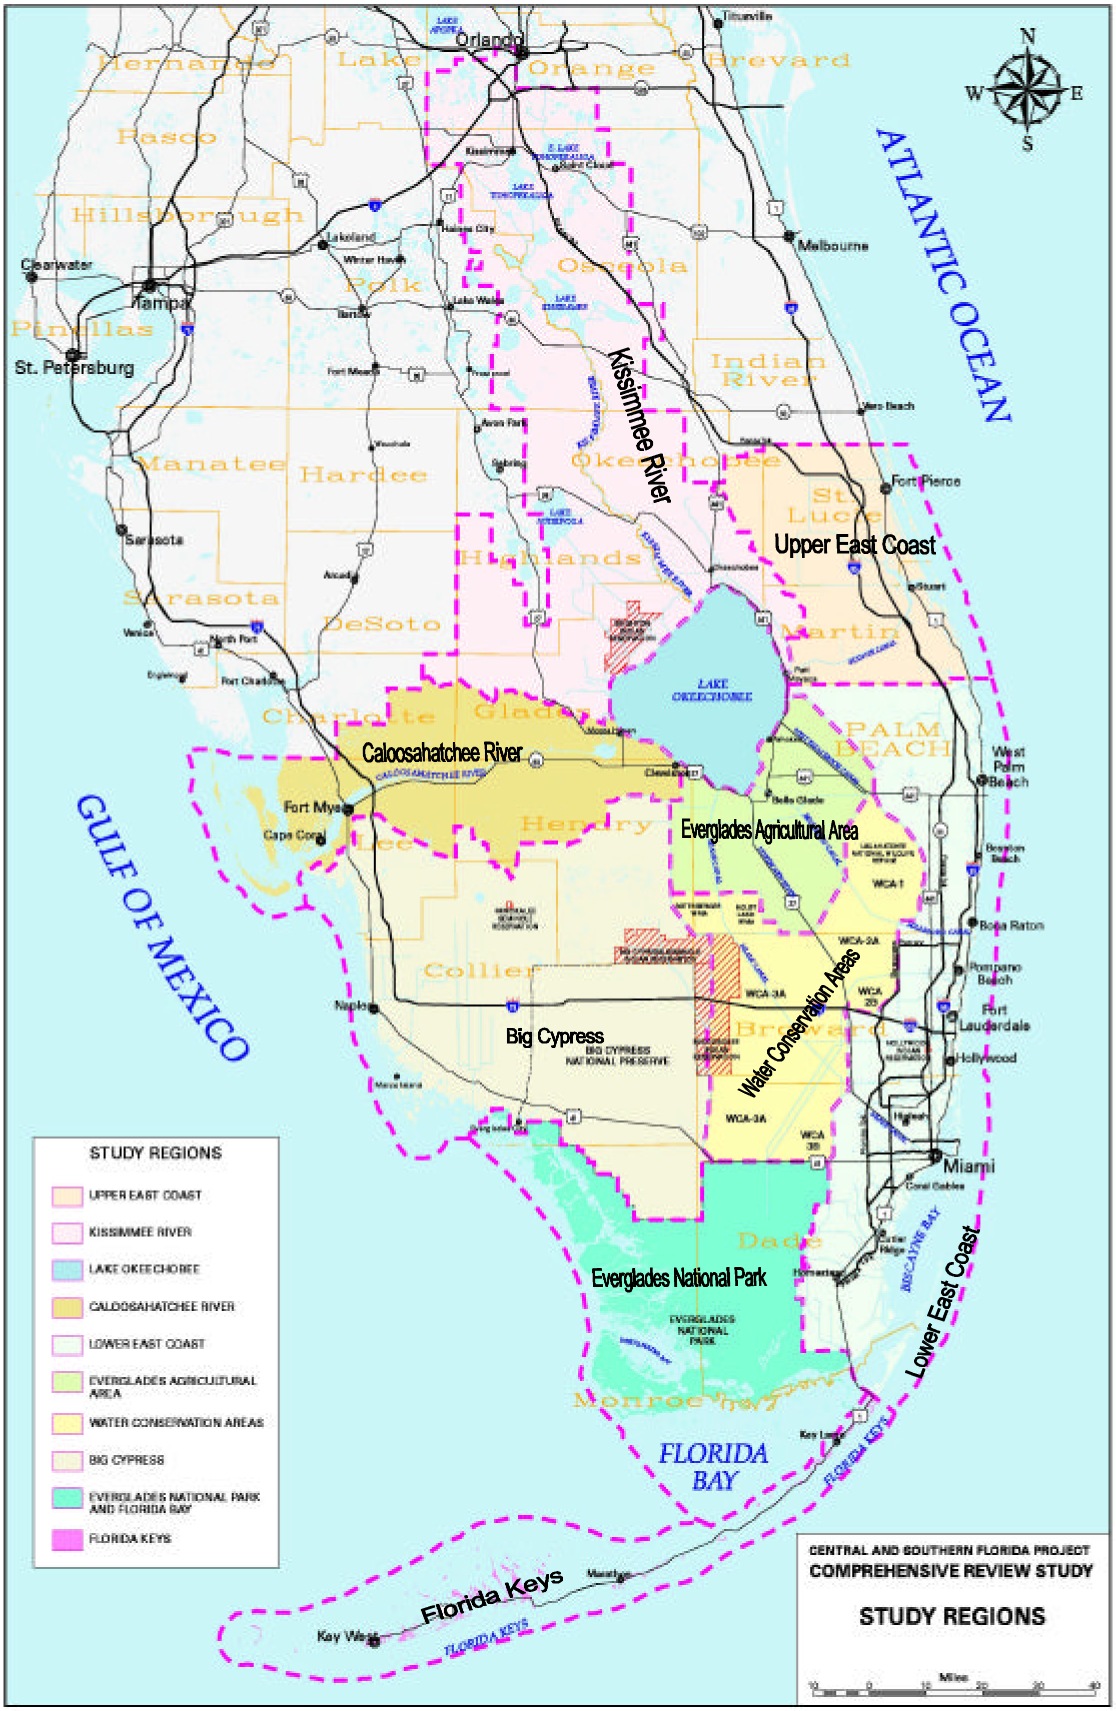

FIGURE 1-3 STUDY REGIONS

The Upper Basin is 1,633 square miles and includes Lake Kissimmee and the east and west Chain of Lakes area in Orange and Osceola Counties. A 758-square-mile Lower Basin includes the tributary watersheds of the Kissimmee River between the outlet in Lake Kissimmee and Lake Okeechobee. The 622-square-mile Lake Istokpoga area provides tributary inflow to the Lower Basin.

1.3.2 Lake Okeechobee

Lake Okeechobee lies 30 miles west from the Atlantic coast and 60 miles east from the Gulf of Mexico in the central part of the peninsula. Lake Okeechobee is a broad shallow lake occurring as a bedrock depression. The large, roughly circular lake, with a surface area of approximately 730 square miles, is the principal natural reservoir in southern Florida.

The lake's largest outlets include the St. Lucie Canal eastward to the Atlantic Ocean and the Caloosahatchee Canal and River to the Gulf of Mexico. The four major agricultural canals – the West Palm Beach, Hillsboro, North New River, and Miami Canals - have a smaller capacity, but are used whenever possible to release excess water to the Water Conservation Areas, south of the lake, when storage and discharge capacity are available. When regulatory releases from the lake are required, excess water can be passed to the three Water Conservation Areas up to the capacity of the pumping stations and agricultural canals, with the remainder going to the Atlantic Ocean and Gulf of Mexico.

The waters of the lake are impounded by a system of encircling levees, which form a multi-purpose reservoir for navigation, water supply, flood control, and recreation. Pumping stations and control structures in the levee along Lake Okeechobee are designed to move water either into or out of the lake as needed.

Other surface water bodies include the Kissimmee River, Fisheating Creek, and Taylor Creek that flow into the lake from the north; the Caloosahatchee River that flows out of the lake to the west; the St. Lucie and West Palm Beach Canals that flow out of the lake to the east; and the Hillsboro, North New River, and Miami Canals that flow out of the lake to the south. The hydroperiod of the lake is partially controlled, permitting water levels to fluctuate with flood and drought conditions and the demand for water supply.

1.3.3 Upper East Coast

The Upper East Coast area encompasses approximately 1,139 square miles and includes most of Martin and St. Lucie Counties as well as a portion of eastern Okeechobee County. Martin and St. Lucie Counties are bounded to the east by the Atlantic Ocean, and a substantial portion of Martin County's western landmass borders Lake Okeechobee. Urban development is primarily located along the coastal areas while the central and western portions are used primarily for agriculture where the main products are citrus, truck crops, sugarcane, and beef and dairy products.

The land is generally flat, ranging in elevation from 15 to 60 feet NGVD[1] in the western portion with an average elevation of 28 feet. The coastal area ranges from sea level to 25 feet. The coastal sand hills adjacent to the Atlantic Intracoastal Waterway are higher than most parts of the county and reach a maximum elevation of 60 feet. This feature is known as the Atlantic Coastal Ridge.

The natural drainage has been significantly altered by the construction of canals, drainage ditches and numerous water control structures which predominately direct stormwater discharge to the east coast. The area contains the C&SF Project Canals C-23[2], C-24, and C-25 drainage basins and the drainage area served by C-44 (St. Lucie Canal).

The St. Lucie Canal is Lake Okeechobee's eastern outlet, extending 25.5 miles from Port Mayaca to the city of Stuart, where it terminates at the south fork of the St. Lucie River. The St. Lucie River Basin is part of a much larger southeastern Florida basin that drains over 8,000 square miles. The St. Lucie River, composed of the North and South forks, lies in Martin and St. Lucie Counties in the northeastern portion of the basin. The South Fork is a relatively short stretch of river. The North Fork, designated as an aquatic preserve by the State of Florida, begins south of Fort Pierce and flows past the city of Port St. Lucie to the St. Lucie River Estuary.

The St. Lucie Estuary is part of a larger estuarine system known as the Indian River Lagoon. The Indian River Lagoon has been designated an estuary of national significance and is a component of the U. S. Environmental Protection Agency sponsored National Estuary program. The Indian River Lagoon is also designated as a state priority water body for protection and restoration under the state's Surface Water Improvement and Management (SWIM) Act. The Surface Water Improvement and Management Act Plan identifies excessive freshwater runoff from the St. Lucie Estuary watershed as a problem within the St. Lucie Estuary.

Much of the St. Lucie River has been channelized and many drainage canals empty into the river, particularly the St. Lucie Canal, C-23 and C-24. The St. Lucie Canal, the largest overflow canal for Lake Okeechobee, is a navigation channel 8 feet deep and 100 feet wide connecting the Atlantic Intracoastal Waterway in Stuart with Lake Okeechobee at Port Mayaca.

---

1 National Geodetic Vertical Datum

2 C&SF Project feature designations: C for canals, L for levees, and S for water control structures and pumping stations.

1.3.4 Everglades Agricultural Area

The lands located immediately south and southeast of the lake are known as the Everglades Agricultural Area. This area of about 700,000 acres is rich, fertile agricultural land. A large portion of the Everglades Agricultural Area is devoted to the production of sugarcane. The average ground elevation is about 12 feet.

The occurrence of surface water in the area is now a direct result of the construction of the numerous conveyance and drainage canals. The primary canals consist of the Miami, the North New River, the Hillsboro, and the West Palm Beach Canals, which traverse the area north south, and the Bolles and Cross Canal, which extends east-west. Water levels and flows are stringently manipulated in the canals to achieve optimum crop growth. Major surface impoundments in the area are non-existent.

1.3.5 Water Conservation Areas

The Water Conservation Areas are an integral component of the Everglades and freshwater supplies for south Florida. The Water Conservation Areas, located south and east of the Everglades Agricultural Area, comprise an area of about 1,350 square miles, including 1,337 square miles of the original Everglades, which averaged some 40 miles in width and extended approximately 100 miles southward from Lake Okeechobee to the sea.

The Water Conservation Areas provide a detention reservoir for excess water from the agricultural area and parts of the Lower East Coast region, and for flood discharge from Lake Okeechobee. The Water Conservation Areas also provide levees needed to prevent Everglades floodwaters from inundating the Lower East Coast, while providing water supply for Lower East Coast agricultural lands and Everglades National Park; improving water supply for east coast communities by recharging the Biscayne Aquifer (the sole source of drinking water for southern Palm Beach, Broward, Miami-Dade, and Monroe Counties); retarding salt water intrusion in coastal well fields; and benefiting fish and wildlife in the Everglades.

Water Conservation Area 1 is designated as the Arthur R. Marshall Loxahatchee National Wildlife Refuge, managed by the U.S. Fish and Wildlife Service. Water Conservation Areas 2 and 3 are public hunting and fishing areas comprising the Everglades Wildlife Management Area maintained by the Florida Game and Fresh Water Fish Commission. The Seminole and Miccosukee Tribes each have reserved rights within Water Conservation Area 3.

1.3.5.1 Water Conservation Area 1

Water Conservation Area 1 (Loxahatchee National Wildlife Refuge) is about 21 miles long from north to south and comprises an area of 221 square miles. The

West Palm Beach Canal lies at the extreme northern boundary, and on the south the Hillsboro Canal separates Water Conservation Area 1 from Water Conservation Area 2. Ground elevations slope about five feet in 10 miles, both to the north and to the south from the west center of the area, varying from over 16 feet in the northwest to less than 12 feet in the south. The area, which is enclosed by about 58 miles of levee (approximately 13 miles of which are common to Water Conservation Area 2), provides storage for excess rainfall, excess runoff from agricultural drainage areas of the West Palm Beach Canal (230 square miles) and the Hillsboro Canal (146 square miles), and excess water from Lake Okeechobee. Inflow comes from rainfall and runoff from the Everglades Agricultural Area through canals at the northern end. Release of water for dry-season use is controlled by structures in the West Palm Beach Canal, the Hillsboro Canal, and in the north-south levee which forms the eastern boundary of the area. When stages exceed the regulation schedule, excess water in Water Conservation Area 1 is discharged to Water Conservation Area 2.

1.3.5.2 Water Conservation Area 2

Water Conservation Area 2 is comprised of two areas, 2A and 2B, measures about 25 miles from north to south, and covers an area of 210 square miles. It is separated from the other Water Conservation Areas by the Hillsboro Canal on the north and the North New River Canal on the south. Ground elevations slope southward about two to three feet in 10 miles, ranging from over 13 feet NGVD in the northwest to less than seven feet NGVD in the south. The area is enclosed by about 61 miles of levee, of which approximately 13 miles are common to Water Conservation Area 1 and 15 miles to Water Conservation Area 3. An interior levee across the southern portion of the area reduces water losses due to seepage into an extremely pervious aquifer at the southern end of the pool and prevents overtopping of the southern exterior levee by hurricane waves.

The upper pool, Water Conservation Area 2A, provides a 173-square-mile reservoir for storage of excess water from Water Conservation Area 1 and a 125-square-mile agricultural drainage area of the North New River Canal. Storage in Water Conservation Area 2A provides water supply to the east coast urban areas of Broward County. Water enters the area from Water Conservation Area 1 and the Hillsboro Canal on the northeast side, and from the North New River Canal on the northwest side. Water in excess of that required for efficient operation of Water Conservation Area 2A is discharged to Water Conservation Area-3 via structures into C-14, the North New River Canal, and Water Conservation Area 2B.

Water Conservation Area 2B has ground elevations ranging from 9.5 feet NGVD in the northern portions down to 7.0 feet NGVD in the southern portions of the area. The area experiences a high seepage rate, which does not allow for long term storage of water, and as a result, water is not normally released from the area.

1.3.5.3 Water Conservation Area 3

Water Conservation Area 3 is also divided into two parts, 3A and 3B. It is about 40 miles long from north to south and comprises about 915 square miles, making it the largest of the conservation areas. Ground elevations, which slope southeasterly 1 to 3 feet in 10 miles, range from over 13 feet NGVD in the northwest to 6 feet NGVD in the southeast. The Miami Canal traverses the area from northwest to southeast, and the North New River Canal separates it from Water Conservation Area 2. The area is enclosed by about 111 miles of levee, of which 15 miles are common to Water Conservation Area 2. An interior levee system across the southeastern corner of the area reduces seepage into an extremely pervious aquifer.

The upper pool, Water Conservation Area 3A, provides a 752-square-mile area for storage of excess water from Water Conservation Area 2A; rainfall excess from approximately 750 square miles in Collier and Hendry Counties and from 71 square miles of the former Davie agricultural area lying east of Pumping Station S-9 in Broward County; and excess water from a 208-square-mile agricultural drainage area of the Miami Canal and other adjacent areas to the north. Water enters Water Conservation Area 3A from various sources on the northern and eastern sides. The storage is used to meet the principal water supply needs of adjacent areas, including urban water supply and salinity control requirements for Miami-Dade and Monroe County, irrigation requirements, and water supply for Everglades National Park.

1.3.6 Lower East Coast Area

The Lower East Coast area, which consists of the coastal ridge section in Palm Beach, Broward, and Miami-Dade Counties, is a strip of sandy land which lies east of part of the Water Conservation Areas. The ground surface of the flatlands in the west ranges from about 25 feet NGVD in the upper part of the region to about five feet NGVD in lower Miami-Dade County. The Atlantic Coastal Ridge is comprised of broad, low dunes and ridges with elevations ranging from 10 to 25 feet NGVD. This ridge area ranges from two to four miles in width at its northern edge to its southern edge in Miami. South of Miami the ridge becomes less pronounced but significantly wider.

The Lower East Coast area is the most densely populated part of the state. The largest population centers are near the coast and include the cities of Miami, West Palm Beach, Fort Lauderdale, and Hollywood. Water levels in coastal canals are controlled near the coastal shoreline to prevent overdrainage and to resist salt water intrusion. Low water levels in these canals may enable salt water to migrate into the ground water, well fields, and natural freshwater systems upon which the urban areas depend for a potable water supply.

This area is characterized by sandy flatlands to the west, the sandy coastal ridge, and the coastal marsh and mangrove swamp areas along the Atlantic seaboard. The northern portion, generally that part north of Miami-Dade County, marks the shore of a higher Pleistocene Sea and occurs as one or more relict beach ridges. The southern portion appears to be marine deposited sands or marine limestones.

Extensive development has resulted in nearly complete urbanization of the coastal region from West Palm Beach southward through Miami, and these physiographical characteristics of the region have been greatly overshadowed. South of Miami, in Miami-Dade County, this coastal area widens as the Everglades bends to the west to include urban areas and agricultural areas that extend almost to the southern coast. Miami-Dade County's agricultural industry covers more than 83,000 acres in the southwest of the coastal metropolitan area. Vegetables, tropical fruits, and nursery plants are grown in this area.

1.3.7 Biscayne Bay

Biscayne Bay is a shallow, tidal sound located near the extreme southeastern part of Florida. Biscayne Bay, its tributaries and Card Sound are designated by the state of Florida as aquatic preserves, while Card and Barnes sounds are part of the Florida Keys National Marine Sanctuary. A significant portion of the central and southern portions of Biscayne Bay comprise Biscayne National Park.

The original areal extent of Biscayne Bay approximated 300 square miles, but it has since undergone major areal modifications, particularly in its northern portions, as a result of development. The bay extends about 55 miles in a south-southwesterly direction from Dumfoundling Bay on the north to Barnes Sound on the south. It varies in width from less than 1 mile in the vicinity of the Atlantic Intracoastal Waterway passage to Dumfoundling Bay, to about 10 miles between the mainland and the Safety Valve Shoals to the east.

While there has been extensive dredging and filling within northern Biscayne Bay, the area still supports a productive and healthy seagrass bed and a few tracts of natural shoreline remain. Northern Biscayne Bay's headwaters are now considered to include dredged areas known as Maule Lake and Dumfoundling Bay, near the northern boundary of Miami-Dade County.

Central and, in particular, southern Biscayne Bay have been impacted less by development than northern Bay. For instance, mangrove-lined coastal wetlands extend from Matheson Hammock Park south along the entire shoreline of Biscayne National Park, Card and Barnes Sounds, a distance of approximately 30 miles. These coastal wetlands are the largest tract of undeveloped wetlands remaining in south Florida outside of Everglades National Park, the Big Cypress Preserve, and the Water Conservation Areas.

Biscayne National Park, in southern Biscayne Bay was established in 1980 to protect and preserve this nationally significant marine ecosystem consisting of mangrove shorelines, a shallow bay, undeveloped islands, and living coral reefs. The park is 180,000 acres in size and 95 percent water. The shoreline of southern Biscayne Bay is lined with a forest of mangroves and the bay bottom is covered with dense seagrass beds. The park has been designated a sanctuary for the Florida spiny lobster. Biscayne Bay and Biscayne National Park support a multitude of marine wildlife such as lobster, shrimp, fish, sea turtles, and manatees. The coral reefs within the Biscayne National Park support a diverse community of marine plant and wildlife.

Depending upon the flood stages reached, all C&SF Project canals in adjacent Miami-Dade County can carry floodwaters to Biscayne Bay. However, much of the time, discharges from project canals represent primarily runoff or seepage from within the flood protected area of the county. These flows originate in the extensive networks of secondary drainage canals and storm sewers that discharge into the project canals. Supplementing the complex system of project canals and secondary drainage systems are many hundreds of other stormwater drainage canals and storm sewer outfalls within Miami-Dade County that discharge freshwater directly into Biscayne Bay.

1.3.8 Everglades National Park

Everglades National Park encompasses 2,353 square miles of wetlands, uplands, and submerged lands at the southern end of the Florida peninsula. The topography is extremely low and flat, with most of the area below four feet NGVD. The highest elevations are found in the northeastern section of the park and are from six to seven feet NGVD. The saline wetlands, including mangrove and buttonwood forests, salt marshes, and coastal prairie that fringe the coastline are subject to the influence of salinity from tidal action.

Everglades National Park, authorized by Congress in 1934 and established in 1947, was established to protect the unique tropical biological resources of the southern Everglades ecosystem. It was the first national park to be established to preserve purely biological (vs. geological) resources. The park's authorizing legislation mandated that it be managed as "…wilderness, [where] no development… or plan for the entertainment of visitors shall be undertaken which will interfere with the preservation intact of the unique flora and fauna and the essential primitive natural condition now prevailing in this area." This mandate to preserve wilderness is one of the strongest in the legislative history of the National Park System.

Everglades National Park has been recognized for its importance, both as a natural and cultural resource as well as for its recreational value, by the international community and the national and state government. At the international level, the park is a World Heritage Site, an International Biosphere Reserve, and a Wetland of International Significance. In 1978, Congress designated much of the park, (86%) as Wilderness under the Wilderness Act of 1964. In 1997, this area was redesignated the Marjory Stoneman Douglas Wilderness. Hell's Bay Canoe Trail and the Wilderness waterway are designated National Trails. The State of Florida has designated the Park an Outstanding Florida Water.

The Park preserves a unique landscape where the temperate zone meets the subtropics, blending the wildlife and vegetation of both. The landscape includes sawgrass sloughs, tropical hardwood hammocks, offshore coral reefs, mangrove forests, lakes, ponds, and bays, providing habitat for dozens of threatened and endangered species of plants and animals. It is the largest designated wilderness, at 1,296,500 acres, east of the Rocky Mountains. It protects the largest continuous stand of sawgrass prairie in North America, the most significant breeding grounds for tropical wading birds in North America, over 230,100 acres of mangrove forest (the largest in the western hemisphere), a nationally significant estuarine complex in Florida Bay and significant ethnographic resources, revealing 2,000 years of human occupation.

1.3.9 Florida Bay, Whitewater Bay, and the Ten Thousand Islands

Florida Bay and the Ten Thousand Islands comprise 1,500 square miles of Everglades National Park. The bay is shallow, with an average depth of less than three feet. To the north is the Florida mainland and to the south lie the Florida Keys. Sheet flow across marl prairies of the southern Everglades and 20 creek systems fed by Taylor Slough and the C-111 Canal provide direct inflow of fresh surface water and groundwater recharge. Surface water from Shark River Slough, the sub-region's largest drainage feature, flows into Whitewater Bay and also may provide essential groundwater recharge for central and western Florida Bay. Exchange with Florida Bay occurs as this lower salinity water mass flows around Cape Sable into the western subregion of the bay.

1.3.10 Florida Keys

The Florida Keys are a limestone island archipelago extending southwest over 200 miles from the southern tip of the Florida mainland to the Dry Tortugas, 63 miles west of Key West. They are bounded on the north and west by the relatively shallow waters of Biscayne Bay, Barnes and Blackwater Sounds, Florida Bay - all areas of extensive mud shoals and seagrass beds – and the Gulf of Mexico. Hawk Channel lies to the south, between the mainland Keys and an extensive reef tract 5 miles offshore. The Straits of Florida lie beyond the reef, separating the Keys from Cuba and the Bahamas.

The Keys are made up of over 1,700 islands encompassing approximately 103 square miles. They are broad, with little relief, have a shoreline length of 1,865 miles, and are inhabited from Soldier Key to Key West. Key Largo and Big Pine Key are the largest islands. The Keys are frequently divided into three regions: 1) the Upper Keys, north of Upper Matecumbe Key; 2) the Middle Keys, from Upper Matecumbe Key to the Seven Mile Bridge; and 3) the Lower Keys, from Little Duck Key to Key West.

The Florida Keys National Marine Sanctuary encompasses approximately 3,668 square miles of submerged lands and waters between the southern tip of Key Biscayne and the Dry Tortugas Bank. North of Key Largo it includes Barnes and Card Sounds, and to the east and south the oceanic boundary is the 300-foot isobath. The Sanctuary also contains part of Florida Bay and the entire Florida Reef Tract, the largest reef system in the continental United States. The Sanctuary contains components of five distinct physiographic regions: Florida Bay, the Southwest Continental Shelf, the Florida Reef Tract, the Florida Keys, and the Straits of Florida. The regions are environmentally and lithologically unique, and together they form the framework for the Sanctuary's diverse terrestrial and aquatic habitats.

1.3.11 Florida Reef Tract

The Florida Reef Tract is an arcuate band of living coral reefs paralleling the Keys. The reefs are located on a narrow shelf that drops off into the Straits of Florida. The shelf slopes seaward at a 0.06 degree angle into Hawk Channel, which is several miles wide and averages 50 feet deep. From Hawk Channel, the shelf slopes upward to a shallower area containing numerous patch reefs. The outer edge is marked by a series of bank reefs and sand banks that are subject to open tidal exchange with the Atlantic. The warm, clear, naturally low-nutrient waters in this region are conducive to reef development.

1.3.12 Big Cypress Basin

Big Cypress Swamp spans approximately 1,205 square miles (771,000 acres) from southwest of Lake Okeechobee to the Ten Thousand Islands in the Gulf of Mexico. The 570,000-acre Big Cypress National Preserve was established by *Public Law 93-440* in 1974 to protect natural and recreational values of the Big Cypress watershed and to allow for continued traditional uses such as hunting, fishing, and oil and gas production. It was also established to provide an ecological buffer zone and protect Everglades National Park's water supply. In 1988, Congress passed the *Big Cypress National Preserve Addition Act* which will add 146,000 acres to the preserve.

1.3.13 Lower West Coast

The Lower West Coast region covers approximately 4,000 square miles in Lee, Hendry, Glades, and Collier Counties and a portion of Charlotte County. This area is generally bounded by Charlotte County to the north, Lake Okeechobee and the Everglades Agricultural Area to the east, the Big Cypress National Preserve to the south, and the Gulf of Mexico to the west. The area is characterized by the sandy flatlands region of Lee County, which give way to sandy though more rolling terrain in Hendry County; and the coastal marshes and mangrove swamps of Collier County.

The Caloosahatchee River sub-watershed includes an area of 550,900 acres in parts of Lee, Glades, Charlotte, and Hendry Counties. From a hurricane gate on the southwest shore of Lake Okeechobee at Moore Haven, the Caloosahatchee Canal drains westerly for about five miles through a very flat terrain into Lake Hicpochee. From there the canal joins the upper reach of the Caloosahatchee River. On its way to the Gulf of Mexico, the river is controlled by navigation locks at Ortona (15 miles downstream from Moore Haven) and at Olga near Fort Myers. Downstream from Ortona Lock, many tributaries join the river along its course to the Gulf. The Caloosahatchee River serves as a portion of the cross-state Okeechobee Waterway, which extends from Stuart on the east coast via the St. Lucie Canal, through Lake Okeechobee and the Caloosahatchee River to Fort Myers on the Gulf of Mexico. The river has been straightened by channelization through most of its 65-mile course from the Moore Haven Lock to Fort Myers.

The J. N. "Ding" Darling National Wildlife Refuge Complex includes Pine Island NWR, Island Bay NWR, Matlacha Pass NWR, and Caloosahatchee NWR, all located on the lower west coast. The health of the estuarine ecosystem they embody is directly tied to the water quality, quantity and timing of flows from the Caloosahatchee watershed and those watersheds which drain into the Caloosahatchee River (i.e. Kissimmee River and Lake Okeechobee watersheds).

1.4 NATIONAL ENVIRONMENTAL POLICY ACT REQUIREMENTS

The National Environmental Policy Act of 1969, as amended, is the nation's charter for environmental protection. The National Environmental Policy Act establishes policy, sets goals, and provides means for carrying out the policy. Section 102(2) of the Act contains action-forcing provisions to make sure that Federal agencies act according to the letter and spirit of the Act, including a provision to prepare a detailed statement - now called an Environmental Impact Statement - on the effects of a proposed Federal action. The Federal regulations for implementing the procedural provisions of the National Environmental Policy Act were published by the Council on Environmental Quality in the Code of Federal

Regulations (CFR) as 40 CFR Parts 1500-1508 (43 Federal Register 55978-56007, November 29, 1978).

This report documents the Corps study of modifications to the C&SF Project to restore the south Florida ecosystem while providing for the other water-related needs of the region in compliance with the National Environmental Policy Act requirements. It employs two concepts established in the Council on Environmental Quality's National Environmental Policy Act regulations - integration and tiering - that are not frequently used, but are appropriate to the planning and design process and schedule for modifications to the C&SF Project that result from the Restudy.

Integration is based on the Council on Environmental Quality provision to combine documents, which states that *"any environmental document in compliance with NEPA may be combined with any other agency document to reduce duplication and paperwork"* (40 CFR 1506.4). The Corps regulations permit an Environmental Impact Statement ("environmental document") to be either a self-standing document combined with and bound within a feasibility report ("agency document"), or an integration of National Environmental Policy Act-required discussions in the text of the report. In view of the ecosystem restoration aspect of the C&SF Project Restudy, and to reduce paperwork and redundancies, and consolidate documentation into one consistent report, the Corps elected to integrate discussions that normally would appear in an Environmental Impact Statement into the feasibility report. Sections in this integrated report that include National Environmental Policy Act-required discussions are marked with an asterisk in the Table of Contents to assist readers in identifying such material.

Tiering was established by the Council on Environmental Quality to provide *"coverage of general matters in broader environmental impact statements (such as national program or policy statements) with subsequent narrower statements or environmental analyses (such as regional or basin-wide program statements or ultimately site-specific statements).... Agencies are encouraged to tier their environmental impact statements to eliminate repetitive discussions of the same issues and to focus on the actual issues ripe for decision at each level of environmental review"* (40 CFR 1508.28 and 1502.20). Tiering has been applied to proposed Federal actions for modifying the C&SF Project as follows:

> *This document is a Programmatic Environmental Impact Statement, which addresses at a general level, the alternatives and environmental effects of the overall project, to the affected environment. Due to the conceptual nature of the Comprehensive Plan and the associated uncertainties, many subsequent site-specific environmental documents will be required for the individual separable project elements. These documents will be either Supplemental Environmental Impact Statements or Environmental Assessments building upon this integrated document, and addressing the individual project separable elements in sufficient detail for final*

decision making and for full compliance with the National Environmental Policy Act requirements.

1.5 STUDY PROCESS

Because of the public, political, and media interest in the restoration of the south Florida ecosystem, the process used to accomplish this study was considered carefully. At the inception of the reconnaissance study in 1993, it was recognized that a “not business as usual” approach was needed to successfully manage and accomplish a system-wide study that addresses all of the water resource problems and opportunities in the region. This approach was continued in the feasibility phase of the Restudy.

Accomplishment of this feasibility study was primarily the responsibility of the Corps of Engineers, Jacksonville District, and the non-Federal cost sharing partner, the South Florida Water Management District. The Restudy Team consisted of an interdisciplinary/interagency professional staff drawn from the technical disciplines necessary to accomplish the study. In February 1995, the Governing Board of the South Florida Water Management District adopted a resolution directing staff to further develop its strong interagency coordination effort to ensure that the South Florida Water Management District’s water supply planning efforts and the Restudy were consistent and cohesive. In furtherance of this resolution, key members of the South Florida Water Management District’s Lower East Coast Regional Water Supply Planning Team joined the Restudy Team to maximize the integration of these processes.

A multiagency approach was used to staff the Restudy Team due to the complexity of the problems to be considered and the continued desire to utilize the skills of specialists in other agencies. Multiagency staffing was essential to facilitate the flow of needed information among agencies, and, more importantly, to achieve approval and ownership by the key public agency stakeholders. This multi-agency approach also fits into the cooperative spirit fostered by the South Florida Ecosystem Restoration Task Force and the Governor’s Commission for a Sustainable South Florida discussed in other sections of this report. The Restudy Team included personnel from other Federal agencies such as the National Park Service, the U.S. Fish and Wildlife Service, the National Marine Fisheries Service, the United States Geologic Survey, the Natural Resources Conservation Service, and the U.S. Environmental Protection Agency. Tribal participation included the Seminole and Miccosukee Tribes. State agency participation included the Florida Game and Fresh Water Fish Commission, the Florida Department of Environmental Protection, and the Florida Department of Agriculture and Consumer Services. Local governments including Miami-Dade County, Broward County, Palm Beach County, Martin County and Lee County also participated.

1.6 THE CENTRAL AND SOUTHERN FLORIDA PROJECT

In 1947, 100 inches of rain fell on south Florida, more than tripling the region's total rainfall for 1945 and ending one of the worst droughts in Florida history. In a few weeks, the rain had drenched farmland and filled lakes and canals. Then in the space of just 25 days, two hurricanes and a tropical disturbance dumped more water on an already saturated area. When the rains finally ceased, 90 percent of southeastern Florida, from Orlando to the Keys, was under water. The Corps estimated the total damage of this disaster at more than $59,000,000.

Following the disastrous flood in 1947, the problems of the area came to a climax. This flood, coupled with the experiences of the drought in 1945 and the intrusion of saltwater into the aquifer made it imperative that immediate corrective action be started. These actions were needed to prevent further loss of life and damage to property because of floods, and to conserve water for beneficial uses during periods of drought.

Acting upon the requests of many local agencies concerned with flood control and water conservation, and under the authority of various flood control acts, river and harbor acts of Congress, and resolutions of appropriate congressional committees, the Corps' Jacksonville District conducted public hearings throughout the area to determine the desires of the many local interests and to collect data from which to formulate a plan.

Views expressed during the public hearings stated that the problems were too large and complex for the capabilities of either the State of Florida or local agencies acting alone, therefore making it practically impossible for either to draft a plan that would be satisfactory to all. A Comprehensive Plan for flood control and water conservation, which would encompass the entire area, while satisfying the major needs expressed by the various agencies, would be beneficial to the greatest number and to the largest portion of the area, and be performed by the Federal government, with local cooperation, seemed to offer the best solution.

A comprehensive report was prepared by the Corps and submitted to higher authority on December 19, 1947. This report stated that the problems of flood protection, drainage, and water control were considered to be physically inter-related, and that the St. Johns, Kissimmee, Lake Okeechobee, Caloosahatchee, and Everglades drainage areas all formed a single economic unit. Accordingly, it recommended a comprehensive program in the interest of *"flood control, drainage and related purposes."*

Congress approved the plan as part of the *Flood Control Act of June 30, 1948*, and the report was published in *House Document No. 643, 80th Congress, Second*

Session. The basic purpose of the overall Central and Southern Florida Flood Control Project, quoted from *House Document No. 643,* reads:

> *"In its natural state the part of central and southern Florida considered in this report was a vast wilderness of water, forest, prairie, and marshland. The forces of nature had combined to establish a fine balance which supported the vegetable, animal and human life that prevailed and resulted in building up the land to the condition in which white man first found it. A large part of this land, the Everglades, was still in a formative stage when its development began. The inherent fertility of the area and its resources made its development and use inevitable. This development, however, resulted in physical changes which altered the natural balance between water and soil, and much of the development was undertaken without any real knowledge of the area or of the hazards involved. The parched prairies and burning mucklands of the Everglades in 1945, the flooding of thousands of acres of farms and communities in 1947, and the intrusion of salt water into land water supplies of the east coast are basically the results of altering the balance of natural forces. The basic problem of this area is, therefore, to restore the natural balance between soil and water in this area insofar as possible by establishing protective works, controls, and procedures for conservation and use of water and land."*

The Governor of Florida approved the plan for the State of Florida in February 1948. The following year, the Florida State Legislature formed the Central and Southern Florida Flood Control District, later to become the South Florida Water Management District, to act as a single agency with which the Federal government could deal on all matters of local cooperation.

The C&SF Project, first phase, was authorized by the *Flood Control Act of June 30, 1948* for the purposes of flood control, water level control, water conservation, prevention of salt water intrusion, and preservation of fish and wildlife. The first phase consisted of most of the works necessary to afford flood protection to the agricultural development south of Lake Okeechobee and to the highly developed urban area along the Lower East Coast of the State. The second phase, consisting of all remaining works of the original *Comprehensive Plan*, was authorized by the *Flood Control Act of September 3, 1954.*

Improvements in Hendry County and Nicodemus Slough (just west of Lake Okeechobee) were added to the project by the *Flood Control Acts of July 3, 1958, and July 14, 1960,* respectively. Improvements in Boggy Creek, Cutler Drain Area, Shingle Creek, South Miami-Dade County, and West Palm Beach Canal were added to the project by the *Flood Control Act of October 23, 1962*. Improvements in southwest Miami-Dade County were added to the project by the *Flood Control Act of October 27, 1965*; the same act also modified the 1958 authorization for the Hendry County improvements.

The Flood Control Act of 1968 expanded the project to provide for increased storage and conservation of water and for improved distribution of water throughout much of the project area and added recreation as a project purpose. Flood control measures for Martin County were added. The 1968 modifications would also facilitate increased delivery of water to Everglades National Park.

Section 2 of Public Law 91-282 enacted June 19, 1970, authorized appropriations for the Corps to accelerate:

> *"construction of borrow canal L-70, canal C-308, canal C-119W, and pumping station S-326, together with such other works in the plan of improvement as the Director of the National Park Service and the Chief of Engineers agree are necessary to meet the water requirements of the Everglades National Park: Provided further, That as soon as practicable and in any event upon completion of the works specified in the preceding proviso, delivery of water from the central and southern Florida project to the Everglades National Park shall be not less than 315,000 acre-feet annually, prorated according to the monthly schedule set forth in the National Park Service letter of October 20, 1967, to the Office of the Chief of Engineers, or 16.5 per centum of total deliveries from the project for all purposes including the park, whichever is less."*

Section 104 of the Everglades National Park Protection and Expansion Act of 1989 (Public Law 101-229) directed the Corps:

> *"to construct modifications to the Central and Southern Florida Project to improve water deliveries into the park and shall, to the extent practicable, take steps to restore the natural hydrological conditions within the park."*

The *Water Resources Development Act of 1992* (Public Law 102-580) authorized modifications to the C&SF Project for ecosystem restoration of the Kissimmee River. Both the Kissimmee River Restoration and the Headwaters Revitalization Projects were authorized.

The authorizing acts require that local interests provide all lands, easements, and rights-of-way; pay for relocations of highways (with certain exceptions), highway bridges, and public utilities which may be required for construction of project works; hold and save the United States free from damages resulting from construction and operation of the works; maintain and operate all works (except certain major regulating structures) after completion and make a cash contribution for each part of the work prior to its initiation.

Construction of the Federal project was began in January 1950. The project provides for an east coast protective levee extending from the Homestead area north to the eastern shore of Lake Okeechobee near the St. Lucie Canal. There are three conservation areas for water impoundment in the Everglades area, west of the east coast protective levee, with control structures to transfer water as necessary. There are also local protective works along the Lower East Coast with an encirclement of the Lake Okeechobee agricultural area by levees and canals. Enlargement of portions of the Miami, North New River, Hillsboro, and West Palm Beach Canals and existing Lake Okeechobee levees are part of the project. Also included are construction of new levees on the northeast and northwest shores of Lake Okeechobee; increased outlet capacity for improved control of Lake Okeechobee; floodway channels in the Kissimmee River Basin, with suitable control structures to prevent overdrainage; and facilities for regulation of floods in the Upper St. Johns River Basin.

The project also provides water control and protection from the recurrence of flood waters for the highly developed urban area along the Lower East Coast of Florida and for the agricultural areas around Lake Okeechobee (including the towns around the lake), in the Upper St. Johns and Kissimmee River Basins, and in south Miami-Dade County. Another project function is the conservation of flood waters for beneficial uses during dry seasons. In accordance with *Public Laws 91-282 and 101-229*, the project also delivers water to Everglades National Park according to a set schedule.

The Corps operates and maintains project works on the St. Lucie Canal; Caloosahatchee River; Lake Okeechobee levees, channels, locks, and major spillways; and the main outlets for Water Conservation Areas 1, 2A, and 3A. The South Florida Water Management District operates the remainder of the project in accordance with regulations prescribed by the Corps. The non-Federal sponsor has an essential role with the Corps in developing water management criteria for the C&SF Project. The non-Federal sponsor is responsible for allocation of water from project storage, except where mandated by Federal law.

1.7 OTHER STUDIES, REPORTS, AND PROJECTS

1.7.1 C&SF Project Authorizations

As noted in the previous section, since its initial authorization in 1948, there have been a number of additional authorizations that have modified the C&SF Project. These authorizations to the project were based on many studies conducted by the Corps. In addition, a number of discretionary changes have been made to the authorized project features in accordance with the discretionary authority granted to the Chief of Engineers by Congress. ***Appendix L - Prior Studies, Reports, and Projects*** provides a detailed description of all the modifications to the project. ***Table 1-1*** summarizes the project authorizations and the project purposes added or modified by these authorizations.

1.7.2 Other Studies

There are a number of ongoing studies being conducted by the Corps and other agencies that may contribute to restoration of the south Florida ecosystem. Some of the major efforts are discussed in this section.

The Corps is currently conducting a feasibility study of Biscayne Bay in order to investigate effects on water circulation, biological communities, and water quality of dredging and filling, spoil islands, and freshwater inputs in northern Biscayne Bay from existing Federal canals. The study would propose solutions to alleviate adverse factors affecting the bay and help to develop guidelines for future management of Biscayne Bay's natural resources. The non-Federal sponsor is Miami-Dade County.

The South Florida Ecosystem Restoration Task Force observed that the restoration effort needed to be founded on scientific information and mandated that it take an ecosystem approach. In support of this effort, the Science Sub-Group completed a report in 1996 entitled South Florida Ecosystem Restoration Scientific Information Needs (Science Subgroup, 1996), which provides information in support of the ecosystem approach. It was the first step in the development of an ecosystem-based South Florida Comprehensive Science Plan that includes monitoring and modeling. The Science Coordination Team (formerly the Science Sub-group) is in the process of developing a science plan to supply the information needs for ecosystem restoration.

The science plan developed by the Florida Bay Interagency Working Group, initiated by Everglades National Park in January 1993, focused upon the research, monitoring, and modeling objectives that must be addressed to guide the restoration of Florida Bay. It represents a synthesis of research plans prepared over past years by several Federal and state agencies. This science plan will serve as the basis for restoration of the Florida Bay portions of Sub-regions 3 and 6 under the aegis of the South Florida Ecosystem Restoration Task Force.

The South Florida Water Management District has undertaken the development of regional and sub-regional level water supply plans to provide for better management of south Florida's water resources. The Lower West Coast Water Supply Plan was completed in February 1994 (SFWMD, 1994b). The Interim Plan for Lower East Coast Regional Water Supply (SFWMD, 1998d), which addresses water-related needs and concerns of southeastern Florida through the year 2010, and the Upper East Coast Water Supply Plan (SFWMD, 1998b), which evaluates future 2020 water demands and supplies for the Upper East Coast of Florida were completed in 1998. A Lower East Coast Plan with a 2010 horizon will be developed by April 2000.

SECTION 2
PRE-DRAINAGE CONDITION

This section provides an overall characterization of the conditions that existed in the south Florida ecosystem prior to drainage and development activities. A significant portion of the information in this section (portions of subsection 2.1 and most of subsections 2.2, 2.3, and 2.4) is taken directly from the Science Sub-Group Report (1993) which was undertaken to provide information to the Corps of Engineers to assist in the reconnaissance study. It is important to understand how the pre-drainage south Florida ecosystem functioned in order to understand how natural system functioning has been impacted. This section also provides an overview of historic water quality conditions in the study area.

2.1 INTRODUCTION

The pre-drainage wetlands of southern Florida covered an area estimated at approximately 8.9 million acres. This region was a complex system of hydrologically interrelated landscapes, including extensive areas of ridge and slough landscape and sawgrass plains, as well as, cypress swamps, mangrove swamps, and coastal lagoons and bays. Prior to drainage, the characteristics of this network of wetland landscapes could be described by a set of physical and ecological features that were present across regional scales, and which gave definition to these ecosystems. It was the defining physical characteristics of this region that provided the spatial and temporal framework necessary for the existence of the components and relationships that defined the ecological characteristics of these southern Florida wetlands.

As a result of land use and water management practices during the past 100 years, the regional wetlands of southern Florida either have been lost or have been substantially altered. It is the premise of the Restudy that an understanding of these defining characteristics, and the factors which caused their loss or alteration, provide focus for setting restoration goals and priorities for the southern Florida wetlands. While it is true that the pre-drainage wetlands can not be fully restored, a successful restoration program will be one that recovers to the extent possible these defining characteristics of the former system. Achievement of this goal should result in the recovery of ecologically viable systems that functionally resemble the pre-drainage Everglades and its interrelated wetland systems.

The fundamental tenet of south Florida ecosystem restoration is that hydrologic restoration is a necessary starting point for ecological restoration. Water built the south Florida ecosystem. Water management changes have adversely affected this ecosystem. Restoration begins with the reinstatement of the natural distribution of water in space and time. The spatial extent of the hydrologically restored area is critical to ecological restoration. Water quality improvement must be an integral part of all hydrologic restoration. The focus is on the wetlands because the greater part of the pre-drainage south Florida ecosystem was wet.

2.2 DESCRIPTION OF THE NATURAL SYSTEM

The study area encompasses approximately 18,000 square miles comprising at least 11 major physiographic provinces, including the Everglades, the Big Cypress, Lake Okeechobee, Florida Bay, Biscayne Bay, the Florida Reef Tract, nearshore coastal waters, the Atlantic Coastal Ridge, the Florida Keys, the Immokalee Rise, and the Kissimmee River Valley. The watersheds of the Kissimmee River, Lake Okeechobee, and the Everglades dominate the system. The system functions as an interconnected mosaic of wetlands, uplands, coastal areas, and marine areas. Wetlands dominated the pre-drainage landscape. Prior to drainage, wetlands covered most of central and southern Florida. The Everglades region was characterized by an extremely low gradient (1 - 2 inches/mile), yet heterogeneous landscape mosaic sculpted by 5,000 years of evolution of hydrologic and biologic forces on a Pleistocene limestone platform. The 1850 era military map (Ives, 1856), which defines the "pre-drainage" system discussed in the Science Sub-Group Report (1993), gives some indication of the pre-drainage hydrologic structure and elevation in the study area.

2.3 FUNDAMENTAL CHARACTERISTICS OF THE PRE-DRAINAGE SYSTEM

The pre-drainage wetland landscapes consisted of swamp forest; sawgrass plains; mosaics of sawgrass, tree islands, and sloughs dominated by *Nymphaea*; marl-forming prairies and cypress strands. The upland landscapes consisted of pine flatwoods, pine rocklands, tropical hardwood hammocks, and xeric hammocks dominated by oaks. The natural seascapes of south Florida consisted of shallow seagrass beds, riverine and fringe mangrove forests, intertidal flats, coral reefs, hard bottom communities, mud banks, and shallow, open inshore waters. These were all interconnected on a topographic gradient that ranged from about 20 feet NGVD at Lake Okeechobee to below sea level at Florida Bay.

The pre-drainage wetland ecosystems of south Florida had three essential characteristics:

- A hydrologic regime that featured dynamic storage and sheet flow
- Large spatial scale, and
- Heterogeneity in habitat.

2.3.1 Dynamic Storage and Sheet Flow

The structure contributing to dynamic storage included the very shallow elevation gradient, the vast expanses of emergent vegetation, the thick peat substrates, sand hills, and highly permeable limestones. The water masses were constantly progressing downslope but so slowly that, in effect, water was stored in the system during one season to use in the next season. Transportion of water masses within a structural element varied from a number of months to a number of years.

Throughout the system, groundwater seepage, driven by hydraulic gradients, provided the base flow of creeks, rivers, and possibly even surface runoff across the mangrove zone. Base flow is the river or stream flow provided entirely by seepage from groundwater sources. For example, in the Kissimmee River in the upper part of the watershed, prior to drainage and channelization, 80 percent of annual river flow was base flow (Burns, 1975; Burns and Taylor, 1979).

The all-important extended hydroperiods of the natural system depended more on the large dynamic storage capacity and delayed flow-through that were natural hydrologic features of this system than on the immediate effects of rainfall. Because of the dynamic storage and slow rate of water flow throughout the natural system, wet season rainfall kept the wetlands flooded and maintained freshwater flow to the estuaries well into the dry season. The carry-over effect of the enormous dynamic storage capacity of the natural system was so great that a year of high rainfall maintained surface water in wetlands and freshwater flow to estuaries even into one or more subsequent drought years (Walters et al., 1992; Fennema et al., 1994; Browder, 1976). The dynamic storage made wetlands and estuaries less vulnerable to south Florida's spatially and temporally variable rainfall.

2.3.2 Large Spatial Scale

The vastness of the pre-drainage wetland extent made it possible for the natural ecosystem to: (1) support genetically viable numbers and sub-populations of species with large feeding ranges or narrow habitat requirements, (2) provide the aquatic production to support large numbers of higher vertebrate animals in a naturally nutrient-poor environment, and (3) sustain habitat diversity through natural disturbance. Population resiliency is undoubtedly proportional to the area of these wetlands because habitat diversity, the amount of seasonal refugia, and the number of dispersal options are proportional to wetland area.

In the pre-drainage era, the nutrients that were the basis of primary production were derived principally from rainfall. The nutrients in water entering from upstream were scrubbed by the vegetation and soils and not available downstream. Sheet flow enhanced the uptake of nutrients from the water column.

The periphyton community, made up of microscopic algae, not only assimilated available nutrients from the water column but also created an environment that precipitated phosphorus, along with calcium carbonate, into the substrate. The system was extremely oligotrophic, given the nutrient loading, spread over the entire areal extent. During seasonal dry-down, topographic depressions (e.g., alligator holes) became areas of concentrated aquatic biomass, producing localized feeding opportunities for large carnivores, including wading birds. The higher vegetation, as well as the periphyton, had adaptations for surviving under low nutrient conditions.

2.3.3 Heterogeneity in Habitat

Habitat heterogeneity maintained by micro-topographic features, small-scale climatic variation, and natural disturbances such as freezes, fire, and storms, acting on the large spatial scale of the wetlands, was a major contributor to biotic diversity and the persistence of populations. The mosaic of habitat types and water depths provided the spatial framework for the production and survival of animals under a wide seasonal and annual range of hydrologic conditions.

The vegetative landscape resulting from this vast, low relief, low gradient landform was a diverse mosaic of plant communities. These communities varied in extent from patches on the order of tens of meters to areas approaching physiographic provinces. The larger expanses had more long-term resiliency than the patches. Large spaces were necessary to maintain resiliency under conditions that changed on scales from seasons to decades. To some extent, maps from the 1800s, when compared with maps of the 1980s, reveal large scale persistence of landscape patterns, even in the face of major anthropogenic disturbance.

2.4 RELATIONSHIPS WITH SPATIAL AND TEMPORAL VARIATION

The diverse and large number of aquatic biota that these systems once supported were maintained by the complex annual and long-term hydrologic patterns of the natural system, as expressed in wet-dry cycles, drying and flooding rates, surface water and water depth patterns, annual hydroperiods, flow volumes, and, at the coast, salinity and mixing patterns. For most animals, annual patterns of production, dispersal, and survival were seasonally regulated by the annual periodicity of wet-dry cycles and by the rates of drying and flooding. Primary and secondary production, including that in the key periphyton communities, depended on depth and duration of surface water.

The production of food for consumption by larger predators was largely a function of surface water area and flooding duration during the annual wet period. Food availability was then determined by the amount of forage produced and the rate and degree that it became concentrated into a smaller space during the annual dry season. The distribution and persistence of large animal populations was further influenced by the seasonal patterns of surface water distributions and, in the coastal wetlands and estuaries, salinity patterns, superimposed over major habitat, or plant community, patterns. For example, large, historic wading bird nesting colonies were once clustered in wetlands adjacent to estuaries, presumably because the prey base for these birds was greatest and most reliable at the estuarine/freshwater interface.

Colonial wading birds were extremely abundant in pre-drainage south Florida and were conspicuously present even into the 1960s and, to a lesser extent, the 1970s. Wood storks, White ibis, Great and Snowy egrets, and other species nested in vast numbers in mangrove swamps along the southern rim of the Everglades and at various interior locations, particularly Corkscrew Swamp in southwest Florida and along the Kissimmee River. Other large predators such as alligator, panther, and bear were common. Fish such as snook, tarpon, sea trout, and red drum were abundant in the estuaries. The Florida Reef Tract supported a healthy living coral reef and a rich diversity of associated fish and other organisms, including snappers, groupers, and spiny lobster.

The estuaries of south Florida had salinity concentrations naturally ranging from about 18 parts per thousand to 36 parts per thousand or slightly greater and lower salinity concentrations (0-18 parts per thousand) in the mangrove zone. These estuaries were naturally well mixed, rather than stratified. They had horizontal salinity gradients, with salinity increasing in an offshore direction and a lower salinity range throughout the estuary during the wet season. Parts of the more enclosed estuaries may have infrequently experienced salinity concentrations of between 36 and 40 parts per thousand during the dry season. The estuaries received freshwater across a broad front, flowing across the mangrove zone, as well as from creeks and rivers, which provided some freshwater inflow throughout the year.

Salinity shifted gradually from high flow to low flow conditions because of the enormous dynamic storage capacity of the upstream system. Shallow, oligotrophic waters promoted the growth of seagrass beds, which supported a resident fauna and the juveniles of many species that spawn offshore but depended upon estuarine nursery grounds. The prop roots of mangroves lining the estuaries and tidal creeks also provided habitat for estuarine life. Schooling coastal migratory species such as Spanish mackerel, bluefish, and pompano entered the estuaries during higher salinity times of the year.

2.5 OVERVIEW OF HISTORIC WATER QUALITY CONDITIONS

The following is a summary of the water quality conditions believed to exist within the study area prior to all historic drainage activities. For a more detailed discussion of the pre-drainage water quality see ***Appendix H: Water Quality, Attachment E: Overview of Historic Water Quality Conditions***.

Prior to efforts to drain portions of the Kissimmee River-Lake Okeechobee-Everglades system in the early 1880's, water quality conditions in this 18,000 square mile wilderness watershed were undisturbed and considered pristine. Over the past 120 years, efforts to drain, dike and convert wetlands and watercourses for urban and agricultural uses throughout the watershed, have resulted in substantial degradation to water quality conditions across the fresh water lakes and marshes, estuaries and coastal marine environments of the area.

2.5.1 Kissimmee River Basin

The general land elevation in the Upper Kissimmee River Basin headwaters area is about 100 feet NGVD. Historic water flows across this area were likely slow and seasonal with surface sheet flows highest during the annual wet season. Due to the long residence time of surface and ground waters in contact with the moist sandy and organic soils, water quality conditions were likely low in dissolved nutrients, high in color with a strong diel dissolved oxygen pattern. Historically, the Kissimmee River flowed south from Lake Kissimmee to Lake Okeechobee over a 98-mile long, shallow, sluggish meandering path with water depths of one to two feet in many locations. An extensive 50,000-acre wetland floodplain moderated high water and wet season flows and sequestered nutrients and sediments before releasing water flows to Lake Okeechobee.

2.5.2 Lake Okeechobee

Lake Okeechobee, a broad, shallow lake with average depths of nine feet, historically was much less eutrophic then its current water quality condition indicates. In the late 1800’s, Lake Okeechobee had a larger, more extensive wetland littoral zone along the shoreline which extended from the lake's northwestern and southern shorelines. In the late 1960’s and early 1970’s, total phosphorus concentrations as low as 50 parts per billion were measured in the Lake (Joyner, 1974). Currently total phosphorus concentrations in the lake have been measured in the 100 parts per billion range (James et al, 1995). It is likely that historic in-lake turbidity was much lower than current conditions as well.

Before the recent development of south Florida and construction of the C&SF Project, Lake Okeechobee had a larger pelagic zone, a littoral zone that extended nearly 20 kilometers to the west of the present lake shore, and the Lake was contiguous with the Florida Everglades to the south. Output from the District's "Natural Systems Model" indicates that lake levels fluctuated between 17 and 23 feet NGVD, as compared to today's fluctuations between 11 and 17 feet NGVD. In the natural system, these fluctuating water levels may have periodically flooded the exposed areas of an expansive, low gradient marsh. However, under both high and low conditions, there likely was abundant submerged and exposed habitat for fish and other wildlife. Today's Lake is constrained within a dike, and the much smaller littoral zone occurs on a sand-bottomed shelf between the dike and a relatively deep drop-off to open water. As a result, water levels above 15 feet NGVD flood the entire littoral region, leaving no habitat for wildlife that require exposed ground. When water levels are below 11 feet NGVD the entire marsh is dry, and not available as a habitat for fish and other aquatic life. During the years following construction of the Herbert Hoover Dike the Lake has experienced numerous occasions when water levels have been above 15 or below 11 feet NGVD for prolonged periods of time (Havens et al., 1996).

2.5.3 Upper East Coast

Prior to drainage activities, the St. Lucie River Basin and southern Indian River Lagoon area (Upper East Coast area) was a low, flat coastal region. It contained poorly drained sandy soil uplands intermixed with numerous scattered isolated freshwater wetlands grading to a broad, shallow coastal lagoon. Tidal flushing throughout the southern Indian River Lagoon was more limited historically and the lagoon waters would have exhibited a much lower salinity than current conditions. Historic lagoon substrates were dominated by freshwater plants rather then the current seagrasses. Water depths in the southern lagoon averaged only three to four feet and contained a luxuriant growth of rooted aquatic plants. The aquatic plants efficiently trapped dissolved and suspended particles and nutrients, and helped to maintain low turbidity in lagoon waters. The major freshwater inflows to the southern Indian River Lagoon were dominated by wet season flows from the St. Lucie River and the Loxahatchee River systems.

2.5.4 The Central Everglades

In the Central Everglades Basin, the Everglades ecosystem developed under extremely low rates of total phosphorus supply. Historically, nutrient inputs to Everglades marsh waters were derived primarily from atmospheric deposition of rainfall and dry fallout. Total phosphorus concentrations in rainfall to the Everglades marsh, in water column concentrations and throughout the central Everglades region was low, ranging from five to 10 parts per billion (McCormick et al., in preparation). Relative to other key water chemistry features, the interior Everglades marsh, Water Conservation Area 2 and 3, and Everglades National Park, were slightly basic and highly mineralized when compared to the northeastern Everglades region, Loxahatchee National Wildlife Refuge area. This northern region was slightly acidic and contained extremely low concentrations of major ions, a condition which reflects the rainfall-driven hydrology of the area (McCormick et al., in preparation). Concentrations of nitrogen and other macronutrients in interior Everglades surface waters were relatively high when compared to total phosphorus. These concentrations varied in the surface water from location to location within the Everglades. However, they would not generally be considered limiting compared with the extremely low total phosphorus concentrations in the Everglades marsh.

2.5.5 Lower East Coast and Biscayne Bay

Water quality conditions in the Lower East Coast would have varied considerably depending on salinity, substrate and nutrient input conditions; however, it can be inferred that water quality conditions were pristine simply because significant pollutant sources were non-existent. Coastal rivers were likely highly stained and low in nutrients while water quality conditions in the shallow freshwater coastal water bodies were likely nutrient poor with high color and low turbidity. Drainage and dredging activities in this area irrevocably and significantly modified salinity conditions in Lake Worth, a coastal freshwater lake.

Historical accounts of Biscayne Bay indicate that prior to inlet dredging and navigational channel dredging, the northern and central portion of the bay had much lower salinity conditions. Biscayne Bay water quality in the late 1800s can be characterized as low in nutrients, low in turbidity and high in light transmittance promoting luxuriant seagrass meadows on the bay bottom.

2.5.6 Florida Bay and the Florida Keys

Florida Bay is a subtropical estuary, averaging three feet in depth. Historically, these estuarine waters could be characterized as warm and very clear with the presence of lush seagrass beds on the bay bottom. Historically, both Florida Bay and Florida Keys estuarine and marine habitats evolved under very low nutrient conditions and were sensitive to increased levels of nutrients. Water quality in Florida Bay was highly variable with substantial variability in bay turbidity and salinity conditions relating to climatological events such as hurricanes and cold fronts, and large freshwater inflows from the southern Everglades during annual wet seasons. In the deeper marine waters off of the Florida Keys, water clarity was excellent with visibility through the water column routinely exceeding 100 feet.

2.5.7 Big Cypress Basin

The Big Cypress Basin is a large, flat area with maximum elevations of 22 feet above mean sea level in the northern region which gradually grades south to sea level in the coastal mangrove region of the Ten Thousand Islands area, on the Gulf of Mexico (Duever et al., 1979). Historic water quality conditions in this region were tied to the predominant carbonate marl soils of the area. Organic peats were found in the low-lying north-south sloughs and strands and in the coastal mangrove areas; however, they covered a relatively small portion of the entire basin. The single largest physiographic region in the Big Cypress was the slightly elevated interior Pineland region indicative of a juvenile karst terrain (Duever et al., 1979) suggesting substantial interaction of rainfall derived surface waters and the surficial aquifer.

Due to the topography, soils and vegetation of the area, water quality conditions had relatively high levels of dissolved constituents, such as calcium, chloride, sodium, potassium, hardness, specific conductance, and dissolved solids (Duever et al., 1979). Watercolor was highly stained with tannins and turbidity would have been relatively low. Historic nutrient concentrations in Big Cypress Basin were relatively oligotrophic in phosphorus and nitrogen compounds (Odum, 1953; Klein et al., 1970; Carter et al., 1973). However, total phosphorus and nitrogen compound levels in Big Cypress surface waters would have been substantially higher than total phosphorus and total nitrogen concentrations in the central Everglades marshes due to differing soil conditions.

2.5.8 Caloosahatchee River Basin

Prior to early drainage work, the Caloosahatchee River was a shallow, meandering river. Water quality was likely dominated by high color and high organics exhibiting the highly stained tannic nature of many south Florida coastal rivers. Dissolved oxygen levels in the river likely fluctuated widely with a daily pattern. In the lower Caloosahatchee River near its convergence with San Carlos Bay, the Caloosahatchee Estuary likely exhibited luxuriant seagrass beds with high light transmittance to the substrate and low nutrient and suspended solids conditions.

SECTION 3
EXISTING CONDITIONS

Southern Florida today is characterized by highly productive agricultural regions and rapidly growing urban areas. These areas directly abut extensive aquatic and wetland ecosystems that are in serious states of decline, largely as a result of water management activities required to support the agricultural and urban systems. A burgeoning urban population occupies most of the higher elevation areas of the Lower East Coast. Extensive agricultural areas cover much of the interior of the peninsula north and south of Lake Okeechobee and along the western fringes of the Lower East Coast. Both urban and agricultural land uses require increasing levels of water supply and flood control.

A channelized and degraded Kissimmee River is currently undergoing ecological restoration. A diked and highly regulated Lake Okeechobee has been reduced in area by half with the loss of extensive littoral wetlands. It now requires frequent regulatory water releases to maintain lowered water levels defined by water regulation schedules. The regulatory releases severely damage the St. Lucie and Caloosahatchee estuarine ecosystems.

The Everglades have also been reduced in area by half due to agricultural and urban expansion. The remaining Everglades ecosystem is in a continuing state of decline largely as a result of altered water regimes and degraded water quality, as evidenced by vegetation change, declining wildlife populations and organic soil loss. In contrast, the Big Cypress region, although modified from its natural condition through major man-caused disturbances (eg. logging, oil and gas exploration, residential development, recreation uses and agriculture). is in relatively good condition as an ecosystem. At the downstream end of the system, Florida Bay, the Gulf of Mexico, and Biscayne Bay estuarine ecosystems experience altered salinity regimes due to decreased freshwater heads and inflows from the Everglades, with damaging effects on habitats, nursery grounds, and estuarine fauna.

The situation in south Florida today, as summarized here, can be attributed largely to a diminished capacity to retain the huge volume of water that once pooled and sheet flowed across the pre-drainage landscape. These waters are now either discharged in massive volumes through canal systems to tide or are stored at unnaturally high levels in remnant diked wetlands of the Everglades. In hindsight, many of these problems are now recognized to be unanticipated effects of the existing Central and Southern Florida (C&SF) Project. They are exacerbated by the inescapable reality that people continue to move to south Florida at one of the highest rates in the nation. The result is a currently non-sustainable system of urban, agricultural and natural environments in south Florida that exceeds the capacity of, or is hampered by, the existing system of water management.

The following discussion is a brief summary of the existing physical, ecological, and socio-economic conditions within the study area. It does not attempt to provide comprehensive coverage of all resources or concerns; rather its purpose is to provide a summary account of the baseline resources present in the study area and which may be affected by implementation of the Comprehensive Plan. Further information on existing conditions within the regional system, and the ten study regions is available in ***Appendix J***. Detailed information on existing water quality is available in ***Appendix H***, existing air quality in ***Appendix I***, and socio-economics in ***Appendix E***.

3.1 GEOLOGY AND SOILS

The geology and soils of south Florida represent many of the opportunities, constraints and impacts of regional water management. The high transmissivity of the Biscayne Aquifer allows rapid recharge of Lower East Coast well fields while it sets the stage for water competition between the Everglades and Biscayne Bay regarding the issue of seepage control. The loss of peat soils of the Everglades provides an indicator of ecosystem change due to drainage activities. The geology and soils of south Florida are important aspects of the hydrologic and ecological framework for the Restudy. Peat soils predominate in previously flooded areas. Peat soils have subsided as a result of oxidation due to drainage, which has affected local topography and hydroperiods. “With peat breakdown, there has been a release of stored phosphorus (previously contained in the peat) into the system.

The Kissimmee River Basin is poorly drained due to the low permeability of fine to medium grained Pamlico sands that were deposited as marine and estuarine terraces during the Pleistocene to Holocene age. Lake Okeechobee and much of the Everglades are underlain by peat and muck that developed in a shallow basin with poor natural drainage under prolonged conditions of flooding on top of the Fort Thompson Formation of Pleistocene interbedded sand, shell and limestone. Bedrock in the Everglades is almost entirely limestone.

The Big Cypress Basin developed on top of sandy, marly, fossiliferous limestone and sand of the Tamiami Formation of Pliocene age. Fine sand and loamy soils with poor natural drainage and scattered areas of rock outcrop overlie the limestone of the Big Cypress Basin. The sandy and loamy soils of the upper East Coast and the Caloosahatchee River Basin lie on top of the Anastasia Formation of variably shelly and sandy limestone and provide moderate natural drainage.

The Lower East Coast on the Atlantic Coastal Ridge is mostly underlain by thin sand and Miami Limestone that are highly permeable and moderately to well drained. To the west of the coastal ridge, soils of the Lower East Coast contain fine sand and loamy material and have poor natural drainage. Rockland areas on the coastal ridge in Miami-Dade County are characterized by weathered limestone surfaces and karst features such as solution holes and sinkholes. Higher elevation marshes of the southern Everglades on either side of Shark River Slough are characterized by calcitic marl soils deposited by calcareous algal mats and exposed limerock surfaces with karst features such as solution pits and sinkholes.

Florida Bay is underlain by burrowed bryozoan facies of Miami Limestone with a highly variable sediment cover consisting of sand, exposed bedrock and mudbanks. Ten Thousand Islands consists of sand that creates barrier islands underlain primarily by the Tamiami Formation. Because of the low relief, numerous marshy backbays or lagoons, such as Whitewater Bay, occupy exposed limestone surfaces behind the slightly higher sand buildup of Cape Sable. The Florida Keys are made up of the highly permeable Key Largo Limestone in the upper Keys and the less permeable Miami Oolite on the lower Keys.

South Florida contains three major carbonate aquifer systems. The surficial aquifer system comprises rocks and sediments from the land surface to the top of an intermediate confining unit. The discontinuous and locally productive water bearing units of the surficial aquifer include the Biscayne Aquifer, the undifferentiated surficial aquifer, the coastal aquifer of Palm Beach and Martin Counties and the shallow aquifer of southwest Florida. Practically all municipal and irrigation water is obtained from the surficial aquifer system. The intermediate aquifer system consists of beds of sand, sandy limestone, limestone and dolostone that dip and thicken to the south and southwest. In much of south Florida, the intermediate aquifer represents a confining unit that separates the surficial aquifer system from the Floridan aquifer system. The Floridan aquifer system is divided by a middle confining unit into the Upper and Lower Floridan aquifers. North of Lake Okeechobee, the Floridan aquifer system yields fresh water, although it is more mineralized along coastal areas and to the south. In the Upper East Coast, the Upper Floridan aquifer is used for drinking water supply. In the Lower East Coast, from Jupiter to south Miami, the Upper Floridan aquifer is being considered for storage of potable water in an aquifer storage and recovery program. In the Lower Floridan aquifer there are zones of cavernous limestones and dolostones with high transmissivities. However, because these zones contain saline water, they are not used for drinking water supply and are used primarily for injection of treated effluent wastewater.

3.2 CLIMATE

The subtropical climate of south Florida, with distinct wet and dry seasons, high rates of evapotranspiration, and climatic extremes of floods, droughts and hurricanes, represents a major physical driving force that sustains the Everglades while creating water supply and flood control issues in the agricultural and urban segments. South Florida's climate, in combination with low topographic relief, delayed the development of south Florida until the Twentieth Century, provided the main motivation for the creation of the C&SF Project 50 years ago, and continues to drive the water management planning of the Restudy today.

Seasonal rainfall patterns in south Florida resemble the wet and dry season patterns of the humid tropics more than the winter and summer patterns of temperate latitudes. Of the 53 inches of rain that south Florida receives annually on the average, 75 percent falls during the wet season months of May through October. During the wet season, thunderstorms that result from easterly tradewinds and land-sea convection patterns occur almost daily. Wet season rainfall follows a bimodal pattern with peaks during May-June and September-October. Tropical storms and hurricanes also provide major contributions to wet season rainfall with a high level of interannual variability and low level of predictability. During the dry season, rainfall is governed by large-scale winter weather fronts that pass through the region approximately weekly. High evapotranspiration rates in south Florida roughly equal annual precipitation. Recorded annual rainfall in south Florida has varied from 37 to 106 inches, and interannual extremes in rainfall result in frequent years of flood and drought. Multi-year high and low rainfall periods often alternate on a time scale approximately on the order of decades.

3.3 AIR QUALITY

The existing air quality within south Florida is considered good, and the region attains all National Ambient Air Quality Standards. An air quality concern that is not addressed by National Ambient Air Quality Standards is the atmospheric deposition of mercury. Detailed information on existing air quality is available in ***Appendix I***.

3.4 NOISE

Within the major natural areas of south Florida, external sources of noise are limited and of low occurrence. Rural areas have typical noise levels in the range of 34-70 decibels, and urban areas may attain 90 decibels or greater. Noise is not considered to be an issue in the development of the Comprehensive Plan.

3.5 VEGETATION

The location of south Florida between temperate and subtropical latitudes, its proximity to the West Indies, the expansive wetland system of the greater Everglades, and the low levels of nutrient inputs under which the Everglades evolved, all combine to create a unique flora and vegetation mosaic. Today nearly all aspects of south Florida's native vegetation have been altered or eliminated by the development, altered hydrology, nutrient inputs, and spread of exotics that have resulted directly or indirectly from a century of water management.

Riparian plant communities of the Kissimmee River and its floodplain are recovering from channelization and drainage. The macrophyte communities of the diminished littoral zone of Lake Okeechobee are now contained within the Hoover Dike. They remain essential for the ecological health of the Lake but are stressed by extreme high and low lake levels and by the spread of exotics. Below the Lake, all of the pond apple swamp forest and most of the sawgrass plain of the northern Everglades have been converted to the Everglades Agricultural Area. Also eliminated is the band of cypress forest along the eastern fringe of the Everglades that was largely converted to agriculture after the eastern levee of the Water Conservation Areas cut off this community from the remaining Everglades. The mosaic of macrophyte and tree island communities of the remaining Everglades within the Water Conservation Areas and Everglades National Park is altered even in seemingly remote areas by changes in hydrology, exotic plant invasion, and/or nutrient inputs.

The problems of the Everglades extend to the mangrove estuary and coastal basins of Florida Bay, where the forest mosaics and submerged aquatic vegetation show the effects of diminished freshwater heads and flows upstream. These problems are exacerbated by sea level rise. The upland pine and hardwood hammock communities of the Atlantic coastal ridge, interspersed with wet prairies and cypress domes and dissected by "finger glades" water courses that flowed from the Everglades to the coast, remain only in small and isolated patches that have been protected from urban development. In contrast, much of the vegetation mosaic in Big Cypress Swamp to the west of the Everglades remains relatively intact. The importance of south Florida's vegetation, in regard to its unique and diverse composition as well as to its critical linkage to the region's fauna, makes its current state of degradation a major concern and objective in any ecological restoration initiative.

More detailed documentation of existing vegetation focuses on wetland systems that have been most seriously degraded and that receive most benefits from the Restudy. Those systems include the Everglades peatland, the Everglades marl prairie and rocky glades, and the mangrove estuaries and coastal basins of Florida Bay and southern Biscayne Bay. Other natural systems in south Florida that already have restoration plans, that have lesser impacts from man, or that are not addressed by the Restudy are described in the Appendix. These systems include the Kissimmee River, where restoration is already in progress, Lake Okeechobee, for which a revised regulation schedule has been developed to protect littoral macrophyte communities, Big Cypress National Preserve, where vegetation impacts and fixes are relatively minor compared to the Everglades, and the Atlantic coastal ridge, where pinelands and hardwood hammocks are little affected by the Restudy.

The Everglades peatland that remains in the Water Conservation Areas and in Shark River Slough of Everglades National Park consists of a mosaic of sawgrass (*Cladium jamaicense*) plains, wet prairies, sloughs and tree islands that are oriented in the directions of flow patterns in the pre-drainage system. Sawgrass commonly forms monospecific strands throughout Everglades peatlands. Cattail (*Typha* spp.) has replaced sawgrass in phosphorus enriched areas, and the exotic melaleuca *(Melaleuca quinquenervia*) has invaded sawgrass in peripheral and overdrained areas.

A less dense wet prairie community characterized by spikerush (*Eleocharis* spp.), maidencane (*Panicum hemitomon*) and other emergent macrophytes grows at slightly lower elevations than sawgrass. The wet prairie blends into a more open water floating and aquatic community characterized by white water lily (*Nymphaea odorata*) and bladderwort (*Utricularia* spp.) in the lowest elevation water courses between the sawgrass ridges.

Wet prairies and sloughs support a luxuriant growth of attached algal communities known as periphyton, which form an important base of aquatic food webs and which are also diagnostic of water quality and hydrologic conditions in the Everglades. Wet prairies and sloughs also provide habitat for aquatic fauna and for feeding wading birds. Sawgrass is filling in wet prairies and sloughs in much of the remaining Everglades peatlands, probably as a result of lowered water levels. Sawgrass has been observed to revert to wet prairie after peat-burning fires. Cattail is filling wet prairies and sloughs in phosphorus enriched areas.

Tree islands dot the landscape in the form of either teardrop-shaped larger islands or round smaller islands. The heads of larger teardrop-shaped islands support swamp forest trees such as red bay (*Persea borbonia*), wax myrtle (*Myrica cerifera*) and dahoon holly (*Ilex cassine*) in the Water Conservation Areas and tropical hardwood trees such as gumbo limbo (*Bursera simaruba*), pigeon plum (*Coccoloba diversifolia*) and West Indian mahogany (*Swietenia mahogani*) in Everglades National Park and southern WCA-3A and WCA-3B. The tails of the islands often support willow (*Salix caroliniana*) and other more water-tolerant species. The smaller round islands are referred to as battery islands or bay heads and support willows or swamp forest species. The larger islands originated approximately 1,200 years ago, while the smaller ones are about 700 years old.

Tree islands provide valuable habitat for their unique forest plant assemblages and also for the vertebrate species that depend upon them, particularly during high water. Tree islands have been destroyed or damaged by lowered water levels, which have resulted in tree island and underlying soil burnout, as well as by unnaturally high water levels that have killed the less water tolerant tree species.

The higher elevation wetlands that flank either side of Shark River Slough in Everglades National Park support the highly diverse landscape of the marl prairie and rocky glades. This mosaic of short stature sawgrass, wet prairie, muhly prairie, and tropical hammock tree islands grows on marl and exposed limestone substrate in areas where the marsh naturally would dry for two to four months during most years. The wet prairie community of the marl prairie and rocky glades shares some species with the wet prairies described above for Everglades peatlands, but it grows under drier conditions and includes the most species rich wetland plant assemblage in the Everglades.

The wetland communities of the marl prairie and rocky glades support a distinct calcareous periphyton mat from which the marl substrate is formed. The periphyton mat is an important base for aquatic food webs and protects aquatic fauna from desiccation during dry periods. The muhly prairie community is particularly important as critical habitat for the endangered Cape Sable seaside sparrow (*Ammodramus maritimus mirabilis*). Tree islands in this landscape support a diverse assemblage of tropical hardwood species mixed with temperate species. Shortened annual duration of flooding in the marl prairie and rocky glades landscape presently supports a primarily terrestrial community that is flooded briefly each year rather than a primarily aquatic community that dries briefly each year. Impacts to vegetation include the loss of species richness in wet prairie communities, the conversion of muhly prairie to sawgrass, the invasion of woody and exotic trees and shrubs into prairie communities, and tree island burnout.

The mangrove estuary between the freshwater Everglades and Florida Bay and southern Biscayne Bay supports a mosaic of mangrove forests, tidal creeks, salt marshes, coastal lakes, tropical hardwood hammocks, and coastal basins. Red mangrove (*Rhizophora mangle*) swamp dominates the landscape along with stands of buttonwood (*Conocarpus erectus*), black mangrove (*Avicennia germinans*) and white mangrove (*Laguncularia racemosa*). Tidal creeks dissect the mangrove forests and are often bordered by salt marsh communities of black sedge (*Schoenus nigricans*) and cord grass (*Spartina* spp.). Tropical hardwood hammocks with canopy trees such as West Indian mahogany, Jamaica dogwood (*Piscidia piscipula*), strangler fig (*Ficus aurea*) and holly grow on elevated coastal embankments.

Coastal lakes and basins support seasonally variable beds of submerged aquatic macrophytes that range from low-salinity to marine communities of bladderwort, widgeon grass (*Ruppia maritima*), Cuban shoal grass (*Diplanthera* *wrightii*) and turtle grass (*Thalassia testudinum*). Reduction in freshwater heads and flows from the Everglades, in concert with sea level rise, has caused community shifts in the submerged aquatic vegetation of the coastal lakes and basins and apparently has contributed to the filling in of tidal creeks. A salinity regime favoring an increased frequency of high salinity events and a decreased frequency of low salinity events in the coastal lakes and basins has resulted in the loss of the low-to-moderate salinity macrophyte communities that seasonal populations of migratory waterfowl once utilized. Tidal creeks, with open water, visibly high flow velocities, and freshwater flora and fauna that were observed earlier this century, have filled with red mangroves to the point they are no longer recognizable today.

3.6 FISH AND WILDLIFE

The life cycles, community structures and population densities of the fauna of south Florida are intricately linked to regional hydrology. The current status of fish and wildlife has been strongly influenced by the cumulative effects of drainage activities early this century, the Central and Southern Florida Project, and the ensuing agricultural and urban development that was made possible by those activities. A major emphasis of the Restudy is to remedy many of the hydrologic aspects of the flood control project that in hindsight have been deleterious to fish and wildlife. Likewise the major emphasis in this section is on those faunal groups that appear to have declined as a result of hydrologic changes caused by the Central and Southern Florida Project and that are expected to benefit from the Restudy. The major linkages between hydrologic alterations and fauna that are addressed by the Restudy and emphasized here include the collapse of aquatic food webs and populations of higher level consumers that depend upon them, shifts in habitats to those less favorable to faunal communities, and the reduction in the spatial extent of the undeveloped greater Everglades wetland system. This section integrates our best current understanding of those linkages, with the recognition that our understanding will continue to improve but will always be incomplete. Thus the information presented here represents many converging lines of evidence that together have produced a sound hypothetical framework of how the south Florida wetland and estuarine systems presently function under the current management system. A more comprehensive catalog of all faunal groups in the region is found in ***Appendix J***.

A critical link in the aquatic food webs, and one that appears to have been broken by hydrologic alterations, is the intermediate trophic level of the small aquatic fauna. The small marsh fishes, macroinvertebrates and herpetofauna form the link between the algal and detrital food web bases of the Everglades and the larger fishes, alligators and wading birds that feed upon them. Aquatic animal populations are currently diminished due to two factors related to water management. Reduction in the spatial extent of Everglades wetlands by half has resulted in a proportional reduction in habitat of aquatic organisms, and changes in the hydrology in remaining wetlands has further reduced their populations.

In the freshwater Everglades, population densities of marsh fishes such as the golden topminnow (*Fundulus chrysotus*), bluefin killifish (*Lucania goodei*), sailfin molly (*Poecilia latipinna*), mosquitofish (*Gambusia affinis*), flagfish (*Jordanella floridae*) and small sunfish are directly proportional to the duration of uninterrupted flooding. This fish assemblage proliferates under extended periods of flooding and may reach maximum population densities only after five to six years of continuously flooded conditions in Shark River Slough. In adjacent areas of higher elevation marl marshes and rocky glades that tend to dry annually, survivors must repopulate each year after retreating into refugia that hold water through the dry season such as alligator holes, solution holes in exposed limestone, algal mats, and longer-hydroperiod marshes of Shark River Slough. The existing duration of uninterrupted flooding in Shark River Slough averages less than two years, compared to more than 15 years pre-drainage. In the marl marshes and rocky glades, where the duration of uninterrupted flooding currently averages only about three months compared to nearly ten months pre-drainage, the refugia that once enabled the survival of aquatic fauna during droughts now often dry completely, and repopulation requires longer distance migration from the longer-hydroperiod marshes of Shark River Slough which also dry frequently. Existing conditions thus keep the marsh fish populations of Shark River Slough and the marl prairies and rocky glades at perpetually low densities compared to pre-drainage conditions.

Aquatic macroinvertebrates live in close association with marsh fishes in the freshwater aquatic community. The amphipod (*Hyallela aztecus*), the freshwater prawn (*Palaemonetes paludosus*), the crayfish (*Procambarus alleni*), and the apple snail (*Pomacea paludosa*) represent ubiquitous and highly abundant processors of detritus and algae that must play key roles as prey species and in the cycling of energy and nutrients through the aquatic food webs of the Everglades and other south Florida wetlands. The crayfish is particularly important in the diet of white and glossy ibis. The apple snail is the sole food of the snail kite (*Rostrhamus sociabilis plumbeus*). The habitat requirements, life histories and population dynamics of these organisms remain largely unknown.

Also abundant in the freshwater aquatic community are amphibians and reptiles including the squirrel tree frog (*Hyla squirella*), green treefrog (*H. cenerea*), ranid frogs such as the pig frog (*Rana grylio*) and southern leopard frog (*R. utricularia*), legless siren (*Siren lacertina*) and amphiuma salamanders (*Amphiuma means*), swamp snakes, water snakes and cottonmouths (*Agkistrodon piscivorus*), and the red-bellied (*Pseudemys nelsoni*), and mud turtles (*Kinosternon subrubrum steindachneri* and *K. baurii*). Amphibia and their larvae represent important prey species for larger predatory fishes, alligators (*Alligator mississippiensis*) and wading birds. Turtles, snakes and amphiuma are commonly consumed by alligators. The pig frog is commercially harvested for frog legs. The high numbers of herpetofauna in the Everglades, particularly of such ubiquitous and abundant species as the squirrel tree frog, suggest that they function as critical energy pathways in food webs. Anecdotal accounts of the Everglades from early this century describe a much greater abundance of amphibians and reptiles compared to densities observed today.

Included in the freshwater aquatic community of south Florida are the larger sport species such as the largemouth bass (*Micropterus salmoides*), sunfishes, black crappie (*Lepomis nigromaculatus*) and important non-sport predators such as Florida gar (*Lepisosteus platyrhincus*) and bowfin (*Amia calva*). Lake Okeechobee is renowned for the trophy bass from its littoral zone and for an abundant black crappie fishery. Largemouth bass also naturally inhabit the deeper-water sloughs and wet prairies of the Everglades, where they grow at a rate of one pound per year of uninterrupted flooding. Wet prairies, sloughs and alligator holes are also the natural habitat of gar and bowfin. Shortened hydroperiods in much of the Everglades in combination with compartmentalization presently confine larger bass mostly to canals, which provide a popular recreational fishery. Unfortunately, Everglades bass contain high body burdens of mercury, presumably through biomagnification in the food chain, which make them unsuitable for frequent human consumption. Restoration of hydroperiods in the Everglades should expand the canal fishery for the largemouth bass to the sloughs and wet prairies where it historically occurred, create new fisheries in water preserve area reservoirs, and displace some existing fisheries in canals that will be filled. Bass fisheries in remaining canals should be substantially improved due to their proximity to marshes with lengthened hydroperiods.

The American alligator is a keystone species in the Everglades. Holes that are excavated by alligators form ponds where aquatic fauna survive droughts, and mounds of sediment that are excavated from the holes create higher-elevation habitat upon which willow and other swamp forest trees grow. In addition to its keystone role in the creation of alligator holes, the American alligator is the top predator in the Everglades and feeds at various stages in its life on every level of the food chain, from small fishes to wading birds.. Everglades alligators construct nests from mounds of vegetation and organic sediment that they excavate from the holes. Eggs are laid at the beginning of the wet season at elevations in the nests that are not likely to be flooded as water levels rise throughout the remaining wet season. Under current conditions, alligators have abandoned the marl prairie and rocky glades landscape where they were once most abundant, and where aquatic fauna were dependent on alligator holes for survival through dry seasons, because shortened hydroperiods have rendered the marl prairie and rocky glades a mostly terrestrial system where the alligator can no longer survive. Presently alligators and their holes are found mostly in the Water Conservation Areas and Shark River Slough, although reproduction is suppressed there. Water level fluctuations and impoundment effects in the Water Conservation Areas and regulatory water releases into Everglades National Park thwart the alligator's ability to lay their eggs at nest elevations that will not be flooded later in the wet season. The result is an increased frequency of drowned nests under current conditions.

In the brackish-water estuarine transition between the Everglades and Florida and Biscayne Bays, a low-salinity mangrove fish assemblage including the sailfin molly, topminnows, sheepshead (*Archosargus probatocephalus*), rainwater killifish, and small sunfishes achieves highest densities under conditions of freshwater and salinity less than five to eight parts per thousand. Under current conditions, decreased freshwater heads and flows upstream in the Everglades frequently allow elevated salinities above the optima for this fish assemblage and infrequently result in saltwater conditions in the estuarine transition. As a result, population densities of the small marsh fishes of the estuarine transition appear to be depressed and more erratic today in comparison to pre-drainage conditions.

The most conspicuous indicators of ecosystem health in the Everglades are the plummeting populations of wading birds, which are presently only ten percent of previous numbers of nesting birds, and which appear to continue to decline. The coastal nesting colony locations where most wood stork (*Mycteria americana*), white ibis (*Eudocimus albus*) and other wading bird species once nested are now abandoned. These locations are in the mangrove estuary of Florida Bay, where the juxtaposition of estuarine environments and persistent freshwater pools at the lower end of the Everglades once assured a dependable food supply throughout most breeding seasons. Particularly critical food bases include larger fishes at least in their second year of life for wood stork, and a wide variety of fishes, other vertebrates and invertebrates for other species, with a particular importance of crayfish to white ibis. These food bases are mostly contained in the freshwater marsh fish assemblage of the Everglades and the low salinity mangrove fish assemblage of the estuarine transition zone that are described above. Abandonment of the traditional coastal breeding colony locations by wading birds is largely attributed to depletion of these food bases in the southern Everglades. This depletion is due to abbreviated hydroperiods in Shark River Slough and the marl prairie/rocky glades, the loss of drought refugia in alligator holes in these regions, and the less desirable salinity regimes in the mangrove estuarine transition.

Under current conditions, most Everglades wading bird nesting colonies are located to the north in the Water Conservation Areas, in areas that were not traditional colony locations. Nesting birds appear to have been drawn to the Water Conservation Areas by persistent pools of water, and populations of prey species, at the lower end of each impoundment. Successful nesting there depends on the persistence of those pools, and on a steady water level recession to condense prey organisms and to provide suitable depth ranges for feeding, throughout dry seasons.

Unfortunately those conditions are not predictable under current operations of the Water Conservation Areas, and wading bird nesting success is low most years.

Another aspect of wading bird reproduction that is diminished under current conditions is the formation of "super colonies" of as many as 75,000 pairs of white ibis in coastal colony locations. Super colonies that traditionally nested in the coastal colonies have shifted to the Water Conservation Areas, where fewer numbers of breeding pairs have uncertain and relatively low reproductive success. Super colonies recur approximately every five to ten years. They coincide with the resumption of relatively normal annual rainfall and water levels during the first year following a drought. Causal factors of super colonies are poorly understood.

Roseate spoonbills (*Ajaia ajaja*) traditionally nested in eastern Florida Bay and fed upon smaller invertebrates in the low salinity coastal marshes of the Taylor Slough basin. Spoonbills have shifted colony locations to current nesting sites in central and western Florida Bay, presumably in response to declining food sources in their previous feeding grounds.

In addition to the abandoned coastal wading bird nesting colonies and depleted populations of low-salinity mangrove fishes, impacts to the mangrove estuarine transition due to diminished freshwater heads and flows upstream include degraded habitats for the American crocodile, migratory waterfowl, and nursery grounds of sport fishes and pink shrimp (*Penaeus duorarum*). Juveniles of the endangered American crocodile (*Crocodylus acutus*) seek low salinity areas of the mangrove estuary, which occur less frequently today, and their survival and growth is reduced at salinity levels above 25 parts per thousand, which occur more frequently today. The winter aggregations of more than 50,000 coots (*Fulica americana*), widgeon and other waterfowl that fed on beds of Chara and widgeon grass in the coastal lakes and basins no longer utilize these areas in large numbers since higher salinities have reduced the abundance of their food plants. Nursery ground suitability for juvenile sport fishes such as spotted seatrout (*Cynoscion nebulosus*), tarpon (*Megalops atlanticus*) and red drum (*Sciaenops ocellatus*) is diminished under the increased frequency of hypersaline conditions in the coastal basins. The same applies to pink shrimp in Whitewater Bay, which contribute to a multi-million annual Tortugas fishery (Sheridan, 1996). Spotted seatrout recruitment is adversely affected at salinity levels above 25 parts per thousand.

The white-tailed deer (*Odocoileus virginianus*) is widespread in most of the Everglades and the Big Cypress Basin. A healthy deer population persists in the Big Cypress basin. In the Everglades, the deer herd currently is higher than it was under pre-drainage conditions because it has benefited from lower water levels. However, during high water periods, massive mortality can occur when the deer are stranded on over-browsed tree islands, and starve. The restoration of the Everglades will reduce deer populations in the Everglades to densities closer to pre-drainage levels, but it will also reduce mortality due to unnaturally high water events.

3.7 THREATENED, ENDANGERED AND STATE LISTED SPECIES

The U.S. Fish and Wildlife Service, by letters dated February 20, 1997 and April 8, 1998 identified 18 Federally listed plant and animal species that would likely be affected by Restudy alternatives within the study area (***Table 3-1***). Of the listed species, Critical Habitat has been designated for the West Indian manatee (*Trichechus manatus*), snail kite, Cape Sable seaside sparrow and American crocodile.

For a description of these critical habitat geographic designations and a complete species description, taxonomy, distribution, habitat requirements, management objectives, and current recovery status, refer to the draft Multi-Species Recovery Plan for the Threatened and Endangered Species of South Florida, Volume I (USFWS, 1998b) or the U.S. Fish and Wildlife Service endangered species web site at ***http://www.fws.gov/r9endspp/endspp.html***. For a complete listing of all the Federally listed threatened and endangered plant and animal species occurring or thought to occur within the study area, reference the above web site. The Florida Game and Fresh Water Fish Commission correspondence dated February 23, 1998 and December 14, 1998 provided information on state listed species likely to be affected by the Restudy or present within the study area (***Table 3-1*** and ***Appendix J***). For a detailed description of existing conditions for the 18 Federally listed species see ***Appendix J***.

TABLE 3-1
THREATENED, ENDANGERED & SPECIES OF SPECIAL CONCERN PLANTS AND ANIMALS LIKELY TO BE AFFECTED BY THE C&SF RESTUDY

Scientific Name	Common Name	USFWS	GFC
Trichechus manatus	West Indian Manatee	E*	E
Felis concolor	Florida panther	E	E
Rostrhamus sociabilis plumbeus	Snail kite	E*	E
Mycteria americana	Wood stork	E	E
Ammodramus maritimus mirabilis	Cape Sable seaside sparrow	E*	E
Crocodylus acutus	American crocodile	E*	E
Ammodramus savannarum floridanus	Florida grasshopper sparrow	E	E
Picoides borealis	Red-cockaded woodpecker	E	T
Haliaeetus leucocephalus	Bald eagle	T	T
Polyborus plancus	Audubon's crested caracara	T	T
Drymarchon corais couperi	Eastern indigo snake	T	T
Aphelocoma coerulescens	Florida scrub-jay	T	T
Cucurbita okeechobeensis	Okeechobee gourd	E	
Amorpha crenulata	Crenulate lead-plant	E	
Euphorbia deltoidea	Deltoid spurge	E	
Galactia smallii	Small's milkpea	E	
Polygala smallii	Tiny polygala	E	
Euphorbia garberi	Garber's spurge	T	
Falco sparverius paulus	American kestrel(SE subsp.)		T
Grus canadensis pratensis	Florida sandhill crane		T
Mustela vison evergladensis	Everglades mink		T
Sciurus niger avicennia	Big Cypress fox squirrel		T
Ursus americanus floridanus	Florida black bear		T
Rana capito	Gopher frog		SSC
Gopherus polyphemus	Gopher tortoise		SSC
Pituophis melanoleucus mugitus	Florida pine snake		SSC
Aramus guarauna	Limpkin		SSC
Egretta caerulea	Little blue heron		SSC
Egretta thula	Snowy egret		SSC
Egretta tricolor	Tricolored heron		SSC
Eudocimus alba	White ibis		SSC
Speotyto cunicularia	Burrowing owl		SSC
Blarina carolinensis shermani	Shermans short-tailed shrew		SSC
Podomys floridanus	Florida mouse		SSC
Sciurus niger shermani	Sherman's fox squirrel		SSC
Liguus fasciatus	Florida tree snail		SSC

E Endangered
T Threatened
* Designated Critical Habitat
SSC State listed Species of Special Concern

3.8 WATER MANAGEMENT

For this section, the Central and Southern Florida Project has been broken down into four hydrologically related geographical areas consisting of: (1) the Kissimmee River – Istokpoga Basin; (2) the Lake Okeechobee and Everglades Agricultural Area; (3) the Water Conservation Areas, Everglades National Park, and Everglades National Park - South Miami-Dade Conveyance Canals; and (4) the East Coast Canal watersheds.

3.8.1 Kissimmee River – Istokpoga Basin

The Kissimmee River – Lake Istokpoga Basin portion of the project includes most of Osceola and Okeechobee and parts of Orange, Polk, Highlands, and Glades Counties. It is bounded on the north by the lakes of the Orlando area, on the west by the Peace River watershed, on the south by Lake Okeechobee and on the east by the Upper St. Johns River Basin and the Taylor Creek-Nubbin Slough Basin. The project purposes include flood control, water supply, navigation, and fish and wildlife. The project protects the lands adjacent to the lakes and along the Kissimmee River from frequent and prolonged flooding. It provides water supply for agricultural uses in the area in and around the lakes and the Kissimmee River. It also provides for navigation on the Kissimmee River and all lakes in the Middle and Upper Kissimmee River Basin. Locks are provided at control structures on the main watercourse between east Lake Tohopekaliga and Lake Okeechobee. Boatlifts are provided at all other structures. Maintaining lake stages at a desirable level for fish and wildlife and for recreational purposes is also important.

The Kissimmee Basin is an integrated system of lake storage capabilities and structure outlet capacities. The Upper Kissimmee Basin structures are operated according to regulation schedules. The regulation schedule essentially represents the seasonal and monthly limits of storage that guide the regulation of the project for the planned purposes. The regulation schedules vary from high stages in the late fall and winter to low stages at the beginning of the wet season. The lakes are drawn down in the spring to provide flood control storage and for fish and wildlife enhancement. The minimum levels are set to provide for sufficient flood control storage and navigation depths. The amount of seasonal fluctuation was derived by determining the effect of various water levels on the flood control, low water regulation, groundwater, fish and wildlife, and recreation. Runoff during the wet season is stored for use in the dry season. The regulation schedules take into account these varying, and often, conflicting purposes.

The Lake Istokpoga Project works were primarily designed to protect lands adjacent to the lake from flooding by lake waters, and provide water supply for agricultural use in areas around the lake and in the Indian Prairie area. At the same time, project works maintain the lake at a desirable level for fish and wildlife, navigation, and for recreational purposes.

The project has decreased the area inundated by major floods with floodwaters being passed for storage in Lake Okeechobee. It also prevents longer duration of low to no-flow water conditions during prolonged periods of drought in the lower basin. This is accomplished by conserving or storing waters within both the controlled pools behind the existing structures and in the channelways for drought protection. Other effects include year-round small boat navigation of the system from Lake Tohopekaliga to Lake Okeechobee with boat access to the Kissimmee River for fishing and recreation. The C-38 pools add to the total volume of water available for aquatic species support. The C&SF Project has, in effect, stabilized lake and river levels, removing both the highest (flood) and lowest (dry down) levels providing year-round navigability.

3.8.2 Lake Okeechobee and Everglades Agricultural Area

Lake water levels in Lake Okeechobee are regulated by a complex system of pumps, spillways and locks. The regulation schedule attempts to achieve the multiple-use purposes as well as provide seasonal lake level fluctuations. The schedule is designed to maintain a low lake stage to provide both storage capacity and flood protection for surrounding areas during the wet season. The schedule is also a guide for the management of high lake stages that might threaten the integrity of the Herbert Hoover Dike and thereby risk flooding of downstream lands. During the winter, lake levels may be increased to store water for the upcoming dry season. The general plan of operation for Lake Okeechobee is based on the following: 1) flood protection from lake waters and hurricane-driven wind tides for lands adjacent to the lake; 2) maintenance of an 8-foot navigation channel across Lake Okeechobee, as part of the Okeechobee Waterway and; 3) storage of water to meet the requirements of the agricultural area south and east of the lake.

Flood control works on Lake Okeechobee consist of a system of about 1,000 miles of encircling levees, designed to withstand a severe combination of flood stage and hurricane occurrence, plus the regulatory outlets of St. Lucie Canal and the Caloosahatchee River. The design discharge of Moore Haven Spillway is 9,300 cfs; that of St. Lucie Spillway is about 16,000 cfs. Following removal of local runoff from the agricultural areas south of the lake, an additional regulatory capability of several thousand cfs is available through the Miami, North New River, Hillsboro, and West Palm Beach Canals by pumping into the three Water Conservation Areas. The crest elevation of the levee system surrounding the lake ranges from 32 to 45 feet, NGVD. The likelihood of overtopping the levees from excess storage is almost non-existent. Possible flooding due to overtopping of levees within the Herbert Hoover Dike system is limited to short duration events involving wave runup in addition to hurricane-induced storm surge. The likelihood of such events is remote and the expected extent of flooding is minimal.

3.8.3 Water Conservation Areas

The primary purposes for the Water Conservation Areas and their appurtenant levees, canals, structures, and pump stations include flood control, water conservation, prevention of salt-water intrusion, recreation, preservation of fish and wildlife, and water supply for Everglades National Park. The Water Conservation Areas are completely contained by levees, except for about seven miles on the west side of Water Conservation Area-3A, which has a tieback levee. There are also levees on the east side of the East Everglades, which protect the agricultural and industrial areas, which otherwise would have been short hydroperiod wetlands, from inundation. This whole region is managed with a system of canals, multiple pump stations, and control structures. The main canals are West Palm Beach Canal, Miami Canal, Bolles and Cross Canals, North New River Canal, South New River Canal, Hillsboro Canal, and Tamiami Canal.

The Water Conservation Areas provide a detention reservoir for excess water from the Everglades Agriculture Area and parts of the East Coast region, and for flood discharge from Lake Okeechobee to the sea. The Water Conservation Areas provide levees to prevent Everglades floodwaters from inundating the east coast urban areas; provide a water supply for east coast areas and Everglades National Park; improve the water supply for east coast communities by recharging underground freshwater reservoirs; reduce seepage; ameliorate salt-water intrusion in coastal wellfields; and provide mixed quality habitat for fish and wildlife in the Everglades.

The regulation schedules contain instructions and guidance on how project spillways are to be operated to maintain water levels in the Water Conservation Areas. The regulation schedules essentially represent the seasonal and monthly limits of storage which guides project regulation for the planned purposes. The schedules vary from high stages in the late fall and winter to low stages at the beginning of the wet season. This seasonal range permits the storage of runoff during the wet season for use during the dry season. In addition, it serves to maintain and preserve plant cover in the Water Conservation Areas, which is essential to fish and wildlife and the prevention of wind tides. Regulation schedules must take into account various, and often conflicting, purposes. Conceptually, reservoir storage is commonly divided into the inactive zone, the water supply (conservation) zone, and the flood control zone. The distribution of water between the flood control and water supply zones varies seasonally in the Water Conservation Areas. The regulation schedules for Water Conservation Area 1, Water Conservation Area 2A, and Water Conservation Area 3A include a minimum water level, as measured in the borrow canals, below which water releases are not permitted unless water is supplied from another source. Note that this does not mean that a minimum stage is maintained in the Water Conservation Areas. When water levels fall below the minimum levels, transfers from Lake Okeechobee or upstream Water Conservation Areas are made to meet water supply demands.

3.8.4 East Coast Canal Watersheds

The East Coast Canals are the flood control and outlet works that extend from St. Lucie County southward through Martin, Palm Beach and Broward Counties to Miami-Dade County, a distance along the Atlantic Coast of about 170 miles. The East Coast Canal watersheds encompass the primary canals and water control structures located along the Lower East Coast of Florida and their hydrologic basins. The main design functions of the project canals and structures in the East Coast Canals area are to protect the adjacent coastal areas against floods; store water in conservation areas west of the levees; control water elevations in adjacent areas; prevent salt-water intrusion and over drainage; provide freshwater to Biscayne Bay and provide water for conservation and public consumption. There are 40 independently operated canals, one levee, and 50 operating structures, consisting of 35 spillways, 14 culverts, and one pump station. The project works to prevent major flood damages. However, due to urbanization, the existing surface water management system now has to handle greater peak flows than in the past.

The South Miami-Dade Conveyance System provides a way to deliver water to areas of south Miami-Dade County. This canal system was overlain on top of the existing flood control system. Many of these canals are used to remove water from interior areas to tidewater.

Areas become flooded during heavy rainfall events due to antecedent conditions that cause saturation and high runoff from both developed and undeveloped areas. When areas become flooded, excess water is removed through the canals. Automatic controls installed on some of the water control structures allow the canal levels to fall into a lower range which provides limited extra storage in the lakes and canals. Thus, during a heavy rainfall event, extra storage is available for the secondary canal system to drain into the larger canals. The automatic controls also allow for frequent gate changes that keep the water levels in the safe range. Saltwater intrusion has declined considerably at coastal structures since the installation of salinity dams downstream and the placement of salinity monitoring sensors near the structures. Damage to agriculture, citrus, and pasturelands due to flooding has been reduced as a result of the effective drainage capabilities of the canals.

The project works maintain optimum stages for the purposes of flood control, water supply, groundwater recharge, and prevention of salt water intrusion. The coastal canals and control structures between St. Lucie and Miami-Dade Counties are designed to permit rapid removal of floodwaters from their immediately adjacent drainage area. The degree of flood protection provided by outlet capacity is dependent on whether the protected area is urban or agricultural. Maximum rates of removal vary from 40-percent to 100-percent Standard Project Flood. The canals and structures are regulated automatically or manually, as designed, in accordance with the optimum water control and design elevations, with the exception of hurricane or tropical storm regulation.

The network of canals and control structures provides for water and salinity control in the area. Wellfields, which are the source of municipal water supplies, are significantly recharged by water from the Water Conservation Areas. Water stored in the Water Conservation Areas can be used to maintain groundwater levels in the coastal area for public water supply, to irrigate the vast agricultural areas interspersed within the project area, and to maintain a freshwater head along the Lower East Coast for salinity control.

The construction and operation of the East Coast Canals for flood protection and the lowering of the ground water table on the east coast ridge significantly affected freshwater deliveries to Biscayne Bay and Biscayne National Park. The patterns of freshwater discharge changed from long, slow releases over a broad front to “pulse” releases from canals following rain events.

3.9 WATER QUALITY

Water quality in the study area is significantly influenced by development. The C&SF Project has led to significant changes in the landscape by opening large land tracts for urban development and agricultural practices, and by the construction of extensive drainage networks. Natural drainage patterns in the region have been disrupted by the extensive array of levees and canals such that nonpoint source (stormwater) runoff and point sources of pollution (wastewater discharges) are now entering the system in many areas. Several pollutants of concern in the study area have been identified. These include:

- Metals - mercury, copper, cadmium, lead, zinc, arsenic, and tributyltin (TBT)
- Pesticides - DDT and derivatives, atrazine, simazine, ametryn, endosulfan compounds, ethion, bromacil, 2,4-D, aldecarb, and fenamiphos
- Nutrients - phosphorus, nitrite/nitrate, and ammonia/un-ionized ammonia
- Biologicals - fecal coliforms and pathogens, and chlorophyll-a
- Physical parameters - pH, dissolved oxygen, conductivity, turbidity, oil and grease, temperature, and salinity
- Other constituents - Polycyclic Aromatic Hydrocarbons (PAHs), dioxins and furans, sulfate, chloride, Polychlorinated Biphenyls (PCBs), and Volatile Organic Carbons (VOCs).

Of this list, phosphorus, pesticides and mercury are considered to be the most important water quality pollutants of the region and are discussed below. A much more thorough discussion of existing water quality conditions including the Federal, State, and Tribal water quality regulations and standards are provided in ***Appendix H***.

Phosphorus: Historically, south Florida waters were low in nutrients (oligotrophic). Due to human activities including the ditching and draining of wetlands and the expansion of agriculture waterbodies from the Kissimmee River southward have become nutrient-enriched to various degrees. The farming areas surrounding Lake Okeechobee in general have contributed to elevated nutrients in the Kissimmee River, Lake Okeechobee, the Caloosahatchee River, and the Everglades. In addition, urban storm water runoff is another potential source of phosphorus to the Everglades and south Florida coastal systems.

In general, the trend for phosphorus concentrations is a decrease from north (Kissimmee River and Everglades Agricultural Area) to south (Everglades National Park) since there are major anthropogenic sources in the agricultural areas in the north. Nutrient removal from marsh water is due to the natural water quality treatment processes associated with south Florida wetlands, notably the Everglades. According to the Florida Surface Water Improvement and Management (SWIM) Act Plan for Lake Okeechobee (SFWMD, 1997f), the highest average phosphorus concentrations (up to over 700 parts per billion (ppb) are measured in waters discharged from the Lower Kissimmee River (S-65D Basin = 770 ppb), Taylor Creek/Nubbin Slough (S-154 Basin = 610 ppb), and the Everglades Agricultural Area (East Beach Drainage District = 560 ppb). The lowest concentrations (about 10 ppb) in the study area are reported for marsh stations within the Everglades National Park (USGS, 1996).

Elevated phosphorus loading of waterbodies and the resulting increased water phosphorus concentrations (eutrophication) may have various ecological effects. These effects may include increased primary productivity, loss of water column dissolved oxygen, algal blooms, changes in vegetation and biodiversity, and accumulation of phosphorus in sediments and muck. The significance of such phosphorus loading may be the reduction or loss of a waterbody's habitat and/or recreational value.

Pesticides: An extensive array of pesticides is applied to (or persists in) south Florida waters, sediments and/or soils. The south Florida region is unique in that a very large and sensitive ecosystem exists in the midst of an ever growing urban population and an extensive and intensive agricultural production area. A variety of pesticides are used in this area for a number of different reasons. Major uses are ground and/or aerial applications related to agricultural production, mosquito control, aquatic plant growth in local waterways, golf course maintenance, and lawn and vegetation maintenance. Pesticides used in these ways are effective in controlling the pests of concern. However the use of pesticides may also pose possible threats to the sensitive ecosystems and human health in Florida. This is due to the intense year-round use of pesticide compounds, coupled with intense storm events, the shallow water tables and the ever-increasing urban sprawl into previously undisturbed areas.

Mercury: Mercury is a toxic heavy metal. Levels of mercury in water, animal tissue, sediments, periphyton, air, and soil have been shown to be elevated in certain areas of south Florida. However, the sources, distribution, magnitude, transport, transformations and pathways of mercury through the Everglades ecosystem are poorly understood. Among the possible mercury sources in south Florida are natural mineral and peat deposits (Rood et al., 1995), and atmospheric deposition from global, regional and local (e.g., fossil-fuel-fired electrical generating plants, municipal waste incinerators, and medical waste incinerators) sources. Sources of mercury are now believed to be primarily from atmospheric deposition. Once elemental mercury is methylated by microbial action, it becomes biologically available for bioaccumulation at various levels of the food chain and for biomagnification up the food chain to top carnivores such as the Florida panther.

3.9.1 Regional Overview of Water Quality Conditions

Under Section 303(d) of the Federal Clean Water Act (CWA) states develop Total Maximum Daily Loads (TMDLs) for their water bodies that are not meeting designated standards under technology-based controls for pollution. For the study area, over 160 priority waterbodies/segments were listed by Florida Department of Environmental Protection. Using basin names designated in the annual Florida Department of Environmental Protection 305(b) reports (prepared for the U.S. Environmental Protection Agency pursuant to Section 305(b) of the Federal CWA), the approximate number of priority listings by basin were as follows.

- Kissimmee River Basin (29)
- Lake Okeechobee (12)
- Caloosahatchee River Basin (11)
- Everglades-West Coast or Big Cypress Basin (14)
- Southeast Florida Basin (95)
- Florida Keys (0)

Lake Okeechobee is at the center of the south Florida drainage system, receiving flow from the Kissimmee River Basin, and to a lesser extent from Everglades Agricultural Area backpumping. It discharges east through the C-44 Canal into the St. Lucie River Estuary, west through the Caloosahatchee River via the C-43 Canal, and south through four major canals into the Water Conservation

Areas. The Lake may be considered an historically nutrient rich water body that is becoming hypereutrophic, due primarily to nutrient inputs from the Kissimmee River and the Taylor Creek/Nubbin Slough Basins. Water quality conditions in the upper Kissimmee River appear to be improving, primarily due to re-routing of wastewater flows from the river to reuse and ground-water discharge sites. However, large quantities of nutrients are still discharged from Lake Tohopekaliga to Lake Kissimmee and other downstream areas. Water quality improves from Lake Kissimmee to near Lake Okeechobee, where the channel flows mostly through unimproved rangeland; however, pollutant loadings significantly increase as cattle and dairies grow more numerous Lake Okeechobee. The lake's total phosphorus levels have doubled in the last 20 years, due in large part to agricultural runoff. This same runoff also has contributed to frequent and widespread algal blooms and at least one major fish kill.

Even with the extensive pollutant abatement programs implemented in Lake Okeechobee watersheds during the past 15 years (i.e., reduction of Everglades Agricultural Area backpumping, dairy buyouts, the Florida Department of Environmental Protection Dairy Rule, the South Florida Water Management District Works of the District Regulatory Program), recent lake water nutrient concentrations and loads show no substantive signs of improvement. Further, because the lake's phosphorus is internally recycled, and a vast reservoir of the nutrient is stored in lake sediments as well as the lake's wetlands and watershed canal sediments, phosphorus levels in lake waters may not reach acceptable levels for many decades.

The Caloosahatchee River forms the major basin to the west of the lake. Water quality conditions are degraded in the upper and lower areas of the basin, due to agricultural and urban runoff, respectively. The channelized section of the river also shows degraded water quality conditions, due to agricultural inputs, as compared to tributaries lying in less developed areas of the basin. Problems associated with the degraded areas of the basin are typified by low dissolved oxygen levels, elevated conductivity, and decreased biodiversity. Conditions in the urbanized sections of the basin are influenced by nonpoint storm water flows, and are manifested in the river by elevated chlorophyll levels, algal blooms, periodic fish kills, and low dissolved oxygen levels.

Extensive agricultural Best Management Practices have been implemented in the Everglades Agricultural Area in the past several years which have reduced the phosphorus load leaving the Everglades Agricultural Area; however, this area remains a primary source of pollutants for the Water Conservation Areas. The Water Conservation Areas are the remaining wetlands in the northern section of the Everglades system. These areas have been isolated from contiguous lands by a series of levees and pump stations. Water moving south from Lake Okeechobee and the Everglades Agricultural Area is pumped into the Water Conservation Areas canals, effectively making these areas act as nutrient filters. The highly altered hydroperiod, resulting from the levees and pump operations, may exacerbate water quality conditions in the Water Conservation Areas, as evidenced by a general degradation of water quality in the areas along the canals and adjacent to pump stations, as compared to conditions in the central portions of the basins. Construction of the Stormwater Treatment Areas upstream of the Water Conservation Areas is expected to improve water quality conditions in the Water Conservation Areas through time.

Water quality conditions in the Upper East Coast are generally good in less developed areas of the basin. However, conditions are degraded in urbanized areas and along the extensive network of canals that drain this area. The worst water quality conditions in the basin are reported in the St. Lucie River and the canals leading from the Everglades Agricultural Area. Other major problem areas are found in Five-Mile and Ten-Mile Creeks (in the areas near Port St. Lucie), the main channel of North Fork in Port St. Lucie, and Manatee Pocket (a small embayment on the St. Lucie Estuary). Although the Savannas State Preserve, a 15-mile-long freshwater marsh between Ft. Pierce and Stuart, has fairly good water quality, mercury concentrations in fish tissue were high enough to warrant a no-consumption advisory for largemouth bass. The major sources of pollution in this basin are urban runoff, agricultural and rangeland runoff, boat discharges, and sewage overflows.

Waterbodies in the Lower East Coast Region are seriously degraded in the heavily urbanized areas, including the numerous man-made canals associated with the coast and drainage canals. For example, water quality in Lake Worth is good near the inlet and fair to good north of the inlet, but poorer to the south, especially in the area between the inlet and the West Palm Beach Canal (C-51 Canal). Water quality in Lake Worth improves again near the South Lake Worth Inlet. A small section of the North Fork of the Loxahatchee River has low dissolved oxygen levels, and in the last decade, seagrass beds in the estuarine portion of the Loxahatchee River have declined dramatically. Canals and waterbodies in and around Ft. Lauderdale are particularly degraded by urban runoff and historical wastewater treatment discharges, and by agricultural runoff in the westernmost areas on the canals. Problems associated with these pollutants are manifested by the dense growth of undesirable aquatic vegetation, low overall biological diversity, and the occurrence of exotic plants and animals. The New River and Miami River run through highly urbanized areas of Ft. Lauderdale and Miami, respectively. Both are polluted by improperly functioning septic tanks, discharges from vessels, industrial activities, improper sewer connections, and storm water runoff. These discharges result in high nutrient concentrations, high coliform bacteria counts, and high concentrations of heavy metals such as tin, copper, zinc, and chromium in sediments at all marina sites. Biscayne Bay has good water quality in the open water areas of its central and southern portions, and degraded conditions in its northern portion north of the Miami River.

In the central Everglades, phosphorus concentrations entering the Everglades National Park were lower in 1997 (Walker, 1998: internet) than the interim and long term limits established by the 1992 Settlement Agreement. While no significant trends in annual average mercury concentrations in water, sediment, or fish have been observed for the past five years, mercury concentrations in fish tissue were high enough to warrant a no-consumption advisory for largemouth bass throughout most of the eastern two thirds of the Everglades National Park, and a recommendation of limited consumption for the southeast corner of the Park. The best water quality conditions in the Everglades National Park were found in the central Shark River Slough and along the coastal regions of the basin.

Some parts of Florida Bay have experienced a massive seagrass and mangrove die-off during the late 1980's and early 1990's that likely stems from a lack of circulation, high water temperatures, and increased levels of salinity. Water diverted into the Lower East Coast primary canal network has reduced freshwater flows, and the salinity of bay water has been recorded as high as 70 parts per thousand. The 1997 Everglades Annual Report states that for 1997, the highest observed salinity levels occurred in Whipray Basin, and ranged from 40.6 parts per thousand to 42.3 parts per thousand (water conditions in the bay are considered hypersaline when salinity exceeds 35 parts per thousand). Hypersaline conditions were observed throughout most of the western portion of the bay during the dry season; however, they decreased below hypersaline levels once freshwater inputs increased in June 1997.

Water quality conditions in the Keys are generally good in areas open to the Atlantic or Gulf. However, many nearshore areas, man-made canals and marinas have water-quality problems that are exacerbated by poor circulation. Most of these problems are localized and generally can be attributed to wastewater plants and small “package plants” discharging to poorly flushed canals; septic tanks and cesspools; marinas lacking facilities to pump out waste from boats; fish processors; and storm water runoff, especially into the canals.

3.9.2 Groundwater Conditions

Ground water in south Florida consists of the surficial Biscayne Aquifer and the Floridan Aquifer. Both are critical to the ecology and economy of south Florida. The Biscayne Aquifer has been classified as a Sole Source Aquifer under the Federal Safe Drinking Water Act based on the aquifer’s susceptibility to contamination and the fact that it is a principal source of drinking water. The Floridan Aquifer system is one of the most productive aquifers in the world and is a multiple-use aquifer system. Where it contains freshwater, it is the principal source of water supply. In several places where the Floridan Aquifer contains saltwater, such as along the southeastern coast of Florida, treated sewage and industrial wastes are injected into it.

Because the Biscayne Aquifer is highly permeable and is at or near the land surface in many locations, it is readily susceptible to groundwater contamination. Major sources of contamination are saltwater intrusion and infiltration of contaminants carried in canal water. Additional sources include direct infiltration of contaminants, such as chemicals or pesticides applied to or spilled on the land, or fertilizer carried in surface runoff; leachate from landfills, septic tanks, sewage-plant treatment ponds; and wells used to dispose of storm water runoff or industrial waste.

Numerous hazardous waste sites (e.g., Superfund and Resource Conservation and Recovery Act (RCRA) sites) have been identified in the area underlain by the Biscayne Aquifer. Remedial action to clean up existing contamination is underway at many of these sites. Waste management practices are generally monitored to prevent further contamination. Additional information on groundwater conditions and contamination in south Florida is presented in ***Appendix H and K***, including specific Superfund (National Priority List: NPL) and RCRA hazardous waste sites in south Florida. Trichloroethylene (TCE) and vinyl chloride are examples of ground-water contaminants of concern.

3.10 WATER SUPPLY

One of the primary functions of the C&SF Project is to provide a highly-efficient flood control system designed to keep urban and agricultural areas dry in the wet season by discharging excess water to tide or into the Water Conservation Areas and Everglades National Park. Rapid wet season flood releases, coupled with the lack of retention in Lake Okeechobee, the reduced area of northern historical sawgrass plains, and loss of the eastern peripheral wetlands and sloughs, have severely reduced storage within the system causing excessive dry season demands on the regional system. The sawgrass plains, for example, once stored and slowly passed on much of the water that overflowed from Lake Okeechobee. Today, a large portion of the sawgrass plains habitat that was converted to agriculture within the Everglades Agricultural Area quickly passes excess runoff to the Water Conservation Areas and the coast during the wet season. Releases of Lake Okeechobee water are then periodically necessary to meet dry season demands. The reduction of storage over multiple years, not the lack of water, is a problem.

Minimum stages are maintained in Lower East Coast canals, principally to provide the volume of water needed to protect the Biscayne Aquifer from saltwater intrusion, a major threat to this water resource. The head created in the canals raises groundwater levels, recharging the aquifer and the urban wellfields. During the wet season, wellfields are recharged by local rainfall and by the regional system that provides ongoing seepage from the Water Conservation Areas and the canals. During the dry season, they are more dependent on the regional system. Unfortunately, during the wet season, "excess" storm water is passed through the canals and out to tide, when it should be stored and used during the next dry season. Without sufficient storage, it has been difficult to have water available during the dry season without causing flooding during the wet season.

Water users within the urban areas argue that the Lower East Coast is largely self-sufficient and efficient because the groundwater seeping through the Lower East Coast would eventually reach coastal waters were it not withdrawn by the utilities. The South Florida Water Management Model illustrates how this works. As demands increase, the volume of water that reaches coastal waters decreases. In the South Florida Water Management Model, at Snake Creek, north of Miami, 121,000 acre-feet of water were lost through groundwater seepage during the wet season in the 1995 base. That amount decreased to 114,000 acre-feet in the 2050 base as urban water supply demand increased. In the Miami River, in the 1995 base, over 192,000 acre-feet were unrecoverable (wet and dry season total). In the 2050 base, only 121,000 acre-feet were unrecoverable.

Others argue that the urban area is far from self-sufficient. The pattern described above occurs during wet seasons and during normal rainfall years. During extremely dry years, no water reaches the coast and the urban wellfields depend heavily on deliveries from the Water Conservation Areas (including the ongoing seepage from these areas) and Lake Okeechobee via the primary canals for water supplies. Even during normal dry seasons when flood releases are minimal, the high demands on the system from urban water supply may be withdrawing water from the natural environment that should be kept in the system for late winter and spring biological rejuvenation. In addition, during drought years, the urban and agricultural areas create additional demands as the need for irrigation increases. Also, a significant percentage of water consumed is used for landscape maintenance, primarily watering lawns from shallow wells.

Another concern is that, at present, the flow of water along the eastern protective levee is from the wetlands to the coast. Keeping the water levels high west of the Atlantic Coastal Ridge, and keeping levels low to the east of it, results in large groundwater losses from the remnant Everglades throughout the year. This situation has also reduced the coastal groundwater flows into estuaries like Biscayne Bay and has made it necessary to import regional water to the Lower East Coast to maintain adequate coastal groundwater levels to prevent saltwater intrusion.

Due to efficiency in application, the amount of water needed to recharge urban wellfields is small compared to the tremendous volumes needed to prevent saltwater intrusion. Preventing saltwater intrusion is important for several reasons. For example, if significant saltwater intrusion occurred even once, the easternmost wellfields would be contaminated indefinitely and would be replaced with wells further west. This situation has already occurred in Metro-Miami-Dade County.

Although significant, the amount of water needed to prevent saltwater intrusion is much less than the wet season coastal releases. It is possible that those flows alone, if captured and stored, would be more than sufficient to maintain the dry season salinity barriers without the need to take water from the natural system. Also, storing coastal outflows in the lower east coast region and maintaining higher groundwater levels along the coastal ridge would allow large quantities of regional water to remain in the C&SF system and to be used for dry-season environmental benefits.

Within the Lower East Coast, there are also ecological benefits in maintaining groundwater levels. Lower groundwater levels can and have caused serious negative effects on estuaries and coastal and freshwater wetlands. Biscayne Bay for example, has suffered the consequences of both ground and surface water losses, including increased salinity, lower visibility, and lower water quality. In Miami-Dade, Broward and Palm Beach Counties, lowered groundwater levels have caused wetland desiccation and produced shifts in vegetation types.

3.11 SOCIO-ECONOMICS

Florida's economy is characterized by strong wholesale and retail trade, government and service sectors. The economy of south Florida is based on services, agriculture, and tourism. Florida's warm weather and extensive coastline attract vacationers and other visitors and help to make the state a significant retirement destination for people from all over the country.

The 16 south Florida counties that make up the study area had a 1990 population of 6.3 million, accounting for nearly half (about 49 percent) of Florida's total. This share has changed very little over the past 20 years and recent U.S Department of Commerce projections predict it will remain stable over the next 50 years. Over 60 percent of this south Florida population is in the three Lower East Coast Counties of Palm Beach, Broward, and Miami-Dade. The study area population is expected to reach over 11 million by 2050, with the Lower East Coast population expected to reach over 6.9 million by then.

Slightly over half of Florida's employment and earnings takes place in the study area. Nearly two thirds of this is concentrated in the populous Lower East Coast three-county area. Excluding the northernmost counties of Polk, Orange, and Osceola, which are technically part of the study area, but which are outside the main focus of the Restudy, the tri-county Lower East Coast area accounts for about 80 percent of the regional aggregate socio-economic activity with in the study area.

Employment and income in the south Florida study area have continued to grow in recent decades faster than the national average. Growth, though slower than that of the Lower East Coast, has been significantly greater in the southwest counties and the Florida Keys (taken as a group--Monroe, Collier, Hendry, Lee, and Charlotte), and in the Counties around Lake Okeechobee (Glades, Highlands, Martin, Okeechobee, and St. Lucie) than in the northernmost counties of the study area.

3.12 LAND USE

The existing use of land within the study boundaries varies widely from agriculture to high-density multi-family and industrial urban uses. A large portion of south Florida remains natural, although much of it is disturbed land. The dominant natural features are the federally protected Everglades National Park, Biscayne National Park, and Big Cypress National Preserve at the southernmost tip of the peninsula, Lake Okeechobee, Biscayne Bay, the state protected Water Conservation Areas in the westernmost reaches of the Lower East Coast counties, and remnant freshwater and coastal wetland and upland systems within and adjacent to the developed areas along the coasts. Generally, urban development is concentrated along the lower east coast from Palm Beach County to Miami-Dade County, in the central Florida / Orlando area, and on the Lower West Coast from Fort Myers to Naples.

Most of the interior of the study area is in agricultural use, which includes sugarcane (the dominant crop) and vegetable farms in the Everglades Agricultural Area of western Palm Beach County and Hendry County; the Agricultural Reserve Area of Palm Beach County; and the south Miami-Dade agricultural area where vegetable crops dominate, especially tropical varieties. There are citrus groves in every county, but citrus is concentrated in St. Lucie and Martin counties on the east coast and Hendry, Highlands, Collier, and Glades Counties on the west. Cattle and dairy farms predominate in Glades, Highlands, and Okeechobee Counties.

In the northern portion of the system, around Orlando, tourism and its attendant service-oriented land uses (for example, hotels/ motels, convenience stores, souvenir shops) make up a significant portion of the landscape. Agriculture, however, continues to play an important role in the region, with over two million acres being farmed, half of which is pastureland. The area surrounding Lake Okeechobee, is largely rural, with agriculture the prevailing land use. There are over 700,000 acres of irrigated farm land in the Everglades Agricultural Area south of the lake. Farm products produced there include sugarcane, the predominant crop, rice, row crops, and sod. There is also extensive pastureland both west and north of the lake. Directly south of the Everglades Agricultural Area lie the Water Conservation Areas. The Water Conservation Areas cover about 878,080 acres and consist mainly of sawgrass marshes and tree islands. The Water Conservation Areas were created by the 1948 C&SF Project for the conservation of water supplies for the Lower East Coast.

The Upper East Coast includes St. Lucie and Martin Counties; the landscape is dominated by agricultural uses. Significant natural resources, the St. Lucie Estuary and Indian River Lagoon, are also contained within this area. Urban land use, which makes up 17 percent of the Upper East Coast, is mainly concentrated along the seaboard coastal and lagoon shorelines. The Lower East Coast extends approximately 100 miles through the coastal portions of Palm Beach, Broward, and Miami-Dade Counties. As the most densely populated subregion in the state, the Lower East Coast is home to one third of the state's population, more than 4.5 million people. The subregion is primarily an urban megalopolis, but it also contains substantial agricultural acreage, particularly in southwestern Miami-Dade County (90,000 acres) and western Palm Beach County (29,000 acres). Rapid population growth and land development practices have resulted in notable western urban sprawl; the predominant land use is single-family residential. The once significant rural population in the western areas of Broward County has practically disappeared, resulting in an urbanized makeup in population. Miami-Dade and Palm Beach Counties are not far behind.

The Florida Keys are made up of over 1,700 islands that encompass approximately 100 square miles, and contains the largest coral reef system in the United States. While a majority of Monroe County is designated as conservation land, due to the land falling within either Everglades National Park, the Big Cypress National Preserve, or the National Key Deer Refuge, land use is primarily either residential or geared towards supporting the region's main industry (tourism). Monroe County's fragile natural resources and vulnerability caused the State of Florida to designate the area as an Area of Critical State Concern in 1975; such designation is intended to protect such resources from degradation by strictly regulating development.

The southwestern counties of Collier and Lee are the fastest growing in terms of population in the state. Population growth is mainly due to the in-migration of retirees, not a high birthrate. The coast has become highly urbanized, with development spreading eastward into agricultural and natural lands. Agriculture is however, a major industry, especially in Lee County where citrus predominates.

The Big Cypress Basin, which encompasses a large, relatively pristine natural area, is threatened by a rapidly growing human population and advancing agricultural development, particularly from the north in Hendry County.

3.13 RECREATION RESOURCES

Recreation opportunities abound in the study area. Central and south Florida is rich in water resources, with easy access to fresh, estuarine and marine resources for fishing, boating, swimming, diving, camping, and sightseeing. Within the upper basin of the Kissimmee River region are dozens of freshwater lakes, popular for boating and fishing. Marinas, fishcamps, and public facilities (boat launching, picnicking, bank fishing) are located around many lakes in the region. Thirty-six miles of the Florida Scenic Trail were designated in June 1990 with additional trail section designations to follow. Lake Kissimmee State Park, Three Lakes, Kissimmee River and Kicco Wildlife Management Areas, and Prairie Lakes Preserve provide upland and water based recreation resources for the region.

Lake Okeechobee is the second largest freshwater lake within the continental United States and is a nationally recognized bass and pan fishing resource. Thousands of "snow birds" flock to the shores of Lake Okeechobee where they spend winter months fishing and enjoying the south Florida weather. The Lake offers other recreational amenities as well. Air boat and swamp buggy rides, bike riding, hiking, picnicking, camping, and nature interpretation are popular land based recreation activities in the region.

The urbanized east coast includes good quality marine based recreation activities such as underwater diving, salt water and estuary fishing, boating, surfing and, of course, the beach. County and state parks, scenic rivers, state reserves and forests, and Federal refuges provide wildlife viewing, nature interpretation, hiking, and canoeing opportunities. The Atlantic Intracoastal Waterway provides a diverse water-based recreation resource opportunity in the region. The Loxahatchee National Wild and Scenic River, Indian River Lagoon, DuPuis Reserve State Forest, J.W. Corbett Wildlife Management Area, and the Loxahatchee River – Lake Worth Creek Aquatic Preserve provide high quality recreation opportunities for boating, fishing, and nature interpretation activities within the coastal region.

Recreation resources in the Water Conservation Area region are inland water and upland resources that include the Arthur R. Marshall Loxahatchee National Wildlife Refuge Rotenberger and Holey Land Wildlife Management Areas, and (FDEP, 1994). These areas provide high quality boating, fishing, and nature interpretation activities. The Miccosukee State Indian Reservation is within the Water Conservation Area region boundary. Hunting, boating, and fishing occur within the reservation. Fishing, hunting, boating and airboating are popular activities within the Water Conservation Areas. North of the Water Conservation Areas, in the Everglades Agriculture Area, there is the CREW Wildlife and Environmental Area and the Lake Harbor Public Waterfowl Area. The L-29 Borrow Canal which divides Water Conservation Area 3 from Everglades National Park is a popular fishing destination for residents of the Lower East Coast region. The L-67A and L-67C Canals are sport fishery resources of state-wide importance and support several bass fishing tournaments throughout the year.

Biscayne Bay offers among the highest quality recreation opportunities within the study area including fishing, shellfishing, sailing, motorboating, swimming, snorkeling, and canoeing. Biscayne National Park provides opportunities for birdwatching, recreational hiking, boating, fishing, snorkeling, diving and picnicking.

Everglades National Park and Florida Bay offer unique and diverse opportunities for a variety of natural resource and wilderness based recreational activities. Day use and camping (front and backcountry) facilities are available throughout the Park. There are over 150 miles of walking and canoe trails, including 2 miles of elevated boardwalk trails and three campgrounds with over 420 campsites and an additional 48 backcountry campsites in the Park. Recreation activities include: hiking, boating and canoeing, fishing, bird and wildlife viewing, and guided interpretive tours.

Everglades National Park has been designated a World Heritage Site, and International Biosphere Reserve, and a Wetland of International Significance. In addition, 86% of the Park is designated Wilderness under the Wilderness Act of 1964. The State of Florida has designated the Park an Outstanding Florida Water.

Diverse ecosystems from sawgrass prairie to pinelands and hammocks to the estuarine environment of Florida Bay area easily accessible from the main park road or the Shark Valley tram road. The main park road ends at Flamingo, a former fishing village, and a main port of entry to Florida Bay, where a variety of self-guided, concession or ranger led walks and boat tours are available. U.S. 29 leads to Everglades City and the Gulf Coast Visitor Center where the island-bay-mangrove ecosystems of the 99 mile Wilderness Waterway and Chokoloskee Bay, Turner River, and the Ten Thousand Islands area can be accessed. Chekika, a former state park, offers a slightly different experience with opportunities for a soak in a sulfur pool as well as for picnicking and hiking. Nearby is the Southern Glades Wildlife and Environmental Area which is managed by the Florida Game and Freshwater Fish Commission.

The Florida Keys, are world renowned as diving and sportfishing destinations. Boating, fishing, diving, and nature interpretation are some of the many recreation opportunities in the region. Five wildlife refuges are located in the region and one of the busiest parks in the state. Several state parks are also within the region including John Pennekamp Coral Reef State Park, Key Largo National Marine Sanctuary, designates for the protection of the delicate reefs outside of Pennekamp, which is also a popular diving destination. Diving is the most popular recreation activity followed by fishing, and bird watching.

The Big Cypress region provides a unique wilderness area where recreation is primarily wetland based with some upland access and facility use. Air boating, fishing, hunting, and nature interpretation are all very popular recreation activities in the region. Camping facilities are also found within the region. Five state parks and recreation areas are located in the region as is a state preserve, the Panther National Wildlife Refuge, and National Audubon Society's Corkscrew Swamp Sanctuary.

The Caloosahatchee River provides approximately 67 miles of navigable waterway with ten Corps recreation facilities that include boating, fishing, picnicking, and camping. The J.N. “Ding” Darling National Wildlife Refuge, a popular birding area, administers Caloosahatchee National Wildlife Refuge, Matlacha Pass National Wildlife Refuge, Island Bay National Wilderness area and Pine Island National Wildlife Refuge, all located near the region’s western edge. In Charlotte county there is the Fred C. Babcock/Cecil M. Webb Wildlife Management Area. Boca Grande Pass is world renowned for record tarpon, Sanibel Island is reported among the top shelling destinations in the Western Hemisphere,

3.14 AESTHETICS

The visual characteristics of the central and south Florida region can be roughly described for the dominant three land use categories (natural areas, such as those areas within the Everglades Protection Area, agricultural lands, and urban areas). Regional aesthetics depends in a large part on one's personal perspective. Where one lives, spends recreational time, makes a living, and who one perceives oneself to be, contributes to a personal perspective and opinion of what is aesthetically pleasing, and what is not.

Very briefly, the natural areas are composed of a variety of upland and wetland based ecosystems including lakes, sloughs, ponds, and vast expanses of marsh and wet prairie with varying vegetative components. Uplands are often dominated by pine, although other sub-tropical and tropical hardwoods such as fig, gumbo limbo, and cypress occur within their ecotone. Overall the land is remarkably flat, with few natural topographic rises such as hills or other geographic undulations. Much of the visible topographic features are man-made, including ubiquitous canals and levees. Additional man-made features of the landscape include pump stations, navigation locks, secondary and primary roads, highways, electrical wires, communication towers, occasional buildings (some abandoned), borrow pits and other features which may or may not detract from the regional aesthetic. Views, when possible from a high perspective such as atop a levee, offer pleasant and unspoiled perspectives on Everglades marsh, often dotted with tree islands, and numerous birds and other wildlife.

One of the most prominent levees in the C&SF Project system is the Herbert Hoover Dike, over 140 miles of levee surrounding Lake Okeechobee. The impact of this levee on the lake's regional aesthetics has been permanent and profound. What is otherwise a scenic and immense natural water body with a profusion of wildlife along the shoreline, is nearly invisible to the casual observer because the Herbert Hoover Dike effectively blocks one's view. This is an example of the types of aesthetic impacts to key regional and local natural resources that the Restudy must strive to avoid.

Other key natural areas of particularly high aesthetic quality include among others, the Loxahatchee Slough, large areas of the Big Cypress National Preserve, the interior of some of the Water Conservation Areas, Loxahatchee National Wildlife Refuge, the Ten Thousand Islands, Everglades National Park, Florida Bay, and Biscayne Bay. The Florida Keys and the coral reef tract provide important aesthetic qualities to the state as well as some of the most significant underwater aesthetics in the world.

Agricultural lands occur throughout the system outside of the Everglades Protection Area. They are comprised largely of open pastureland north of Lake Okeechobee, in the Caloosahatchee region and northern Big Cypress region, where dairy and beef cattle operations predominate. The Kissimmee River region, for instance, is primarily pasture, with patchy natural areas, that function to retain water for the regional system. The Lower Basin of the Kissimmee River region is largely undeveloped and presents a panoramic landscape largely untouched by mankind for miles. The C-38 Canal is straight and wide and in the process of being "restored". Project earth moving equipment, as well Avon Park Bombing Range aircraft, break the panoramic scenery and detract from the otherwise high visual quality.

In the Everglades Agriculture Area, sugarcane production, and to a lesser extent sod, vegetables and rice lend a uniform and organized appearance to the landscape, largely devoid of trees and other non-agricultural vegetation. The view is rather monotonous and of marginal value. Agriculture in the Upper East Coast and in South Miami-Dade County is somewhat less intensive than the Everglades Agriculture Area and so a more traditional agricultural landscape, with more diverse crops such as citrus and a variety of tropical trees, shrubs and landscape plants predominates. Both the natural areas described above, and the agricultural areas are relatively open, with low population density, few buildings and other structures interspersed across the landscape, and are generally quiet.

The urban areas, other than the scattered small to medium sized municipalities characteristic of the interior regions, occur mostly along the highly urbanized east coast. This includes such sprawling, mostly low level cityscapes as Stuart, Fort Pierce, West Palm Beach, Boca Raton, Pompano Beach, and nearby urban areas. Fort Lauderdale and Miami and their surrounding suburban areas epitomize the highly urbanized scene described above, only with significant high rise buildings in the downtown area nearest the coast or on nearby barrier islands. These cities are visually congested with immense residential areas, composed mostly of one or two story buildings, well-trafficked roads, seemingly endless impervious surfaces, parking lots, strip malls, high rise hotels, and industrial and commercial enterprise. The urbanized east coast begins more or less at the Florida Turnpike, and extends eastward to the coast. It includes intensively developed residential communities, highways and heavily used roads, and other development immediately adjacent or nearby to protected natural areas or agricultural lands. Visual aesthetics are marginal except in areas where urban landscaping assumes a high priority.

Along the coast, the Atlantic Ocean and Atlantic Intracoastal Waterway shorelines provide panoramic aesthetic views from many locations. White shoreline sand contrasts sharply with blue and green waters of the ocean and Atlantic Intracoastal Waterway in the region. High-rise structures, often hotels to serve the tourist industry, restrict visual access to the ocean's panoramic scenery and tend to diminish the visual experience from the shoreline. Visual access to the scenic Atlantic Intracoastal Waterway is also limited.

3.15 CULTURAL RESOURCES

The earliest widely accepted date of occupation of Florida is around 12,000 years ago. This earliest cultural period is termed the Paleo-Indian stage and lasted until about 7500 B.C.

The Archaic stage (ca. 7500 B.C. - ca. 500 B.C.) is thought to be a reflection of man's adaptation to the changing environment at the start of the Holocene, when our basically modern climate and biota were established. Foraging and hunting are the main subsistence activities throughout the Archaic stage, with Late Archaic people exploiting a larger territory and wider range of aquatic and terrestrial food resources.

In the Okeechobee Basin, the Belle Glades culture sequence (ca. 500 B.C. - A.D. 1500) is subdivided into four periods based on ceramic and other material remains. A complex political system practiced by the Calusa was recorded in the late Belle Glades sequence. Objects of Spanish origin obtained from European contact or shipwreck salvage have been recovered from sites dating to the late periods of the Belle Glades.

The Caloosahatchee River is often identified as a separate cultural area. During the pre-Columbian period the river likely served as a vital transportation route to the Okeechobee Basin and the Glade culture areas. Large shell mound and shell midden sites characterize the Caloosahatchee coastal area. Sand burial mounds and shell and earth middens are typically found inland along the river. Smaller dirt middens are found on interior hammocks near freshwater marshes.

During the early historical period, beginning with the first Spanish colonial period (1513 - 1763), European contacts were limited to the coastal areas. It is estimated that approximately 10,000 Calusas inhabited southern Florida prior to contact with Europeans. The Calusas were hunters and gatherers concentrated primarily in coastal areas, subsisting by fishing, collecting shellfish, and gathering wild plants for food.

Interaction between Spanish and French explorers and the Calusas occurred during the 16th century. The European settlers attempted to convert the Native Americans to Christianity and alter their social structure. The Spanish retreated from Florida in the 1570's, leaving the Calusas undisturbed during the 1600's. Approximately 6,000 Calusas remained, but disease and occasional European invaders continued to reduce the population.

The Miccosukees are descendants of the Hitchiti-speaking Lower Creeks, and the Seminoles of the Muskogee-speaking Upper Creeks. These groups migrated to Florida in the 18th and 19th centuries from Georgia and Alabama. Then as now, the ethnic distinction between the Miccosukees and Seminoles stems mainly from a difference in language.

By the early 1800's, the migrant Native American population of Florida had grown to about 5,000. Miccosukee and Seminole Indians settled primarily in Northern Florida originally. Removal and relocation of many Indians to reservations west of the Mississippi River occurred as a result of the Seminole Wars of the 1800's and the Indian Removal Act of 1830. Following the United States government policy of Indian removal, the remaining Miccosukees and Seminoles moved farther south and established themselves in the Everglades, Big Cypress Swamp, and the Ten Thousand Islands. Most of the people lived on upland tree islands (hammocks), and used dugout canoes for transportation, hunting, and trading. Dwellings, called chickees, were constructed of cypress logs and palm fronds. The traditional lifestyle endured for the remainder of the century and still endures to a certain extent.

The first efforts to drain and reclaim the Everglades began in 1881. Agriculture began in the Everglades, south of Lake Okeechobee, after drainage projects of the 1906-1927 era. During this period, the first settlements, Okeelanta and Glade Crest were established just south of the lake. By 1921, there were 16 settlements on or near Lake Okeechobee, with a total estimated population of 2,000. Settlement and agricultural activities escalated during the subsequent decades.

By the early 20th century, hundreds of sport and commercial hunters were exploiting the Everglades resources. The opening of Tamiami Trail in 1928 ensured easy access for hunters and trappers to the southern Everglades. Permanent homes were rare, and the isolation and harsh environment compelled people to be self-reliant. Although soils in the area were fertile, it was the exploitation of fishery resources, along with animals and birds for skin and feathers, which was most economically important.

3.16 HAZARDOUS, TOXIC AND RADIOACTIVE WASTE

A preliminary Phase I Hazardous, Toxic and Radioactive Waste (HTRW) assessment was conducted in August 1998 to address the existence of potential for occurrence of HTRW on lands, including structures and submerged lands, in the study area. The assessment included a project review, review of site literature and Alternative D-13R project features, database search, review of available records and aerial photography, site inspections and interviews. The following potential indicators were looked for: landfills, dumps, disposal areas, aboveground and underground storage tanks, vats, containers of unidentified substances, spills, seepage, slicks, odors, dead or stressed vegetation, water treatment plants, wells, ditches, abandoned buildings, and transport areas (such as boat yards, harbors, rail yards, airports, truck terminals, and fueling stations).

The assessment covered all Restudy regions, within the general vicinity of proposed project features or existing features proposed for significant modification. Several site visits were conducted over the past few years, with the most recent field survey having been performed during the week of 10-14 August 1998. The project conditions assume that any HTRW found during any phase of the project would be remediated in accordance with local, state and Federal laws. The results of the Phase I assessment and data base search are included in ***Section 8*** and ***Appendix K***.

SECTION 4
FUTURE "WITHOUT PLAN" CONDITION

This section provides a definition as to what is meant by the future "without plan" condition and how and why it is developed. In the context of the Restudy, the term "plan" refers to alternative comprehensive plans and not to the existing C&SF Project (although Project modifications will be important parts of the alternative plans).

4.1 "WITH AND WITHOUT" COMPARISONS

The U.S. Water Resources Council's *Principles and Guidelines* provides the instructions and rules for Federal water resources planning (USWRC, 1983). One *Principles and Guidelines* requirement is to evaluate the effects of alternative plans based on a comparison of the most likely future conditions with and without those plans. In order to make this kind of comparison, descriptions - often called forecasts - must be developed for two different future conditions: the future without plan condition, and the future with-plan condition.

The future without plan condition describes what is assumed to be in place if none of a study's alternative plans are implemented. The without-plan condition is the same as the alternative of "no action" that is required to be considered by the Federal regulations implementing the *National Environmental Policy Act of 1969 (NEPA).*

Future "with plan" conditions describe what is expected to occur as a result of implementing each alternative plan that is being considered in a study. With plan conditions are developed for each alternative plan; therefore, there are as many with plan conditions as there are alternative plans.

The differences between the "without plan" condition and the "with plan" condition are the effects or impacts of the plan. Note that the plan referred to in this context is any one of the alternative plans that have been considered in the Restudy. The formulation of alternative plans is described fully in ***Section 7*.**

4.1.1 "With-and-Without" Versus "Before-and-After"

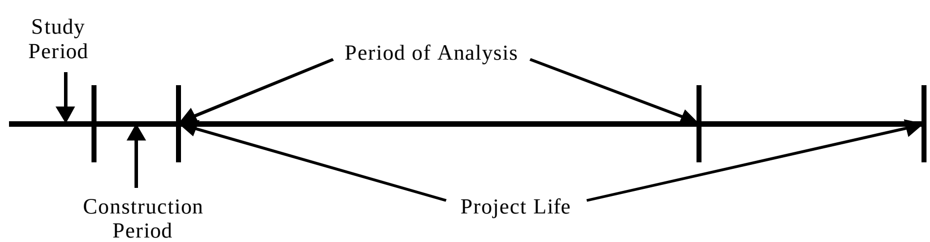
Many people typically think about the effects of alternative plans in terms of "before and after"; that is, they compare the condition that exists now, before it is changed by a plan, to the condition they expect to exist in the future after it has been changed by a plan. For example, if a proposed levee were to cover four acres of an existing 10-acre wildlife habitat, then, using a before-and-after comparison, the levee could be said to result in a loss of four acres of that habitat.

Another way to think about effects is to compare the conditions that are expected to exist in the future if no alternative plan is implemented, the without plan condition, to the conditions that are expected to exist in the future if a particular plan is implemented. Returning to the example, let's say that the 10-acre wildlife habitat is already included in a residential development plan that would convert three of its acres to residential sites. Now suppose that a proposed levee would cover four acres of the 10-acre site, including the same three acres that would be converted to residential sites. Using a “with-and-without” comparison, the levee would be said to result in a loss of only one acre since three of the four acres would be affected even if the levee were never constructed. With-and-without comparison recognizes that the future is often different from the existing condition; and, unlike before-and-after comparisons, accounts for future changes in the comparison.

4.2 PLANNING HORIZON

The planning horizon encompasses the feasibility study period, the construction period, the economic analysis period, and the effective life of the project. How long a time period should be used when forecasting future without-project and with-project conditions, and considering the impacts of alternative plans? This time frame is called the period of economic analysis, and is also known as the period of analysis. It is the period of time over which we think it is important to extend our analysis of plan impacts. This time period is frequently confused with the planning horizon, which is a longer and more encompassing concept. ***Figure 4-1*** shows that the period of analysis is part of the planning horizon.

Figure 4-1: Planning Horizon



The period of analysis for water resources projects is usually 50 years and never over 100 years. Forecasting conditions and impacts beyond 100 years is pure guessing, even if some structural projects may last more than 100 years.

If significant impacts do not last 50 years, the period of analysis should be restricted to the duration of the significant impacts. One of the most common measures of impacts has to do with the time value of money. Future dollar values, whether benefits or costs, are worth less than current dollar values. Discounting is the process used to place dollar values incurred at different times on an equivalent time basis. After 50 years, the discount factor alone reduces monetary values to a mere fraction of their former value. Unless the future dollar values being discounted are large there is no apparent point to continue to include these values among project impacts. Therefore, the period of economic analysis for the purposes of this study will be 50 years.

4.3 CLIMATE

The hydrologic data used for modeling in this study are based on a 31-year period of record. For the modeling effort, the climatic record from 1965 to 1995, was used for both the existing (1995) condition, and the future (2050) without plan condition. This climatic record is considered appropriate in that it includes wet, dry and average years which are and have been typical of conditions in south Florida. The wet years are considered to be 1969-1970, 1982-1983 and 1994-1995, the dry or drought years are 1971, 1975, 1981, 1985 and 1989 and a typical, average year is 1984. Rainfall and potential evapotranspiration are the key climatic inputs. This same record was used in the evaluation of plan alternatives. For the purpose of this study, it is assumed that the 31-year period of record used for the hydrologic modeling is representative of conditions that are expected to occur in the study area in the future.

4.4 SEA LEVEL RISE

The U.S. Environmental Protection Agency (EPA) completed a study of the probability of sea level rise in 1995 (USEPA, 1995). Some conclusions from this study follow. "Many climatologists believe that increasing atmospheric concentrations of carbon dioxide and other gases released by human activities are warming the Earth by a mechanism commonly known as the 'greenhouse effect". The Earth's average surface temperature has risen approximately 0.6^0 C (1^0 F) in the last century, and the nine warmest years have all occurred since 1980. Global warming is most likely to raise sea level 15 cm (0.48 ft) by the year 2050 and 34 cm (1.09 ft) by the year 2100." The report estimates that "*along most of the U.S. Atlantic and Gulf coasts, there is a 50 percent chance that sea level will rise at least one foot by the year 2050, and two feet by the year 2100.*"

The Environmental Protection Agency published historic rates of sea level rise at various locations in the United States. Those of interest to the study area are shown in ***Table 4-1***. Estimates of sea level rise in future years for specific locations within the study area are shown ***Table 4-2***. These normalized projections estimate the extent to which future sea level rise will exceed what would have happened if current (historic) trends in ***Table 4-1*** simply continued.

TABLE 4-1
HISTORIC RATE OF SEA LEVEL RISE

Atlantic Coast		Gulf Coast	
Mayport, FL	2.2 mm/yr	Key West	2.2 mm/yr
Miami Beach, FL	2.3 mm/yr	St. Petersburg	2.3 mm/yr

Source: Sea Level Variations for the United States1855-1986, National Oceanic and Atmospheric Administration, National Ocean Service, Rockville, MD., Lyles, S.D., Hickman, L. E., Debaugh, H. A., 1987

TABLE 4-2
ESTIMATING SEA LEVEL RISE AT SPECIFIC LOCATION
Normalized Sea Level Projections, Compared with 1990 Levels (cm)

Cumulative Probability	Year 2025	Year 2050	Year 2100
10	-	-	1
20	1	3	10
30	3	6	16
40	4	8	20
50	5	10	25
60	6	13	30
70	8	15	36
80	9	18	44
90	12	23	55
95	14	27	66
97.5	17	31	78
99	19	38	92
Mean	5	11	27
Standard Deviation	6	10	23

To estimate sea level rise at a particular location, the historic sea level rise is added to the projected rise that would occur if current trends were to continue. For example, the historic rate of sea level rise at Miami Beach is 2.3 mm per year (***Table 4-1***). Under current trends, sea level will rise 14 cm between 1990 and 2050. Adding 14 cm to the normalized values in ***Table 4-2***, the median estimate for 2050 is 25 cm, with a one percent chance of a 52 cm rise, and a 50 percent chance that sea level will rise at least 24 cm.

Most coastal areas of the United States are moving vertically as the result of tectonic forces, glacial rebound, the consolidation of sediments, or the extraction of water, gas and oil. Therefore, the evaluation of the impacts of sea level change require the development of sea level projections that are relative to the land motion. Rates of land elevation change for the study area are shown in ***Table 4-3***.

TABLE 4-3
RATES OF LAND ELEVATION CHANGE

	Trend		
Location	mm/yr	cm/yr	ft/yr
Mayport, FL	+1.0	+0.10	+0.0032
Miami Beach, FL	+1.1	+0.11	+0.0035
Key West, FL	+1.0	+0.10	+0.0032
St. Petersburg, FL	+0.8	+0.08	+0.0026

Source: Sea Level Variations for the United States1855-1980, National Oceanic and Atmospheric Administration, National Ocean Service, Rockville, MD., Lyles, S.D., Hickman, L. E. Jr., Debaugh, H. A., 1983

To estimate relative sea level rise at a particular location, the rate of land elevation change is added to the sea level rise that would occur if current trends and future projections were true. For example, at Miami Beach, land elevation change is estimated to be +6.6 cm by the year 2050. Therefore, the median relative sea level rise estimate at Miami Beach for 2050 is 18.4 cm (0.59 ft), with a one percent chance of an 45.4 cm (1.46 ft) relative rise, and a 50 percent chance that sea level will rise at least 17.4 cm (0.56 ft).

To determine the sensitivity of the C&SF Project to sea level rise a modeling scenario was completed for the future without plan condition utilizing a 15 cm rise in sea level so that the impacts of such a change on the performance of the water management system can be assessed. The sea level rise changes the boundary conditions of the South Florida Water Management Model in the Lower East Coast. The South Florida Water Management Model assumptions for the rise are as follows: specific coastal canals were maintained higher, flood control releases were delayed to allow a higher maintenance level, but the water level at which maximum releases were made was not altered, and trigger levels for water supply cutbacks were also raised by 15 cm with the exception of one interior trigger in Palm Beach County. Analysis of this scenario showed that the sea level rise had the most impact on the coastal canals and communities with loss of flood protection and salt water intrusion being the primary impacts. Lower East Coast water supply cutbacks are expected to increase significantly as well as deliveries to Lower East Coast service area. Coastal ecosystems and estuaries were adversely affected and would require additional deliveries of fresh water. The performance measures for the interior of south Florida did not appear to be influenced by the sea level rise. This was probably due to the higher ground elevations than those found along the coast. A detailed description of this modeling scenario can be found in ***Appendix B.***

4.5 POPULATION AND SOCIO-ECONOMIC CONDITIONS

The south Florida 16-county study area is characterized by higher average incomes, and greater economic and population growth than the rest of the State and the Nation. This is particularly true of the Lower East Coast (Palm Beach, Broward, and Miami-Dade Counties), and while true in average terms for the study area as a whole, some localities do not share in this overall trend. The important features of the economic landscape are agricultural activity, construction, fishing, tourism, and recreation. This picture is expected to continue to be the case for 2050.

The south Florida study area is home to just over six million people, about half of Florida's population. This relationship between the study area's population and that of the state has been so for some time and is likely to continue. Population growth tends to exceed the national rate of growth, a trend expected to continue, although at a declining rate from that of the past.

The Lower East Coast population is expected to grow by 72 percent from just over four million in 1990 to nearly seven million by 2050 (G.E.C., 1996). The 16-country study area counties are expected to experience population growth during this period from 6.3 million to 11 million. The Monroe County population is projected to grow from 78,000 in 1990 to 126,000 by 2050.

Florida's economy is characterized by strong wholesale and retail trade, government and service sectors. Florida's warm weather and extensive coastline attracts vacationers and other visitors and helps to make the state a significant retirement destination for people from all over the country. Agricultural production and fisheries are also important sectors of the state's economy, and are especially significant to portions of the study area. While compared to the national economy, the manufacturing sector has played less of a role in Florida, but high technology manufacturing has begun to emerge as a significant sector in the State over the last decade. Total employment in the study area is expected to grow from about three million in 1990 to about five million by 2050. Lower East Coast employment by 2050 is projected to be about 2.7 million.

Most of the population and economic activity in the study area is concentrated along the Lower East Coast (Miami-Dade, Broward, and Palm Beach Counties). Per capita income for the study area as a whole is above that for the State. The three-county area's per capita income is even higher. These relationships will likely continue to 2050.

The Lower East Coast three-county area comprises about 9.5 percent of the State's land area but is home to 31 percent of Florida's population. Population growth is fueled by in-migration, as it continues to be both a leading location for retirement as well as a haven for refugees from such places as Cuba and Haiti. By contrast, the group of primarily agrarian counties bordering the shores of Lake Okeechobee (Glades, Highlands, Martin, Okeechobee, St. Lucie, and Hendry Counties, but excluding Palm Beach County), while similar in size to Lower East Coast counties, comprise only about three percent of the study area's population.

The Big Cypress and Caloosahatchee River regions (Lee, most of Collier and Hendry, and part of Charlotte and Glades Counties) are two of the fastest growing regions in the nation. The estimated total population of these counties for 1990 was 632,000. The total population is projected to increase 63 percent to 1,032,000 by the year 2010. It is expected to continue to increase through 2050 at a lower rate to 1,401,000.

Population in the Upper East Coast region, Martin and St. Lucie Counties, is expected to more than double by 2050. Despite this anticipated population growth, the region is not expected to have the large population like its neighboring counties to the south. The population in 2050 will be 529,000 or five percent of the study area.

Although there is population growth anticipated in the Big Cypress, Caloosahatchee, and Upper East Coast regions by the year 2050, the Restudy modeling effort was not sensitive to changes in these regions. These regions are outside of the modeling domain of the South Florida Water Management Model.

The population growth rate for the south Florida study area is expected to continue to exceed the national rate, but this trend is expected to lessen. By the year 2050, the population of the study area is estimated to still be about half of the state's population of 23 million people. Over 60 percent of this population are expected to inhabit the three southeast coast counties of Palm Beach, Broward, and Miami-Dade. To accommodate this growth, urban development will continue.

4.6 LAND USE AND LAND COVER

Land use in the future without plan condition is expected to be characterized by the continued urbanization of the developable lands which lie east of the Water Conservation Areas in the Lower East Coast, and continued urbanization of the Osceola and southern Orange County area associated with the development of Disney's properties. Southwest Florida is currently experiencing a very rapid rate of population growth; this trend is expected to continue.

For the coastal basins, 2050 land use projections were based on local government Comprehensive Plans. The Florida Legislature adopted the Local Government Comprehensive Planning Act in 1975 requiring each local governmental jurisdiction to prepare and adopt a local Comprehensive Plan. The

Future Land Use Element is a major component of the local plan designed to guide the future disposition of land use. Urban land use coverage in the future without plan condition was developed from the 2010 Comprehensive Plans and modified to include estimated decreases in agriculture, increases in golf course coverages, and other changes, such as identifying areas approved for development.

The urban portion of Palm Beach County to the east is home to a fast growing population. Palm Beach County is expected to become much denser as the population grows by over 600,000 people by 2050. This represents an almost doubling of the 1995 population. The amount of land available is somewhat limited since the other land-uses, agriculture, water conservation areas and publicly owned lands compete for space with urban development. Conversion of vacant, agricultural and low-density areas to higher density land use is expected throughout the county. North Palm Beach County may experience greater expansion into vacant or open areas since this portion of the county is not associated with the large population centers of West Palm Beach or Boca Raton, yet is expected to grow more rapidly.

In Palm Beach County, the majority of the agricultural areas is inland, and includes most of the Everglades Agricultural Area. The size of the Everglades Agricultural Area has been projected to decline somewhat as areas have been identified and scheduled to be used for Stormwater Treatment Areas by 2006. A total of approximately 44,000 acres will be shifted to that use. Another agricultural area, namely the Agricultural Reserve, is located adjacent to the urbanized eastern areas. The amount of land available for agriculture is limited and under high pressure to be developed in the future. The Agricultural Reserve is not expected to expand in the future.

In Broward County, suitable land for any type of development is limited. Almost all of the conversion from open or vacant land to urbanized development has already taken place. It is expected that most of the development to accommodate an additional projection of 800,000 persons will either infill small vacant parcels east of the levee or significantly increase the density in highly attractive areas adjacent to the coast. Greenhouse and nursery operations accounted for approximately 3,000 acres in 1995 and are expected to remain somewhat constant. The Water Preserve Areas project may accelerate the rate of infill and increases in density as the only remaining significant tracts of land are purchased.

Miami-Dade County is expected to continue to urbanize and become more dense within its urban development boundary as the greatest increase in the number of persons within the study area are expected to live here. Miami-Dade County's population will grow by approximately 1.1 million by 2050. Much of the growth will be accommodated on already developed lands; however, expansion into south Miami-Dade County and its agricultural areas as well as into areas west of the existing urban core will also occur. Urban development in south Miami-Dade

County and the strip west of the urban core will entail conversion of agricultural lands and wetlands. Increased flood protection, loss of storage in the surficial aquifer and the addition of pollutants associated with urban development will affect the hydrology of these areas.

Land use in the Upper East Coast, Martin and St. Lucie Counties, has been predominately agricultural and is expected to remain so in the future. However, the percentage of agricultural land use in Martin and St. Lucie Counties is anticipated to decrease while urban land uses increase as a result of anticipated population growth. Urban growth will cause conversion of some of the geographically desirable agricultural areas as well as expansion into vacant or natural areas.

Citrus is by far the dominant irrigated crop in this area and occupies over four-fifths of the irrigated agricultural acreage in the region. Irrigated citrus in this area is projected to grow by 32 percent in just the first 25 years of the planning horizon, from 134,000 acres in 1990 to 176,000 acres in 2020. Agricultural water demand is not projected to grow as rapidly although citrus, a high water use crop, is expected to remain the dominant crop.

Land use in the Big Cypress and Caloosahatchee River regions is projected to intensify to accommodate the growing population and demands on water resources will increase proportionately. However, agricultural demand is projected to remain the single largest category of land use in Big Cypress and Caloosahatchee River regions. In addition, agriculture is expected to remain the largest type of demand for water in southwest Florida over the planning horizon.

Citrus is the largest category of agricultural land use in the Big Cypress and Caloosahatchee River regions, and has been the fastest growing citrus acreage of any area in Florida. Recently, sugarcane acreage has begun to increase significantly as well. The initial clearing, draining, and planting and subsequent water withdrawals required to establish agricultural operations replaces natural habitats and modifies the natural hydrology of the area. Urban growth in Lee and Collier Counties also has the potential to impact the region's environmental and water resources. Drainage of wetlands for urban expansion, loss of natural surface water storage areas and contamination from urban land use are the major water related issues in urban areas.

Agriculture, predominately citrus and sugarcane, is expected to expand in the Lake Okeechobee Service Area, but at a slower rate than in the Big Cypress and Caloosahatchee River region. The expected increase in population and resulting urban development are not expected to significantly alter the current land uses. Much of the growth may not be centralized and will be more rural in nature.

Land cover (vegetation classes and spatial distribution) within the Everglades Protection Area in the future without plan condition is not expected to be greatly different at regional scales, from the vegetation patterns for the existing (1995) condition. Changes that could occur are expected to be local, and could include the continued invasion by exotic and native woody species into overdrained marl prairies and the northern portions of the Water Conservation Areas, and the continued loss of natural marsh communities in overponded portions of the Water Conservation Areas.

4.7 WATER QUALITY

The future without plan condition assumes no further hydrologic restoration actions beyond the presently planned/approved construction or maintenance actions in the study area, including those contained within the 1992 Settlement Agreement to the Federal lawsuit (United States et al v. South Florida Water Management District et al, Case No. 88-1886-CIV-Hoeveler) and the State of Florida's 1994 Everglades Forever Act (Stormwater Treatment Areas, Everglades Agricultural Area Best Management Practices and Phase 2 water quality technology).

The following subsections describe the projects by region that affect water quality and that are assumed to be in place in the future without plan condition.

4.7.1 Kissimmee River Region

Several planned and ongoing environmental restoration projects are expected to be completed which would beneficially affect water quality in the Kissimmee River watershed. Of particular importance is the Kissimmee River Restoration Project (including the Headwaters Revitalization and Modified Level II Backfilling projects). The Kissimmee River Restoration Project is expected to result in the restoration of approximately 26,500 acres of former wetlands in the vicinity of the Kissimmee Chain of Lakes (USACE, 1996) and at least 24,000 acres of former (drained) wetlands south of Lake Kissimmee (USACE, 1991).

4.7.2 Lake Okeechobee

Several watershed and in-lake cleanup projects are currently proposed (flow diversion projects for four Florida Statutes Chapter 298 Water Control Districts, diversion of flows from the 715 Farms area, and a critical project authorized pursuant to Section 528 of the Water Resources Development Act of 1996 – the Lake Okeechobee Water Retention/Phosphorus Removal Critical Project) to incrementally reduce inputs of nutrients to the lake. However, to sustain water quality improvements brought about by in-lake cleanup projects, pollutant source reduction programs (e.g., agricultural land acquisition, and implementation of best management practices) in the lake watershed must be implemented concurrently. The Florida Department of Environmental Protection is at present developing a Total Daily Maximum Load pollutant loading program which is expected to result in additional pollutant load reduction activities in watersheds flowing to Lake Okeechobee.

4.7.3 Upper East Coast

Several ongoing watershed management/planning programs in the Upper East Coast and Indian River Lagoon area are expected to be completed which would beneficially affect water quality conditions in the St. Lucie River and estuary, Indian River Lagoon and other freshwater waterbodies in the area. The South Florida Water Management Districts' Indian River Lagoon Surface Water Improvement and Management Plan has developed numerous programs and objectives to improve water quality conditions in the area. Many of the water quality remediation activities being implemented by the Surface Water Improvement and Management Plan focus on reducing agricultural pollutant loads in the Indian River Lagoon watershed and urban/suburban pollutant loads in the rapidly developing coastal region surrounding the St. Lucie Estuary and Indian River Lagoon. Implementation of more environmentally sensitive Lake Okeechobee regulation schedules should also reduce pollutant loading to the St. Lucie Estuary/ Indian River Lagoon systems. The Indian River Lagoon National Estuary Program, jointly administered by the U.S. Environmental Protection Agency and the State of Florida will also result in water quality improvement activities and a reduction of pollutant loads to the Indian River Lagoon in the future. In summary, as a result of these ongoing watershed management programs, water quality in the Upper East Coast is expected to improve in the future.

4.7.4 Everglades Agricultural Area

Recent monitoring results indicate that phosphorus loads in Everglades Agricultural Area runoff have declined approximately 51 percent (three year average, SFWMD, 1997b). The current average concentration of total phosphorus contained in Everglades Agricultural Area runoff is approximately 100 parts per billion (Havens, 1997). Construction of the Everglades Construction Project involves converting approximately 44,000 acres of existing agricultural land. The construction project is explained in more detail below.

4.7.4.1 Everglades Forever Act

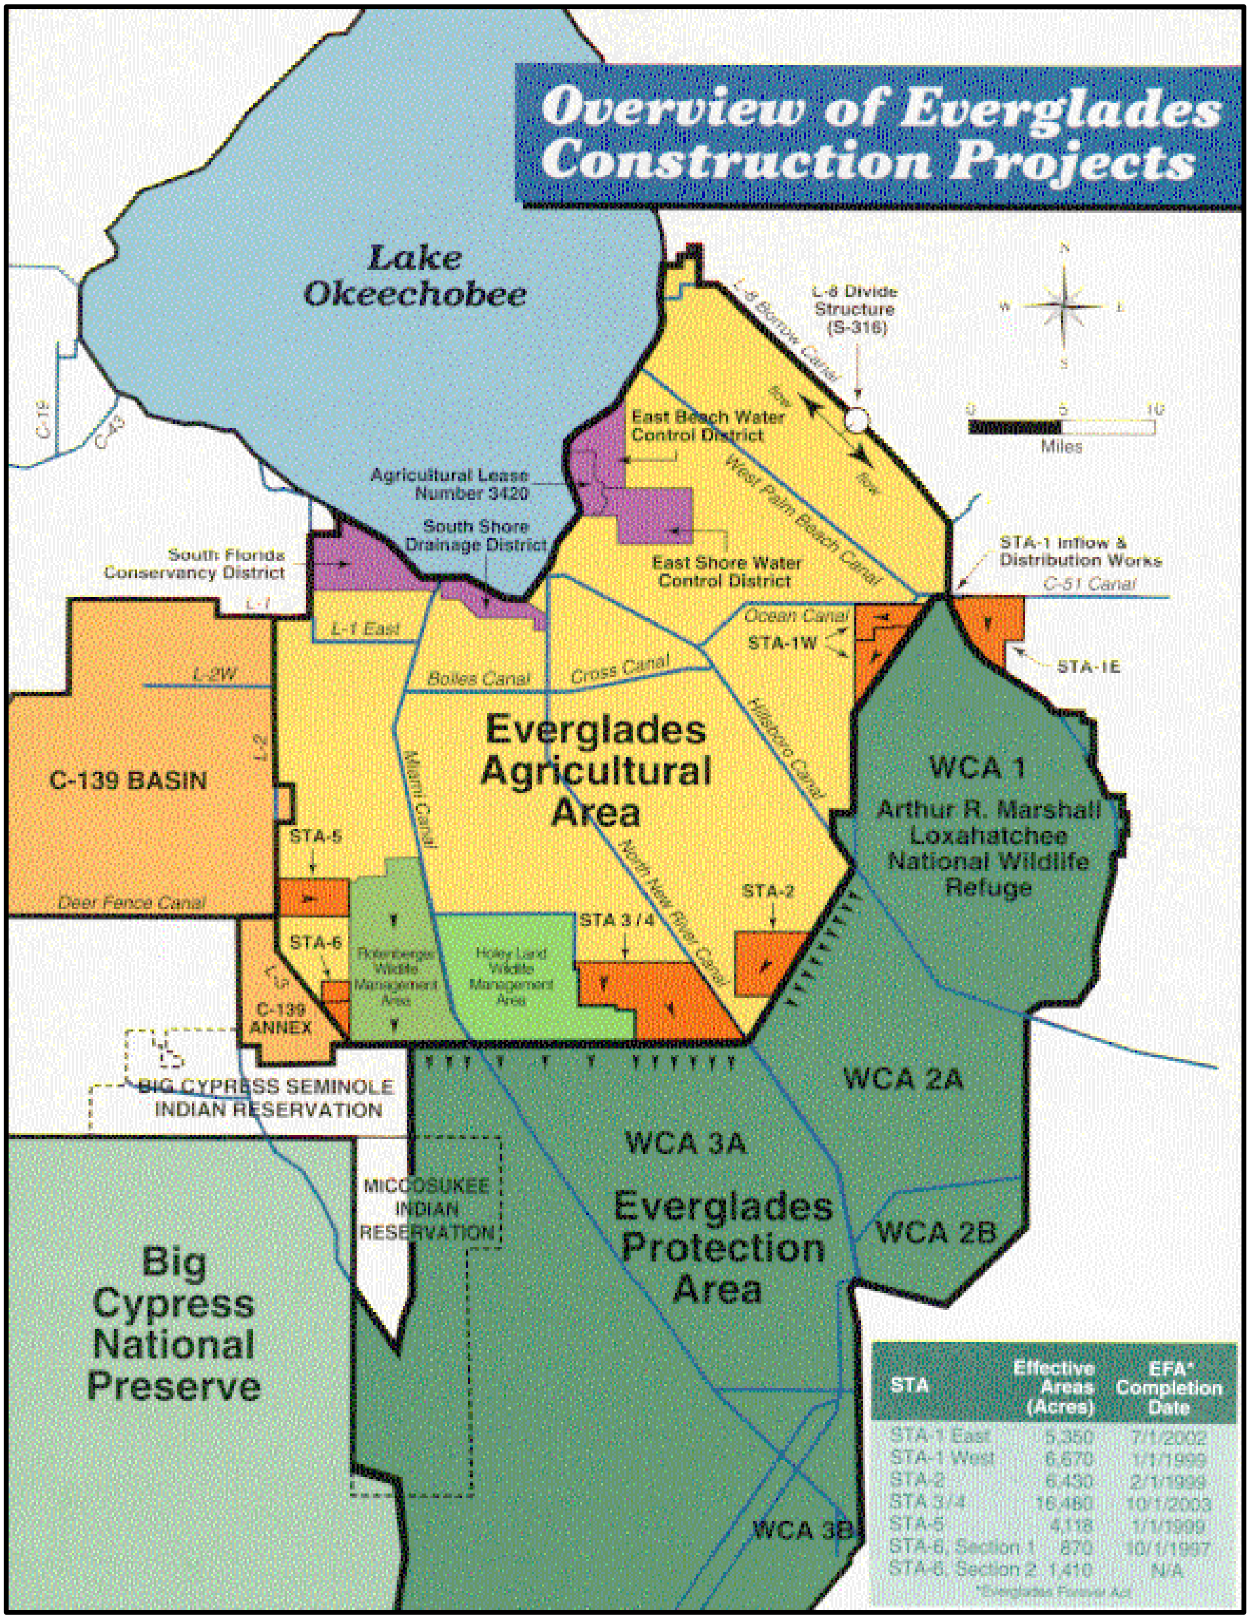
The Everglades Forever Act's principal water quality treatment strategy for improving water quality in the Everglades Protection Area which includes the Water Conservation Areas 1 (Loxahatchee National Wildlife Refuge), 2A and 3A; the Rotenberger Wildlife Management Area and the Holey Land Wildlife

Management Area centers around five requirements: The Everglades Construction Project, Everglades Agricultural Area Best Management Practice programs, Everglades research and monitoring program, evaluation of water quality standards and long-term compliance permits. Each element is further examined below.

The Everglades Construction Project consists of six large wetlands treatment facilities deemed Stormwater Treatment Areas containing approximately 44,000 acres of land previously used for agricultural purposes. These areas are designed to treat Everglades Agricultural Area runoff prior to discharge into the Everglades Protection Areas (***Figure 4-2***).

The Everglades Construction Project is designed to treat Everglades Agricultural Area runoff to meet an interim phosphorus concentration target of 50 parts per billion in discharges to the Everglades Protection Area (Burns and McDonnell, 1994). Stormwater Treatment Areas 1 East and 1 West will discharge into the L-7 and L-40 borrow canals in the Loxahatchee National Wildlife Refuge (WCA-1). Stormwater Treatment Area 2 will discharge to Water Conservation Area 2A via the L-6 borrow canal. Stormwater Treatment Area 3/4 will discharge to Water Conservation Area 3A via the L-5 borrow canal. Stormwater Treat Area 5 will discharge to Rotenberger and Holey Land Wildlife Management Areas and Water Conservation Area 3A along the L-4 borrow canal. Stormwater Treatment Area 6 discharges to Water Conservation Area 3A through the L-4 borrow canal. Stormwater Treatment Area 6 Section 2 will discharge to Rotenberger Wildlife Management Area. The future base condition assumes all of the treatment areas are completed and operational with the exception of Stormwater Treatment Area 6 Section 2. Stormwater Treatment Area 6 Section 2 was not included in hydrologic regional modeling since the conceptual design for the Stormwater Treatment Area did not include this element (Burns and McDonnell, 1994).

Another component of the Everglades Construction Project targeted for completion in 2003 is the diversion of runoff from five special districts (four chapter 298 districts and the 715 Farms area established under Florida Statutes). These special districts are located adjacent to Lake Okeechobee north of the Everglades Agricultural Area. Currently, the districts discharge directly to Lake Okeechobee. According to the Everglades Forever Act, approximately 80 percent of the historic flow volumes and total phosphorus loads are to be diverted away from the lake. The future base condition assumes that the diversion of flows and loads has been completed.



STA	Effective Areas (Acres)	EFA* Completion Date
STA-1 East	5,350	7/1/2002
STA-1 West	6,670	1/1/1999
STA-2	6,430	2/1/1999
STA 3/4	16,480	10/1/2003
STA-5	4,118	1/1/1999
STA-6, Section 1	870	10/1/1997
STA-6, Section 2	1,410	N/A

*Everglades Forever Act

Figure 4-2 Everglades Construction Project Features

According to the Everglades Forever Act, based upon research, field-tests and expert review, the Everglades Agricultural Area Best Management Practices are determined to be the most effective and practicable on-farm means of improving water quality to a level that balances water quality improvements and agricultural productivity. The act establishes monitoring programs, permit requirements, research, field-testing and evaluation programs designed to improve water quality prior to discharge into conveyance canals in the Everglades Agricultural Area. The act provides a tax incentive for phosphorus concentration reductions of 25 percent or more. As a consequence, the future base condition assumes a 25 percent phosphorus concentration reduction from best management practices.

In addition to the Everglades Construction Project and best management practices, the Everglades Forever Act directs that an Everglades Research and Modeling program shall seek means of optimizing the design and operation of the Stormwater Treatment Areas. This program shall include research to reduce outflow concentrations and identify other treatment and management methods and regulatory programs that are superior to Stormwater Treatment Areas in achieving the intent and purposes of the act. The research and monitoring program is also directed toward development of a permanent (threshold) phosphorus criterion in the Everglades Protection Area by the Florida Department of Environmental Protection and evaluation of existing state water quality standards applicable to the Everglades area. The criterion is to be adopted by December 31, 2003 or a default criterion of 10 parts per billion total phosphorus will be established. Currently, research efforts have not drawn any conclusions that affect treatment area designs, planned operations or the threshold phosphorus criterion. Research to determine superior or supplemental technologies and the threshold phosphorus standard is on going.

The Everglades Forever Act does specify that compliance with water quality standards shall be based upon a long-term geometric mean of concentration levels to be measured at sampling stations reasonably representative of receiving waters in the Everglades Protection Area. Discharges to the Everglades Protection Area from outside the Everglades Agricultural Area (non-Everglades Construction Project structures) also require evaluation to determine appropriate strategies. The act requires the South Florida Water Management District and the Florida Department of Environmental Protection to take such action as may be necessary so that water meets state water quality standards in all parts of the Everglades Protection Area.

The Everglades Forever Act further directs that long-term compliance permit requirements shall be modified to achieve compliance with the phosphorus criterion cited in the paragraph above. If the Florida Department of Environmental Protection has not adopted this criterion by rule prior to December 31, 2003, then the phosphorus criterion shall be 10 parts per billion in the Everglades Protection Area. This default criterion or the criterion adopted by the Department (phase II) is to be imposed by 2006. The act specifies that as of December 31, 2006, no permittee's discharges shall cause or contribute to any violation of water quality standards in the Everglades Protection Area. In view of the fact that the phase II phosphorus criterion has not been established, the future base condition assumes that the default standard of 10 parts per billion has been attained.

Design of the Everglades Construction Project was initiated in 1995 and construction in 1997. Stormwater Treatment Area 6 Section 1 was completed in October 1997 and operation was initiated in December 1997. Construction is currently underway at Stormwater Treatment Areas 1 West, 2 and 5 with completion scheduled on or before September, November and July 1999, respectively. Scheduled construction completion for Stormwater Treatment Area 1 East and 3/4 is set for July 1, 2002 and October 1, 2003, respectively.

A demonstration-scale wetlands treatment area project of nearly 3,800 acres has been operating adjacent to Water Conservation Area 1 (Loxahatchee National Wildlife Preserve) on the same site as future Stormwater Treatment Area 1 West since 1994. Stormwater Treatment Area 1 West will encompass the demonstration project when completed. The Everglades Nutrient Removal project was designed to reduce phosphorus from an inflow concentration of 190 parts per billion to an outflow concentration of 50 parts per billion. The settling rate constant for the demonstration project was set at 10.2 meters per year. These were the same parameters established for the Everglades Construction Project Stormwater Treatment Area design. Three years cumulative data from the demonstration project reflects that these criteria have been significantly exceeded. Additionally, on-farm best management practices have averaged 51 percent, considerably higher than the projected 25 percent contained in the future base condition for the Everglades Agricultural Area.

It is too early to predict what conclusions research and analyses will drive with regard to the findings outlined above. An optimistic one is that the best management practices reduction in phosphorus concentrations will increase Stormwater Treatment Area operations such that concentrations lower than the interim criterion will be achieved. Also, the higher settling rate constant and low phosphorus concentration outflows could significantly improve performance of the Stormwater Treatment Areas; thus, reduce phase II treatment needs. Only time and further operations of the treatment areas will judge whether the long-term findings will be supportive of the optimism suggested by current best management practices and Everglades Nutrient Removal findings. The current findings certainly should affect the research into what supplemental technologies may be necessary to achieve the phase II phosphorus criterion.

During the alternative development and evaluation phase of the Restudy, a preliminary study was conducted by Walker (Walker, 1998) to evaluate the performance of the Stormwater Treatment Areas based upon Restudy generated flows from the South Florida Water Management Model in the future base condition and the preferred alternative. A phosphorus removal model developed by Walker was used in the study. Modeling results indicated that some of the Stormwater Treatment Areas did not meet the interim phosphorus criteria of the Everglades Forever Act under either the future base condition or the preferred alternative. A closer examination reveals some of the reasons for the apparent underachievement. First, the periods of records differ. The Everglades Construction Project used a 10-year period of record from 1979 to 1988. The Restudy uses the 31-year period from 1965 to 1995. Second, the operational concepts differ. The Restudy uses rain-driven operational procedures whereas the Everglades Construction Project uses the current calendar-based regulation schedule. Third, because Stormwater Treatment Area 6 Section 2 was not modeled in the Restudy, the treatment area was not considered in the phosphorus modeling. Therefore, a treatment area totaling nearly 2,000 acres was not considered and the inflows scheduled for this area were all routed through Stormwater Treatment Area 5. Finally, although the period of record was changed from ten years to 31 years, the fixed parameters of the settling rate of 10.2 meters per year and targeted outflow concentration of 50 parts per billion remained unchanged from the Everglades Construction Project.

These two parameters (settling rate constant and outflow phosphorus concentration target) are two of the three most significant factors in determining the required area of treatment cells. Walker's study did indicate that when the 51 per cent best management practice phosphorus reduction rate experienced over a three-year period was used in lieu of the 25 percent estimate, all Stormwater Treatment Areas met or bettered the interim phosphorus criterion with the exception of Stormwater Treatment Area 5. Stormwater Treatment Area 5 did not meet the criteria in the modeling outcome due to the third reason cited in the preceding paragraph.

At first blush, the reasons cited above appear to mitigate the Walker findings of Stormwater Treatment Area underachievement. Although only time and continued operation of the treatment areas will provide proof, the findings should, in any case, direct research efforts toward ensuring that phase II treatment technologies are sufficient to meet the adopted threshold standard. Regardless of the Walker study or the demonstration project findings, the fact remains that the phase II (threshold) phosphorus standard must be met by 2006. The default criterion of 10 parts per billion is the target assumed in the 2050 future base condition. At that point, the interim standard becomes obsolete. When research efforts determine the optimal method of operation and supplemental technologies needed to meet the Everglades Forever Act permanent (phase II) phosphorus criterion, both the Everglades Construction Project and treatment elements of the

Restudy components must be modified to attain the designated water quality standard.

4.7.5 Natural Areas

The natural areas of the study area include the Rotenberger and Holey Land Wildlife Management Areas, the Loxahatchee National Wildlife Refuge, Water Conservation Areas 2 and 3, Big Cypress National Preserve, and Everglades National Park. The Rotenberger and Holey Land Wildlife Management Areas are adjacent to the Everglades Agricultural Area and are contained within the same hydrologic basin. The Everglades Construction Project, which is part of the future without plan condition, is designed to achieve hydrologic restoration objectives for the Rotenberger and Holey Land tracts by redirecting Everglades Agricultural Area runoff through Stormwater Treatment Areas into those areas to create preferred hydropatterns.

A fundamental underlying assumption for the Restudy is the full implementation of the State of Florida's Everglades Program contained in the Everglades Forever Act (F.S. 373.4592) by December 31, 2006. Implementation of the Everglades Forever Act includes completion of construction of the Stormwater Treatment Areas as described in the conceptual design for the Everglades Construction Project (Burns and McDonnell, 1994; scheduled to be completed in 2003), setting of a numeric phosphorus criterion for the Everglades Protection Area, by December 31, 2003, and compliance with that criterion by December 31, 2006.

In addition to the Everglades Construction Project and water quality treatment facilities developed as a result of the non-Everglades Construction Project requirements of the Everglades Forever Act, the currently authorized C-111 Project and the Modified Water Deliveries to Everglades National Park Project are assumed to be implemented in 2050.

4.7.6 Lower East Coast and Biscayne Bay

The major watershed management/planning program ongoing in the Lower East Coast region that will beneficially effect future water quality conditions is the State's Biscayne Bay Surface Water Improvement and Management Plan (SFWMD, 1995). The Biscayne Bay Surface Water Improvement and Management Plan has developed numerous water quality improvement related strategies and projects to reduce pollutant loading in Biscayne Bay and its tributaries. The extent to which this program is implemented, however, is limited due to funding constraints. Also, the Lake Worth Lagoon Management Plan will result in water quality improvement projects being implemented in the Lake Worth Lagoon area. Although implementation of these water quality improvement activities will result in beneficial effects to Lower East Coast waterbodies, the net future condition of waterbodies in this region is not expected to improve due to the dramatic additional urban development, and associated additional pollutant loads, projected to occur in this region.

4.7.7 Florida Bay

Both the Modified Water Deliveries to Everglades National Park and C-111 Projects are assumed to be completed in the future without plan condition. The first project to be implemented is the C-111 Project. Notably, the C-111 spoil (dredged material) mounds in the marsh on the southern leg of the C-111 Canal were removed in 1997. The purpose of that project was to promote overland flow out of the canal into the marshes in the northeastern part of Florida Bay. In addition, two other features of the C-111 Project are scheduled to be completed in the near future which would beneficially affect water quality in Florida Bay. A new pump station, S-332D, is scheduled to begin pumping operations to deliver increase stages in the L-31W borrow canal, preventing seepage from Everglades National Park from draining east into the canal network and downstream to tide. Operation of S-332D is intended to promote overland flow during high water conditions. Also, the existing single-span bridge over Taylor Slough in Everglades National Park is to be replaced with two longer-span bridges and two box culverts. Removing sections of an existing fill road (Ingraham Highway) across Taylor Slough will augment the bridge replacement project.

Furthermore, agricultural non-point pollution sources in the C-111 Basin are currently being investigated as required by the non-Everglades Construction Project structures requirements of the Everglades Forever Act and the C-111 / Modified Water Deliveries projects implementation process.

4.7.8 Florida Keys

The major ongoing water quality improvement program in the Florida Keys, which is expected to result in improved water quality conditions in the future, is the Water Quality Protection Program of the Florida Keys National Marine Sanctuary Program. The U.S. Environmental Protection Agency and the Florida Department of Environmental Protection are jointly responsible for implementing water quality improvement activities throughout the Florida Keys region as part of the Water Quality Protection Program. Implementation of these activities will result in improved water quality conditions in the Florida Keys in the future.

4.7.9 Big Cypress Basin

The South Florida Water Management District has identified the S-190 water control structure (a gated culvert at the confluence of the North Feeder and West Feeder Canals) as a structure discharging into the Everglades Protection Area that requires an assessment of pollution loads and the development of a water quality improvement strategy in accordance with the non-Everglades Construction Project structures requirement of the Everglades Forever Act. South Florida Water Management District water quality data (SFWMD, 1998a) indicate that agricultural areas upstream of the Seminole Reservation contribute significant nutrient loads (particularly phosphorus) into the canal system that drains into the North and West Feeder Canals and ultimately across the northeast corner of Big Cypress National Preserve. Water quality improvements required under the Everglades Forever Act are to be completed by December 31, 2006, to assure that all water quality standards are met in the Everglades Protection Area.

4.7.10 Caloosahatchee River Region

The South Florida Water Management District's Caloosahatchee River Water Management Plan is the main ongoing watershed management program that is likely to result in water quality improvement activities in the basin. In the future, although implementation of new Lake Okeechobee regulation schedules and the Caloosahatchee River Water Management Plan will reduce pollutant loading to the Caloosahatchee River/estuary, in general, water quality conditions throughout the basin in the future without plan condition are expected to be similar to current water quality conditions

4.8 URBAN AND AGRICULTURAL WATER SUPPLY DEMANDS

Future water supply demands for urban and agricultural areas that utilize the C&SF Project for water supply were projected for the study area.

4.8.1 Lower East Coast Region

The urban area of the Lower East Coast has been subdivided into four service areas. The North Palm Beach Service Area includes northeastern Palm Beach County east of the L-8 Canal and north of the C-51 Canal. Service Area 1 includes central and southern Palm Beach County as well as portion of northern Broward County. Service Area 2 includes central and southern Broward county and a small portion of northern Miami-Dade County. Service Area 3 is made up of the remainder of northern, central and southern Miami-Dade County and Monroe County. For the urban areas of the Lower East Coast projections are based on the use of the IWR-MAIN water demand forecasting software; underlying population and economic growth assumptions are a combination of the University of Florida Bureau of Economic and Business Research (short term) and Bureau of Economic Analysis, U.S. Department of Commerce (long term) growth projections. For Service Area 3 public water supply demands have been increased to reflect Miami-Dade

County's estimation of its future population growth as influenced by recent immigration legislation and other factors.

Two projections of future water consumption for the year 2050 have been made for the Lower East Coast study area. The two scenarios differ in terms of the assumed level of water use conservation. The higher estimate, Projection A (***Table 4-4***), is based on the same percentage distribution and usage of conservation flow devices, and irrigation restrictions, in effect in 2050 as in 1990. The lower estimate, Projection B (***Table 4-5***), is based on the full implementation of existing South Florida Water Management District mandatory regulations and programs.

The higher Projection A estimate for the year 2050 is about 1,450 millions of gallons per day. The lower Projection B estimate is about 1,200 millions of gallons per day, approximately 18 percent less than Projection A. In this study, the 2050 base condition (the without plan condition) assumes a more moderate application of conservation practices and effectiveness, representing a level of consumption about 12 percent below the 2050 Projection A estimate.

The Projection A average daily Municipal and Industrial demand for water use in the year 2050 is summarized in ***Table 4-4***. The table shows that water use is fairly evenly distributed among the Lower East Coast counties. The Service Areas that coincide mainly with the developed portion of Palm Beach County account for 30 percent of total forecast Municipal and Industrial use. Service Area 2, which roughly coincides with Broward County accounts for a little over 29 percent of use. Service Area 3 use, representing demand in most of Miami-Dade County and the Florida Keys (Monroe County), is somewhat higher in terms of its share of the total.

TABLE 4-4
SUMMARY 2050 MUNICIPAL AND INDUSTRIAL DEMANDS BY SERVICE AREA – PROJECTION A

Area	Million Gallons Per Day (MGD)	Percent of Total
North Palm Beach Service Area	101.25	7
Service Area 1	349.20	24
Service Area 2	422.24	29
Service Area 3	577.00	40
Total	1449.69	100

As stated above these 2050 Projection A estimates reflect a level of conservation practices that is the same as estimated to be in place in 1990. That is, the same percentage distribution of the use of restrictive flow devices among all uses in place in 1990 is assumed to be in place for the 2050 usage, and therefore probably can be viewed safely as an upper bound forecast estimate.

Another set of forecast use estimates, full implementation of the South Florida Water Management District's mandatory water conservation program for all consumers by 2050, was also made. The 2050 summary results of this conservation Projection B scenario, which can be viewed as a lower bound forecast estimate, are shown in ***Table 4-5***.

TABLE 4-5
SUMMARY 2050 MUNICIPAL AND INDUSTRIAL DEMANDS BY SERVICE AREA – CONSERVATION PROJECTION B

Area	Million Gallons Per Day (MGD)	Percent Reduction [1/]
North Palm Beach Service Area	83.66	17.37
Service Area 1	294.18	15.76
Service Area 2	345.72	18.12
Service Area 3	474.80	17.71
Total	1198.36	17.34

[1/]From Projection A

The IWR-MAIN forecasts have been categorized by residential, commercial, industrial, public administration, and unaccounted-for uses. The following percentage breakdown (***Table 4-6***) provides a profile of these uses in the study area for 2050 for Projection A. As the tabulation shows, this profile is generally similar throughout the study area, although residential use is more heavily weighted in southern areas.

TABLE 4-6
PERCENTAGE DISTRIBUTION OF 2050 DEMAND BY END USE AND BY SERVICE AREA

End Use	NPB	SA1	SA2	SA3	Total
Residential	47	49	56	58	54
Commercial & Industrial	36	37	28	22	29
Public & Other	17	14	16	20	17
Total	100	100	100	100	100

The demand projections made using IWR-MAIN are made by large areas because the projections are driven by economic and demographic projections, which have been made at the county-wide level. But the South Florida Water Management Model input requires that the demand input be in the form of well withdrawals, by month, in millions of gallons per day, spatially identified by grid-cell location. This information has been developed for existing well pumpages. The conversion of the above projected service area water use into grid-cell based well withdrawal data has been developed using known existing well field locations, and the likelihood of future locations and operations.

The IWR-MAIN estimates excluded golf courses and landscape irrigation (estimated by the South Florida Water Management Model simulation as a part of the evapotranspiration simulation calculation runs), deep well withdrawals from the brackish Floridan aquifer, and some other uses which are not consumptive. For example, water is used in rock mining operations, but it is returned immediately after use (consisting mainly of washing rock cuttings), and therefore such use is not really a consumptive use. Instead, it is more representative of moving water from one place to another in the system. Floridan aquifer withdrawals do not represent a withdrawal from the water system modeled by the South Florida Water Management Model and are outside of the Everglades system.

Total irrigation demands for the Lower East Coast areas are projected to increase by 21 percent by the year 2050 to a total annual average demand of 707,800 acre-feet. Irrigation demands have been divided into three general categories; landscape, golf course and agriculture.

Landscape irrigation demands are supplied by either public water supply utilities or self-supplied sources such as wells or canals. Those demands provided by public water supply utilities have been included in the IWR-MAIN estimates. Self-supplied landscape irrigation demand estimates are based on future land use maps developed for local government comprehensive plans. Future self-supplied landscape irrigation is estimated to increase by 48 percent with average annual demands of 499,000 acre-feet.

Golf course irrigation that uses self-supplied sources for irrigation is estimated to increase by 31 percent with average annual demand of 71,800 acre-feet.

Agricultural irrigation in the Lower East Coast area includes irrigation for row crops, citrus, tropical fruits and nurseries. Overall, most agricultural irrigation is expected to decline in the future with the exception of nursery irrigation, which is expected to increase. Total agricultural irrigation demands for the Lower East Coast are estimated to decline by 28 percent to a total annual average demand of 136,600 acre-feet. Nursery irrigation is estimated to increase by 164 percent to a total annual average demand of 52,900 acre-feet.

4.8.2 Everglades Agricultural Area Region

The only source for irrigation water in the Everglades Agricultural Area is surface water. Irrigation demands for the Everglades Agricultural Area are not expected to increase in the future. The demand of the Everglades Agricultural Area is estimated to be 430,000 acre-feet per year on an average annual basis.

4.8.3 Upper East Coast Region

The Upper East Coast region is approximately 1,200 square miles and includes most of Martin and St. Lucie Counties and a small part of Okeechobee County. There is a transition in land use in the region from urban in the east to agricultural in the west.

The Upper East Coast Region municipal and industrial water demand forecast by sector is shown in ***Table 4-7***. Figures are based on University of Florida Bureau of Economic and Business Research population and employment projections. A range of projected water supply usage is provided to reflect water usage based on implementation of the South Florida Water Management District mandatory regulations and programs. The data is shown for both restricted and unrestricted water usage for the Upper East Coast region for 1990 and 2050. Overall, municipal and industrial water supply demands are projected to increase up to as much as 125.8 million gallons per day by the year 2050 from 53.6 million gallons per day in 1990. This is a 135 percent increase over the 60-year period. In the Upper East Coast Region groundwater is the predominant source of water for municipal and industrial uses. This trend is expected to continue in the future.

TABLE 4-7
UPPER EAST COAST MUNICIPAL AND INDUSTRIAL DEMANDS
(MILLION OF GALLONS PER DAY)

End Use	2050 Range of Unrestricted to Restricted Demand
Residential	83.6 –70.1
Commercial & Industrial	33.5 – 31
Public & Other	8.7 - 7.9
Total	125.8 – 108.9

Agriculture is the predominate land use of the Upper East Coast region, accounting for 85 percent of the overall water demand. Currently, citrus crops occupy four-fifths of the irrigated agricultural acreage in the region (Gulf South Research Corp. & G.E.C. Inc, 1998). St Lucie Canal (C-44) Basin demands are estimated to be approximately 28,000 acre-feet on an average annual basis; these demands are not expected to increase in the future (Gilpin-Hudson et al., 1998a). The same trend is expected for the remainder of the Upper East Coast Region with irrigation demands remaining stable in the future (Gilpin-Hudson et al., 1998b).

The primary source of water for agriculture in the Upper East Coast Region is surface water however, in some areas the Floridan Aquifer System is an important source of water (SFWMD, 1998c).

4.8.4 Big Cypress and Caloosahatchee River Regions

The Big Cypress and Caloosahatchee River regions extend across approximately 4,300 square miles in southwest Florida. The regions include all of Lee county and portions of Charlotte, Collier, Glades, Hendry, Miami-Dade and Monroe Counties. Total water demand in these regions is estimated to increase by approximately 26 percent over the next 20 years. Urban demand is projected to increase by 84 percent, while agricultural demand is projected to increase by 13 percent (SFWMD, 1998b). In the Big Cypress and Caloosahatchee Regions groundwater is the predominant source of water for municipal and industrial uses with the exception of the City of Ft. Myers and Lee County Utilities, which withdraw water from the Caloosahatchee River. Lee County estimates that future demand for this source of water will be 50 cubic feet per second. The predominant source of water for agriculture in these regions is ground water and with the exception of the Caloosahatchee River Region have not been included in the modeling analysis for this plan.

In the Caloosahatchee River Region surface water from the Caloosahatchee River is the primary source of irrigation and has been included in the modeling analysis for the future without plan condition. The Caloosahatchee River Region demands are estimated to increase by 40 percent by 2050 to a total average annual demand of 125,000 acre-feet. (Gilpin-Hudson et al., 1997) These demand estimates are based on analysis of the suitability of land for growth in irrigation and land ownership (Mazzotti et al., 1992).

4.9 PHYSICAL FACILITIES AND OPERATIONS

This section discusses the physical facilities operational changes that are planned for the study area and are assumed to be in place for the future without plan condition.

4.9.1 C&SF Project Modifications

The C&SF Project was authorized by the Flood Control Act of 1948 and modified by subsequent acts, as a plan of improvement for flood control, drainage, and other purposes covering a 18,000 square mile area of both central and southern Florida. A number of efforts are currently underway by the Corps of Engineers to modify the project for environmental improvement. The following is an inventory of C&SF Project modifications either in the planning, design, or construction phase.

For the purpose of evaluating effects of alternative plans, they are included in the future without plan condition.

4.9.1.1 Kissimmee River Restoration

In the future without plan condition, the Kissimmee River restoration project will be in place and functioning. The restoration project, authorized by the Water Resources Development Act of 1992, will create a more natural physical environment in the lower Kissimmee River Basin. The major components of the project include: (1) reestablishment of inflows from Lake Kissimmee that will be similar to historical discharge characteristics (headwaters component), (2) acquisition of approximately 85,000 acres of land in the lower Kissimmee Chain of Lakes and river valley, (3) continuous backfilling of 22 miles of canal, (4) removal of two water control structures, and (5) recarving of nine miles of former river channel. The Kissimmee River Basin contributes about 30 percent of the water input to Lake Okeechobee. The supply of water to Lake Okeechobee is anticipated to be reduced by about 1.60 percent due to the implementation of this project.

As a component to the Kissimmee River Restoration project, the modification of the Upper Chain of Lakes regulation schedules and associated canal and water control structure modifications, known as the Headwaters Revitalization Project, will restore the ability to simulate the historic seasonal flow from Lake Kissimmee to the Lower Basin, and provide higher fluctuations of water levels in the lakes. The project will result in the expansion of the lakes' littoral zones by up to 18,500 acres, and improved habitat to fish and wildlife on Lakes Kissimmee, Hatchineha, Cypress, Tiger, and Jackson. The project will also increase spatial and temporal dynamics produced through long-term fluctuations of seasonal water levels.

The Headwaters Revitalization Project will meet two hydrologic conditions (criteria) that must be reestablished to restore the Lower Basin ecosystem. These conditions are; the reestablishment of continuous flow with duration and variability characteristics comparable to prechannelization records; and reestablishment of stage hydrographs that result in flood plain inundation frequencies comparable to prechannelization hydroperiods, including seasonal and long-term variability characteristics.

4.9.1.2 C-111 Project

Plan 6a, recommended in the Corps' General Reevaluation Report dated May 1994, will create the operational capability and flexibility to provide restoration of the ecological integrity of Taylor Slough and the eastern panhandle areas of the Everglades and maintain flood protection to the agricultural interests adjacent to C-111.

In the future without plan condition, C-111 Plan 6a will protect the natural values of a portion of Everglades National Park, and will maintain flood damage prevention within the C-111 Basin, east of L-31N and C-111. The project, which consists of both structural and non-structural modifications to the existing project works within the C-111 Basin, will restore the hydrology in 128 square miles of Taylor Slough and its headwaters in the Rocky Glades. In addition, the hydroperiod and depths in 1,027 square miles of Shark River Slough are beneficially impacted by the higher stages in the Rocky Glades, resulting in a net increase in water volume within Shark River Slough. The project will provide adequate operational flexibility to incorporate management strategies that will evolve as a result of continued monitoring and studies.

4.9.1.3 Modified Water Deliveries to Everglades National Park

The Modified Water Deliveries to Everglades National Park Project was authorized by the Everglades National Park Protection and Expansion Act (Public Law 101-229). The purpose of the project is to provide for structural modifications to the C&SF Project to enable the restoration of more natural water flows to Shark River Slough in Everglades National Park. The project is being implemented by the Corps in conjunction with the acquisition of about 107,600 acres of land by the Department of Interior. Land acquisition for the levee, canal, and pump station for the flood mitigation system in the 8.5-square-mile area is underway.

This project is presently in the design and construction phase. Project construction is scheduled for completion in 2003. In the future without plan condition, the Modified Water Deliveries Project will provide more natural flows to Shark River Slough in Everglades National Park. Water flows will be spread across a broader section of Shark River Slough to include the East Everglades between L-67 Extension and L-31N.

The addition of water control structures and culverts will help to reestablish the natural distribution of water from Water Conservation Area 3A into Water Conservation Area 3B. Outlets from Water Conservation Area 3B (S-355A & B) will be constructed to discharge into Northeast Shark River Slough. An existing levee and canal (L-67 Extension) along the eastern edge of the existing Everglades National Park boundary will also be removed. A Miccosukee Indian camp has been flood-proofed to avoid periodic flooding that would otherwise be caused by the project.

In order to prevent adverse flood impacts to the 8.5-square-mile residential area, the authorized project includes the construction of a seepage levee and canal around the western and northern edges of the area and a pump station (S-357) to remove excess seepage water. These project features are designed to maintain the existing level of flood protection in the residential area after the Modified Water

Deliveries to Everglades National Park project returns water levels in Northeast Shark Slough to higher levels. A second pump station (S-356) will be constructed to pump excess seepage water from the L-31N borrow canal and residential area into the L-29 borrow canal. This water will then flow through culverts under US Highway 41 into Northeast Shark River Slough. A locally preferred option which would modify the project features in the 8.5-square mile area is currently under consideration.

The structural modifications were designed to provide for maximum operational flexibility so that as more is learned through the continued iterative testing program, the operation of the project can be adjusted accordingly.

4.9.1.4 C-51 Project

The current Design Memorandum was completed in February 1998 and submitted for review and approval and contains the same National Economic Development plan as the June 1992 Detailed Design Memorandum but references an “authorized” plan, which includes the replacement of the 2.5-square-mile detention area with Stormwater Treatment Area 1E from the Everglades Construction Project. The “authorized” plan is also a product of the Technical Mediated Plan, which has been agreed to by Department of Justice, Department of Interior, Department of Army, the State of Florida, and the South Florida Water Management District. The State of Florida's Everglades Forever Act is based, in part, on the Technical Mediated Plan. The current “authorized” plan was authorized by the Water Resources and Development Act of 1996. The Act included language for the western C-51 project that additional work, as described in the “Everglades Construction Project”, shall be accomplished at full Federal cost.

The authorized plan is recommended in the C-51 Design Memorandum and has many of the same physical features proposed in the 1992 Detailed Design Memorandum. It is described below. The project will provide 10-year flood protection for the western basin of C-51. The major physical difference between the 1992 Detailed Design Memorandum National Economic Development plan and the authorized plan is the replacement of the 1,600 acre detention area with the 5,350 acre “locally preferred” Stormwater Treatment Area 1 East. The most significant modification will be the reduction of discharges to Lake Worth, with C-51 West Basin runoff directed instead to Water Conservation Area 1 (Arthur R. Marshall Loxahatchee Wildlife Refuge). Runoff from the C-51 West Basin will pass through Stormwater Treatment Area 1 East for water quality improvement prior to its discharge to Water Conservation Area 1. In addition to the flood damage reduction benefits provided by the 1992 plan, the authorized plan would provide water quality improvement, reduction of damaging freshwater discharges to Lake Worth, and increased water supply for the Everglades and other users.

4.9.1.5 Manatee Protection

The West Indian manatee (*Trichechus manatus*) is listed as a Federally endangered species and is one of the most endangered species in Florida. As a response to recent manatee mortality trends associated with water control structures, this project will provide operational changes and implement the installation of a manatee protection system at seven sector gates at navigational locks near Lake Okeechobee. The beneficial outcome of this project will be the reduction of risk, injury, and mortality of the manatee. The seven sector gates include S-193 at Okeechobee and S-310 at Clewiston on Lake Okeechobee; St. Lucie Lock and Port Mayaca Lock on the St. Lucie Canal; and Moore Haven Lock, Ortona Lock, and W. P. Franklin Lock on the Caloosahatchee River.

The mechanism proposed would use hydroacoustic and pressure sensitive devices that will immediately stop the gates when an object is detected between the closing gates. These systems will transmit an alarm and signal to stop the gate movement when a manatee is detected. When an object or manatee activates the gate sensors, the gate will stop and open approximately six inches to release a manatee. As a result, a manatee will be able to travel between the open gates. After the gate opens, the operator can fully close the gate unless an object remains between the gates. Then the opening process will repeat the cycle as the sensors are activated again. Due to these structural modification, manatees will be at a significantly less risk as they encounter locks with sector gate.

The future without plan condition assumes that the automatic gate sensor devices are installed these lock sector gates.

4.9.1.6 Emergency Interim Plan

Legislation known as the Emergency Interim Plan for Florida Bay (Chapter 373.4593 FS) was passed by the Florida Legislature in May of 1994. Its purpose was to *"...provide for the release of water into Taylor Slough and Florida Bay by up to 800 cfs, in order to optimize the quantity, timing, distribution & quality of fresh water, and promote sheet flow into Taylor Slough."*

Section 2(e) called for acquisition of the western three sections of the agricultural area known as the Frog Pond in Miami-Dade County. The South Florida Water Management District took title to all eight sections of the Frog Pond in February of 1995. This effectively became phase 1 of the Emergency Interim Plan, as acquisition of this land eliminated land use conflicts between Everglades National Park and farming taking place in the Frog Pond. Elimination of these conflicts prevented the unnatural reduction in canal stages that had previously taken place each year in the fall to facilitate those farming activities. In addition, it allows greater flexibility in implementation of a rainfall driven plan for water levels in L-31W.

Phase 2 of the Emergency Interim Plan was designed to provide additional pumping capability into the L-31W canal, which formed the western boundary of the Frog Pond. Pump Station S-332D (C-111 Project and Experimental Program of Water Deliveries to Everglades National Park) was built for this need and expanded to 500 cfs.

4.9.1.7 Lake Okeechobee Regulation Schedule

Lake Okeechobee has undergone numerous changes since the initial construction of Herbert Hoover Dike. Today, the Lake Okeechobee's water level is managed to provide a range of desired purposes including, flood protection, water supply and environmental protection using "regulation schedules." In 1995, the South Florida Water Management District requested the Corps of Engineers to study a range of regulation schedules intended to be more responsive to lake ecosystem, down stream users and receiving water bodies. Those studies are currently underway. Due to the uncertainty of the recommendation that will result from that study, the Restudy assumed the current schedule, known as Run 25, for hydrologic modeling of the future without plan condition.

4.9.2 Critical Projects

The Water Resources Development Act (WRDA) of 1996 authorizes the Secretary of the Army to expeditiously implement restoration projects that are deemed critical to the restoration of the south Florida ecosystem. These projects are referred to as "Critical Projects." This authority resulted in an expedited study to identify projects that would meet the criteria set forth in the authorizing legislation. A total of 35 projects were nominated as Critical Projects under this authority by the Working Group of the South Florida Ecosystem Restoration Task Force (***Section 11***). This nomination process involved considerable input from the Governor's Commission for a Sustainable South Florida (***Section 11***) and the public. Based on the priorities developed during the nomination process, the U.S. Army Corps of Engineers conducts an abbreviated study and produces a letter report that is transmitted to the Secretary of the Army to obtain approval for construction of the project.

For the Critical Projects, the future without plan condition is defined as those Critical Projects that have Secretary of the Army approval and are anticipated to be funded under the Critical Projects program. To date, the following twelve Critical Projects have received approval:

- East Coast Canal Structures
- Tamiami Trail Culverts
- Melaleuca Eradication Project – New Facility

- Florida Keys Carrying Capacity Study
- Western C-11 Water Quality Treatment
- Seminole Tribe Big Cypress Water Conservation Plan (west)
- Southern Golden Gate Hydrologic Restoration
- Southern Crew Project Addition/Imperial River Flowways
- Lake Okeechobee Water Retention/Phosphorous Removal
- Ten Mile Creek Water Preserve Area
- Lake Trafford Restoration
- L31-East Flow Redistribution

Of these twelve approved projects, it is anticipated that the top five will be funded through the Critical Projects program:

- East Coast Canal Structures
- Tamiami Trail Culverts
- Melaleuca Eradication Project – New Facility
- Florida Keys Carrying Capacity Study
- Western C-11 Water Quality Improvements

Furthermore, it is anticipated that the North Fork of the New River Restoration Critical Project will receive approval and can be funded through the remainder of the Critical Projects program funds. Accordingly, the following seven Critical Projects are included in the without plan condition:

- East Coast Canal Structures
- Tamiami Trail Culverts
- Melaleuca Eradication Project – New Facility
- Florida Keys Carrying Capacity Study
- Western C-11 Water Quality treatment
- L31-East Flow Redistribution
- North Fork of the New River Restoration

Appendix A5 contains additional information about the Critical Projects Program.

4.9.3 Interim Plan for Lower East Coast Regional Water Supply

The Interim Plan for Lower East Coast Regional Water Supply, produced by the South Florida Water Management District, identified water resources and water supply development projects, both structural and non-structural, that should be initiated before 2000 to help meet the growing needs of the region (SFWMD, 1998d). The Interim Plan also identified local basin planning and other analytical programs to support the Lower East Coast 2020 Plan development and the Restudy.

The analyses conducted during the Lower East Coast Regional Water supply planning process demonstrated the need for increased storage capabilities throughout the system to help meet the increasing agricultural, environmental and urban demands.

The following components of the interim plan are included in the future without plan condition.

4.9.3.1 Wellfield Expansion in Service Areas 1 and 2

This component provides for relocation of future and some existing withdrawals from existing (1995) wellfields. Demands of the following utilities were evaluated assuming new wellfield locations: Lake Worth, Manalapan, Lantana, Boca Raton, Fort Lauderdale, Hollywood and Hallandale. The evaluations assumed that, for these utilities, demands shifted to new wellfields were the same as those identified in the Draft Lower East Coast Regional Water Supply Plan (SFWMD, 1997g). Generally this means that 1995 levels of demands continued to be met from existing facilities while the portion of new demands beyond 1995 levels were met from the newly expanded wellfields. The new wellfields were generally evaluated as being located along the western boundary of each utility's service area.

4.9.3.2 Northeastern Broward Secondary Canal Recharge Network

This component includes pump stations and structures that would maintain higher levels in secondary canals in eastern Broward County between the Hillsboro and the North New River Canals during the dry season. The control of seasonally higher canal elevations along the coast could help recharge the aquifers being used by local public water supply wellfields, and further reduce saline encroachment into the coastal fresh water aquifers. The selected canals are located where recharge from the canals would help to hold back the salt water front and protect the production capability of wellfields to the east.

4.9.3.3 Miami-Dade County Utility Aquifer Storage and Recovery

This component includes aquifer storage and recovery wells and related facilities that would be installed associated with wellfields of the Miami-Dade Water and Sewer Authority Department. These facilities would be operated to store water in the Floridan Aquifer in the wet season and recover this water in the dry season. For the future without project condition, the evaluations were for a daily injection and recovery capacity of approximately 150 million gallons per day, a maximum recovery percentage of injected water of 90 percent, an annual injection period of seven months and an annual recovery period of five months.

4.9.3.4 Selected Elements of L-8 Project

The goal of the selected elements of the L-8 project is to redirect runoff from the southern L-8 Basin away from Water Conservation Area 1 and the C-51 canal to the West Palm Beach Water Catchment Area and the Loxahatchee Slough via the M Canal and the C-18 Canal. Subsequently, this water may be used to meet urban water supply demands for West Palm Beach, to meet environmental water demands of the Catchment Area and Loxahatchee Slough, and may provide recharge for the Jupiter and Seacoast Utilities Authority wellfields. In addition, this project would be expected to reduce the incident and volume of harmful freshwater releases into Lake Worth lagoon via the C-51 Canal. The project includes: an improved structural connection from the West Palm Beach Water Catchment Area to the Loxahatchee Slough aquifer storage and recovery wells at the West Palm Beach Water Catchment Area or the Indian Trails Improvement District impoundment and a coastal recharge delivery system.

4.9.3.5 Minimum Flows and Levels

This component involves operational adjustments associated with the establishment of minimum flows and levels for the Biscayne Aquifer and the Everglades. Minimum levels for the Biscayne Aquifer involves maintaining water levels in coastal canals to prevent saltwater intrusion. Minimum flows and levels for the Everglades focuses on preservation of hydric soils. No net outflow from Water Conservation Areas are allowed if water levels are less than minimum level marsh triggers or less than minimum operating criteria in the canals of the Loxahatchee National Wildlife Refuge (Water Conservation Area 1): 14 feet, Water Conservation Area 2A: 10.5 feet, Water Conservation Area 3A: 7.5 feet. Marsh level triggers will be those used in the Interim Plan for Lower East Coast Regional Water Supply.

4.9.3.6 Modify Pump Station G-404

This component involves increasing the capacity of proposed pump station G-404 as part of the Everglades Construction Project to increase its capacity from 570 cfs to 1,000 cfs. This will provide the ability to deliver more water from L-5 to L-4, which will in turn improve Everglades hydropatterns in the northwest corner of Water Conservation Area 3A.

4.9.3.7 Water Conservation Areas and Everglades National Park Rainfall-Based Rainfall Water Delivery Plans

In the future without plan condition, the rainfall delivery plan is based on antecedent rainfall and natural system hydropatterns for Water Conservation Area

2A and 3A and Everglades National Park, with quantities to approximate Best Management Practices Replacement water quantities.

4.9.4 Northwest Dade Lake Belt Area

This component assumes that the conditions caused by the currently permitted mining exist and that the affects of any future mining are fully mitigated by the mining industry.

4.9.5 East Cape and Homestead Canals

The East Cape and Homestead Canals, located within Everglades National Park, were constructed by local interests in the early 1900s to assist in the drainage of the Everglades prior to authorization of the park in 1936. After the Everglades National Park was established, the canals were plugged to prevent overdrainage of upstream fresh water systems and saltwater intrusion during high tides in the dry season. The passage of Hurricane Andrew resulted in extensive damage to both plugs. The project repaired the plugs in August 1997.

4.10 LAND ACQUISITION PROGRAMS

Besides land acquisition for ongoing C&SF Project Modifications, the State of Florida, the South Florida Water Management District, Miami-Dade County, and the Federal government have land acquisition programs or are funding land acquisitions within south Florida through a variety of funding sources or programs. Lands within the study area have been acquired and will continue to be acquired by these entities for a variety of purposes.

4.10.1 Save Our Rivers Program, Preservation 2000 and Conservation and Recreation Lands

In 1981, the State of Florida enacted the Resource Rivers Act, also known as the Save Our Rivers Program, Florida Statutes section 373.59. The Act created the Water Management Lands Trust fund. The program uses bond proceeds, supported by the general revenue portion of the State's Documentary Stamp Tax, to acquire lands for the purposes of water management, water supply, and the conservation and protection of the State's water resources. Manageability, surface and ground water systems, and the formation of corridors for the critical interaction of wildlife populations are major considerations in the land acquisition process. Prime requisites in managing these public lands are to ensure that the water resources, fish and wildlife populations, and native plant communities are maintained in an environmentally acceptable manner, and made available for appropriate outdoor recreational activities consistent with their environmental sensitivity. The

Preservation 2000 Act (Florida Statutes 375.045) enacted by the State of Florida in 1990 also added land acquisition funds to the Save Our Rivers Program. The South Florida Water Management District is allocated 30 percent of the yearly moneys in the Water Management Lands Trust Fund. To date the District has acquired more than 330,000 acres with the Save Our Rivers Program funding.

Florida Statutes section 259.032 entitled Conservation and Recreation Lands Trust Fund, established within the Department of Environmental Protection a nonlapsing, revolving fund to fund the Land Acquisition Trust Fund for the Save Our Rivers Program and to purchase other lands for state-designated parks, recreation areas, preserves, reserves, historic or archaeological sites, geologic or botanical sites, recreational trails, forests, wilderness areas, wildlife management areas, urban open space, or other state-designated recreation or conservation lands.

All of the above programs assume that the lands can be purchased from willing sellers.

The South Florida Water Management District's P-2000 needs and priority study, identified an additional 491,000 acres of priority projects; however, available funding from P-2000, plus funds from other federal, state and local programs will allow for the purchase of 316,000 acres. The South Florida Water Management District has other 50 identified projects.

One of the projects directly related to the Restudy is the East Coast Buffer. The East Coast Buffer consists of approximately 66,400 acres in Palm Beach, Broward and Miami-Dade Counties and was approved for acquisition under Save Our Rivers by the South Florida Water Management District Governing Board in June 1995 with the understanding that the concept would be incorporated into the Restudy. In July 1997 the Board approved an expansion of the buffer by 5,657 acres. To date, approximately 16,000 acres have been acquired. The East Coast Buffer, as evaluated during the South Florida Water Management District's Lower East Coast Regional Water Supply planning process and incorporated into the Restudy process as the Water Preserve Areas, is a series of marshes, reservoirs, and groundwater recharge areas along the east side of the Water Conservation Areas. The function of the buffer, once constructed, is to reduce the impacts of development on the Everglades, reduce levee seepage from the Everglades, increase ground water recharge, capture stormwater discharged to tide, and enhance wetland areas east of the conservation areas. The Without Plan Condition assumes that a portion of the lands for the East Coast Buffer are in public ownership; however, the Without Plan Condition does not assume that all the lands needed for the East Coast Buffer are in public ownership or that the physical facilities necessary for the operation of the storage of water on these land are constructed.

Another of the projects directly related to the Restudy Project is the Model Lands Basin. This land acquisition project is located in southern Miami-Dade County. The project includes the acquisition of approximately 42,000 acres, of which only 1,270 acres have been acquired. These lands form a contiguous habitat corridor with the Everglades National Park, the Southern Glades Save Our River project, Biscayne National Park, Crocodile Lakes National Wildlife Refuge, John Pennekamp State Park, and the existing National Marine Sanctuary.

4.10.2 Miami-Dade County Environmentally Endangered Lands Program

In 1990, Miami-Dade County approved a program to fund the acquisition, protection and maintenance of environmentally endangered lands. The Miami-Dade County Environmentally Endangered Lands Program specifically established an Environmentally Endangered Lands Management Trust Fund in Chapter 24A of the Code of Miami-Dade County, providing for:

> *" ...the preservation, enhancement, restoration, conservation and maintenance of environmentally endangered lands which either have been purchased with monies from the EEL Acquisition Trust Funds, or have otherwise been approved for management pursuant to Section 24A-8(2)." (Appendix X, Chapter 24A, Code of Miami-Dade County)."*

The Environmentally Endangered Lands program considers acquisition of sites proposed by the public and by other government agencies. Sites are inspected and then recommended for acquisition. Once approved for acquisition, the seller must be willing to sell the land to Miami-Dade County. No land is acquired from those landowners unwilling to sell. For the Without Plan condition, it is assumed that lands purchased through this program will be managed in accordance with Chapter 24A of the Miami-Dade County code.

4.10.3 Farm Bill

The U.S. Congress on April 4, 1996 enacted the Federal Agriculture Improvement and Reform Act of 1996 (Public Law 104-127). Section 390 entitled Everglades Ecosystem Restoration, provides the Secretary of the Interior with $200,000,000 to: conduct restoration activities in the Everglades ecosystem in south Florida, which shall include the acquisition of real property and interests in real property located within the Everglades ecosystem; and to fund resource protection and resource maintenance activities in the Everglades ecosystem. The Secretary of Interior can also transfer funds to the State of Florida, the Army Corps of Engineers or the South Florida Water Management District. The Secretary of Interior has executed Grant Agreements with the South Florida Water Management District designed to provide land acquisition funds for the purchase of lands within the East Coast Buffer and in the Everglades Agricultural Area. The Secretary of Interior has also executed a Grant Agreements with the State of Florida Department of

Environmental Protection for the purchase of lands within Southern Golden Glades Estates. The Department of Interior is also providing funds to purchase the Talisman Property in the Everglades Agricultural Area.

4.11 RECREATION

South Florida's climate and unique ecosystem offer a wide variety of recreational opportunities. Due to the region's high population growth rate, more recreational facilities and opportunities will be needed in the future. Without the plan, hunting, fishing, boating and wildlife viewing will continue; however, the quality of these recreational activities can be expected to decline concurrent with ecosystem decline. Given the likelihood of an increased demand in these activities occurring in direct proportion to the growth in population in the south Florida area, the impacts of the potential loss of recreational opportunities due to ecosystem decline is predictable.

SECTION 5
PROBLEMS AND OPPORTUNITIES

Water resources projects are planned and implemented to solve problems, meet challenges, and seize opportunities. In the planning setting, a problem can be thought of as an undesirable condition, while an opportunity offers a chance for progress or improvement. The identification of problems and opportunities gives focus to the planning effort and aids in the development of planning objectives. Planning objectives are statements of what a plan is attempting to achieve; they communicate to others the intended purpose of the planning process. Problems and opportunities can also be viewed as local and regional resource conditions that could be modified in response to expressed public concerns. This section describes the problems and opportunities in the study area and the planning goals and objectives developed for the study.

5.1 PUBLIC CONCERNS

At the heart of the identification of problems and opportunities process is an understanding of the public's concerns. As part of the reconnaissance phase of the study, an extensive public program was designed to determine the public's concerns through responses to three questions:

Question #1 - What are the **important resources** in the south Florida ecosystem?
Question #2 - What do you think are the **problems and opportunities** in the ecosystem?
Question #3 - How will you recognize **successful restoration** of the ecosystem?

Ten public workshops to address these questions were conducted across the study area in December 1993; about 2,200 people attended these workshops. Additional responses to the three questions were received through the mail primarily during January and February 1994.

All of these responses were read to identify the public's ideas about important resources, problems, opportunities and success. These ideas were grouped in ten general categories that covered the full range of concerns expressed by the public. While it is not possible to provide a count of the number of times any given concern was stated, the review provided a very good sense of the public's perception of the magnitude of each concern. Based on this review, the magnitude of public concerns can be grouped as follows:

Most people identified concerns about:
ecosystem health
uncontrolled growth

Many people identified concerns about:
water quality
water supply
balance
"they're the problem"

Some people identified concerns about:
flood control
recreation
economy
social considerations

A technical analysis of conditions in south Florida was conducted concurrent with the identification of public concerns. The technical analysis was designed to investigate and verify the dimensions of the concerns identified by the public, as well as to reveal other problems and opportunities that had not been identified by the public. The analyses covered:

- Ecosystem health
- Water quality
- Water supply
- Flood control
- Recreation
- Economic and social considerations

The public also expressed concerns about growth, “they’re the problem”, and balance that did not result in technical analysis.

Management of local and regional growth issues, including changes in population and development, is the responsibility of state, county, city, and other local interests. Although, in this study, alternative plans were not formulated to address public concerns about growth, the possible effects of alternative restoration plans on population, development, and other growth issues were evaluated and presented in the assessment of the effects of alternative plans.

The study team recognized many people's views about other interests being the cause of one or more problems, especially the view that government is "the problem" in south Florida. This study has been designed to elicit and use ideas and information from as many individuals and interest groups as desired to participate. It is through this extensive program of public involvement that the study hopes to build better understanding among all the concerned interests, and demonstrate the Corps' commitment to responsive public service.

One of the major steps in the planning process is the evaluation of the effects of alternative plans. Evaluation will reveal the plans' important effects, including effects that reflect progress toward meeting the objectives and constraints, as well as effects that are of interest for other reasons. Evaluation will cover the full range of effects on the human environment, including ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social and health effects, whether direct, indirect, or cumulative (Council on Environmental Quality, 1978). This information about the plans effects will provide interested members of the public and responsible decision makers with a basis for judging trade-offs within and among alternative plans; that is, for determining what they individually believe is a "balance" in view of likely beneficial and adverse effects. In short, this study will provide information that people can use to make decisions about "balance".

As a result of this effort, the reconnaissance study produced an initial set of planning objectives and constraints. As a part of this feasibility study, the reconnaissance study problem identification was refined further.

5.2 ECOLOGICAL PROBLEMS AND OPPORTUNITIES

Natural resource specialists agree that the remaining ecosystems in south Florida no longer maintain the functions and richness that defined the pre-drainage system, and that these measures of ecological health will continue to decline without preventative actions. Not only is it certain that these natural systems will not recover their defining attributes under current conditions, it is unlikely that even the current, unacceptable ecological conditions can be sustained into the future. For example, wading birds, key indicators of broad, regional patterns of aquatic production, continue to show declines in the total number of birds initiating breeding in south Florida colonies. Other examples are the declines in population levels of commercially and recreationally important fish species in the St. Lucie and Caloosahatchee Estuaries, and Biscayne and Florida Bays. High water levels in recent years in Lake Okeechobee have resulted in widespread losses of the emergent and submerged plant communities that provide habitat for economically important fish. If this trend continues, there may be substantial declines in the lake's fisheries. Regulatory releases to the Caloosahatchee and St. Lucie Estuaries can have damaging effects on the plants and animals inhabiting these areas. Prolonged high volume releases from Lake Okeechobee are believed responsible for the defoliation of seagrasses, fish kills, and deformed fishes within the St. Lucie Estuary during 1998, for example.

Many of the defining characteristics of the pre-drainage ecosystem (spatial extent, habitat heterogeneity, and dynamic storage) have either been lost or substantially altered as a result of land use and water management practices during the past 100 years in south Florida. Loss in spatial extent of natural areas has been most severe in the past 50 years with the construction of the C&SF Project, including the construction of Herbert Hoover Dike around Lake Okeechobee. Nearly half of the original Everglades ecosystem has been converted to agricultural and urban uses. The ecological effects of this loss in spatial extent include:

- a substantial reduction in habitat options for fish and wildlife,
- reduction in the system-wide levels of primary and secondary production, changes in the proportions of community types within the remaining system, and
- increasing concentrations of pollutants in remaining natural system surface waters, sediments, and wetlands and degradation of water quality.

The hydrology of the remaining Everglades has become altered by the operation of the C&SF Project, which has generally:

- reduced average annual flows and surface water stages,
- lowered regional ground water,
- either increased or decreased annual hydroperiods, depending on location,
- geographically relocated long and short hydroperiod wetlands,
- reduced the extent of long hydroperiod refugia,
- altered the frequency, duration and magnitude of interannual wet and dry cycles, and
- altered salinity levels in estuaries.

Overall, the construction and operation of the C&SF Project and its subsequent modification of the natural system have:

- contributed to the substantial reduction in spatial extent and system resiliency,
- provided a network of canals and levees which have accelerated the spread of polluted water, sediments, and exotic species,
- greatly reduced the water storage capacity within the remaining natural system, and
- created an unnatural mosaic of impounded, fragmented, and both over-inundated and over-drained marshes throughout the natural system.

Some level of ecological improvement is expected to occur as a result of the implementation of a number of projects such as: changes in the Lake Okeechobee regulation schedule, the addition of the stormwater treatment areas as part of the

Everglades Construction Project, rainfall-based schedules for Water Conservation Areas 2 and 3, implementation of Minimum Flows and Levels for the Everglades and Lake Okeechobee, and the completion of the C-111 and Modified Water Deliveries projects. The effects of these projects on the regional system were modeled and analyzed. The magnitude of the cumulative, regional benefits from these improvements, relative to the level of ecological improvements required to recover a functional, Everglades-type system, is uncertain. The best professional opinion is that these projects will contribute less than 25 percent of the overall, improvement in hydrological patterns required for the recovery of a regionally integrated ecosystem, or to achieve the ecological targets that were contained in the performance measures used to define the restoration objectives. In general, these projects are expected to produce a higher level of improvement in the quality of water in the remnant natural system. Further discussion of water quality follows this section.

Translating these levels of improvement in hydrological patterns and water quality conditions into predictions of regional ecological health is risky business. A large question in this evaluation is concerned with ecological thresholds, and whether modest improvements in hydrological patterns are sufficient to shift production and animal behavior patterns towards more Everglades-like patterns. The prevailing technical opinion is that these modest hydrological improvements are not expected to produce major, and in some cases, measurable, improvements in regional ecological conditions or in habitats critical to several species of endangered species. As mentioned above, relatively greater levels of improvement are expected for water quality conditions. Reduced inputs of excessive nutrients should slow the spread of cattails and other plants with high nutrient tolerances, and should produce a slow recovery of natural vegetation patterns in some nutrient-stressed parts of the system.

5.3 WATER QUALITY PROBLEMS AND OPPORTUNITIES

5.3.1 Regional Overview

Many of the regulatory and environmental restoration programs, which are assumed to be in place in 2050 (see Section 4.8) are projected to result in a net improvement in water quality in south Florida. In addition to those assumptions, water quality improvement actions undertaken to comply with the requirements of the Federal Clean Water Act (P.L. 92-500) as implemented by the U. S. Environmental Protection Agency, the Florida Department of Environmental Protection, the South Florida Water Management District, the Seminole and Miccosukee Tribes, and local governments are expected to result in improvements in regional water quality necessary to comply with state, tribal, and local water quality standards. Examples of these programs include: Municipal Separate Storm

Sewer Systems (MS4) and other National Pollutant Discharge Elimination System (NPDES) point and non-point source pollution reduction permitting requirements, Total Maximum Daily Loads established under Section 303(d) of the Clean Water Act., and Pollutant Load Reduction Goals (PLRGs) established pursuant to the State of Florida's Surface Water Improvement and Management (SWIM) Act for designated priority waterbodies.

From a regional perspective, the most comprehensive of these programs is the TMDL program implemented by the Florida Department of Environmental Protection and the Seminole and Miccosukee Tribes. Under Section 303(d) of the Clean Water Act, states and tribes are required to identify water bodies within their jurisdictions not meeting water quality standards and rank those water bodies in terms of the severity of the pollution and designated and actual uses of the water bodies. The 303(d)-listed water bodies are to be reported to the U.S. Environmental Protection Agency in accordance with Section 305(b) of the Clean Water Act. TMDLs are to be developed for 303(d)-listed water bodies consistent with the priority ranking and are to be established "at a level necessary to implement the applicable water quality standards with seasonal variations and a margin of safety which takes into account any lack of knowledge concerning the relationship between effluent limitations and water quality." However, the TMDL program, for the most part, has not been implemented in the study area.

In its 1998 report to the U.S. Environmental Protection Agency, the Florida Department of Environmental Protection identified approximately 160 impaired water bodies in the study area in accordance with the requirements of Section 303(d) of the Federal Clean Water Act. The Florida Department of Environmental Protection has developed a strategy for assessing watersheds (basins) and developing TMDLs and remediation plans for pollutants causing impairment of 303(d)-listed water bodies (FDEP, 1996a and FDEP, 1996b). (It should be noted that excessive nutrient loads were typically identified as the most common pollutant causing impairment.) The Florida Department of Environmental Protection's statewide strategy for implementing TMDLs involves five-year cycles for basin assessment, monitoring, data analysis and TMDL development, development of basin management plans, and implementation of basin management plans. However, it should be noted that this strategy has not yet been approved by the U.S. Environmental Protection Agency, and would take up to 15 years to complete (statewide) once approved. It should be further noted that the Florida Department of Environmental Protection's strategy for TMDLs does not give regional priority to south Florida; rather, the strategy was developed from a statewide perspective. Nevertheless, several key water bodies in south Florida will receive priority for TMDL development, including Lake Okeechobee and the Indian River Lagoon.

Development and implementation of TMDLs is an essential step for achieving overall ecosystem restoration in south Florida. Water quality restoration targets are necessary for detailed design of Restudy recommended plan components to achieve water quality restoration performance objectives. Further, implementation of basin management plans developed under the TMDL program is necessary to achieve ecological restoration in watersheds "downstream" of recommended plan components.

The triennial review of state and tribal water quality standards performed under Section 303(c) of the Clean Water Act is another essential step for achieving ecosystem restoration in south Florida. States and tribes are required to periodically review their water quality standards to ensure that standards are adequate to protect designated uses of waters. Within the study area, there are no specific numeric water quality criteria for many pollutants (e.g., nutrients and several pesticides) detected in ongoing water quality monitoring activities. The extent of the contribution of such pollutants to overall "impairment" levels in 303(d)-listed water bodies is also unknown. As part of the triennial review process, Florida Department of Environmental Protection and the Seminole and Miccosukee Tribes may propose modifications to existing water quality criteria and propose additional water quality criteria (as appropriate) to protect water resources. Modified and additional water quality criteria should be integrated with future detailed planning and design activities to assure that recommended plan components are operated consistent with water quality restoration targets.

The South Florida Water Management District is also developing pollution load reduction goals (PLRGs) for SWIM-listed water bodies. In south Florida, SWIM-listed water bodies include Lake Okeechobee, the Indian River Lagoon, and Biscayne Bay. PLRGs are similar to TMDLs in that numeric water quality targets are promulgated and remediation programs are developed. TMDLs and PLRGs are essential water quality restoration targets to be integrated into future detailed planning and design activities for recommended plan components during the implementation period.

Several larger municipalities within the study area are required to apply to the U.S. Environmental Protection Agency for "Municipal Separate Storm Sewer System" (MS4) permits to address non-point source pollution sources within their jurisdictional boundaries. MS4 permit requirements apply to master drainage systems of local governments with populations greater than 100,000. The U.S. Environmental Protection Agency has generally implemented the MS4 permitting program on a countywide basis, incorporating cities, Ch. 298 drainage districts, and the Florida Department of Transportation (FDOT) where appropriate. Cities with populations greater than 100,000 are permitted separately. The following municipal governments in the study area are currently subject to MS4 permitting: Reedy Creek Improvement District, Broward County (25 co-permittees), City of Ft.

Lauderdale, City of Hollywood, Palm Beach County (39 co-permittees), City of Hialeah, Dade County (20 co-permittees), City of Miami, and Lee County (12 co-permittees). Local government regulatory programs to control smaller point and non-point sources of pollution will compliment state and tribal water quality regulatory and remediation programs.

The following Sections 5.3.2 through 5.3.11 summarize projected water quality problems and opportunities in study area sub-regions. Accurately projecting future water quality conditions in the Restudy area is difficult, due to the vast scope of the study area, uncertainty in future growth and land use changes, and in part to the lack of comprehensive water quality data indicative of statistically reliable trends (FDEP, 1996a). The following sub-sections predict water quality changes expected to occur within each of the C&SF Project sub-regions based on current water quality data and descriptions of existing conditions, available trend data, future population growth projections and the assumed implementation of certain specific regulatory and environmental restoration and water supply projects. Actual improvements in water quality conditions, where projected to occur, depend in large degree upon the successful implementation of the programs and projects included in the future without plan assumptions. For mercury (***Section 5.3.12***), conditions are projected for the regional system as a whole.

5.3.2 Kissimmee River Region

By 2050, water quality conditions in the Kissimmee River watershed south of urbanized Orange County are expected to be improved overall compared to existing conditions due to ongoing and planned ecological restoration programs in the drainage basin. In its 1998 303(d) list, the Florida Department of Environmental Protection identified approximately 25 waterbodies or segments of waterbodies within the Kissimmee River watershed where water quality was not adequate to sustain designated uses. Several of the 303(d) listed waterbodies are actually reaches of the Kissimmee River. Most of the watershed is classified as Class III ("fishable–swimmable") waters; several waterbodies within the watershed are designated Outstanding Florida Waters by the State of Florida. Pollutants and/or water quality criteria identified contributing to impairment of designated use include: low levels of dissolved oxygen, excessive nutrients, coliform bactieria, high biochemical oxygen demand, several trace metals including mercury (based on fish-consumption advisories), turbidity, and un-ionized ammonia.

Kissimmee River restoration projects are expected to reduce net pollution loading to the Kissimmee River and in downstream Lake Okeechobee through the restoration of remnant wetlands presently used as agricultural lands currently contributing pollutants to wetlands. Restored wetlands will also have a pollutant assimilation function, resulting in improved water quality in downstream water bodies (tributaries and oxbows). Additional ongoing land acquisition activities by the South Florida Water Management District will supplement ongoing environmental restoration projects (SFWMD, 1997a).

The extent of urbanization in the vicinity of the cities of Orlando and Kissimmee, north of the Kissimmee River Chain of Lakes is expected to increase. While new developments must comply with water quality treatment requirements for stormwater runoff, the net load of pollutants, particularly those typically associated with urban stormwater runoff contributed to the watershed north of the Kissimmee Chain of Lakes is expected to increase. Most of this increased pollution load would be expected to be retained in the Kissimmee Chain of Lakes and not enter the Kissimmee River – Lake Okeechobee system. Urbanization and attendant pollution loads in the region are not expected to increase significantly south of Lake Kissimmee.

5.3.3 Lake Okeechobee

Lake Okeechobee is a Class I waterbody (potable water supply) according to Florida Administrative Code rule. Class I waterbodies generally have the most stringent surface water quality and pollution control criteria in Florida. However, water quality data for Lake Okeechobee indicate that the lake is in a eutrophic condition, primarily due to excessive nutrient loads from agricultural sources both north and south of the lake.

The main tributary to Lake Okeechobee is the Kissimmee River. As stated above, several waterbodies within the Kissimmee River watershed, including segments of the river itself, are impaired to various levels. Degradation of water quality in the Kissimmee River watershed contributes to downstream degradation in Lake Okeechobee. Lower reaches of the Kissimmee River contribute high levels of nutrient loading to Lake Okeechobee.

Another important tributary to the lake is the Taylor Creek/Nubbin Slough basin. The Taylor Creek/Nubbin Slough basin contributes high levels of nutrient loading, low levels of dissolved oxygen, and elevated coliform bacteria and turbidity levels to the lake. The Taylor Creek/Nubbin Slough basin contributes only 4 percent of the total volume of inflows to Lake Okeechobee, but accounts for approximately 29 percent of the total phosphorus inflow loads.

Eight segments of Lake Okeechobee are also included on the Section 303(d) list. Water quality parameters/criteria causing impairment at eight different monitoring locations in Lake Okeechobee include: excessive nutrients, low levels of dissolved oxygen, and high concentrations of unionized ammonia, iron, chlorides, and coliform bacteria. The Fisheating Creek and C-41 basins on the northwest side of the lake also contributes pollutants causing impairment in Lake Okeechobee.

Water quality in Lake Okeechobee is expected to slowly improve between 1999 and 2050. Field and laboratory studies of phosphorus stored in lake sediments indicate that sediment bound phosphorus is a dominant pollutant affecting lake water quality (Reddy et al., 1995). Currently, the average cumulative phosphorus load to the lake exceeds the Surface Water Improvement and Management Plan target by approximately 100 tons per year (SFWMD, 1997f). Phosphorus loads to the lake eventually become sequestered in lake sediments. The phosphorus in these sediments, which has accumulated over time from excessive external loads, is frequently resuspended (primarily by wind-aided mixing: Havens, 1997) and will tend to maintain a high phosphorus concentration in the water column, even if all sources of phosphorus in the contributing watershed are controlled consistent with regulatory and watershed management programs. Although short-term water quality conditions in Lake Okeechobee are not expected to improve, in place pollutant reduction programs in the lower Kissimmee River and Taylor Creek/Nubbin Slough basins are expected to result in long-term reduction in Lake Okeechobee water column nutrient concentrations

Urban development in the Lake Okeechobee watershed and non-point source pollution loading associated with urban stormwater runoff is not expected to increase significantly by 2050.

5.3.4 Upper East Coast and Indian River Lagoon

The Upper East Coast region includes Martin and St. Lucie Counties and a small portion of Okeechobee County. The principal water body is the Indian River Lagoon, which includes the St. Lucie River. The Upper East Coast is hydrologically connected to the Everglades and Florida Bay ecosystems through the C-44 (St. Lucie) Canal. The Indian River Lagoon is a SWIM priority water body. Most of the Upper East Coast watershed consists of Class III waters; however, there are small areas of Class II waters (shellfish propagation or harvesting) within the watershed. Class II waters are generally afforded greater protection than Class III waters. Currently, nine locations in the St. Lucie (C-44) Canal, the North and South Forks of the St. Lucie River, and several sub-basins draining to the Indian River Lagoon are listed by the Florida Department of Environmental Protection on the 1998 303(d) list of impaired waterbodies. Pollutants/constituents causing impairment include: low levels of dissolved oxygen, excessive nutrients, high levels of total suspended solids (TSS), high biochemical oxygen demand, coliform bacteria, and mercury (based on fish consumption advisories). There are an additional eight monitoring locations in the southern Indian River Lagoon area also included on the 1998 303(d) list. In addition to the above-listed constituents, copper and turbidity were identified to be causing use impairment at some of the monitoring sites.

Overall, water quality conditions in the Upper East Coast and the Indian River Lagoon are expected to be somewhat improved by 2050, compared to existing conditions. Lake Okeechobee freshwater discharges via the St. Lucie Canal (C-44) alter ambient salinity levels and deliver nutrients and other pollutants contained in Lake Okeechobee water and runoff from localized sources (agricultural and urban) to the estuary. The C-23/C-24/C-25 Canal system in St. Lucie County facilitates drainage to sustain agricultural (primarily citrus groves) and urban development in the vicinity of those canals. Implementation of a different regulation schedule for Lake Okeechobee is also expected to improve water quality conditions in the Indian River Lagoon Estuary by reducing the frequency and volume of fresh water delivered to the estuary. It is also expected that agricultural non-point source pollution loads delivered to the estuary via secondary and tertiary canals connected to C&SF Project canals will be reduced compared to existing conditions through the implementation of agricultural Best Management Practices and the conversion of some agricultural lands to other uses (e.g., conservation, urban/suburban development).

The extent of urbanization in the watershed is expected to increase by 2050. New growth and development in the watershed will be regulated to comply with water quality regulations governing point and non-point source discharges; however, the net pollution load contributed to the St. Lucie River and the Indian River Lagoon system from these sources is expected to increase compared to existing conditions. Ongoing and planned pollutant load reduction activities in the Upper East Coast region should help offset additional pollutant loads expected to occur from future urbanization.

5.3.5 Everglades Agricultural Area

According to the Florida Department of Environmental Protection's 1998 303(d) list of use-impaired water bodies, there are approximately 10 canal segments within the Everglades Agricultural Area not meeting designated uses for Class III waters. For the most part, these include canal segments affected by operation of the primary pump stations and canals discharging water from the Everglades Agricultural Area to downstream areas (e.g., S-7, and S-8 pump stations; North New River, Hillsboro, and West Palm Beach Canals). In addition to excessive nutrient loads, low dissolved oxygen levels and high levels of mercury (based on fish consumption advisories), coliform bacteria, total suspended solids, turbidity, and unionized ammonia contributed to use impairment in Class III waters within the Everglades Agricultural Area. It should be noted that within the Everglades Agricultural Area, there are many agricultural canals or ditches in agricultural water management systems controlled by water control structures permitted by the South Florida Water Management District. Such water bodies are classified as Class IV waters (agricultural water supply) pursuant to Rule 62-302.600(3)(a), Florida Administrative Code. Generally, the water quality criteria for Class IV waters are less stringent than those for Class III waters. None of the 303(d)-listed segments within the Everglades Agricultural Area are in Class IV waters.

Water quality conditions within the Everglades Agricultural Area are expected to improve in 2050 compared to existing conditions. It is important to note that the existing conditions for the Everglades Agricultural Area demonstrate significant water quality improvements compared with recent past conditions. Recent water quality improvements in the area have occurred as a result of the implementation of the Everglades Agricultural Area regulatory program (Florida Administrative Code Rule 40E-63) beginning in 1993. The regulatory program requires Best Management Practices and monitoring to achieve a 25 percent reduction in phosphorus loading from the Everglades Agricultural Area to the Everglades Protection Area. Recent monitoring results indicate that phosphorus loads in area runoff have declined approximately 51 percent (three year average, SFWMD, 1997b). The current average concentration of total phosphorus contained in Everglades Agricultural Area runoff is approximately 100 parts per billion (Havens, 1997). Best Management Practices are also expected to have resulted in a net reduction of other pollutants contained in agricultural runoff, although the extent of load reduction for other pollutants has not been fully quantified since the implementation of the program; nor is it a specific objective of that program.

5.3.6 Natural Areas

Approximately 18 waterbody segments within Loxahatchee National Wildlife Refuge (Water Conservation Area 1), and Water Conservation Areas 2 and 3 were listed as use-impaired on the Florida Department of Environmental Protection's 1998 303(d) list. Pollutants/water quality parameters contributing to use-impaired conditions include: excessive nutrient loads, low dissolved oxygen levels, high levels of mercury (based on fish consumption advisories), un-ionized ammonia, coliform bacteria, total suspended solids and certain trace metals. There are also four waterbody segments in Everglades National Park on the 303(d) list. Those water body segments include: ENP Shark Slough, ENP L67 Culvert @ US 41, Taylor Slough, and the Tamiami Canal. Problem constituents in Everglades National Park waters include low levels of dissolved oxygen, and high levels of nutrients, mercury (based on fish consumption advisories), iron, other trace metals. Many of the water body segments in the Water Conservation Areas and Everglades National Park may eventually be removed from subsequent 303(d) lists because the Everglades Forever Act includes schedules and strategies for achieving compliance with water quality standards, consistent with the requirements of the Clean Water Act.

Water quality conditions in the Rotenberger and Holey Land Wildlife Management Areas, Loxahatchee National Wildlife Refuge, the Water Conservation Areas and in downstream Everglades National Park are expected to be significantly improved in 2050 compared to current (without the Everglades Construction Project) conditions.

In the southern Everglades, implementation of the C-111 and Modified Water Deliveries Projects may also involve developing water quality treatment features necessary to assure that regulatory requirements are met. Minimally, implementation of the C-111 Project involves acquisition of the Frog Pond agricultural area adjacent to the C-111/L-31W levee/borrow canal system, which will result in a net reduction of pollution loading (nutrients, pesticides) into Everglades National Park via the existing canal system from non-point source agricultural runoff.

5.3.7 Lower East Coast and Biscayne Bay

For Restudy planning purposes, the Lower East Coast consists of Palm Beach, Broward, and Miami-Dade Counties, including Biscayne Bay and Lake Worth Lagoon. According to the Florida Department of Environmental Protection's 1998 303(d) list, approximately 42 waterbody segments (both fresh and marine waterbodies) within the Lower East Coast are use-impaired. Pollutants/water quality constituents causing impairment include low levels of dissolved oxygen, high levels of mercury (based on fish consumption advisories) and other trace metals, and high levels of coliform bacteria, total suspended solids, bio-chemical oxygen demand, and un-ionized ammonia.

Four of the main C&SF Project canals delivering flows from Lake Okeechobee and the Water Conservation Areas (the West Palm Beach, Hillsboro, New River, and Miami Canals) traverse the Lower East Coast. In addition to conveying Lake Okeechobee and Water Conservation Area flows, the C&SF Project canals and a network of connecting secondary and tertiary canals provide drainage in the Lower East Coast, which conveys stormwater runoff and attendant pollution loads to estuarine waters. Management of stormwater runoff and flooding via the existing canal system has been implicated as the chief cause of water quality degradation in the region, particularly in the northern portion of Biscayne Bay.

Improving water quality in the Lower East Coast to meet water quality standards in all impaired water bodies will likely be difficult, considering the extent of urban development, minimal or non-existent water quality treatment for non-point source runoff, and other direct (point source) and indirect discharges adversely affecting water quality in the Lower East Coast. Water quality conditions are expected to worsen in the Lower East Coast (central and southern Palm Beach, Broward, and Miami-Dade Counties) by 2050 compared to current conditions. Florida Department of Environmental Protection's 1996 Section 305(b) report to the U.S. Environmental Protection Agency describing water quality conditions in the region indicates that most of the region exhibits "fair" or "good" water quality. The report goes on to state that "most pollution (in the region) comes from stormwater", although bacteriological contamination from wastewater discharges and septic tanks is also a significant problem, particularly in the Miami River, downstream in Biscayne Bay, and urban areas west of the intracoastal waterway in Broward

County and north of the New River. Water quality conditions in receiving water bodies in 2050 are expected to be further degraded, due to the developed condition of the watershed and the continued accumulation of pollutants in sediments in receiving water bodies.

Nearly all of this heavily urbanized watershed drains to estuarine waters. Net pollution loads, especially from non-point sources, to receiving waters in the Lower East Coast are expected to increase as a result of projected population increases. The expected increase in net pollution loads may not be directly proportional to population growth. New growth and urban/suburban development in the Lower East Coast must comply with water quality treatment requirements for non-point source runoff, whereas much of the existing development in the Lower East Coast does not include facilities for treatment of non-point pollution sources. Nevertheless, the projected addition of approximately 2.7 million people to the region is expected to cause water quality conditions to be further degraded, especially in those basins which are already stressed by existing pollution loads.

In Palm Beach County, the Lake Worth Lagoon Estuary is the receiving water body for most of that urban watershed. There are approximately eight use-impaired waterbodies in Palm Beach County on the Florida Department of Environmental Protection's 1998 303(d) list. Listed waterbody segments include coastal canals and freshwater areas further inland. Water quality conditions are expected to improve (in terms of estuarine salinity targets) as a result the C-51 (Stormwater Treatment Area 1 East) Project, which will divert fresh water discharges to Lake Worth Lagoon to a treatment area prior to discharge to Water Conservation Area 1. However, net non-point source pollution loads to Lake Worth Lagoon may increase commensurate with increases in population and development.

Although there are no extensive estuarine water bodies in Broward County, remaining mangroves in southern Broward County canals and along the Intracoastal Waterway provide similar habitat. There are approximately 21 303(d)-listed use-impaired water body segments in Broward County. These waterbody segements are primarily coastal canals providing drainage. Due to the extent of existing urban development in the watersheds of those canals, it is not likely that there will be a significant increase in future non-point source pollution loads into these water bodies. However, it is also unlikely that basin-wide stormwater best management practices (e.g., retention/detention facilities, filtration, etc.) can be implemented effectively in heavily urbanized watersheds, due to the lack of available land for such facilities. Future basin planning efforts during TMDL development and implementation may result in more effective controls of other direct (point source) and indirect discharges of pollutants (e.g. car washes and other industrial facilities). At best, the long-term prognosis for improving all use-impaired water bodies in coastal areas of Broward County is uncertain.

In Miami-Dade County, approximately 13 waterbody segments were identified as use-impaired on the Florida Department of Environmental Protection's 1998 303(d) list. Most are coastal canals providing drainage of runoff to Biscayne Bay. Biscayne Bay is the largest estuarine water body in the Lower East Coast, and is the receiving water body for most of the developed area of Miami-Dade County. Most of Biscayne National Park is located within the central and southern portion of the Biscayne Bay Estuary. As with some of the Broward County canals, controlling non-point sources of runoff in heavily urbanized areas in Miami will be difficult, due to the lack of available land for basin-wide best management practices. Some incremental improvement of non-point source pollution loads may be realized through the basin management plans to be developed by the Florida Department of Environmental Protection. Point sources and other direct discharges of pollutants to Biscayne Bay and tributary canals should be significantly improved if basin management plans are fully implemented. However, overall, it is not expected that water quality in coastal canals draining to Biscayne Bay will be improved to the point that all surface water quality standards will be achieved. Furthermore, any water quality benefits achieved as a result of the Biscayne Bay Surface Water Improvement and Management Plan may be offset by increases in non-point source pollution loads associated with projected population increases.

5.3.8 Florida Bay

Barnes Sound is the only segment of Florida Bay included on the Florida Department of Environmental Protection's 1998 303(d) list. Excessive nutrients, chlorides, and low dissolved oxygen were identified as constituents of concern in ambient water quality monitoring. Other areas of the bay also experience periodic water quality problems. Salinity is the primary water quality parameter of concern in the bay. Bay waters are periodically hypersaline or too low in salinity, depending upon the frequency of hurricanes and other significant storm events and flood release discharges from Central and Southern Florida Project features. Advective conditions in the bay have also contributed to extensive algal blooms. Water temperature levels are also periodically elevated above prescribed temperature limitations. Seatrout collected from Florida Bay also exhibit elevated mercury levels.

Water quality conditions in northeastern Florida Bay should improve in 2050 compared to existing (1995) conditions. Full implementation of the Biscayne Bay SWIM Plan elements should benefit water quality conditions in Florida Bay also. When fully completed, it is anticipated that the C-111 Project would improve water quality conditions in the vicinity of Taylor Slough through the implementation of structural and operational changes necessary to achieve preferred hydrologic conditions. It is expected that the net load of agricultural non-point source pollution entering the C-111 Canal and south into Florida Bay will be reduced in 2050 compared to existing conditions. The Modified Water Deliveries to Everglades

National Park Project is also expected to result in water quality improvements in Florida Bay through the delivery of increased volumes of fresh water to the bay via Northeast Shark River Slough.

5.3.9 Florida Keys

The Florida Keys as a whole were identified as having use-impaired water quality on the Florida Department of Environmental Protection's 1998 303(d) list; however, water quality problems are generally restricted to canals, marina basins, and nearshore waters as opposed to adjacent open waters. The principal pollutants of concern are excessive nutrient loading and fecal coliform bacteria from inadequate wastewater treatment and disposal facilities, although low dissolved oxygen levels are also common in Keys canals.

Due to recently imposed growth management regulations and limitations on expanded urban development, the population of the Keys is not expected to greatly increase by 2050. In addition, the Florida Keys National Marine Sanctuary Plan (National Oceanic and Atmospheric Administration, 1996) contains a Water Quality Protection Program developed by the U.S. Environmental Protection Agency (USEPA, 1996) in cooperation with the Administration and the Florida Department of Environmental Protection. The Water Quality Protection Program Document, approved in 1996, contains a set of initial recommendations for corrective actions, monitoring, research, and education/outreach. These recommendations have been included in a Water Quality Action Plan focusing on wastewater, stormwater, marinas and live-aboard vessels, landfills, hazardous materials, mosquito spraying, canals and research and monitoring. If the recommended wstewater and stormwater corrective actions are implemented, water quality conditions in the Florida Keys region are expected to be improved in 2050 compared to existing conditions.

The U.S. Environmental Protection Agency, other federal, state and local agencies and citizen stakeholders have identified wastewater infrastructure as the single most important investment to improve nearshore and canal water quality. The cost of wastewater improvements necessary to improve nearshore and canal water quality in the Florida Keys has been estimated at between $184 to $418 million, depending on the percentage reduction in wastewater nutrient loadings to be achieved and which treatment system or systems are ultimately selected. Improvements of stormwater management in the area of the Florida Keys is also needed. The cost of stormwater management and treatment necessary to reduce pollutant loadings in the Florida Keys is estimated at between $370 to $680 million, depending on the percentage reduction in stormwater pollutant loadings targeted to be achieved and which areas are selected to be retrofitted. Water quality improvements in Florida Keys canals and nearshore areas are expected to result from improved wastewater collection, treatment, and disposal implemented through the Monroe County Wastewater Master Plan and through implementation of the Monroe County Stormwater Master Plan, both of which are major components of the Water Quality Protection Program.

5.3.10 Big Cypress Basin

The Big Cypress Basin (the watershed of Big Cypress National Preserve) includes agricultural areas west of the Everglades Agricultural Area, the Seminole Tribe's Big Cypress Reservation, most of the Miccosukee Tribe of Indians' reservation lands, and developed areas of the west coast including Naples and Marco Island. Five waterbody segments within the Big Cypress Basin were included on the Florida Department of Environmental Protection's 1998 303(d) list. Pollutants/constituents of concern include excessive nutrients, coliform bacteria, biochemical oxygen demand, mercury (based on fish consumption advisories), and low levels of dissolved oxygen. It should be noted that none of the 303(d) list sites are within the Big Cypress National Preserve. However, the L-28 Interceptor Canal, on the east side of the Big Cypress Basin was listed as use-impaired due to elevated nutrient levels and low levels of dissolved oxygen. It should be further noted that due to the scarcity of ambient monitoring sites in coastal waters of the basin, actual water quality problems are likely to be more severe in coastal waters than as described in the Florida Department of Environmental Protection's 1996 305(b) Report due to development pressure and point and non-point source pollution loading in developing areas.

Water quality in interior areas of the Big Cypress Basin (the watershed of Big Cypress National Preserve) is not expected to be significantly changed in 2050 compared to existing conditions. However, the rapidly expanding extent of agricultural (citrus) development in the north-central area of the region (Immokalee, southwestern Hendry County) could create an increase in non-point source pollution associated with agricultural activities in Mullet Slough and East Hinson Marsh. Water quality in coastal areas is expected to decline consistent with projected population growth.

Excessive drainage and the introduction of water of poor quality into Big Cypress National Preserve via the existing canal system constitutes the most significant existing and future water quality problem for Big Cypress National Preserve. It should be noted that the canals contributing pollutants into Big Cypress National Preserve are not part of the C&SF Project. Existing pollution loads entering the Big Cypress National Preserve from northwestern areas of the watershed (Big Cypress Seminole Indian Reservation, C-139 Basin and C-139 Annex agricultural areas) are expected to be reduced in 2050 through the implementation of planned and ongoing water quality improvement projects.

5.3.11 Caloosahatchee River Region

The Florida Department of Environmental Protection listed approximately 14 water body segments in the Caloosahatchee River basin and in downstream coastal waters on its 1998 303(d) list. Water quality parameters of concern include excessive nutrients, coliform bacteria, biochemical oxygen demand, and depressed levels of dissolved oxygen. As with the Big Cypress Basin, the number of monitoring locations in coastal waters of the region used to prepare the 305(b) Report is probably inadequate to accurately characterize the extent of water quality degradation in coastal areas. Extensive urban development (Ft. Myers and vicinity, Cape Coral) at the mouth of the Caloosahatchee River contributes significant point and non-point source pollution loads into coastal canals and downstream into the Caloosahatchee estuarine system.

In 2050, water quality conditions in the upper (eastern) and central portions of the watershed are expected to be unchanged compared to existing conditions. Water quality in downstream coastal areas is expected to decline as a result of increased population growth and urban and agricultural development. Water quality impacts from increased agricultural development are expected to be most readily observed in downstream areas of the watershed. The projected increase in population growth in urban areas of the Caloosahatchee River region's watershed is expected to exacerbate existing water quality problems in coastal waters, particularly those associated with wastewater discharges. Offsetting the coastal development and inland agricultural development water quality impacts is the implementation of a different regulatory schedule for Lake Okeechobee, which is expected to improve water quality conditions in the Caloosahatchee River and estuary by reducing the frequency and volume of large quantities of nutrient/sediment laden Lake Okeechobee flood regulation waters.

5.3.12 Mercury

There is much uncertainty about the sources of mercury in south Florida and the Everglades marsh mercury cycling processes that control mercury bioaccumulation. Controlling mercury contamination of the Everglades ecosystem depends on actions that are beyond the scope of the Restudy. The major external source of mercury for the Everglades ecosystem is atmospheric deposition. Some estimate that a high percentage of the mercury deposited into the Everglades could be contributed from local atmospheric emission sources in the urban area (Dvonch, 1998). Others estimate that most of the mercury deposited on the Everglades originates from outside Florida. Research indicates that mercury deposition rates in portions of North America have greatly increased since the turn of the century (Swain, et al, 1992). Some of this historically accumulated mercury is being recycled by the ecosystem; however, this historical mercury could also be buried beneath the recycling zone by accumulating peat if new sources are shut off.

The effect of this burial process hypothesis has been estimated with a mercury cycling model (Ambrose et. al., in press). The model predicts that as little as a 50 percent reduction in atmospheric mercury deposition over the next 50 years (2050) will decrease methylmercury concentrations in Everglades water and fish. Recent and potential future regulatory emission controls may be needed to reduce the atmospheric loading to the system from local sources; however, the significant global atmospheric mercury component is much more difficult to control and will require international agreements.

If control of atmospheric mercury deposition can be affected by decreasing local emission sources in concert with the implementation of the 44,000 acres of Stormwater Treatment Areas constructed as part of the Everglades Construction Project, additional benefits may accrue. However, the complex interactive modeling predictions have not yet been done. The long-term efficiency of the Stormwater Treatment Areas in removing phosphorus and other water quality constituents is presently uncertain, as is the effect of these water quality changes on mercury cycling downstream. Among the key factors that are thought to influence mercury cycling within the Everglades are complex inter-relationships involving phosphorus, sulfur, oxygen, carbon, periphyton, peat accretion and sediment redox conditions. There is no scientific consensus as to which of these factors will dominate, and whether the driving factors will be the same throughout all portions of the 4,000 square mile Everglades ecosystem. Given the 80 percent reduction in total phosphorus obtained in the Everglades Nutrient Removal Project during the early years of operation, it is possible that a decrease in the methylation of mercury could occur downstream due to the declining nutrient concentrations to the marsh and the reduced stimulation of both producers and decomposers. However, it is unclear what effect changes in sulfur forms will have on mercury methylation, and which influence will dominate.

5.4 ECONOMIC AND SOCIAL WELL-BEING PROBLEMS AND OPPORTUNITIES

The C&SF Project, by providing flood protection and water supply, has enabled the population of south Florida to grow from approximately 900,000 persons in 1950 to over 5.5 million in 1995. By 2050, population is projected to grow to 11.6 million. Increases in population growth intensify the competition for and stress upon regional water resources.

With the current C&SF Project, the availability of water from regional surface and ground water sources remains relatively constant. The growing demand for inexpensive, high quality water for agriculture, industry, and an increasing population could exceed the limits of readily available sources. When factoring in the needs of the natural system, upon which a good part of the region's economy depends, conflicts among water users may become even more severe. In addition, the human community is fundamentally dependent on the project for public health, safety, and welfare.

In the south Florida region in general and the Lower East Coast in particular, per capita income levels are higher than in the rest of the state. There is a strong per capita income difference between the urbanized Lower East Coast and the agricultural areas surrounding Lake Okeechobee. Employment and income opportunities in the important industries of agriculture and tourism are heavily reliant on the benefits provided by the C&SF Project.

Agriculture and tourism were identified as "critical industries" by the Governor's Commission for a Sustainable South Florida. Agriculture depends upon the system for vital water supply and flood protection. The tourism industry is dependent upon the project in a myriad of ways. For example, a healthy ecosystem and its attendant tourism are the mainstays of the Monroe County economy, as reflected by the relative domination of economic activity there in the services, retail trade, and fisheries industries. The ability to sustain the region's economy and quality of life depend, to a great extent, on the success of the efforts to protect and better manage the region's water resources.

Predictions of water shortages in the future indicate serious – and probably unacceptable – levels of water supply cutbacks. Modeling shows that for the Lake Okeechobee Service Area, 24 percent of water supply demands could not be met over a 30-year period. This translates into 16 years (out of 30) in which the area was in water supply cutbacks. In the Lower East Coast, water supply cutbacks were predicted to occur in a range from 15 years in northern Palm Beach County and Miami-Dade County to 29 years in Broward County. The monetary losses incurred by these shortages are quantified in ***Appendix E*** of this report.

5.5 PLANNING GOALS AND OBJECTIVES

The purpose of the Restudy is to review how well the C&SF Project is functioning and determine what modifications may be needed. The precursor to the feasibility phase of the study - the reconnaissance study – was completed in 1994 and identified a set of regional-scale planning objectives. The Governor's Commission for a Sustainable South Florida also developed a set of regional-scale objectives for the Restudy as part of their effort to develop the *Conceptual Plan for the Restudy*. A synthesis of these has resulted in an inclusive set of objectives to achieve two general goals for the south Florida ecosystem: enhance ecologic values, and enhance economic values and social well being. These goals, and the study objectives associated with them, are shown in ***Table 5-1***.

TABLE 5-1
GOALS AND OBJECTIVES FOR THE C&SF RESTUDY

Goal: Enhance Ecologic Values
• Increase the total spatial extent of natural areas • Improve habitat and functional quality • Improve native plant and animal species abundance and diversity
Goal: Enhance Economic Values And Social Well Being
• Increase availability of fresh water (agricultural/municipal & industrial) • Reduce flood damages (agricultural/urban) • Provide recreational and navigation opportunities • Protect cultural and archeological resources and values

5.5.1 Enhance Ecologic Values

Healthy natural systems are integral to the sustainability of south Florida. These systems provide numerous functions such as:

- habitat for numerous plant and animal species,
- recreation and educational opportunities (photography, fishing, hunting, bird watching, etc.),
- water quality filtration including removal of nutrients and silt,
- ground water recharge,
- soil formation,
- hydrologic linkages,
- ground water quality protection,
- interception of airborne pollutants,
- shoreline stabilization, and
- protection against erosion.

Each natural area is uniquely important. Wetlands and lakes, in particular, retard floodwater and provide surface water storage. Mangroves and estuaries provide important feeding areas for manatees and breeding habitat for numerous finfish and shellfish, including several of commercial interest. Upland natural systems function as noise buffers, urban green space, habitat for plants and animals (such as tree snails, deer, hundreds of species of birds, and the endangered panther and indigo snake), and travel corridors for these same animals. Thus, plant and animal habitat, although perhaps the most obvious benefit or function, is just one of many functions that natural systems provide. Collectively, these systems benefit the natural ecology and support agricultural, urban, and other human interests as well. The ecological health and hydrologic characteristics of Lake Okeechobee and south Florida's freshwater wetlands directly affect the quality of the receiving water bodies, including the St. Lucie and Caloosahatchee Estuaries, and Biscayne and Florida Bays.

Two documents are particularly important in framing the Restudy's goal for enhancing *ecological* values. These documents, which were prepared by many of the leading experts on Everglades ecology, are *The Science Sub-Group Report, Federal Objectives for the South Florida Restoration* (Science Sub-Group, 1993), and *Everglades, the Ecosystem and Its Restoration* (Davis and Ogden, 1994). Another earlier publication, *Ecosystems of Florida* (Myers and Ewel, 1990) also contributed substantial input into the Restudy.

5.5.1.1 Spatial Extent

Scientists have identified the large spatial extent of the south Florida wetlands as one of the defining physical characteristics of the pre-drainage ecosystem. The size of the south Florida wetlands, in combination with the complex mosaic of habitats, enabled multiple populations of plants and animals to persist over time. The size of the pre-drainage area made it possible for the natural ecosystem to: 1) support genetically viable numbers and sub-populations of species with large feeding ranges and/or narrow habitat requirements, 2) provide the aquatic production to support large numbers of higher vertebrate animals in a naturally nutrient-poor environment, and 3) sustain habitat diversity despite natural disturbances. The ability of animal populations to recover from disturbances decreases as the available habitat area decreases since habitat diversity, the amount of seasonal refugia, and the number of dispersal options also decrease.

Roughly 50 percent of the pre-drainage wetland area and 90 percent of pinelands have been lost to development. Lake Okeechobee was much larger then it is at present with an extensive littoral/marsh system extending to the north, west, and south. The resulting loss of these natural areas has caused wading bird, snail kite, and panther populations, for example, to be stressed. Assuring adequate spatial extent for natural systems, necessary to support the mosaic of habitats characteristic of the pre-drainage ecosystem, will provide for genetically viable numbers and populations of native species and habitat diversity.

5.5.1.2 Habitat and Functional Quality

Adverse changes in natural habitats, including sawgrass, mangroves, seagrass beds, and other native wetland habitats, as well as in many native fish and wildlife species, such as wading birds, alligators, shrimp, and lobsters, that depend on healthy habitats for survival have occurred in the south Florida ecosystems. The specific functions that wetlands or uplands perform are closely associated with their condition or quality. A reduction in the quality of these areas results in the loss of many or all of the functions that these areas historically performed. Improving the functional quality of the remaining natural areas is important to system-wide restoration given the loss of spatial extent and, thus, function of the historic wetlands and uplands.

South Florida natural habitats have been physically and hydrologically altered and manipulated. Consequently, these Florida ecosystems are now substantially less productive and diverse than the historic system. For example, although many of the historic short hydroperiod wetlands no longer exist, wetlands that were historically much wetter now have short hydroperiods. Another example is the alteration of wetlands in the Water Conservation Areas. These areas are managed as separate entities and are hydrologically different from historic conditions resulting in changed hydropatterns and quality of the wetlands and tree islands. Aquatic productivity has been reduced or highly altered throughout the marshes of the central Everglades and the estuaries. Reductions in aquatic productivity have affected the abundance of birds as well as fish. Changes in habitat, construction of deep canals, and abnormally extreme water levels impact the foraging ability of birds. Additionally, changes within interior and coastal wetlands have adversely influenced downstream commercial fish and other species in coastal ecosystems such as Florida Bay.

Invasive plant and animal species have also impacted the quality of the south Florida landscape. Invasive species include both native (i.e. cattails) and non-native species (e.g. Melaleuca, Brazilian pepper, and Australian pine). The increasing dominance of any community by a single species ultimately reduces the habitat variability necessary to sustain a healthy community of both plants and animals. Water management has encouraged the spread of these invasive species by creating conditions under which they can out-compete the native habitat that existed under pre-drainage conditions. For example, high phosphorus loads and increased hydroperiods have contributed to cattails out-competing sawgrass; altered hydrologic regimes have increased the spread of Melaleuca and Brazilian pepper; and the construction of levees has contributed to the spread of Australian pine and Brazilian pepper. Eliminating the invasive and exotic species and the conditions that favor these species will contribute to restoration of native plants and animal species and a more natural ecosystem hydrology and function.

5.5.1.3 Species Abundance and Diversity

The changes that have taken place in the natural system have led to decreases in native animal and plant populations. One of the most obvious indicators that the south Florida ecosystems have experienced ecologically significant reductions in productivity is the decline in wading bird populations. Several species are now so reduced in numbers that their long-term existence is jeopardized unless measures are taken to ensure their sustainability. Other species have a naturally restricted range; these species are also vulnerable to extinction if their specialized habitats are altered. In addition to considering these species, it is important to recognize that maintaining balanced communities of the more abundant species is also essential to a sustainable ecosystem. It is also important to recognize that a balanced community is dynamic; population levels fluctuate widely from year to year as natural conditions fluctuate. Unnaturally small, isolated populations can be quickly extinguished by natural conditions.

Increasing spatial extent and improving habitat quality can provide a basis for improving species abundance and diversity. However, compartmentalization caused by construction of physical barriers such as dikes, canals, levees, and roads, or even hydrologic barriers (such as the Water Conservation Areas) has fragmented the system by creating a series of poorly connected natural areas. These barriers have restricted the movement of many fish and consequently reduced their range. Fragmented communities are more likely to lose species because the number of individuals in each fragment may be too small to persist. The smaller the fragment, the higher is the likelihood of losing species or favoring an imbalance in the species that do inhabit the areas. Moreover, fragmentation itself alters the landscape by breaking connections between the various habitat types that were distributed historically across the landscape. Therefore, improving the connectivity of habitats will improve the range of many animals and their prey-base and provide for a more natural balance of species within the system. The physical barriers that created the fragmented environment themselves affect species abundance. The introduction of deep canals which act to drain surrounding areas, affect the ability of wading birds to forage over large areas.

5.5.2 Enhance Economic Values and Social Well Being

The C&SF Project provides economic benefits through regional water supply, flood damage reduction, navigation, and recreation. While most people recognize the need for a healthy ecosystem to support the region's economy and jobs, many people are concerned that restoration projects will displace farms and other businesses, limit development, reduce available water supply, and reduce job opportunities. By contrast, continued degradation of the south Florida ecosystem will adversely affect the tourism and recreational industry that are important to the regional economy.

5.5.2.1 Water Supply

Drainage, water supply, and flood protection afforded by the C&SF Project have provided for the growth of south Florida's population, which by 1990 was 5.2 million. Local governments in south Florida are predicting that total population will reach 8 million by 2010 and will range from 12-15 million people by 2050. Approximately 88 percent of the region's current population are concentrated in the coastal urban counties of Miami-Dade, Broward, Palm Beach, Lee, and Collier; this distribution pattern is projected to continue. Urban water supply demands could increase from approximately one billion gallons of water per day today to two billion gallons of water per day by 2050. Lake Okeechobee is an important source of water to both natural and developed areas, particularly during low rainfall years. The growing demand for dependable water for agriculture, industry, and a burgeoning population at a reasonable cost could rapidly exceed the limits of readily accessible sources. If the needs of the region's natural systems are factored in, conflicts for water among users will become even more severe.

In the study area, surficial aquifers supply the majority of water for urban use. These aquifers are vulnerable to salt water intrusion. In the Lower East Coast area, salinity intrusion has resulted from two major events. The first is the lowering of the ground water table in the area due to drainage and reduced recharge as well as the increased withdrawal of water by pumping. The second reason is the construction of numerous drainage and navigation canals from inland areas to the coastal waters.

In order to prevent saltwater from entering the local surficial aquifer and contaminating nearby well fields, the water table in coastal areas should be maintained at the level needed to stabilize the fresh water - saltwater interface. Existing criteria to protect against saltwater intrusion requires maintenance of a one-foot mound of fresh water between the withdrawal point and the saline interface. This is accomplished by maintaining canal levels high enough so that the hydraulic interconnection of the canals and the aquifer maintains a fresh water gradient that is adequate to prevent intrusion of saltwater into the fresh surficial aquifer.

5.5.2.2 Flood Protection

The C&SF Project was conceived and authorized to provide regional flood protection for south Florida. The system of canals, levees, water control structures and pump stations conveys and confines flood waters to regional storage facilities such as Lake Okeechobee and the Water Conservation Areas, or to tidal receiving waters. Further, additional protection is afforded by the local systems operated by special taxing districts, private property owners, and local governments.

Throughout the C&SF Project area, there are varying levels of flood protection. This is primarily due to variations in the original design goals and changes in land use that have occurred. Many areas that were expected to remain in agriculture have been developed, thereby changing the level of flood protection offered by the project. However, the existing investment in flood protection infrastructure was never intended to totally eliminate flooding in developed areas and flooding does occur periodically. In addition, natural areas have also suffered damage as a result of operating the flood control system to benefit the developed areas. For example, damaging releases to estuaries, unnaturally high water levels in the Water Conservation Areas, and backpumping to the Water Conservation Areas have occurred as a consequence of flood control.

Flood protection needs have increased since the original flood control project was constructed. As agricultural and urban development continues, the volume, duration, and frequency of floodwaters may increase; the actual level of flood protection may have declined in some areas. There is an opportunity to further reduce the extent of damages from flooding through operational and structural changes to the C&SF Project and local drainage systems.

5.5.2.3 Recreation and Navigation

Public use has been an important consideration of the C&SF Project since it was first developed. The C&SF Project provides opportunities for a wide range of outdoor activities, including: fresh water and estuarine fishing, boating, hunting, camping, picnicking, nature watching, and photography. It also provides the public with access to areas where they can simply "get away from it all." The opportunity to pursue these activities is very important to the economy of south Florida and to the people who make use of these opportunities, including residents, visitors, eco-tourists, and the Native American Tribes. Restoration and protection of the remaining Everglades system, the Keys, south Florida estuaries (including Florida Bay), and reef tracts are essential to the economic base provided by these recreational and traditional uses.

5.5.2.4 Social and Cultural

Societal sustainability requires the preservation of the rich cultural diversity of the region, such as the Native American communities and the multi-generational culture of the agricultural communities. The rapidly growing population of south Florida is decreasingly dependent directly on the environment for its sustenance, with the exception of water needs. Yet that population is increasingly dependent indirectly on a restored and sustainable environment, such as for support for the economic base of tourism as well as the heightened awareness of the environmental ethic to preserve and sustain this unique natural environment for the future generations to experience and value.

5.6 ECOSYSTEM RESTORATION

Following the development of the planning objectives, there were a number of principles and issues which were developed to guide the overall ecosystem restoration effort. This section defines and discusses these principles and issues.

5.6.1 Why Restore the South Florida Ecosystems?

South Florida ecosystems are highly valued at local, national, and international levels. Locally, people value these areas as places to go to interact with nature, to escape from the pressures of "city life," or as a means of making a living. In response to national recognition and concern for its future, a portion of the historic Everglades was designated as the Everglades National Park in 1947. Internationally, the Park is recognized as an International Biosphere Preserve and a World Heritage Site. Additional recognition of the region's wetlands occurred with the establishment of the Big Cypress National Preserve in 1974, and the Biscayne National Park in 1980.

Lake Okeechobee is one of the largest natural lakes in the United States. Lake Okeechobee is commonly referred to as the “liquid heart” of Florida. It is a vital component of the interconnected Kissimmee River, Lake Okeechobee, Everglades, St. Lucie and Caloosahatchee Estuaries, and Florida and Biscayne Bays ecosystems. This lake is important not only to its resident fish and wildlife species but also to wide-ranging animals, particularly wading and migratory birds. Thus the health of Lake Okeechobee affects not only its own resources but resources throughout south Florida, including the estuaries and bays.

At the ecosystem level, the south Florida lakes and wetlands are not only beautiful to see but help reduce the damage of floods, droughts, and contaminants. Inland freshwater lakes and marshes reduce the danger of floods by collecting runoff, storing it, and releasing it over longer periods of time. The effects of droughts are often offset by the vast quantities of water which are stored as groundwater or in shallow marshes during normal wet seasons. Wetlands clean water by removing organic and inorganic nutrients and toxic materials from water that flows across them. Freshwater wetlands are closely associated with groundwater recharge, and the hydraulic pressure of wetlands along the coast keeps saltwater at bay.

A number of plant and animal species which live in south Florida are in danger of becoming extinct. If these species are removed from the gene pool, the functions and other benefits they provide (known or unknown at this time) will be lost. Without top predators, for example, populations of prey species such as raccoons, rabbits, and rats could explode. The crucial roles of many species in the natural community are only now being determined -- sometimes only as the consequences of their absence are felt. Loss of a species represents an irreplaceable loss of genetic material. The benefits such lost species would have provided will never be known.

Estuaries and bays are also important ecosystems in south Florida. Commercially harvested fish and shellfish depend on estuaries for nursery areas. Estuaries and bays are habitat to numerous fish and wildlife species. The estuaries and bays depend on the health of the freshwater wetlands upstream which are their source of water. These areas are dependent on appropriate volumes of water, which affects salinity; timing of flows, which effect breeding animals; and quality of flows, which effects species composition and abundance. Consequently, estuaries and bays have been impacted by detrimental conditions within the south Florida freshwater ecosystems. Likewise, the health of the south Florida economy is closely linked to the health of all of these interconnected/interdependent ecosystems.

5.6.2 Certainties and Uncertainties

The restored wetlands of south Florida will be smaller in area than the historical ecosystems, and will have different landscape components and proportions. Within this framework of change in spatial scales, it is impossible to predict with certainty how animal populations will respond to restored or improved hydrological conditions. More needs to be known about animals in the south Florida wetlands than the basic biological characteristics of the species, and relationships with abiotic features of the environment, in order to predict responses (DeAngelis and White, 1994). Changes in the spatial scale and landscape patterns of the system create *"... a multitude of complicating factors that are difficult to anticipate, including the importance of population histories, biological feedback on abiotic driving forces, species interactions, and species invasions"* (DeAngelis and White 1994).

The result of these changing conditions is that fundamental relationships between species of animals and the environment may change. For example, Ogden (1994) has shown that the hydrological conditions that stimulate the creation of large nesting colonies of wading birds have changed several times during the past 60 years. At different periods during the evolution of water management practices in the Everglades, nesting wading birds have responded in different ways to any given hydrological pattern, due to shifting patterns of production, distribution and survival of the bird's prey related to management practices. For American alligators, Craighead (1968) suggested that the population centers in the southern Everglades have changed from the marl prairies and interior, mainland estuaries to the central Shark River Slough, as a result of changes in regional hydrological patterns. Although a restoration objective might be to "shift" the centers of high alligator density from the central and northern Shark River Slough to the marl prairies east of Shark River Slough, it remains to be known where, in a restored system, these centers will be.

Our ability to predict animal responses is further complicated by the fact that we *"...rarely have full understanding of the nature of driving forces in an ecosystem..."* *(White 1994). "Although our collective knowledge of the Everglades ecosystem may be much stronger...",* today than 10 years ago, *"...this baseline of information still contains many gaps"* (Davis and Ogden, 1994). The South Florida Ecosystem Restoration Working Group's Science Subgroup (1993), Davis and Ogden (1994) and Hoffman (1994) agree that a regional hydrological restoration program is an essential prerequisite for ecological restoration, but precise answers to questions of how various natural components will respond, in such a physically altered system, do not exist with certainty.

It also should be recognized that the wetland ecosystems of south Florida are undergoing continual change independent of management and restoration programs (Davis and Ogden, 1994). Gleason and Stone (1994) have documented the continuing evolution of environmental conditions in this geologically young system. Alternating bands of peat and marl soils below Everglades marshes reveal an ecosystem that is passing through longer wet and dry cycles than are normally recognized in more contemporaneous discussions of the dynamics of these wetlands. And Wanless et al. (1994) has proposed that an increasing rate of sea level rise in southern Florida can produce profound changes in environmental conditions in the lagoon and estuarine regions, and on the extent of freshwater wetlands, throughout the Everglades and Big Cypress Basins.

Uncertainties in defining optimum hydrological targets for restoration also are created by uncertainties in the accuracy of the Natural System Model output. Because the Natural System Model has played such an important role in defining restoration targets, it is appropriate to summarize what is known regarding the accuracy of this model. Although a technical review of the Natural System Model (Bales et al., 1997) endorsed the value of the model for *"...estimating pre-drainage hydrologic responses in south Florida."*, the review also offered a number of cautionary comments. The review demonstrated that uncertainty in the model is due to a number of factors, including input data (e.g., topography), model assumptions (e.g., rainfall & evapotransporation distributions), parameters (e.g., Manning's *n* and evapotransporation coefficients), and model discretization. The review suggested that the model's *"...total uncertainty cannot be quantified. However...it seems appropriate to interpret the Natural System Model simulated water levels and ponding depths with about a plus or minus 1 foot uncertainty."* The review added that, *because "...the model should not be used to simulate discharges in pre-drainage south Florida... the maintenance of acceptable water levels and hydroperiods, rather than flows, is probably the key to restoration..."* A final conclusion of the review was that, *"The Natural System Model is a regional-scale model (Fennema and others, 1994), and results need to be interpreted at a regional scale rather than cell by cell... restoration success likely will be judged on ecological criteria, rather than on the ability of the water-management system to meet certain hydrologic targets. Much stronger linkages between hydrologic conditions and biological responses are needed."*

5.6.3 Different Views

The vision of the future wetlands in south Florida is influenced by different views of how restoration goals for the system are determined (Hoffman, 1994). The future Kissimmee River, Lake Okeechobee, Everglades, Big Cypress, and Florida Bay ecosystems can be, to some extent, what society wants them to be, based on value systems, and decisions about what conditions and components constitute a restored ecosystem. The different perspectives on a restored ecosystem are represented by one view that says that these wetlands will have been restored once certain population levels have been reached, for wading birds, alligators, endangered species, etc. In contrast, a different view is that restoration will have been achieved when certain defining ecological conditions (functions and relationships) that characterized the pre-drainage ecosystems have been recovered, without setting specific population levels as goals. It may be true that these different restoration targets are nothing more than different ways of characterizing recovered ecosystems, and that achieving one will achieve the other. There is agreement by proponents of both perspectives that a set of performance measures will be required to show whether the restoration programs are carrying these ecosystems in the correct direction. These measures should include the trends in numbers and distribution patterns of characteristic wetland species of wildlife, and the patterns of habitat mosaics, for comparisons with what is known about these species and habitats in both the current and pre-drainage systems. Selection of a set of ecological and hydrological performance measures assumes that a vigorous monitoring program will be maintained, to determine if the restoration program is properly directed, and to serve as a basis for mid-course corrections (adaptive assessment) if problems are detected.

5.6.4 The Recovered Ecosystems

Although there are different views of what these south Florida ecosystems should look like in the future, most of these differences seem to be ones of degree, or different focuses on the elements of the system that need to be measured in order to show that goals have been reached. What is broadly recognized is that there were specific ecological and physical characteristics of these pre-drainage wetlands, which defined “The Everglades”, “The Big Cypress”, and “Florida Bay” as uniquely distinct ecosystems. It must be assumed that these defining characteristics must be recovered before these ecosystems can be recovered and sustained over time, and before the restoration program can be considered to have been successful.

The ecological and physical features that specifically defined these ecosystems have been reviewed and discussed by the Science Sub-Group (1993), Davis and Ogden (1994), Hoffman (1994) and Ogden et al. (1994). These authors identified three ecological and two physical features of the pre-drainage wetlands of south Florida that defined these systems. The process used for selecting these defining ecosystem features was to identify features that best describe the dynamics of animal and plant communities at system-wide scales, and which were present in the pre-drainage systems.

5.6.4.1 Ecologic Features

The ecological features that defined the pre-drainage, south Florida wetland ecosystems are defined below:

(1) Large populations of wetland species of vertebrates were able to maintain long-term stability only by operating over large spatial scales, across community and landscape boundaries, within the system. Populations of several hundred thousand wading birds (herons, egrets, ibis, storks), along with large numbers of snail kites, limpkins, mottled ducks, and other waterbirds, depended on a spatially broad mosaic of feeding and nesting site options, which differed in importance along temporal scales, depending on seasonal and interannual variations in rainfall and surface water patterns.

(2) A second defining ecological feature was that heterogeneous habitat patterns were created and maintained within and across community boundaries due to the dynamic interplay among such factors as micro-topographic features, local climatic variation, fires, freezes, storms, and animal impacts (alligator holes and trails, for example), acting across the large spatial extent of the pre-drainage wetlands. The resulting mosaic of upland and lowland habitat types provided the spatial and temporal network for the production and survival of animals under a wide seasonal and annual range of hydrological conditions. DeAngelis and White (1994) have described how environmental heterogeneity at a variety of scales, in combination with large ecosystem size, functions to enable persistence and resilience of populations of plants and animals.

(3) The third defining ecological characteristic was that the pre-drainage freshwater wetlands evolved as an oligotrophic system, with the very limited input of nutrients coming primarily as phosphorus in rainfall. The low-nutrient environment was essential for the support of green algae/diatom periphyton communities, which were a major food base for the production of aquatic invertebrates and fishes in relatively long hydroperiod, freshwater marshes of the Everglades. The large spatial scale of the historic Everglades and the organizing affects of seasonal and multi-year patterns of flooding and drying, created the pulses of secondary production and the prey densities that were necessary for the support of large populations of the larger species of vertebrates.

5.6.4.2 Physical Features

The physical features that defined the pre-drainage south Florida wetlands are defined below:

(1) Clearly, one defining physical feature was the large spatial scale of the network of pre-drainage wetland ecosystems. The large spatial extent was essential for supporting the regional levels of production necessary for maintaining robust populations of animals with large spatial requirements, and for supporting the range of physical features and the ecological and climatological processes that created and maintained the habitat mosaics of the region.

(2) The second defining physical feature of the pre-drainage wetlands was the region's dynamic patterns of water storage and sheet flow. It was these dynamic hydrological patterns, *"...operating over an extensive region, that made the Everglades a much wetter system than it is today, that organized and concentrated the primary and secondary production of the wetlands, established the salinity gradients in the estuaries, and created the substantial network of dry season refugia that were essential habitats for all freshwater animals"* (Ogden et al., 1994).

5.6.5 Role of Adaptive Assessment

Adaptive assessment is an approach which can be utilized during the implementation and evaluation of large, complex, long-range projects. In a discussion of a national restoration strategy, the National Research Council states that adaptive planning and assessment involve a decision-making process based on trial, monitoring, and feedback. Rather than developing a fixed goal and an inflexible plan to achieve the goal, adaptive assessment recognizes that there always will be gaps in knowledge regarding the relationships within and among natural and social systems, and that these information gaps require that plans be modified as technical knowledge improves and social preferences change. For adaptive assessment to succeed, the new knowledge gained (through monitoring) should be translated into restoration policy and program redesign over time and be shared across restoration programs at all levels of government (National Research Council, 1992). Adaptive assessment is a process which involves the iterative use of models, research, and monitoring in conjunction with on-going planning, in order to revise, improve, and fine tune management procedures (Science Sub-Group, 1993). It involves an iterative process of developing management tactics, and provides a process for breaking impasses where agencies are unwilling to proceed because of an inadequate knowledge base (Hoffman, 1994).

Lack of an adaptive assessment approach during the implementation and evaluation of large and complex projects can result in unintended and unexpected adverse environmental impacts. The initial C&SF Project is an example of what happens when plans are carried out in the absence of clearly defined long-term ecological goals and without provisions for adequate monitoring of project effects. Lack of a strategy resulted in several unanticipated changes being made to the C&SF Project beginning relatively soon after its construction was initiated in 1948. Water Conservation Areas 3A and 3B and a southern extension of Levee 67 were completed in the 1960s. As a result, natural flows to the Everglades National Park were eliminated and water was provided according to a regulation schedule. Sporadic and insufficient flows resulted in ecological decline in the Park. Consequently, in 1971 a minimum monthly schedule of water deliveries was established. Under this water delivery system, unseasonable regulatory releases often occurred during dry season months. During the period of the minimum delivery schedule, the ecological values of the southern Everglades declined at an accelerated pace. The Everglades National Park again requested modifications to the project and the Experimental Program of Water Deliveries to Everglades National Park was initiated in April 1984. Additional projects designed to modify the areas existing hydrologic regime to restore more natural flow and hydropatterns are the Modified Water Deliveries to Everglades National Park, and the Canal 111 (C-111) Project.

A barrier to viewing these projects as part of a larger scale, long-term restoration program has been that much of the information needed to develop the larger plan did not exist. The impact that this barrier has on restoration planning can be substantially reduced through an adaptive assessment process, which recognizes these inadequacies and provides a planning strategy for collecting the necessary information. Shabman (1993) has suggested that adaptive assessment assumes that no knowledge base is adequate for defining and implementing the socially correct and technically feasible long-term plan of action. Instead, decision making should proceed as sequential adjustments in response to new insights about social and economic priorities, and in response to new understandings of the ecological system. Consequently, an adaptive assessment strategy would require that plans be formulated which are designed to create new information. This planning approach maximizes the collection of new information by viewing each iteration as one “experiment” within a series of experiments. Each experiment should be designed from one or more technically-based hypotheses regarding the expected results, which in turn are measured by a monitoring program based on the same set of hypotheses.

For the C&SF Restudy, the conceptual ecological models of south Florida wetland landscapes identify the major hypotheses used to set planning priorities and restoration performance measures. The regional ecological monitoring program will evaluate how well the restoration projects correct the stresses shown in the conceptual models, and at the same time, allow for refinement of the hypotheses which were used as a basis for planning the major components of these projects.

5.6.5.1 Monitoring

The restoration of the wetland ecosystems of south Florida requires that a comprehensive monitoring program be in place to provide information that is essential to the planning and evaluation processes. It is assumed in this report that the south Florida ecosystem restoration program will most likely be successful in achieving its goals if implementation of the program is conducted by means of an adaptive assessment strategy. This strategy calls for the incremental implementation of the components of the plan, with each increment treated as one experiment within a stair-step evolution of experiments, each planned and designed to carry the program one step closer to the ultimate goal of systems restoration. An incremental process is required for the south Florida ecosystem restoration program, because of the large and complex nature of the ecosystem and its problems, and because of the uncertainties regarding the ecological responses that will occur as more natural hydrological conditions are established. These uncertainties are inherent where major alterations in the region's spatial scale and landscape components have in some cases substantially changed ecological relationships among species, habitats, and communities throughout the region. A regional monitoring program becomes the framework for designing the sequence of incremental steps, by providing information on how the ecosystem responds at each step as a basis for designing the next steps.

A fundamental requirement of a successful monitoring program is that it be focused on the biological and physical elements in the system which are most likely to reveal how the system responds to project actions. There should be broad agreement on restoration targets, and on the ecological changes that constitute improvements, as a prerequisite for determining which parameters in the system must be monitored. Because of the uncertainties inherent in any effort to restore such a complex and altered ecosystem, specific restoration targets and measures of success can only be provisionally identified. Nevertheless, these targets and measures need to be identified in order to design a monitoring program that is well focused and efficient, to assure that it provides the kind of information that is required for the implementation of an adaptive assessment strategy.

5.6.5.2 Conceptual Ecological Models

Conceptual ecological models have been developed at landscape and physiographic scales for the natural regions of south Florida. These models have performed an essential role in the Restudy, in that they provide a comprehensive framework for organizing existing scientific knowledge about the natural systems in south Florida into formats that are directly applicable to the planning, implementation and evaluation of restoration projects. The conceptual models are simple, non-quantitative tools which illustrate the collective opinion of a group of natural resource specialists for how existing, empirically and intuitively derived understandings of wetlands in south Florida should be organized to show the important ecological relationships in these systems.

The models were developed by teams of resource specialists during a series of workshops between October 1996 and July 1997. Conceptual models have been developed for Lake Okeechobee, the Caloosahatchee and St. Lucie Estuaries, the ridge and slough portions of the central and southern Everglades, the Big Cypress, the southern Everglades marl prairies, the southwestern Gulf Coast Estuaries, Florida Bay, and Biscayne Bay. Each model consists of a schematic representation of the major elements in the system, and a narrative interpretation of the model. An example of a completed conceptual model and narrative statement, for Lake

Okeechobee, is attached to ***Appendix D***. A technical report describing all of the models is in preparation (Ogden and Davis, in prep).

The conceptual models for south Florida show the major cause and effect relationships in stressed natural systems. Each model identifies the principal sources of human influences on the natural systems (societal drivers), the ecological stressors originating from these drivers, and the ecological effects from these stressors. The models also suggest the best set of ecological attributes (endpoints, indicators) and measures, which, collectively, characterize the overall "health" of the system relative to the effects from the stressors.

The broad purposes for creating the conceptual models have been to (1) create a set of measurable indicators of success as a basis for evaluating how well the projects meet the broad, policy-level goals that have been established for the regional restoration programs, and (2) develop a suite of causal hypotheses linking the most important hydrological stressors with the major ecological effects, as a basis for predicting responses to the restoration projects.

For the Restudy, the conceptual models have been used more specifically (1) to help set priorities among the hydrological issues to be resolved by the study, based on links between water management practices and the major ecological problems in the natural systems, (2) as a basis for creating performance measures for evaluating alternative plans for resolving the major ecological problems, and (3) to recommend a priority set of ecological indicators (attributes) to be monitored as a basis for evaluating how well the restoration projects correct the hydrological stressors in the natural systems. The recommended approach for accomplishing (3) will be to design performance measures and the components in a regional monitoring program so that they relate to the hydrological stressors and the ecological attributes shown in each model. The assumption from the conceptual models is that the restoration projects should focus on improving performance among the hydrological stressors, and that the success of the projects in meeting these objectives can best be measured by monitoring the behavior effect on the key ecological attributes in each natural system.

5.7 SOUTH FLORIDA ECOSYSTEM RESTORATION VISION

While a primary goal of the Restudy is the ecological restoration of the Everglades and other natural wetlands in south Florida, the Restudy Team, as well as the broad scientific community, recognizes that complete ecological restoration in this region is not possible. Traditionally, restoration has been defined as the full recovery of a natural system to a condition that existed during some pre-altered period. For the Everglades, this goal would require the creation of a system that mimicked the natural conditions that was here prior to the construction of the first drainage canals and levees, in the 1880s.

For at least two overwhelming reasons this goal is not possible. First, there have been substantial and irreversible reductions in the spatial extent of the wetland systems in south Florida (including an approximately 50 percent reduction in the extent of the true Everglades), and in the total water storage, timing, and flow capacities of these systems. These changes, coupled with the altering affects of sea level rise, infestations of exotic plants and animals, subsidence, and losses of organic soils, are among the factors which preclude any serious consideration of achieving true restoration. The second major hurdle to complete restoration is that few of the quantitative, ecological characteristics of the pre-drainage wetlands of south Florida are known. Simply stated, the pre-drainage Everglades is as much a vision created by opinion as by fact. For these reasons, and because complete restoration is not possible, the natural resource specialists in south Florida lack a strong consensus as to the restoration “endpoint”; i.e., there is a range of legitimate answers to the question, “what constitutes restoration?”

Because the pre-drainage Everglades cannot be recreated in its original form, the restoration goal for the Restudy is to create a “new” Everglades, one which will be different from any system that existed in the past, and one which will be substantially healthier than the current system. For this restoration project to be successful, it must recover important ecological components and patterns which are thought to have characterized the pre-drainage system, and it must be able to sustain these recovered ecological attributes over long time scales. The Restudy Team has attempted to understand the pre-drainage system, using such tools as the Natural System Model, and by creating conceptual ecological models of the major landscape features of Florida. These conceptual models have been developed from a series of hypotheses about the ecological relationships and biological components of the pre-drainage system, which have been derived from studies of the current system. The “new” Everglades must include key features that characterized the earlier natural system, if it is to again become an Everglades-type ecosystem. It also must acquire other natural attributes which are important to people who share an interest in the natural systems in south Florida, and the roles that these systems have in our lives. For example, modifications to the Everglades should recover certain wading bird and alligator patterns of behavior that were characteristic of an earlier, more natural system. It also should recover certain traits that are important to our society, such as clear water and good fishing in Lake Okeechobee, improved salinity ranges in the Caloosahatchee and St. Lucie Estuaries, and an enhanced role for the remaining natural system as a refugia for endangered species in a shrinking natural world.

It is too early in the south Florida ecosystem restoration process to state with certainty exactly what the “endpoint” for the restored Everglades should become. It is likely that the length of time required to implement the restoration projects, and the varying time lags in ecological responses, will mean that the current, managed system will evolve into a “new” Everglades over long time scales. During these transitional years, understandings of ecological patterns and relationships will continue to improve (almost certainly causing a change in the hypotheses currently being used to predict ecological responses to the restoration projects), unexpected responses to the initial restoration projects will occur, and the remaining wetland systems will continue to evolve in response to a wide range of continuing human and natural influences (e.g., sea level rise, hurricanes, long-term rainfall and temperature patterns). Thus, the point at which restoration is achieved, and the precise characteristics of that “restored” system, represent questions that are not completely answerable at present.

At the same time, it is important to not overstate or to be overly concerned about the uncertainties that are a part of the restoration planning process. For example, there is considerable professional agreement that recovery of the regional hydrological patterns depicted by the recent versions of the Natural System Model will result in substantial improvements in the ecological health of the wetland systems. An overall much wetter system, characterized by such features as multi-year hydroperiods in the sloughs, higher, dry season groundwater levels on the marl prairies, and increased flows of freshwater into Florida and Biscayne Bays, will produce dramatic improvements in the ecological health of these systems.

Because of these considerations and uncertainties, the Restudy Team, as well as most resource specialists in south Florida, view ecosystem restoration in south Florida much more as an open-ended process than as a specific set of targets (endpoints). Restoration planning has become a balancing act between the need to agree on desirable directions of change and the general features that should be present in a restored system, and the need to encourage flexibility in thinking about how and when certain objectives are achieved, and what the restored system should look like. For example, is it possible, in order to recover the fundamental ecological patterns that are an essential part of an Everglades-type system, that some features or components may need to be recovered at different scales or locations than were found in the pre-drainage system? This view of the restoration process is in part a response to the point made above, that current opinions still vary among resource specialists on how to set quantitative, ecological targets for a restored system.

More importantly, the realistic perspective at present is that it is premature to force the debate over the question of, “what constitutes restoration?” At this point, it is sufficient that there is broad agreement, demonstrated in the conceptual ecological models, over the identity of the water management and development practices that have caused much of the ecological damage in the south Florida ecosystem. Restoration projects geared to correcting these hydrological stresses should produce strong improvements in the health of these ecosystems. Consensus over the question of what a restored south Florida ecosystem should be, especially over the specific spatial, temporal and numerical targets for restoration, should emerge over time, as system responses from initial restoration projects begin to provide focus for the debate, and new modeling results and empirical data become available.

SECTION 6
GOVERNOR'S COMMISSION CONCEPTUAL PLAN FOR THE RESTUDY

This section describes the development of the *Conceptual Plan for the Restudy*, which was developed by the Governor's Commission for a Sustainable South Florida. The Water Resources Development Act of 1996 directs that the conceptual framework provided in the *Conceptual Plan for the Restudy* (GCSSF, 1996b) be considered in the development of the Comprehensive Plan. The acknowledgement of the Commission that hydrologic restoration is the key and a prerequisite to ecosystem restoration led to the development of the Conceptual Plan: the vehicle to specifically address water resource issues and natural system restoration. That document provided a framework for the formulation and evaluation of alternative plans for the Restudy. Most of the information in this section was taken directly from the *Conceptual Plan for the Restudy* published by the Commission.

6.1. GOVERNOR'S COMMISSION FOR A SUSTAINABLE SOUTH FLORIDA

On March 3, 1994, Governor Lawton Chiles created the Governor's Commission for a Sustainable South Florida through the Governor's Executive Order 94-54. The Commission's charge was to make recommendations that will move south Florida toward a healthy ecosystem that can coexist with, and be mutually supportive of, a sustainable south Florida economy and quality communities. This Commission consists of business, agriculture, government, public interest, and environmental organization representatives. A number of Federal agencies are represented on the Commission as non-voting members. Toward this end, the Commission unanimously adopted two successive documents: the *Initial Report,* (GCSSF, 1995) containing overall recommendations for a sustainable South Florida; and, *A Conceptual Plan for the C&SF Project Restudy*, (GCSSF, 1996b), which provided initial recommendations for the Restudy.

6.2. INITIAL REPORT

The Commission's *Initial Report* (GCSSF, 1995) contained 110 recommendations with a central theme of sustainability – meeting the needs of the present without endangering the ability of future generations to meet their needs – revolving around the management of water. In that report, the south Florida ecosystem was defined as a community of organisms, including humans, interacting with one another and the environment in which they live. The Commission recognized that *"Our quality of life is inextricably linked to the health and viability of natural systems"* and *"that a healthy Everglades system is vital to natural plant, animal and human population alike."* The Commission also unanimously agreed that the south Florida ecosystem is not sustainable on its present course.

Many of the recommendations in the *Initial Report* addressed the need to integrate all elements of water resource management including: water supply, flood protection, water quality, and natural resources restoration, protection and management. In addition the *Initial Report* also addressed a number of Restudy-related recommendations (see ***Table 6-1***).

TABLE 6-1
INITIAL REPORT: RESTUDY RECOMMENDATIONS

- The Corps and the District should "assure that the Restudy addresses the need to achieve a sustainable south Florida economy by ... proposing reliable, cost-effective measures to provide the necessary water supply." (Recommendation 11)
- "The Commission should provide a mechanism to enable input and integration of the state's concerns and interests with the U.S. Army Corps of Engineers and the south Florida Ecosystem Restoration Task Force in the Restudy and other Federal activities." (Recommendation 12)
- The Corps and the District should: "(1) address water supply needs for urban and agricultural users; (2) address natural water level fluctuations within the natural system and restoration of natural water quality, timing, volumes, and distribution to the Everglades; and (3) expedite the Restudy schedule without sacrificing thoroughness or quality of the final product." (Recommendation 13)
- "The Restudy should integrate all elements of water management (water supply, flood protection, water quality protection, and natural systems management). Redesign should provide for sustainability for human and natural system requirements." (Recommendation 15)
- "All plans, and especially the Restudy, should assure that new demands do not adversely affect the sustainability of human and natural systems." (Recommendation 16)
- "In the Restudy, the South Florida Water Management District and the Corps should ensure that the redesign of the system allows for resilience for a healthy natural system." (Recommendation 17)
- The agencies and interested parties should "redesign and develop new operations for the south Florida water management system at all levels to conserve and sustain the natural system, to maximize the capture of stormwater, and to conserve water for the benefit of all users." (Recommendation 23)
- The Corps and the District "should reduce the extent of damage from flooding to human and natural systems." (Recommendation 27)

6.3. DEVELOPMENT OF THE CONCEPTUAL PLAN

The Commission's *Conceptual Plan for the Restudy* consists of a strategy for coordinating and implementing a number of the water resource projects in south Florida into a cohesive whole, ensuring that they are consistent with the Commission's goals for a sustainable south Florida. While some projects are in various phases of implementation, these projects, by themselves, do not result in restoration. The Commission identified the need for additional and integrated efforts. The on-going projects form a foundation from which they developed the *Conceptual Plan for the Restudy*. Because the entire C&SF Project is hydrologically linked, all water management activities impact one another. Therefore, the Commission believes that implementation of the ongoing projects and programs must be closely coordinated by sharing information as they proceed from planning and design through implementation and operation. These on-going efforts, while not intended to be all-inclusive, are included as elements of the thematic concepts.

6.3.1. Commission's Planning Objectives

In developing the Conceptual Plan, the Commission first formulated a number of planning objectives ranging from restoring fish and wildlife, to increasing water supply for urban, agricultural and natural areas, to improving coastal and marine conditions. The Commission's objectives fall into three general categories: ecologic, hydrologic, and socio-economic. The Commission believes that if these objectives can be achieved, the goals of restoring the ecological health of the natural areas (including adjacent watersheds and tributaries) and enhancing the region's economy and quality of life can be achieved. The 23 planning objectives are listed in ***Table 6-2***.

The ecologic planning objectives focus on restoring environmental quality to a system that has experienced a massive loss of natural resources. They aim to expand habitat through reclamation and to improve habitat quality and heterogeneity consistent with the characteristic mosaic habitat of the pre-drained Everglades and the coastal and associated marine ecosystems.

The hydrologic objectives focus on ensuring adequate water quality; water supply; timing of flows; flood control for urban, natural, and agricultural needs; restoring more natural hydropatterns, including sheetflow; regaining lost storage capacity; reducing per capita consumption; and encouraging water reuse to achieve the ecologic objectives stated earlier.

TABLE 6-2
GOVERNOR'S COMMISSION
GENERAL PLANNING OBJECTIVES FOR THE RESTUDY

ECOLOGIC
• Improve habitat quality and heterogeneity. • Improve connectivity and reduce fragmentation of habitats. • Provide the spatial extent of natural areas required to support the mosaic habitat characteristic of the pre-drained Everglades ecosystem. • Improve and protect habitat quality, heterogeneity, and biodiversity in coastal and associated marine ecosystems. • Provide for sustainable populations of native plant and animal species with special attention to threatened, endangered, or species of special concern. • Restore and, where appropriate, improve functional quality of natural systems (including both wetlands and uplands). • Reduce the spatial extent of invasive nonnative species to the extent that they do not affect the natural system. • Halt and/or reverse the conditions causing the spread of native species that are threatening (and perhaps dominating) areas as a result of disturbances such as nutrient enrichment.
HYDROLOGIC
• Restore more natural hydropatterns, including associated sheetflow. • Provide more natural quality and quantity, timing and distribution of freshwater flow to and through the natural Everglades. • Provide more natural quality and quantity, timing, and distribution of freshwater flow to estuaries and coral reef ecosystems. • Ensure adequate water supply and flood protection for urban, natural, and agricultural needs. • Regain lost storage capacity. • Restore more natural organic and marl soil formation processes and arrest soil subsidence. • Improve water quality, including reduction of toxins, and ensure appropriate water quality consistent with designated uses including restoration and protection of the natural systems. • Control saltwater intrusion into freshwater aquifers. • Integrate the Project with local stormwater, wastewater, and other water management functions.
SOCIO-ECONOMIC
• Establish levels of provided flood protection in terms of frequency, depth, and duration. • Reduce damages from flooding to public and private property. • Provide water management that supports economic diversity and sustainability derived from the natural and developed systems. • Enhance economic opportunities consistent with sustainable marine ecosystems. • Protect and preserve cultural and archeological resources and values. • Increase recreational opportunities consistent with sustainable natural systems.

Finally, the economic and social objectives provide for water management that supports economic diversity and sustainability for natural, agricultural and developed systems. The Commission believes the need to integrate regional water management systems with local stormwater, wastewater, and other water management functions must be considered when developing alternatives.

6.3.2. Preferred Alternatives

As a first step toward identifying the additional actions needed to develop the Conceptual Plan for the Restudy, the Commission considered 66 options/ideas formulated from a myriad of Federal, state, and local agencies; interest groups; and other members of the public. Many of these options had been evaluated to varying degrees during the reconnaissance phase of the Restudy and the South Florida Water Management District's Lower East Coast Regional Water Supply Planning effort. The ideas ranged from non-structural options to ones that require major structural modifications or additions to the existing C&SF Project. Five additional options were generated by members of the Commission.

Through a series of three workshops, the Commission considered and grouped the options together to form alternative plans. This process helped the Commission gain an understanding of the interrelationships among the various options and set the framework for determining which options had common support and which ones did not. Facilitated discussion allowed for a systematic review and screening of each option.

The result of this process was a list of 40 preferred options, to be evaluated as modifications to the C&SF Project. The Commission agreed to support these options for technical evaluation in the Restudy, although conditions or limits were placed on certain ones. The conditions were intended to clarify important issues and to provide specific recommendations describing the Commission's alternatives for consideration in the Restudy in more detailed study of these options. ***Table 6-3*** includes the list of the 40 preferred options and the conditions (in italics) placed on those options.

Fundamental general concepts pertaining to the 40 preferred options were:

- The burden and responsibility for water storage should be shared across the system.
- Water quality and treatment should be addressed and optimized throughout the system.
- The Commission supports projects in general that salvage, clean up, and reuse water.

TABLE 6-3
40 PREFERRED OPTIONS (With Conditions)

Kissimmee River Area including Native American Tribal Lands
- Kissimmee River Pool A Restoration
- Paradise Run Restoration
- Kissimmee Region - Water Treatment Areas – *Project design must address water quality concerns. Holding areas should be multi-purpose.*

Lake Okeechobee Area
- Maximize Lake Storage Without Environmental Harm - *No significant impacts to the littoral zone or water quality should be allowed. Damage to the east and west coast estuaries by the current regulation schedule must be addressed.*
- Restore More Natural Fluctuations of Lake Levels - *No significant impacts to the littoral zone or water quality should be allowed. Other state agencies (e.g., FGFWFC) should be involved.*
- Restoration of Kreamer, Torry, and Ritta Islands
- Lake Okeechobee - Aquifer Storage and Recovery (Aquifer Storage and Recovery) - *The maximum additional storage and cost effectiveness should be evaluated. Impacts to the littoral zone should be minimized.*

Everglades Agricultural Area (Everglades Agricultural Area)
- Everglades Agricultural Area - Water Storage Areas (Reservoirs) – *Sufficiency of land to accomplish storage should be based on need, science, and appropriate cost-benefit analysis. Up to the entire Talisman property should be considered as a target of opportunity for increased storage with any portions not needed returned to agriculture; additional areas may be considered as necessary. Land acquisitions should be made with willing sellers and in consultation with local landowners. The burden of water storage should be shared across the system.*
- Increase Groundwater Levels to Control Soil Subsidence

Lower West Coast including Caloosahatchee River
- Caloosahatchee - Water Storage Areas (Regional Attenuation/Reservoir Facilities) – *Locations of potential storage areas should be chosen in consultation with local landowners.*
- Caloosahatchee – Water Treatment Areas - *Project design must address water quality concerns. Holding areas should be multi-purpose and located in consultation with local land owners.*
- Restoration of Golden Gate Estates - *Consistent with the South Florida Water Management District's restoration plan.*
- Caloosahatchee - Aquifer Storage and Recovery - *The maximum additional storage and cost effectiveness should be evaluated. Impacts to the littoral zone should be minimized.*
- Remove Organic Sediment Deposits from Caloosahatchee Estuary - *Any such removal should be evaluated as to cost effectiveness; pollution impacts from removal process; sediment disposal; and how to prevent resiltation.*

TABLE 6-3 (continued)
40 PREFERRED OPTIONS (With Conditions)

Western Basin including Native American Tribal Lands

- Water Treatment Area for L-28 (Interceptor)

Upper East Coast Area (UEC)

- UEC - Water Storage Areas (Regional Attenuation Facilities) - *Locations of potential storage areas should be chosen in consultation with local landowners.*
- Stabilize St. Lucie Canal Banks
- Remove Organic Sediment Deposits from St. Lucie Estuary - *Any such removal should be evaluated as to: cost effectiveness; pollution impacts from removal process; sediment disposal; and how prevent resiltation.*

Water Conservation Areas (Water Conservation Areas) including Holey Land and Rotenberger Wildlife Management Areas

- Modify Water Conservation Areas to Create Contiguous Natural Area – *Restore the connectivity of the Water Conservation Areas to the maximum feasible extent consistent with the ability to maintain flood protection and habitat quality, and to replace, through storage in the overall system, any existing urban water supply that may be lost.*
- Modify each Water Conservation Areas to Enhance Wetland Habitat – *Habitat should be enhanced to the maximum extent feasible. Public water supply may be addressed through storage in the overall system, and flood protection should be maintained.*
- Remove Invasive Non-Native Plants

Lower East Coast Area

- Water Preserve Areas
- Seepage Control - *All methods should be considered and evaluated.*
- Saltwater Treatment (Reverse Osmosis, Blending) – *Employ only as a last resort. Cost effectiveness should be evaluated. The technology does not stand alone.*
- LEC - Aquifer Storage and Recovery - *Use in conjunction with storage in buffer areas. Cost effectiveness, technical feasibility, and water quality should be addressed.*
- Wastewater Reuse
- Raise Coastal Canal Stages Coupled with Increased Discharge Capacity
- Water Treatment Area for S-9
- Inter-connect Local Water Management Systems – *There should be shared costs and a clear delineation of responsibilities. The responsibility to solve regional concerns should be included.*
- Implement Southern L-8 Basin / Loxahatchee Slough - *There should be no negative environmental impacts. This option is an example of a project that could salvage, clean-up, and reuse water. It would require local governmental consultation and review in concert with the Restudy.*
- Lake Belt/Seepage Barrier - *All methods of seepage control should be considered and evaluated.*
- Remove Invasive Non-Native Plants (LEC)
- 8 ½ Square Mile Area - *The progress of the East Everglades 8 ½ Square Mile Area Study should be monitored. The western 1/3 to ½ should be bought by the public and included in the buffer.*
- Control Structure in C-4 Canal

TABLE 6-3 (continued)
40 PREFERRED OPTIONS (With Conditions)

Big Cypress National Preserve

- Modify L-28 and L-28 Tieback Levees to Restore More Natural Flows Through Big Cypress National Preserve – *Increased conveyance through Tamiami Trail from CR 951 to 40 Mile Bend and Loop Road should be included.*

Everglades National Park

- Degrade L-29 Levee and Raise Portions of Tamiami Trail
- Add More Culverts Under Tamiami Trail – *Includes the entire reach of Tamiami Trail.*
- Flamingo Road Improvements to Improve Hydrologic Flow
- Incorporate Water Quality and Supply into C-111 and Modified Water Deliveries Projects

Florida Bay/Biscayne Bay/Florida Keys

- Hydrologic Improvements in the Model Lands Basin in Dade County
- Hydrologic Improvements in North, Central, and South Biscayne Bay Basins in Dade County

6.4. CONCEPTUAL PLAN ELEMENTS

After reaching consensus on the 40 preferred options, the Commission asked for additional analysis and information in order to refine the preferred options for possible inclusion into the Conceptual Plan for the Restudy. As part of the Restudy, the Commission's preferred options were screened and a process for analyzing them further was developed. Due to the similarities in function, the 40 preferred options were grouped into 13 thematic concepts to form a broad-based Conceptual Plan for the Restudy. These concepts include the spectrum of the preferred options identified by the Commission but are less specific. By generalizing the concepts, the Commission hoped to provide the Restudy with sufficient information to evaluate the broad spectrum of options and the trade-offs among them without restricting development of new options. Together with the potential modifications to the C&SF Project contained in the 40 preferred options, these concepts must be viewed holistically, not individually, since they come together to form an overall vision for the Restudy. In addition, many of the concepts will serve multiple purposes. For example, storage areas can help supplement natural system needs as well as provide water supply for agricultural and urban areas. The Commission recognized the need for detailed analyses conducted as part of the Restudy to develop specific projects. However, the concepts that comprise the *Conceptual Plan for the Restudy* provide a basis for the formulation and evaluation of specific plans.

Table 6-4 identifies the various thematic concepts and illustrates how the 40 preferred options fit within these concepts. Table 6-4 also identifies ongoing projects and the Federal Agriculture Improvement Act of 1996 (P. L. 104-127, known as the "Farm Bill") priority projects that fit under these thematic concepts. In addition, Figure 6-1 schematically portrays many of the concepts in relative geographic locales.

Note: Projects Underway noted by *; Governor's Commission for a Sustainable South Florida's Farm Bill Priority Projects noted by **

The following sections provide a description of each of the concepts which include those projects currently underway or programmed and additional features the Commission determined important to meet its objectives for the Restudy. The description of the concepts is taken directly from the Commission's report. The thirteen concepts broadly covered four major themes: regional storage for natural systems, water supply and flood protection; natural areas enhancement and restoration; improved water quality; and improved operation, management and implementation practices.

6.4.1. Concept 1: Regional Storage Within The Everglades Headwaters And Adjacent Areas

Sufficient water to meet competing demands can only be provided by maximizing storage. Water storage should be provided throughout the entire system and in such a way that no single area is environmentally damaged by excessive storage requirements or bears a disproportionate share of the storage burden. This storage must be achieved in all areas of the south Florida system using every practical option. As part of this concept, regional storage would be evaluated for the northern reaches of the Everglades system (Caloosahatchee, St.

Lucie, and Kissimmee River Basins). The additional storage in these basins should increase the water supply capabilities of the system and could ultimately reduce demands on Lake Okeechobee, thereby providing additional water during the dry season and reducing damaging high water conditions and harmful discharges to the east-west estuaries during the wet season.

6.4.1.1. Kissimmee River Basin

The Kissimmee Chain of Lakes forms the headwaters of the Everglades system and provides a critical source of water for Lake Okeechobee. The Kissimmee River Restoration Project, as currently planned, includes operational changes of lake levels in Lakes Kissimmee, Hatchineha, and Cypress to increase storage capacity necessary for the restoration of the Kissimmee River. Additional efforts that should be considered under this concept include examination of the operational plans for the remainder of the Upper Chain of Lakes to discern if they could provide additional storage capabilities to benefit the health of Lake Okeechobee and potentially reduce the volume of water shortages in the system.

Additional storage within the Kissimmee River Basin could reduce the amount of runoff entering Lake Okeechobee during the wet season when the lake typically approaches high levels. This could shorten the duration of high water levels within the lake that damage its littoral zone and could reduce the frequency of high volume discharges to the east and west coast estuaries. The increase in water levels within the Upper Chain of Lakes could be restricted to avoid natural system impacts of high water levels and the need to maintain flood protection to lakeside residential development throughout the area. In support of the Commission's sociological and economic goals, this concept must be designed to balance the need for storage with the need to maintain flood protection to lakeside developments and should not result in the relocation of communities and agricultural areas.

6.4.1.2. St. Lucie Canal and Caloosahatchee River Basins

Creating additional storage or enhancing the storage capacity on existing private or public facilities and open areas within the St. Lucie Canal and Caloosahatchee River Basins may reduce water supply demands on Lake Okeechobee by providing a supplemental source of water for irrigation and environmental base flow for the estuaries. The water conserved in Lake Okeechobee could be available for sustaining the health of the lake and downstream natural areas and other uses. Storage facilities could also attenuate local basin runoff that presently upsets the salinity balance in estuaries and adversely impacts seagrasses, invertebrates, and fisheries.

Pumping local basin urban and agricultural runoff into storage areas could attenuate flows during the wet season and provide storage into the dry season.

Restoring hydropatterns in large natural areas and storing excess water in wet pastures could attenuate flows and help restore cleaner and more natural inputs to the estuaries. Restoration of natural areas can also help meet the goal of expanding and enhancing the spatial extent of short hydroperiod wetlands. Dry period releases from these storage areas could be used for agricultural irrigation and for meeting minimum flow requirements of the estuaries. During those periods when supplemental irrigation requirements could not be met by the storage areas, water supply releases from Lake Okeechobee could still be provided. Attenuating stormwater runoff will provide some water quality benefits, although additional treatment may be required depending on the use of the discharged water. Water clarity is very important to aquatic vegetation, particularly grasses. For example, storing stormwater may allow suspended solids to settle out, consequently improving the transparency of the water.

The storage areas and their associated water treatment facilities should be sized and designed to be ecologically consistent with the location. The total storage volume, coupled with the size and depth of the storage areas, need to be optimized as a part of detailed design during the Restudy. The storage areas could require perimeter levees, pump stations, and conveyance canals to move water from the canal system into the storage areas and to control water supply and environmental releases from the storage areas. Ideally, individual upland storage areas would be divided among the various sub-basins and would be interconnected to provide for maximum flexibility of water management options among basins. The siting of these facilities should, to the maximum extent practicable, avoid primary or secondary impacts to existing wetlands and adjacent uplands, both of which contribute to a viable ecosystem and economy. The Indian River Lagoon Feasibility Study is examining the option of on-site retention for large dischargers within the St. Lucie Basin not presently providing such facilities; this concept should be examined for other areas as part of the Restudy effort.

6.4.2. Concept 2: Lake Okeechobee Operational Plan

Lake Okeechobee provides a critical source of water for the Everglades Agricultural Area (EAA), the urbanized areas of the Lower East Coast, portions of the Lower West Coast, the remaining portions of the historic Everglades system, and other wetland components of the south Florida ecosystem. Prior to manmade alterations, lake levels rose in response to rainfall and served as a valuable source of freshwater spilling into the Everglades during a relatively small number of high rainfall years. Today a lake regulation schedule triggers different management activities according to different lake levels. The current regulation schedule, known as Run 25, was developed for multiple purposes including water supply, flood control, navigation, and environmental protection. Since some of these goals conflict, achieving all of them under current conditions is impossible. Past efforts to meet all of these conflicting goals have resulted in damage to the lake's littoral zone and to the east and west coast estuaries. The Commission believes a new operational plan for the lake is needed that maximizes storage opportunities, protects the east and west coast estuaries, restores the ecological health of the lake, and enhances wildlife populations. The ability to accomplish these goals greatly depends on additional storage throughout the system and on other improvements to the overall C&SF Project.

Within the constraints imposed by these conflicts, the operational guidelines for Lake Okeechobee are currently being reviewed to attempt to optimize the natural resources within the lake, water discharges for the purpose of restoring the natural hydropattern of the Everglades, and flows to the estuaries without adversely impacting flood control or urban and agricultural water supply. Avoiding environmental harm to the St. Lucie and Caloosahatchee Estuaries caused by massive lake releases is an important goal. Equally important is protection of the lake littoral zone from prolonged high water. Maximizing storage for environmental, agricultural and urban needs while protecting the lake and estuaries will require creative new operational schedules. This interim study of operational guidelines for the lake is being conducted in conjunction with South Florida Water Management District's Lower East Coast Regional Water Supply Plan. In addition, the South Florida Water Management District's Surface Water Improvement and Management Plan requires specific regulatory and non-regulatory activities to address water quality conditions, including ongoing development and testing of agricultural Best Management Practices to reduce pollutants and assure water quality compliance for discharges into the lake. Additional actions may be necessary since current nutrient loads to the lake remain above the established target. Nutrient levels contained in lake water would need to be lowered before it could be discharged into the Everglades. These ongoing efforts should serve to benefit the health of the lake through improved water quality and operational changes which are more desirable for the lake's littoral zone without compromising other project purposes such as flood control and water supply. To fully resolve these conflicting demands on the lake, additional storage areas throughout the system and methods to improve water quality are required.

Until additional storage options are available elsewhere in the system, temporary storage capacity in the lake could help meet projected demands for urban and agricultural water supply and natural system needs. Revisions to the operational plan for Lake Okeechobee may allow additional water to be stored in the lake during wet periods and may help meet the projected demands during dry periods while maintaining ecologically desirable water fluctuations and lake levels. This could be accomplished by allowing periodic lower levels during droughts and higher water levels during wet periods, providing there is no significant adverse impact to the lake's littoral zone, or the east and west coast estuaries. A new operational plan needs to be identified that triggers management activities for high lake levels and "supply-side" management actions for low lake levels. Modified lake operations could increase the storage capacity of the lake, while reducing impacts to other parts of the regional system. All operational options that seek to increase lake storage capacity, while protecting the littoral zone and the east and west coast estuaries, must be carefully examined.

Lake Okeechobee's littoral zone provides important nursery grounds and habitat for fish and other aquatic organisms. It also supports large populations of wading birds and migratory waterfowl. The current location of the littoral zone is the result of the construction of the existing dike system, and the lowering of the lake level by drainage. Colonization by aquatic plants creates a littoral zone where fluctuating water levels are sufficient to support emergent vegetation. A diverse littoral zone cannot survive under periods of prolonged inundation. Timing of varying water levels and light penetration in the shallows are key factors in maintaining a viable littoral zone. The existing littoral zone was established when lake regulation levels fluctuated between 13.0 and 15.5 feet NVGD. In 1978, the regulation schedule was set at 15.5 to 17.5 feet to increase lake water storage. Assuring the continued health of the existing littoral zone is an important goal. All available information should be used to design a lake regulation schedule that preserves a healthy littoral zone, maximizes lake storage, and allows attenuation of floodwaters to protect the east and west coast estuaries. If it is determined to be feasible, raising the regulation schedule above the current limits may require costly structural changes such as raising existing levees, modifying or adding water control structures, constructing new pump stations, canals, and tie back levees. Also, State Road 78 may need to be raised and additional flood easements acquired. Recent high lake levels and the resulting dike seepage problems indicate levee repairs and improvements may be required even if the current regulation schedule is not raised. In addition, the Seminole Tribe's Brighton Reservation is located on the northwest side of Lake Okeechobee. As Federal Trust Property, this reservation should be considered in any decision regarding modifications to the water levels of the lake. The Restudy must consider all of these aspects when evaluating the role that Lake Okeechobee will play in the future.

6.4.3. Concept 3: Everglades Agricultural Area Storage

Much of the supplemental water supply for the Everglades Agricultural Area in the dry season is currently met by deliveries from Lake Okeechobee. Additional water storage in the Everglades Agricultural Area will lessen its dependency on Lake Okeechobee for irrigation water and potentially reduce the ecologically damaging high water conditions in the Water Conservation Areas and backpumping into Lake Okeechobee during the wet season. Regional above-ground impoundments or storage areas within the Everglades Agricultural Area could capture and store Everglades Agricultural Area runoff or excess water from Lake Okeechobee during the wet season. During the dry season, reservoir releases could be made to the primary canals for agricultural irrigation and for restoration of the downstream Everglades ecosystem. Lake Okeechobee would then no longer serve as the only supplemental source for meeting Everglades Agricultural Area irrigation demands. During the periods when supplemental irrigation requirements could not be met by the storage areas, water supply releases from Lake Okeechobee could still be provided.

The Commission recommends that the determination of sufficient land to accomplish storage in the Everglades Agricultural Area be based on need, science, and appropriate cost-benefit analyses. The Talisman property is currently being considered for acquisition by the State for use as a water storage area. The Commission supports the acquisition of up to the equivalent of the Talisman property as a target of opportunity for increased storage. Additional areas may be considered. Until the total storage volume, size, and depth of storage areas are designed and optimized during the Restudy, based on analyses of costs, benefits, needs, and impacts, all land acquisition should be made with willing sellers and in consultation with local landowners. Acquired lands could be returned to agricultural use if not needed for restoration activities.

Properly sized and designed storage areas have the potential of improving the quality of water being delivered to the natural system by reducing Everglades Agricultural Area runoff entering the stormwater treatment areas, thereby reducing the nutrient loading coming from the Everglades Agricultural Area and aiding the stormwater treatment areas in meeting target phosphorus levels entering the Water Conservation Areas. Further, detention of stormwater for attenuation purposes will improve water quality. However, additional water treatment may be required if the water within these storage areas is to be used to meet natural system demands.

Ongoing efforts to improve flood control capacity within the Everglades Agricultural Area and water quality of downstream flood control discharges, include the Everglades Construction Project and the reevaluation of the Bolles and Cross Canals. Presently, the design of the major canals of the Everglades Agricultural Area is constrained in moving water internally within the Everglades Agricultural Area or from Lake Okeechobee to the south. By incorporating expanded or modified Everglades Agricultural Area canals with stormwater treatment areas and new water storage areas, the increased operational flexibility could provide additional flood protection to the Everglades Agricultural Area while protecting the Water Conservation Areas and the coastal estuaries from damaging high water levels and untimely discharges. When Lake Okeechobee exceeds its regulation schedule, water that currently impacts the lake's littoral zone or disrupts the east and west coastal estuaries could be moved southward into new storage areas or, water quality permitting, to the Water Conservation Areas.

6.4.4. Concept 4: Water Preserve Areas

The purpose of the Water Preserve Areas concept is to: (1) increase storage and hold more water in the system by controlling seepage from natural areas; (2) capture and store excess stormwater currently discharged to coastal waters, thus retaining an important water supply source for both urban and natural systems; (3) provide a buffer between the natural and developed areas; (4) preserve and protect wetlands outside the publicly owned Everglades; and (5) provide important transitional land uses between the natural and developed areas. The Water Preserve Areas concept may also enhance flood control in areas to the east of the Water Preserve Areas. Attempts to meet these various goals should be coordinated and developed in a consistent manner.

Hydrologic modeling of the regional system has demonstrated seepage control is a critical component for achieving restoration targets in the southern Everglades and Florida Bay. Much of the water that seeps out of the Everglades is collected in the secondary canal network and discharged into the regional canal system, resulting in excessive releases to coastal waters. The Water Preserve Areas concept must include a cost-effective implementation of one or all of these alternatives to achieve the multi-purpose functions and operational flexibility needed to meet the Commission's objectives. Water Preserve Areas should enhance regional capabilities for meeting environmental, urban, and agricultural water demands, while simultaneously providing protection of certain designated wetlands outside the Water Conservation Areas and Everglades National Park. The Water Preserve Areas concept consists of a series of surface water impoundments, interconnected and managed as a system of marshlands, storage areas, and/or aquifer recharge basins. These areas provide the potential to backpump stormwater currently discharged to coastal waters and serve to control urban sprawl into remaining peripheral wetlands. Some examples of seepage control alternatives which should be evaluated for inclusion in the Water Preserve Areas are creating areas to store excess urban runoff, creating a step down of water levels toward the east, building collection and backpumping facilities, and installing subterranean barriers.

Water quality becomes an important consideration where enhancement of existing wetlands or backpumping into the Water Conservation Areas or wellfield recharge areas is desired. Untreated stormwater should be diverted to a treatment facility or should undergo other treatment options necessary to achieve water quality standards prior to discharge to a wetland area, wellfield recharge area, or surface water supply source areas. In particular, the S-9 pump station must also be considered. The S-9 pump station is the only major C&SF Project facility that currently discharges untreated urban stormwater into the Everglades. Other urban stormwater discharge into the Everglades by local drainage districts must also be addressed. Structures that discharge into Water Conservation Areas should have appropriate permits to discharge effluent, should be monitored, and should meet all applicable state and Federal water quality standards and laws. A water treatment facility could remove phosphorus and other constituents from stormwater prior to discharge into the Water Conservation Areas.

The Water Preserve Areas concept includes the remaining natural areas and open spaces along the eastern boundaries of Everglades National Park and the Water Conservation Areas and extends north into the Upper East Coast area. This concept is considerably more extensive than the existing South Florida Water Management District East Coast Buffer Project boundaries, that is a land acquisition initiative that preserves, where possible, design flexibility for future water preserve elements. For example, Palm Beach County has proposed that the Water Preserve Areas concept be extended east and northeast into the Loxahatchee Basin.

In June 1995, the Martin and St. Lucie County Commissions established a Water Preserve Areas Task Force to facilitate selection of suitable sites for Water Preserve Areas in those counties. In Martin and St. Lucie Counties, Water Preserve Areas could provide for the diversion of surplus runoff from the C-23, C-24, and C-25 drainage basins to storage areas where the water could be used for agricultural purposes or, with treatment, could be discharged into the estuary to enhance needed baseflow. The Task Force has completed a draft report that evaluated a number of potential Water Preserve Areas sites and conducted a design charette for a potential site at Allapattah Ranch. Water Preserve Areas in these two counties could help alleviate the problems caused by excessive inflows of freshwater to the St. Lucie Estuary and Indian River Lagoon.

The area of northwestern Miami-Dade County proposed as a future "Lake Belt" by the South Florida Limestone Mining Coalition lies east of Water Conservation Areas-3B and comprises a large portion of land being considered for the Water Preserve Areas. The Florida Legislature recognized that one of the few remaining high-quality, construction grade limestone deposits suitable for the production of aggregates, cements and road base materials in the state is located in this area. Therefore, the legislature established the Northwest Dade County Freshwater Lake Plan Implementation Committee and further defined the proposed lake plan boundaries. The objective of the legislation is to develop a plan that:

> *"(a) enhances the water supply for Dade County and the Everglades; (b) maximizes efficient recovery of limestone while promoting the social and economic welfare of the community and protecting the environment; and (c) educates various groups and the general public of the benefits of the plan."*

A public/private partnership may offset the cost or reduce the need for acquiring portions of the Water Preserve Areas (including but not limited to land donations, land swaps, and less than fee simple acquisitions). However Lake Belt Plan development is proceeding in advance of the Water Preserve Areas design component of the Restudy. Coordination between these two planning efforts is necessary to avoid difficulties associated with Everglades restoration. It is important that the future lake plan be consistent with economic and environmental sustainability and flexible enough to ensure compatibility with south Florida natural system restoration and other objectives set forth by the Governor's Commission.

The Water Preserve Areas concept should extend seepage control south of Tamiami Trail to the eastern panhandle of Everglades National Park including the 8 1/2 Square Mile Area and the C-111 Basin. The stretch of the L-31N from Tamiami Trail to the 8 1/2 Square Mile Area is of significant concern because of the extreme rates of seepage along the eastern border of Northeast Shark River Slough. Raising water levels in the L-31N Canal is a critical element in restoring hydropatterns in Everglades National Park. This cannot be achieved without seepage control due to the flooding threat to the 8 1/2 Square Mile Area and areas to the east of the L-31N Canal. One suggestion in support of the Water Preserve Areas concept is to install a divide structure in the C-4 Canal. This would increase the potential volumes of stormwater that could be captured by various backpumping configurations as well as help recharge wellfields and improve flood protection for urban areas.

Because the 8 1/2 Square Mile Area is located adjacent to the Everglades National Park boundary, flood control could affect restoration of natural hydropatterns, flows and water quality within the Park. The currently authorized flood mitigation for the 8 1/2 Square Mile Area does not provide adequate protection for the community. The 8 1/2 Square Mile Area deserves consideration by the Restudy, consistent with the recommendations of the Governor's Committee on the 8 1/2 Square Mile Area.

The exact extent, design, and operation of the Water Preserve Areas should be evaluated and determined as part of the Restudy. However, time is of the essence as lands in some of the proposed Water Preserve Areas are rapidly being converted to uses that are incompatible with their potential use as Water Preserve Areas. Therefore, The Commission believes that accelerated acquisition of critical lands is needed to ensure that this concept remains viable.

6.4.5. Concept 5: Natural Areas Continuity

Historic freshwater wetland habitats in south Florida have been reduced spatially, compartmentalized, and hydrologically altered as a result of the C&SF Project. Further, habitats have been unnaturally fragmented. Reestablishing the hydrologic and ecologic continuity of the remaining natural areas is expected to benefit the entire Everglades ecosystem by recovering the pre-drainage functions and habitat values of historic freshwater wetlands, reducing the fragmentation, and restoring more natural hydropatterns including associated sheetflow. These actions may also help restore the ecological processes and relationships, and the diversity and numerical abundance of animals that can only come by reestablishing the central and southern Everglades and Big Cypress into a single, fully integrated ecosystem. This concept proposes to restore ecological continuity to areas that are currently treated as geographically and hydrologically distinct. These areas include the three Water Conservation Areas, the Rotenberger/Holey Land Wildlife Management Areas, the Big Cypress National Preserve, Ten Thousand Islands, Fakahatchee Strand, Mullet Slough, Corkscrew Swamp, Caloosahatchee Slough, Rookery Bay, Everglades National Park, the Model Lands, Florida Bay, the Florida Keys, and associated estuarine and marine waters. This concept involves structural and/or operational changes within the remaining natural areas for the benefit of the entire ecosystem. These structural changes should also include examining the effects and/or proposing changes to U.S. 27, which bisects the Water Conservation Areas, to enhance natural conditions.

Water quantity and water quality are important aspects of this concept, however, features to achieve these goals will generally come from outside the boundaries of the remaining natural areas. This concept assumes that appropriate quantity and quality of water needed to meet ecosystem goals in the natural areas will be available and that the Water Conservation Areas will be managed to the maximum extent feasible for natural values. Existing legislation by the State of Florida, the Everglades Forever Act, addresses non-point source pollution from agricultural activities in the Everglades Agricultural Area. Best Management Practices and treatment of runoff from the Everglades Agricultural Area through stormwater treatment areas are designed to reduce phosphorus levels in water released to the Everglades to 50 parts per billion, an interim goal for the discharges. Additional water quality treatment may be necessary if more stringent water quality standards are applied and additional water for restoration is required. Where possible, the Everglades Forever Act implementation schedule should also be accelerated.

Several efforts are currently underway that will help achieve the goals of restoring the hydrological function and reestablishing ecological connections between natural areas and wildlife communities. These ongoing projects include the Experimental Program of Modified Water Deliveries to Everglades National Park, the C-111 Project, and the Florida Bay Emergency Interim Plan (Taylor Slough Demonstration Project). The Commission believes implementation of these projects will help achieve these goals while maintaining and, where possible, improving levels of water supply and flood protection to the adjacent agricultural areas.

The Experimental Program of Modified Deliveries to Everglades National Park was initiated in 1984 to test alternative operational plans and to provide more natural hydrologic conditions in the Everglades during the testing process. Initial tests addressed water deliveries to Shark River Slough and have since incorporated tests of water deliveries to Taylor Slough. The program will continue through the design and construction of the Modified Deliveries to Everglades National Park and the C-111 Projects. The Modified Water Deliveries to Everglades National Park Project is aimed at restoring the original deep water portion of Shark River Slough and reducing the impacts of large flood releases in western Shark River Slough. The C-111 Project will create a buffer area along the eastern boundary of the Park to allow increased water levels in Taylor Slough and gradually lessen water levels from west to east. C-111 Project design modifications should also ensure natural water deliveries to the panhandle area of Everglades National Park and the Model Lands area east of U.S. 1. In addition, the Florida Bay Emergency Interim Plan, required by the Everglades Forever Act, should increase the amount of freshwater reaching Florida Bay by acquiring the Frog Pond and raising canal stages to promote more freshwater to flow through Taylor Slough into Florida Bay. Flood protection will be maintained and, where possible, improved for adjacent, existing urban and agricultural lands as these projects are implemented. Results should be monitored to evaluate effectiveness or identify needed modifications. The goal is to replicate flows, more natural hydropatterns, and flows in natural areas to maintain and restore native wetland, upland plant communities, and wildlife communities.

In the development of this Conceptual Plan for the Restudy, the Commission identified additional efforts needed in the region to fully meet its objectives for hydrologically and ecologically reconnecting natural areas. These are described as follows:

6.4.5.1. Water Conservation Areas

Historically, the three Water Conservation Areas were an expansive mosaic of habitats including uplands, hammocks, sawgrass plains, wet prairies, sloughs, lakes, and marl-forming marshes that constituted the central and northeastern portions of the historic Everglades. Construction of the three Water Conservation Areas has resulted in the management of each of the areas according to a regulation schedule based on inflow and outflow of water through water control structures and system demands.

As part of this concept, structural modifications to the levees and structures currently compartmentalizing the Water Conservation Areas and changes in operational plans will be investigated for the purpose of restoring more natural hydrologic and ecologic continuity within all of the Water Conservation Areas. Preliminary hydrologic modeling conducted during the reconnaissance phase of the Restudy indicated some levees and structures may still be necessary to create desirable hydrologic and ecologic conditions throughout the area. Further, the current Water Conservation Areas regulation schedules need to be modified to schedules based on more natural conditions. The goal is to replicate more natural hydropatterns within the Water Conservation Areas and to maintain and restore native wetland and upland plant communities. It is important to note that the movement of water through these areas has been altered by soil subsidence. Current flow patterns are much different than historic flow patterns. For these and other reasons, more detailed hydrologic modeling is necessary to determine changes in hydrologic patterns that result from modifications to the amount, timing, and distribution of water flowing into and through the Water Conservation Areas. As part of the Restudy, restoring the connectivity of the Water Conservation Areas with the other portions of the Everglades should be consistent with the ability to maintain flood protection and existing water supply for agricultural and urban areas.

6.4.5.2. Big Cypress National Preserve

The Big Cypress National Preserve area is a mosaic of evolving habitat types resulting from both natural and manmade forces. Historically, long hydroperiods limited the invasion of shrubs and pines into cypress forests and frequent fires prevented hardwoods from dominating cypress and pine forests. Infrequent hot fires burned holes into peat soils that created new pools. The result of these conditions was a balance of shifting successional communities. Construction of the L-28 levee, Tamiami Trail, and Loop Road altered flows and changed the habitat cycles of floods and fires.

As part of this concept, hydrological and ecological conditions will be improved by providing more historic-like flows along the eastern border of Big Cypress National Preserve. This will provide for more natural inter-annual and seasonal variations of flow that will, in turn, result in a more natural cycle of floods and fires in the area. As more natural patterns of fires and floods are restored, overall habitat heterogeneity will increase and a more natural interspersion of uplands and wetlands will return. Additional benefits of this concept may include improvements in water table elevations in the coastal mangrove forests in the Ten Thousand Islands area of Everglades National Park. Impacts to threatened and endangered species such as the Cape Sable Seaside Sparrow and the West Indian manatee will need to be considered and addressed.

The L-28 Levee presently separates Water Conservation Area 3A and the Big Cypress National Preserve. To restore hydropatterns within Big Cypress National Preserve, this levee, Tamiami Trail, and Loop Road may need to be modified. Further upstream, the L-28 Interceptor Canal (L-28I) collects water from the Seminole Reservation and upstream basins and discharges it into Water Conservation Area 3A. Allowing this canal to discharge further upstream in the northeast corner of Big Cypress National Preserve could rehydrate Mullet Slough and the headwaters of Big Cypress Natural Preserve, while still providing flood protection to the Seminole and Miccosukee Reservations. Facilities for water treatment will be necessary to improve water quality entering natural areas from the C-139 and the L-28I canals that presently flow directly into Water Conservation Area 3A. The Seminole Tribe's Water Conservation Plan provides a greater opportunity to restore more natural hydropatterns in the Big Cypress National Preserve by creating flows further north and west. Bypass structures will be placed under the West Feeder Canal on the Big Cypress Reservation that will sheetflow clean water south along the length of the west Feeder Canal into the Big Cypress Preserve Addition.

6.4.5.3. Everglades National Park

Tamiami Trail (U.S. 41) and L-29 form an ecological and hydrological barrier between Water Conservation Area 3 and Everglades National Park. Two on-going projects have identified ways to improve hydrologic and ecologic conditions within Everglades National Park; the Modified Water Deliveries to Everglades National Park and C-111 Projects. These projects will help improve conveyance into Everglades National Park and provide some seepage control south of Tamiami Trail. While these projects will improve conditions in Everglades National Park in the interim, additional measures may be needed to further control seepage and restore conveyance to historical levels. These issues need to be addressed through the Restudy and evaluated collectively. Structural modifications to the L-29 levee and improving conveyance through Tamiami Trail (bridge structure) from CR 951 to 40 Mile Bend and Loop Road need to be evaluated by the Restudy from the perspective of restoring the hydrologic and ecologic continuity of Water Conservation Area 3, Everglades National Park, the Big Cypress, and Ten Thousand Islands.

Groundwater seepage loss is the main impediment to any kind of restoration within Everglades National Park. Its impact is far reaching, affecting every water management decision along Tamiami Trail. To address this problem, the Water Preserve Areas concept has been extended south of Tamiami Trail to control the extreme seepage losses that occur on the east side of the Park. At a minimum, the areas of concern include the 8 ½ Square Mile Area, Bird Drive Basin, and the Pennsucco Wetlands.

Flamingo Road, which is the main road through Everglades National Park, is the only road providing access to the Flamingo visitor center. This roadway acts as a levee during high flow conditions and impedes sheetflow through portions of Everglades National Park. This concept addresses improving conveyance through this road. Adding culverts, bridges, or other improvements to Flamingo Road will remove a hydrological barrier and restore more natural flows within the area, resulting in improved hydrologic and ecologic continuity.

6.4.5.4. Biscayne National Park

Large public works projects in South Miami-Dade County (e.g. U.S. 1, the C&SF Project, etc.) have interrupted natural freshwater flows into Biscayne Bay. The pending transfer of Homestead Air Force Base to Miami-Dade County, and the public acquisition of the Model Lands provide important opportunities to improve these hydropatterns. The Commission supports the sustainable conversion of the air base and redevelopment of appropriate areas in southeast Miami-Dade County as critical economic development projects. Water management changes that result from these activities must be made in ways that protect Biscayne National Park and other vital environmental resources in southeast Miami-Dade County, reconnect drained wetlands east and west of U.S. 1, and reinforce the sustainable agricultural goals of this Commission. The reconnection of Biscayne Bay to more natural freshwater flows from the mainland will complete the "natural area continuity" at the southeastern end of the natural system.

6.4.6. Concept 6: Water Supply and Flood Protection for Urban and Agricultural Areas

The flood protection and water supply provided by the C&SF Project have facilitated the development of urban and agricultural areas in south Florida. Population growth and the intense development in south Florida are expected to continue resulting in significant increases in the demand for water and pressure to maintain and enhance flood protection. The Commission recognizes that flood protection and water supply for all users are critical components of sustainability of the region. The Commission also recognizes the continued importance of the C&SF Project to meet these needs. It is the goal of the Commission to maintain existing levels of water supply and flood protection and, where consistent with restoration goals, to balance future flood protection and water supply.

C&SF Project facilities allow the Water Conservation Areas and Lake Okeechobee to serve as a critical source of water for meeting urban needs during periods of low rainfall. This includes providing recharge to the surficial aquifer along the Lower East Coast and maintaining surface water supplies to the Caloosahatchee Basin and the West Palm Beach Water Catchment Area. In addition, the lake serves as a direct source of water for lakeside communities.

The South Florida Water Management District is currently developing four water supply plans that, together, cover the entire boundaries of the South Florida Water Management District. Each regional plan analyzes the available water supply and makes projections of future demand through the year 2010. Working with public advisory committees, the South Florida Water Management District is determining the likelihood of future water supply problems, and is developing potential solutions to these problems. The majority of the C&SF Project facilities fall within the boundaries of the Lower East Coast Regional Water Supply Plan. An interim plan was completed in early 1998. The Lower West Coast Water Supply Plan was completed in 1994. The Upper East Coast Water Supply Plan was completed in 1998 and the Kissimmee Water Supply Plan is underway. The plans will make recommendations to address immediate water supply issues and will also make long term recommendations to the Restudy.

One important option under consideration in both the Lower East Coast Regional Water Supply Plan and the Restudy is the Water Preserve Areas concept, which will benefit regional water supply. Capturing and storing excess stormwater runoff in the Water Preserve Areas could serve as additional storage areas for urban water supply and enhance recharge of the Biscayne Aquifer. Other regional concepts, such as modification of the regional and secondary canal systems to improve water management and recharge capability are possible methods of increasing recharge to the surficial aquifer. Options that have been identified for this purpose include raising coastal canal stages (with appropriate means to maintain flood control) and interconnecting local surface water management systems and the southern L-8 Project in northern Palm Beach County.

Other alternatives, while less regional in nature, include new inland wellfields, public water supply aquifer storage and recovery, wastewater reuse, the reduction of per capita water usage, and the use of brackish or saltwater sources of water. Utility or local government programs for plumbing retrofit and landscape water conservation programs may also be useful in slowing the increase in urban demands. It is anticipated that the implementation of a combination of alternatives will be necessary, depending on the type of user and the circumstances that the user encounters. It is critical that the Restudy effort work closely with local water utility departments to further develop these alternatives. The Commission believes the Restudy must take a regional view toward water supply. Further, the Commission recognizes that regional water supply deliveries from the C&SF Project are critical to achieving sustainability. The Restudy must develop plans to mitigate and replace any water supply lost through system modifications for environmental restoration.

The C&SF Project has provided regional flood protection throughout the entire system. Flood protection provided to existing agriculture and development should be maintained. In a number of areas, some features of the Project have never been constructed and development and agriculture have occurred in areas not previously anticipated to be converted. Of particular concern is the south Miami-Dade area where projects such as the Modified Water Deliveries to Everglades National Park and the C-111 Project are underway. These south Miami-Dade projects must incorporate appropriate flood protection into their design. The Commission has identified a number of water storage options throughout the C&SF Project system that will provide increased flood protection. These options, including the Water Preserve Areas and storage areas, should also include flood protection as their purpose.

6.4.7. Concept 7: Adequate Water Quality for Natural System Functioning

A fundamental requirement for maintenance and restoration of the Everglades ecosystem, Florida Bay and the coastal estuaries is the delivery of adequate amounts of clean water. Just as restoration of water quantity in proper volumes and timing to the Everglades is the cornerstone of Everglades restoration, the Commission believes that the natural system can only be restored through the supply of clean rainwater and surface water from upstream marshes, rivers, sloughs, and Lake Okeechobee.

Drainage from the extensive agricultural development in the Everglades Agricultural Area delivered to the Everglades marsh via the C&SF Project structures resulted in the degradation of Everglades marsh surface waters. Stormwater runoff from extensive urban development on both coasts has degraded water quality in the coastal estuaries and certain portions of the Everglades where urban stormwater/drainage water is backpumped (i.e., the C-11 Basin) via the C&SF Project structures. Since the natural Everglades ecosystem is oligotrophic, with high plant biomass and very low nutrient concentrations in marsh surface waters, it is acutely vulnerable to eutrophication by elevated nutrient levels. The estuaries, notably Florida Bay, Biscayne Bay, and the St. Lucie Estuary, have been damaged by degraded water quality or unnaturally high volumes of water facilitated by the C&SF Project canals.

Large scale Everglades restoration planning and implementation must include the delivery of clean water to the Everglades marsh. Ecological restoration cannot be accomplished if water flowing to the Everglades contains high nutrients and ecologically damaging levels of pesticides, heavy metals, and other constituents. If, in the future, the Everglades marsh consists of large expanses of cattail monoculture, the ecologic integrity of the Everglades will not be equivalent to restoration of a diverse, heterogeneous system of sawgrass marsh intermingled with spikerush flats, deep water sloughs, tree islands and upland hardwood hammocks.

A number of activities are currently underway or programmed by various agencies to address the issue of water quality entering Lake Okeechobee, the Everglades, Florida Bay and the region's estuaries. These activities serve to improve the quality of water currently being discharged into lake, wetland, and estuarine ecosystems from existing water management infrastructure and are a critical and integral component of the Commission's Conceptual Plan for the Restudy. Evaluations of these water quality improvement activities must occur to insure their adequacy in meeting the goal of restoration.

The Florida Department of Environmental Protection's water quality standards program develops designated uses and classifications of State waters. Narrative and numeric water criteria are set for various water quality parameters to protect the designated use of the water body. The Everglades Forever Act mandates that the Florida Department of Environmental Protection, in conjunction with the South Florida Water Management District, develop numeric water quality criteria for phosphorus in the Everglades Protection Area by the year 2001. The development of numeric water quality criteria, particularly for phosphorus in the Everglades marsh, is a critical step in developing ecosystem-wide water quality and ecological restoration strategies. The Seminole and Miccosukee Tribes have also been delegated the authority to set water quality standards. These standards will address protection of wetlands with cypress and sawgrass communities.

Because enforcement of state narrative and numerical water quality standards is critical to protecting the ecological health of the Everglades ecosystem, the Commission recommends that structures discharging into the Everglades Protection Area be appropriately permitted, as provided by law, and that discharge effluents be monitored to ensure all applicable state and Federal water quality standards and laws are met.

Non-point source pollution associated with urban or agricultural land uses adversely impacts both groundwater and surface water resources and must be controlled in basins draining to both the Everglades Protection Area and the coastal estuaries. Specifically, non-point source pollution associated with the backpumping of untreated water into Water Conservation Area 3-A at pump structure S-9, in the C-11 drainage basin in western Broward County, must be adequately addressed and controlled by local, state and Federal water pollution control agencies.

In addition, high levels of methyl mercury have been found in fish and wildlife in Everglades marshes and canals. In Florida, the highest concentrations of mercury in fish have been found in Water Conservation Area 3A. Human consumption advisories have been issued by the State banning consumption of several fish species in Water Conservation Areas 2A, 3A and the Park, and limiting consumption in Loxahatchee National Wildlife Refuge (Water Conservation Area 1). Possible sources of mercury include atmospheric deposition, effects of drainage, soil disturbance, hydroperiod alteration and historic storage of mercury in the Everglades. An extensive interagency state-Federal mercury research program is underway to identify and quantify mercury sources and transport systems to the Everglades. The Environmental Protection Agency (EPA), DEP and the United States Geological Society (USGS) are developing models to evaluate the effect of various mercury source control and water management strategies on the Everglades mercury problem. The South Florida Water Management District and the Florida Game and Fresh Water Fish Commission (FGFWFC) are also working as part of the multi-agency effort to better understand this ecological problem and develop appropriate responses.

Florida Department of Environmental Protection and the South Florida Water Management District are also involved with numerous water quality improvement efforts throughout south Florida aimed at establishing appropriate criteria for discharges and streamlining the permitting process. These efforts are consistent with the Commission's objectives for sustainability in that they support integration of human activities with the needs of south Florida's natural resources and allow for an ecosystem management perspective.

About 700 million gallons of wastewater are treated and discharged in south Florida daily, much of it to tide. Some urban areas in south Florida have experienced problems with sewage overflow and lack of capacity. The tripling of population anticipated in south Florida in the next few decades may result in three times as much wastewater. There must be adequate capacity to treat this wastewater to a quality that does not adversely impact groundwater or receiving surface waters such as canals, estuarine areas or near-coastal waters. In addition, if properly treated, reuse of this wastewater for appropriate purposes would help meet regional water supply needs.

In addition to areas that generate large quantities of wastewater, there are also numerous communities in south Florida that utilize on-site sewage disposal systems, such as septic tanks and cesspits, for wastewater treatment. Throughout the region, concentrations of such systems pose significant water quality problems. Replacement of these systems with centralized wastewater disposal systems or other technologies which significantly reduce nutrient impacts may be expensive, but necessary, and is often beyond the means of many of the region's small communities, particularly around Lake Okeechobee and the Florida Keys.

The Seminole Tribe's Water Conservation System Conceptual Project provides for sustainable development of their Big Cypress Reservation and balances the needs of the environment with the Tribe's needs for economic sustainability on its homeland. It provides for a network of surface water management structures and the implementation of a comprehensive system of best management practices. This effort helps the Tribe meet the numerical standard for phosphorus concentration in waters discharged from the Reservation, thereby supporting sustainable agriculture while contributing to restoration of the western Everglades ecosystem. The Seminole Tribe is also contributing to the improvement of water quality in the Western Basins through the Landowners Agreements and an Agreement with the South Florida Water Management District. The Everglades Forever Act only covers flows from the C-139 Basin and the C-139 Annex. These waters currently flow through the L-28 into Water Conservation Area 3A. Water from these basins will be diverted and treated through STA 5 and STA 6 of the Everglades Construction Project. In order to address high phosphorus inflows to the Reservation, the Seminole Tribe has entered into these agreements and will be embarking on an enhanced water quality monitoring program.

Of the 23 planning objectives developed by the Commission for the Restudy, 12 are either directly or indirectly dependent on attainment of adequate water quality conditions (see Table 6-1). Many of the concepts considered for inclusion into the Restudy require further water quality evaluation and could have either a positive or a negative influence on the Everglades. As the Restudy progresses, the water quality aspects of individual alternatives must be assessed. In particular, certain concepts give rise to opportunities to address water quality issues including: the Everglades Agricultural Area water storage concept, Water Preserve Areas, and the regional storage within the Everglades headwaters concept. The Commission also proposes specific water quality improvement projects to be considered under this concept including water treatment facilities for the Kissimmee River, Caloosahatchee River, S-9, C-111, and L-28 Interceptor Canal.

6.4.8. Concept 8: Increased Spatial Extent and Quality of Wetlands Beyond the Everglades

Roughly 50 percent of the Everglades have been destroyed by land conversion to agricultural, urban, and industrial development. They continue to be lost through wetland permitting programs. Wetland loss has reduced landscape heterogeneity, eliminated habitat of wetland dependent species, and threatened the long-term viability of vertebrate species that require extensive territory (e.g., wading birds and panthers). The protection and restoration of wetlands outside the publicly owned lands, not just the Everglades, could substantially increase success in reestablishing many native communities. This concept focuses on the protection and restoration of existing wetlands including smaller, isolated wetlands not contained in the remnant Everglades. It includes ongoing restoration efforts, such as the wetland conservation strategies and multi-species recovery planning, as well as additional efforts that address the Commission's objective for increasing the spatial extent and quality of wetlands. A regulatory permitting strategy coupled with a land acquisition program for the remaining wetlands is needed immediately to ensure their values are protected and restoration opportunities are not precluded.

The State of Florida's Conservation and Recreation Lands and Save Our Rivers Programs use bond proceeds, supported by the general revenue portion of the State's Documentary Stamp Tax, to acquire lands for the purposes of water management, water supply, and the conservation and protection of the State's water resources. Manageability, surface and groundwater systems, and the formation of corridors for the critical interaction of wildlife populations are major considerations in this land acquisition process. Prime requisites in managing these public lands continue to ensure water resources, fish and wildlife populations, and native plant communities are maintained in an environmentally acceptable manner, and that they are made available for appropriate outdoor recreational activities consistent with their environmental sensitivity.

The Kissimmee River, once a meandering river with associated marshlands that provided water storage for the Everglades system and habitat for birds, fish, and wildlife, was channelized into a 56-mile ditch (the C-38 Canal) as part of the C&SF Project. Channelization drained approximately 20,000 acres of wetlands. The Corps and the South Florida Water Management District are currently restoring portions of the Kissimmee River's floodplain.

Two areas of the Kissimmee River not presently under consideration for restoration, but supported by the Commission, are Pool A and Paradise Run. Pool A is situated south of Lake Kissimmee. The existing C-38 flood control channel there will remain in place to ensure flood protection in the Upper Chain of Lakes. Flow-through marshes, encompassing approximately 3,000 acres, could be created to improve the quality of water delivered southward and to restore additional high quality floodplain wetland habitat. Paradise Run, 8.5 miles in length, lies immediately north of Lake Okeechobee and west of the old Kissimmee River channel. It now consists of 1,200 acres of wetlands. The restoration of Paradise Run would result in more natural hydrologic conditions and improved habitat for fish and wildlife resources, and would add an additional 2,200 acres of high quality floodplain wetlands.

The Herbert Hoover Dike was built around portions of Lake Okeechobee in the 1930s, largely as a consequence of the 1926 and 1928 hurricanes. The C&SF Project completed the impoundment of the lake in the 1950s and 1960s. This impoundment separated large natural areas located adjacent to the northern, western, and, to a more limited extent, the southern portion of the lake from their connection to the lake. These areas, once upper elevation marshlands, are drier than they were historically and no longer function as they once did. Wetland enhancement to areas that once formed the littoral system would contribute to the quality of fish and wildlife habitat. Any activities related to this restoration need to consider impacts to the Seminole Tribe's Brighton Reservation on the northwest side of Lake Okeechobee.

Kreamer, Torry, and Ritta Islands, located in the southern end of Lake Okeechobee, were formerly used for agricultural purposes. The restoration of these islands would involve degrading selected levees to allow more natural water levels and transplanting native vegetation. These actions would not affect existing private properties. They could result in additional habitat for water birds, fish, and other wildlife. Contaminant studies need to be completed prior to restoration design.

The Big Cypress Basin provides freshwater to the coastal marsh and mangrove communities of the southwestern Everglades. Construction activities associated with the defunct Golden Gate Estates development has altered the basin's natural drainage patterns through over-drainage and has affected biologic habitat and natural hydropatterns. Restoration of the southern portion of the Golden Gate Estates (between I-75 and Tamiami Trail) would restore sheetflow over an area of 113 square miles. This, in turn, would improve habitat quality and heterogeneity, notably for the endangered Florida panther, reduce the incidence of destructive wildfires, and improve the quality and timing of freshwater discharges to Faka Union Bay, Pumpkin Bay, Rookery Bay, Ten Thousand Islands, and Naples Bay.

The areas along the Lower East Coast are generally included in the Water Preserve Areas concept and should be carefully examined to ensure remaining areas are preserved or restored, where feasible. The Model Lands Basin that is located in southern Miami-Dade County is one such area. It is predominately east of U.S. 1 and encompasses approximately 79,000 acres. U.S. 1 and Card Sound Road have impeded the flow of water to the basin, impacting wetland habitat and necessitating discharges to downstream bays. Restoring hydrologic connections and functions to the Model Lands, including improving the hydrologic connections under U.S. 1, would not only improve the functional quality of these wetlands, but would also help restore Barnes

Sound, Card Sound, and Biscayne Bay. Additionally, it would complete a contiguous wildlife corridor stretching from the basin southward to the Florida Keys National Marine Sanctuary. Similarly, the Pennsucco wetlands, west of the Dade-Broward levee in northwestern Miami-Dade County, are peripheral wetlands used by foraging wading birds, including endangered species. Management of the Pennsucco wetlands, the final footprint of which is being considered by the Northwest Dade County Freshwater Lake Implementation Committee, should include maintaining and enhancing the habitat and foraging benefits of this area for wildlife.

The South Florida Ecosystem Restoration Working Group, the Chair of the Governor's Commission, and the Miami-Dade County Commissioners have supported the need to protect open spaces and wetlands that serve vital hydrologic functions for Biscayne Bay. This refers to lands between Biscayne National Park and Miami-Dade County's present Urban Development Boundary. These lands are all that remain of once vast coastal uplands, prairies, and wetlands in the Biscayne Bay Basin that filtered, conditioned, and dispersed freshwater flowing east into Biscayne Bay. These lands have been drastically reduced in area and in hydrologic integrity. The protection and hydrologic improvement of these areas is needed to sustain agriculture and the marine systems of Biscayne National Park.

6.4.9. Concept 9: Invasive Plant Control

Non-native ("exotic") plant species, such as melaleuca, Australian pine, Brazilian pepper, torpedo grass, and hydrilla have invaded large portions of the south Florida ecosystem. This occupation resulted in the displacement of native species and/or the degradation of habitat essential to native plants and animals. Melaleuca is especially damaging because of its high rate of evapotranspiration compared to native grasses that may contribute to lowering water levels in the Everglades and Lake Okeechobee. Aerial and other types of surveys reveal the proliferation of exotic plants has resulted in the formation of melaleuca monocultures in some areas of the Water Conservation Areas. Surveys also show their occurrence throughout most areas east of the Water Conservation Areas, particularly those that may be included as Water Preserve Areas. Even when these plants do not occur in natural areas, they act as seed sources and pose a threat to natural areas. Control or eradication of invasive exotic plants is necessary to improve and protect habitat quality and heterogeneity.

This concept includes the development and evaluation of methods to control invasive (exotic) plants throughout south Florida, the application of these methods to control exotics within the C&SF Project area, and the establishment of success criteria combined with appropriate biological monitoring. Successful control of exotic pest plants depends on the formation of cooperative intergovernmental and public/private partnerships.

Existing methods to remove invasive exotics are being used throughout south Florida. These methods include mechanical harvesting, application of herbicides, and use of biological agents. Because extensive use of herbicides is contrary to water quality improvement, alternative methods, such as biological controls, need further investigation or testing on a trial basis.

While past and present invasive exotic eradication activities have been limited, it appears that future activities may be further reduced because of Federal budgeting priorities. The Commission believes that a comprehensive invasive exotic plant control program that includes monitoring activities designed to map the distribution and abundance of exotics throughout south Florida must be developed and implemented to control and eventually remove invasive exotics from natural habitats. Additionally, melaleuca should be added to the Corps' list of invasive aquatic plants so that funds can be allocated for its control. The use of volunteers, analogous to the University of Florida's Institute for Food and Agricultural Science's Lake Watch program, should also be considered as part of a sustained eradication strategy.

The Science Subgroup of the South Florida Ecosystem Restoration Working Group, in their November 15, 1993, report, recommended that short hydroperiod wetlands should be reestablished. The Restudy process should investigate the role of short hydroperiod wetlands in south Florida natural system restoration and, if additional short hydroperiod wetlands are determined to be necessary, their location and spatial extent must be determined.

6.4.10. Concept 10: Aquifer Storage and Recovery

This concept addresses the potential use of Aquifer Storage and Recovery technology as a means of storing water in aquifers for future use. Water is injected into an aquifer during periods of surplus for later recovery during dry periods. Storing water in an aquifer, such as the upper Floridan, using Aquifer Storage and Recovery technology may provide greater storage efficiency when compared to the land requirements and high seepage and evapotranspiration rates associated with above ground reservoir storage. Areas that could potentially benefit from Aquifer Storage and Recovery include the Everglades Agricultural Area, the Caloosahatchee Basin, St. Lucie Basin, Lake Okeechobee and the urbanized lower east coast. Aquifer Storage and Recovery technology should be investigated to determine its feasibility at a regional scale, as well as its environmental impacts.

Water quality concerns, particularly regarding untreated surface water, currently limit the ability to use Aquifer Storage and Recovery. Aquifer Storage and Recovery should be tested to evaluate technical uncertainties with high capacity applications (GCSSF, 1996a). In planning a pilot study for large-scale Aquifer Storage and Recovery, several issues need to be addressed. These include environmental and health concerns regarding water quality, current regulatory constraints, costs of the project, and potential benefits of having additional clean water at the chosen site.

Potential locations for Aquifer Storage and Recovery pilot projects include sites on the fringe of Lake Okeechobee, to store excess lake water that would either be lost through discharge to tide or create harmful, prolonged high water conditions in the lake's 100,000 acre marsh. Since the higher lake regulation schedule was fully implemented in 1979, discharges to the estuaries have exceeded 400,000-acre feet in 10 of the following 17 years. During six of those years, discharges exceeded 1,000,000-acre feet; during two years discharges exceeded 2,000,000-acre feet; and during one year discharges exceeded 3,000,000-acre feet. Damaging prolonged high water levels also covered the lake's marsh for a number of those years. When the rain comes, we cannot refuse to accept it. When the lake rises to damaging or dangerous levels, our current choices are limited to accepting damage to lake's marsh, or the estuaries, or both. If the goals of protecting the estuaries and the lake's marsh, while improving the quality, heterogeneity, and expanding the spatial extent of Everglades system natural habitats are to be achieved, development of alternative water storage methods for the massive amounts of water entering Lake Okeechobee is vital.

Current water supply demands are projected to increase to meet environmental goals and expanding water supply needs. There is also a need to both protect the lake's marsh and to establish minimum levels for natural waterbodies. Storage of excess water during years of surplus for use during drought years will become increasingly important. Acquiring sufficient lands to hold all of an average year's estuarine discharge is cost prohibitive. Using Aquifer Storage and Recovery in combination with Everglades Agricultural Area storage has the potential to store large amounts of water at its source and close to the demand while protecting the ecological health of the estuaries and the lake. A proposed Aquifer Storage and Recovery project utilizing Lake Okeechobee water is currently under review by the U.S. Environmental Protection Agency and Florida Department of Environmental Protection. The Commission supports this pilot project.

The possibility of conducting pilot projects at other sites, using other aquifers, should also be considered. Sites within the Lower East Coast which could store, in the upper Floridan aquifer, water taken from the Water Preserve Areas should also be considered. If large-scale Aquifer Storage and Recovery is shown to be feasible, more extensive regional scale facilities utilizing untreated surface water runoff and Lake Okeechobee discharges could be beneficial in meeting additional demands within the region. Detention facilities or canals that intercept and hold excess water for injection into the aquifer may be required at some sites. The quality of untreated stormwater runoff may preclude its injection for Aquifer Storage and Recovery purposes under current regulations

Regional scale Aquifer Storage and Recovery facilities could be beneficial in meeting demands in the Caloosahatchee River and St. Lucie River Basins, or other basins. Water quality concerns would also be present in these areas. Regional scale Aquifer Storage and Recovery in association with the Water Preserve Areas has also been proposed for western Miami-Dade, Broward, and Palm Beach Counties. The source of water would be surface water backpumped into the Water Preserve Areas or canal flow. Utilization of Aquifer Storage and Recovery in these areas may increase the storage capability of the Water Preserve Areas and provide more urban water supply benefits for these areas. The feasibility of Aquifer Storage and Recovery in association with the Water Preserve Areas may be limited due to many of the same water quality concerns that face projects using untreated surface water in other areas. The Commission recognizes that water injected into the aquifer may not meet appropriate water quality standards. Water recovered from the Aquifer Storage and Recovery system may not have the appropriate quality for its intended use. A final consideration is that Aquifer Storage and Recovery facilities are most useful at the site of water treatment plants, where clean treated water can be injected, plant operation economies can be realized, and conveyance losses can be eliminated.

6.4.11. Concept 11: Protection and Restoration of Coastal, Estuarine, and Marine Ecosystems

Florida's estuaries and bays have been harmed by human alterations to the ecosystem within the last 50 years. Without drainage canals to divert storm and surface waters, development in low-lying coastal areas would never have been possible. Unfortunately, too much water is diverted too efficiently. Untreated stormwater is rapidly funneled out to sea through the estuaries instead of being stored in wetlands. What remains of the inland marshes seldom receive their full share of water. Estuaries suffer from a glut of freshwater following heavy storms and a lack of freshwater when not enough water is stored in the system to make it through Florida's dry winters and periodic droughts.

These alterations have radically changed the volume, timing, and quality of freshwater flow to south Florida's estuaries. From the Indian River and St. Lucie estuaries to the Biscayne and Florida Bays, the Ten Thousand Islands to the Caloosahatchee tidal river estuary, the quality of estuarine habitat for fish and other marine resources has been affected by freshwater flow changes associated with the C&SF Project and other water control efforts (e.g., the Golden Gate Estates canal system). In general, channelization decreases the time lag between rainfall and runoff. This increases the rate of flow to certain downstream estuaries during the wet season and decreases the flow during the dry season. Estuarine life is negatively impacted both by the wet season excesses and the extended dry season deficiencies. Surface water also permeates the soil and becomes groundwater, whose quantity, quality, and distribution is equally important to coastal systems, such as Biscayne and Florida Bays. An extreme example of this problem is in the upper Ten Thousand Islands, where 200 square miles of the Big Cypress wetlands is channelized into Faka Union

Bay. Freshwater flow has been diverted away from Florida Bay and the mangrove estuaries of the Lower Southwest Coast (e.g., Whitewater Bay), possibly resulting in both wet season and dry season deficits. In the St. Lucie and Caloosahatchee Estuaries, regulatory releases from Lake Okeechobee have exacerbated the problems of excess flows.

Water quality in the Keys and on the reef tract is declining due to macro-scale regional development in south Florida, the diversion of water away from Florida Bay, and detrimental water quality activities locally and regionally. Over the years, the cumulative effect of these changes is catastrophic. Murky water and algal blooms have replaced the clear waters of Florida Bay. Similar degradation is occurring in northern Biscayne Bay. The highly productive seagrass beds and fisheries of the St. Lucie and Caloosahatchee Estuaries, as well as Florida Bay, are now in decline as a result of dramatic fluctuations of freshwater input into estuarine and marine waters. Diseases and eutrophication threaten the coral reef systems of the Florida Keys. The Commission places a high priority on protecting and restoring south Florida's coastal and marine ecosystems, not only for their intrinsic value, but for protecting the fisheries, the fishing and tourist industries, and the characteristic south Florida lifestyles that depend on nature's bounty. Understanding the linkage between the lower watersheds, the Ten Thousand Islands, and Florida Bay is critical to developing solutions that provide for sustainability of the Keys.

The Florida Keys, including Florida Bay and the offshore coral reefs and sea grasses, are a threatened resource of international significance. In response to the Governor's Executive Order directing public agencies to take action to improve environmental conditions in the Keys, a carrying capacity study of the Florida Keys has been initiated by the Corps with funding provided by the Florida Department of Community Affairs. The study will result in an information base upon which informed development and infrastructure investment decisions can be made to achieve a balance between the economic and environmental needs of the area. Research activities in Florida Bay are being coordinated by the Florida Bay Program Management Committee. The Program Management Committee has developed the Florida Bay Research Plan and is utilizing adaptive management in the implementation of that plan. Although numerous research and monitoring activities are currently underway in Florida Bay by a variety of governmental agencies and private organizations, a process to collectively evaluate the information and develop a comprehensive plan of action is not currently planned or programmed. A program is needed to ensure effective coordination of all efforts in Florida Bay, identify all the problems and their sources, and develop a plan of action and implementation process. A comprehensive literature search and data analysis will serve to ensure that all activities influencing the bay are identified and that adequate monitoring activities are implemented. The program should also include analyses that give sufficient consideration to any improvements of current state and Federal water quality standards that may be needed to achieve the Commission's goal of sustainability.

The programmed and proposed projects that form previously described concepts of the Commission's Conceptual Plan for the Restudy involve restoring appropriate freshwater flows to bays and estuaries to protect natural salinity gradients, restore water clarity and quality, and improve water supply through management changes within the south Florida Region. The Florida Bay Emergency Interim Plan (Taylor Slough Demonstration Project), the C-111 Project, Modified Water Deliveries to Everglades National Park Project, the Lake Okeechobee Operational Plan, and the creation of water storage areas in the Water Preserve Areas, Caloosahatchee Basin, and the Upper East Coast area will help protect the region's coastal estuaries from the detrimental effects of excessive stormwater runoff and will improve essential baseflow of freshwater during dry seasons. Projects identified as part of the regional Surface Water Improvement and Management plans will serve to improve the quality of water delivered to the coastal areas through development and implementation of best management practices for agricultural and development activities, retrofitting of existing stormwater management facilities to reduce pollutant loads, and elimination of sewage effluent discharges and septic tank impacts. The various regional Surface Water Improvement and Management plans need to be integrated and coordinated with other adjacent local restoration efforts such as those for the Miami River and the New River.

Other major projects underway to achieve the Commission's goals for sustainability include the development of hydrodynamic circulation models for Biscayne Bay and Florida Bay. A hydrodynamic model of Florida Bay is under development for use in simulating water movement patterns in the Bay. Among other things, the model will enable salinity predictions from varying temporal and spatial freshwater inflows. The Florida Bay model will accept output from the hydrologic models used to predict overland flows to determine the impacts that the modifications and operational changes to the C&SF Project will have on Florida Bay. (Often, the hydrologic models can predict the volume and location of flows across the mangrove zone.) The model will be multi-dimensional, allowing two dimensional vertically averaged calculations at a minimum, and perhaps some three dimensional calculations where stratification is evident. The hydrodynamic model will be linked with a water quality model. Development of a mathematical computer simulation model system for Biscayne Bay is currently underway as a first step to investigate the effects of the C&SF Project on water circulation and salinity patterns. This effort must be further developed to assess impacts to biological communities and water quality in the Bay. The South Florida Water Management District developed a one-dimensional hydrodynamic model that predicts salinity throughout the St. Lucie Estuary under various inflow conditions from the watershed. This model was used to identify a salinity range that is favorable to the development and maintenance of a healthy estuarine ecosystem. This effort must be further developed and expanded to assess the C&SF Project freshwater discharge impacts on the Indian River Lagoon. These model efforts are essential to the identification of existing conditions and the evaluation of the effects of any proposed modifications to the C&SF Project on these important coastal resources.

6.4.11.1. Sediment Removal and Control in Estuaries

Accumulated organic sediments have been deposited in the Caloosahatchee and St. Lucie Estuaries. Organic sediments settle out in the estuaries as a result of sediment runoff and the interaction between fresh and estuarine water. These organic sediments deplete the dissolved oxygen and degrade water quality through resuspension during periods of physical disturbance. Removal of these sediments could improve water quality and possibly expose coarse-grained substrate suitable for aquatic plant growth along the littoral shelf of the estuaries. Small scale pilot projects should be implemented to determine the feasibility and environmental effects of muck removal or stabilization from the St. Lucie Estuary.

A report on a potential muck removal demonstration project for the St. Lucie Estuary was previously completed. The report recommended that further studies be conducted prior to proceeding with a demonstration project. The report concluded that large scale sediment removal may improve water quality by reducing re-suspension of fine sediments and would reduce oxygen demands in the water column, assuming upstream sediment sources were eliminated.

The St. Lucie Canal was constructed in the 1920s by the Everglades Drainage District. The canal banks are unstable in a number of areas along the length of the canal and material from the banks that sloughs off is transported and deposited as shoals in the St. Lucie Estuary. Stabilizing the canal banks with rip-rap, or reshaping and restoring vegetation on the canal banks could reduce the sediment loading to the estuary. The Restudy should include an analysis of the bank erosion and its impacts to the estuary. It may be possible to acquire additional rights-of-way and reshape the canal banks to create a functional littoral zone. Such projects could reduce erosion and produce other benefits such as water quality and habitat improvements. Additional study will be necessary to evaluate and quantify the benefits to the estuary from environmentally sensitive bank stabilization measures.

6.4.12. Concept 12: Conservation of Soil

Conservation of soils in the agricultural areas bordering the Everglades increases the opportunity for long-term sustainability of agriculture and natural areas. In particular, organic soil subsidence, caused by man's drainage facilities including the C&SF Project, is adversely impacting natural areas and agriculture in south Florida. Subsidence is created by a number of factors, including the oxidation of organic soils resulting from lowered water tables for extended periods of time, fires, wind erosion, and peat shrinkage.

In the Everglades Agricultural Area, soil loss has diminished the higher ground elevations that maintain the hydraulic head which drives water south. In some areas more than eight feet of organic soil was lost by 1984. Soils continue to oxidize; however, Best Management Practices should slow down the rate of oxidation. Some areas in the southern Everglades Agricultural Area, where shallow soils overlie bedrock, already have less than two feet of soil remaining. As soils subside, the movement of stormwater out of the area requires increased pumping. Soil conservation is also important in southern Miami-Dade County, where agriculture still forms a vital part of the local economy as well as a buffer between urban development and the natural system. In this area, soil conservation and sustainable agriculture programs will enhance the long-term viability of the ecosystem.

Research has shown that if soil moisture content of the organic soils is maintained for longer periods of time throughout the year, soil subsidence can be significantly reduced. Limited research is now underway to develop sugar cane varieties that can tolerate higher water levels, yet maintain an acceptable yield. These types of crops, some conversion to traditional wet-pasture beef cattle production, aquaculture, rice production, best management practices, and improved water management may significantly increase the long-term sustainability of agricultural activities in the Everglades Agricultural Area.

Increasing groundwater levels in the Everglades Agricultural Area will reduce the overdrainage that has caused the oxidation of organic soils. Under this concept, rainfall during the wet season will reduce the need for water from Lake Okeechobee to be used in maintaining these higher water tables. This should result in benefits to the natural system, including increased water storage in the Everglades Agricultural Area, decreased vulnerability to floods, and decreased necessity to send large pulses through the east coast and west coast estuaries. Further, water quality should be improved by reducing phosphorus inputs from oxidation and erosion of the soil through application of best management practices and maintenance of higher water tables.

Soil subsidence has also impacted portions of the natural system. Restriction and diversion of natural sheet flow has overdrained portions of the Water Conservation Areas, the Holey Land and Rotenberger Wildlife Management Areas resulting in areas of major subsidence. Overdrainage has also caused additional soil loss as a result of severe muck fires. In addition, tree islands have been destroyed through such soil loss. As soil elevations are altered, water levels change and the associated biological community is altered. Restoration of more natural flows and hydropatterns in the Everglades, Holey Land and Rotenberger Wildlife Management Areas and other natural areas should control the subsidence and potentially reverse the trend by creating conditions favorable to the accretion of peat soils.

The goal of current public and private research efforts is for modified water management to provide conditions enabling soil accretion rather than soil oxidation. This soil conservation activity, in both natural and agricultural areas, can serve as a measure of both the environmental and economic sustainability of restoration efforts. Opportunities exist to expand on these research efforts through public/private partnerships.

6.4.13. Concept 13: Operation, Management, and Implementation of the C&SF Project Modifications and Related Lands

The south Florida ecosystem is a water-driven system encompassing a massive, unique, and fragile natural system that is also home to five million human inhabitants. The C&SF Project provides a physical and operational framework around the south Florida ecosystem that offers options for managing the natural functions of the Everglades and other natural areas. The C&SF Project also provides other benefits, including flood control and water supply for the human population of south Florida. The interconnection of the C&SF Project, both within and without its boundaries, cannot be ignored for its contributions and complexity. This Project is a multi-purpose public works system that has inherent conflicts among the competing priorities of water management.

The Commission seeks to maximize the benefits of the C&SF Project while reducing the problems it has caused. In addition to the structural changes to the C&SF Project as expressed in the 40 options, and the other 13 thematic concepts, new operational and management measures for the system will be required. How the system is managed hydrologically affects virtually every aspect of the south Florida ecosystem. This suggests that the operational changes throughout the system are critical and thus require specific attention during the Restudy. The Restudy must incorporate the best available research and modeling to ensure the multi-purpose objectives are balanced and maximized. Effective monitoring programs must be developed that allow for the implementation of adaptive management strategies to ensure that the Commission's objectives are met.

Where project operations are expected to affect lands (and their associated communities) being protected and restored as natural wetlands, operational planning needs to be consistent with sound biological science. Adequate provision is needed for monitoring biological impacts, especially where these operational changes may affect recovery efforts for endangered species and the protection of sensitive habitats.

As a first attempt to restore hydrology in Everglades National Park, a rainfall-based plan for water deliveries has been developed and implemented. A rainfall-based plan is a delivery formula that delivers water to natural areas based on antecedent climatic conditions. The Restudy should investigate the potential use of rainfall-based delivery formulas to determine if natural areas, including the Water Conservation Areas, and estuaries, can benefit from such operational changes to water deliveries.

Further, the Restudy and other efforts to provide for the sustainability of the south Florida ecosystem will ultimately determine both the extent of lands needed for the Project and the management of these lands. Rapid development of some areas of south Florida is limiting the ability to fully implement these modifications to the C&SF Project, which are needed for sustainability. As a result, the Commission has recognized the need to expedite certain land acquisitions prior to final planning and design of the modifications to the C&SF Project. Because lands are such a critical component to all restoration efforts in south Florida, recent Federal funding was provided to expedite implementation of potential project features. This has required the Commission and other decision makers to prejudge certain land acquisition projects without having all the scientific and engineering analyses completed. Acquisition of these identified priority lands should be limited to voluntary/willing sellers. Careful consideration must be given to determine the potential uses of the lands and, to the extent possible, the justification for acquisition of these lands should be based on available science.

Once acquired, these lands must be managed to meet the environmental and economic needs of the region. Meeting these needs will require the inclusion of advanced planning and land management strategies as part of the acquisition process. Such planning will ensure that the lands are properly utilized and managed consistent with the intended objectives. For example, one mechanism to help promote economic sustainability of the region would be to return agricultural lands back to agriculture, so long as such use does not conflict with long-term land use/management objectives, until a final project design utilizing these lands is completed. Therefore, these lands could be secured at an overall lower cost with less disruption to the south Florida economy.

SECTION 7
PLAN FORMULATION AND EVALUATION

The purpose of this Section is to explain the process, called plan formulation, used in the Restudy to develop and evaluate alternative plans. This process involved the development of potential solutions to the water resource problems and the evaluations used to select the Comprehensive Plan. The iterative planning process followed during the Restudy is fully presented in this Section. In being so transparent and thorough, this Section presents information about planning iterations that is not typically found in a Corps feasibility report. While the process of following several progressive and comparative iterations is not unusual in water resources planning, it may be unusual to find it so rigorously documented. It would be more likely to find a simple presentation of the final array of alternatives (see ***Section 7.5***), with only a brief overview of the iterations that led to that array. In presenting all of the iterations, the Restudy has fully disclosed the decision making process that led to the recommended plan. Such full disclosure may carry the price of some confusion when it so clearly shows that the basis for making decisions continue to change with each iteration.

7.1 PLAN FORMULATION AND EVALUATION METHODOLOGY

Plan formulation is a repetitive, or iterative, process of identifying alternative plans that achieve a set of planning objectives and allows those plans to be modified as more information becomes available. Each subsequent iteration of this process provides an opportunity to refine and sharpen the planning focus. Key steps in formulating the alternative plans are shown in ***Figure 7-1***.

This plan formulation process evolved over three years, ultimately resulting in selection of a recommended plan. During this time frame, the Restudy team used an iterative process to identify and evaluate the merits of individual components and the effect of combining these components into “comprehensive plans.” This process involved separate sequential steps that allowed plans to be modified, as more information became available, allowing the opportunity to refine and sharpen the planning focus. This process resulted in discreet steps of formulation results that are displayed, as such, in this section. These discreet plan formulation steps are displayed in ***Table 7-1***.

FIGURE 7-1

Other Project Elements (Separable Elements)	Added to Initial Draft Plan to form Recommended Plan

7.2 IDENTIFICATION AND SCREENING OF PLAN COMPONENTS

Plan formulation began by developing a list of the many different ideas to achieve the planning goals and objectives. These different ideas are called “components”. Components are the individual building blocks that can be combined in various ways to form alternative plans. They include both structural measures, such as reservoirs, pump stations, and canals, and nonstructural measures, such as reservoir operating schedules.

7.2.1 Identification of Plan Components

The Restudy was not the first effort to develop a list of components for water management in south Florida. Rather, it was able to take advantage of a vast array of previous studies and plans with similar planning goals and objectives. The Restudy's first list of components was developed in January 1996 and included components identified in the Reconnaissance Study (U.S. Army Corps of Engineers, 1994), the South Florida Water Management District's Draft Lower East Coast Regional Water Supply Plan (SFWMD, 1994a), and other sources. These sources were reviewed and discussed by the Restudy Team, and a first group of components were subsequently listed, described and linked to the planning goals and objectives.

This first list of components was considered and refined by the Governor's Commission for a Sustainable South Florida in its development of the *Conceptual Plan for the Restudy* (GCSSF, 1996b). The Conceptual Plan contained 40 components ("preferred options"), assembled into 13 thematic concepts, and served as the Restudy's initial framework for organizing components and developing a Comprehensive Plan (see ***Section 6*** of this report).

The Restudy Team met again in November 1996 to design a formulation and evaluation strategy for developing comprehensive plans. This meeting resulted in the development of the document entitled *Restudy Plan Formulation* (see ***Appendix A*** of this report) which outlined the Restudy goals and objectives, and listed and briefly described the components to be considered in developing alternative comprehensive plans.

The *Restudy Plan Formulation* document was subsequently used at 20 stakeholder focus group meetings throughout south Florida between January 1997 and May 1997 (see ***Section 11*** of this report). These meetings helped to ensure that most stakeholders were satisfied with the range of components to be considered and the strategy for formulating and evaluating alternative plans.

7.2.2 Screening of Plan Components

By the end of 1996, these efforts had produced an extensive inventory of potential components. Even after an initial screening of these ideas, the list of components numbered 112 (see ***Appendix A, Section 1*** of this report). The approach adopted by the Restudy Team to use these components in formulating a Comprehensive Plan was to begin with the formulation of a single plan. This plan, which the Restudy Team called the "Starting Point", would combine many of the listed components and could progressively be refined and shaped into the best possible Comprehensive Plan. In order to determine which components to include in the Starting Point plan, as well as in subsequent refinements, the list of components were evaluated to:

(1) optimize the general size, location, and configuration of certain components based on hydrologic criteria;

(2) rank order similar components in terms of their dollar costs and the magnitude of their non-dollar outputs; and

(3) reduce the number of components to a more manageable number for consideration in subsequent steps.

This evaluation process was called screening, and involved developing information bases from the Lower East Coast Regional Water Supply planning process and the Water Preserve Areas Land Suitability Analysis; hydrologic modeling primarily using the Everglades Screening Model; and a cost effectiveness analysis. The conclusions of the screening analysis are in ***Appendix A, Section 1*** of this report.

7.2.2.1 Screening Using the Lower East Coast Regional Water Supply Planning Process

The South Florida Water Management District's Lower East Coast Regional Water Supply planning process modeled and evaluated a series of five alternatives. Of the 112 Restudy components, 35 were previously modeled and evaluated in the Lower East Coast Regional Water Supply planning process.

Preliminary results from these alternatives provided information about the relative storage capabilities of components. In addition, it also provided insight into the system-wide affects and interactions among components. For example, the plan revealed the combined effects of modifications of the Lake Okeechobee operation schedule and storage facilities outside the Lake. This information was useful in establishing the best range of storage volumes. In addition, the benefits of rainfall driven delivery schedules for the Everglades were also evaluated.

7.2.2.2 Screening Using the Water Preserve Areas Land Suitability Analysis

The Water Preserve Areas concept was initially proposed by the National Audubon Society (1994) as a way to capture and store excess surface waters that are normally discharged into the coastal waters through the C&SF Project canals. This area would also serve as a buffer between the Everglades and the urban areas to the east. This concept has evolved from a number of studies including the South Florida Water Management District's East Coast Buffer Feasibility Study (CH2M-Hill, 1994) as part of the Lower East Coast Regional Water Supply planning process.

In 1995, a feasibility study for the Water Preserve Areas was initiated by the Corps and the South Florida Water Management District to accelerate the formulation and evaluation of Water Preserve Areas components. This study's land suitability analysis provided information about land cover, hydroperiod regime, and soils that was useful in determining the best places to: (1) store water, (2) recharge the aquifer, and (3) restore degraded wetlands.

This information provided considerable insight to determine the best locations for the Water Preserve Areas components. For example, the land suitability analysis identified sensitive wetlands that should be restored and less sensitive wetlands that could be used for water management purposes.

7.2.2.3 Screening Using the Hydrologic Screening Models

The Everglades Screening Model was the primary hydrologic computer model used for screening. This model simulates how water moves through south Florida and how operational and structural modifications to the C&SF Project may affect water movement. A complete discussion of the hydrologic modeling is in ***Appendix B***.

The Everglades Screening model was used to quickly evaluate and narrow the range of water storage concepts in the Everglades Agricultural Area, the Kissimmee River Basin, the Caloosahatchee Basin, and the St. Lucie Basin. It was also used to identify the range of storage options for: alternative Lake Okeechobee operation schedules; Lake Okeechobee aquifer storage and recovery systems; and Water Preserve Areas reservoirs and wetlands. It also provided information about how much water could be retained in the Water Conservation Areas using seepage barrier components.

7.2.2.4 Screening Using Cost Effectiveness Analysis

Cost effectiveness analysis was used to help identify the least expensive options to achieve a desired effect. Cost effectiveness analysis is typically done near the end of a study to compare complete alternative plans. However, the analysis can also be used earlier to compare similar components to assist in the formulation of cost effective alternative plans. A summary of how the analysis was used in the Restudy Plan Formulation is included in ***Appendix A, Section 2*** of this report.

Of the 112 Restudy components, 47 were analyzed using the cost effectiveness analysis. These components were grouped into seven different functional categories of output including, for example: reducing phosphorus loading to Lake Okeechobee, increasing water storage capacity in the Lower East Coast, and increasing acres of wetlands throughout the study area.

The cost effectiveness analysis provided information about the least costly way to achieve each level of output. For example, the analysis revealed that storage reservoirs in the Caloosahatchee Basin were more cost effective than Aquifer Storage and Recovery around Lake Okeechobee. Therefore, the reservoirs would be a better initial financial investment. This type of information was useful in selecting the best size of a component as well as a priority for selecting components based on the cost for the level of output achieved. However, the analysis was limited in scope such that only a single output was measured for each component. For example, a storage reservoir in the St. Lucie Basin not only increases water supply but it also reduces damaging flows to the St. Lucie Estuary. In this case, the one-dimensional approach used for the analysis resulted in under-estimating the effectiveness of the component. However, in other cases there were negative effects that were not measured. For example, backpumping to Lake Okeechobee results in increased water supplies but it could impact the Lake's littoral zone and this impact was not measured during this analysis.

Further, without a target, the screening conclusion was limited to identification of the most efficient component. That is, the component with the lowest cost per unit of output desired. If an output target was available, and the most efficient component failed to meet its target, the analysis was used to identify the next most efficient component or group of components.

7.2.2.5 Screening Using Other Analyses and Best Professional Judgement

In addition to the other screening techniques, the Restudy Team used information from a variety of sources including previous C&SF Project studies, and South Florida Water Management District Surface Water Improvement and Management (SWIM) Plans. The Restudy Team also took advantage of the extensive knowledge and experience of the team members and others that have lived and worked in south Florida and had a day-to-day familiarity with the water resources issues being addressed in this feasibility study.

7.2.3 Screening Conclusions

A summary of the major findings from the screening analysis is shown in ***Table 7-2***. For more detailed screening conclusions about each of the 112 components, see ***Table 5*** in ***Appendix A, Section1***.

TABLE 7-2
SCREENING CONCLUSIONS SUMMARY

KISSIMMEE RIVER REGION
• Storage reservoirs effective for Lake level management
• Water quality treatment very cost effective for improving Lake Okeechobee
• Paradise Run most cost effective way to increase spatial extent of wetlands in this basin
UPPER EAST COAST REGION
• Storage reservoirs for C-44 Basin effective to improve estuary conditions
• Increased backpumping of treated water to Lake Okeechobee cost effective; however, adverse impacts to Lake's littoral zone were not evaluated
• Adding Aquifer Storage & Recovery to storage reservoirs should be considered
• Opportunities to increase spatial extent of wetlands in this basin
• C-23, C-24, and C-25 Basins being considered in detail as part of Indian River Lagoon Study
CALOOSAHATCHEE RIVER REGION
• Storage reservoirs effective.
• Lake Hicpochee should be considered as first increment for storage
• Increased backpumping of treated water to Lake Okeechobee cost effective; however, adverse impacts to Lake's littoral zone were not evaluated
• Adding Aquifer Storage & Recovery to storage reservoirs should be considered
LAKE OKEECHOBEE REGION
• Increases to Lake levels cost effective; however, adverse impacts to Lake's littoral zone were not evaluated
• Regional Aquifer Storage & Recovery not cost effective in this area for Lake level management (however, later screening analyses showed that this component was effective at reducing flows to the St. Lucie and Caloosahatchee Estuaries)
EVERGLADES AGRICULTURAL AREA REGION
• Storage reservoirs effective
• Increased backpumping of treated water to Lake Okeechobee cost effective; however, potential adverse impacts to Lake's littoral zone were not evaluated
WATER CONSERVATION AREAS REGION
• Detailed modeling required to evaluate components to reconnect habitats
• Rainfall driven delivery schedules are needed to achieve hydropattern restoration
BIG CYPRESS REGION
• Restoration of southern Golden Gate Estates very cost effective to increase spatial extent of wetlands
LOWER EAST COAST REGION
• Southern L-8 project effective in delivering water to North Palm Beach County and Loxahatchee Slough
• Urban Water Supply: (depending on location) wellfield relocation/expansion, utility Aquifer Storage & Recovery, and secondary canal operations are effective
• Regional Aquifer Storage & Recovery is very effective on C-51 and Hillsboro Canals
• Opportunities to increase spatial extent of wetlands in Northern Palm Beach County, Model Lands, and Biscayne Bay coastal areas
WATER PRESERVE AREAS
• Storage reservoirs adjacent to Water Conservation Areas effective in a number of basins
• Aquifer Storage & Recovery should be considered to reduce size of storage reservoirs
• Seepage collection and backpumping generally most cost effective seepage management component
• Water quality treatment needed if drainage water is backpumped to natural areas
• Opportunities to increase spatial extent of wetlands

7.3 FORMULATION AND EVALUATION OF ALTERNATIVE PLANS

The next phase of plan formulation involved assembling components into alternative plans to meet the planning goals and objectives. These plans came from an iterative process that began with the formulation of a Starting Point plan based on the screening conclusions. Subsequent iterations methodically created new plans based on how well they performed relative to the objectives and associated performance measures and targets.

7.3.1 Methodology for Formulation and Evaluation of the Alternative Plans

Alternative plans were formulated and evaluated by two teams, the Alternative Development Team (ADT) and the Alternative Evaluation Team (AET). Each of these teams had a specific planning purpose. The Alternative Development Team was responsible for designing each alternative plan in response to the Alternative Evaluation Team's evaluations of the previous plan iteration. The designs of these alternative plans were built into the South Florida Water Management Model, a regional-scale hydrologic model (see ***Appendix B*** of this report), to identify plan effects. The Alternative Evaluation Team was responsible for evaluating each plan's strengths and weaknesses, and describing plan shortfalls to the Alternative Development Team. This repetitive formulation and evaluation process progressively refined and improved the performance of subsequent alternative plans.

Communication between these teams and among team members was facilitated by several mechanisms. First, a small cadre of interdisciplinary experts participated on both the Alternative Evaluation Team and the Alternative Development Team to assure timely and consistent communication between the teams. Second, the over 100 members of the overall Restudy Team met seven times during this process and had the opportunity to participate in both the formulation and evaluation processes.

Finally, because of the large and geographically dispersed number of people involved and interested in the Restudy, the Internet was used to communicate formulation and evaluation results. This allowed the Restudy Team to solicit comments from a broad base of the public and permitted people to participate as team decisions were being made. The Restudy Internet address is ***http://www.restudy.org***.

7.3.1.1 Alternative Development Team

The Alternative Development Team was a multi-agency team of about 30 planners, engineers and scientists. The team identified and designed specific components to be simulated in the South Florida Water Management Model with the intent to improve the performance of each alternative plan and to test different strategies for component modification identified by the Alternative Evaluation Team.

7.3.1.2 South Florida Water Management Model

The South Florida Water Management Model (see ***Appendix B***) is a regional-scale computer model of the water resources system from Lake Okeechobee to Florida Bay. This is an integrated surface water – groundwater model based on historical climatic data for the 31-year period between 1965 and 1995. This period includes a range of drought and wet periods that are believed to encompass a number of extreme hydrologic events for simulation purposes.

The model simulates the major elements of the hydrologic cycle in south Florida including rainfall, evapotranspiration, infiltration, overland and groundwater flow, canal flow, canal-groundwater seepage, levee seepage and groundwater pumping. As the water management control structures and operational rules are changed, the model simulates the effects on these hydrologic conditions.

The model has been calibrated and verified using water level and discharge measurements at hundreds of locations distributed throughout the region. Technical experts have extensively reviewed and accepted this model as the best available tool for analyzing regional-scale structural and operational changes to the complex water management system in south Florida.

The model was used to estimate hydrologic responses to proposed structural and operational modifications to the water management system in south Florida. The large scale and spatial extent of the model allows it to perform system-wide evaluations. For example, the model can estimate hydrologic conditions, such as the depth of water, in the Water Conservation Areas and Everglades National Park, if changes are made in Lake Okeechobee's operations.

7.3.1.3 Alternative Evaluation Team

The Alternative Evaluation Team was also a multi-agency team of about 50 biological and physical resource specialists, planners, and engineers. The team was responsible for plan evaluation, including:

(1) developing quantitative indicators of plans' performance (called performance measures) and targets for each indicator,

(2) comparing model results against performance targets to identify the most significant strengths and shortfalls of each alternative plan,

(3) providing the "top 10" shortfalls of each plan to the Alternative

Development Team,

(4) performing the evaluation and comparison of the final array of comprehensive alternative plans, and

(5) collating and considering comments from the public and Restudy Team regarding each alternative plan.

The Alternative Evaluation Team used multiple analytical tools to accomplish the alternative plan evaluations: performance measures from the South Florida Water Management Model computer simulations, the Across-Trophic-Level System Simulation (ATLSS) model, and water quality models.

7.3.1.3.1 Performance Measures

The Alternative Evaluation Team developed a set of performance measures as the basis of its evaluations for all areas of concern. Each performance measure was implicitly linked to one or more of the planning objectives, and consisted of a measurable indicator and target. The performance measures were largely indicators of hydrologic characteristics. The performance measures were used to judge how well each alternative met the objectives.

Many of the performance measures used to measure progress toward the ecological objectives were based on hydrologic patterns revealed by the Natural System Model. This model was developed from the South Florida Water Management Model by removing the complex network of canals, structures and levees in the current system and replacing them with the pre-drainage rivers, creeks, and transverse glades. The topography of subsided areas are adjusted in the Natural System Model to estimated pre-drainage levels. The output from the Natural System Model represents the best available approximation of the pre-drainage condition and is the basis for many of the restoration targets. Refer to ***Appendix B*** of this report for a more detailed description of the Natural System Model.

The hydrologic patterns shown by the Natural System Model are generally consistent with what is known or hypothesized about the optimum hydrologic patterns for a number of characteristic plant and animal communities in the historic Everglades. The Alternative Evaluation Team agreed that it was appropriate to use the model as a basis for setting targets if appropriate scales were used. For example, it would be appropriate to use the model to get targets for the duration of inundation, depth and distribution patterns over a broad area; but it would not be appropriate for development of depth targets at scales less than plus/minus 0.5 feet, or to be used for estimates of flow volumes.

Performance measures were also developed to evaluate the degree to which the alternative plans are likely to meet water supply objectives. These considered the frequency, duration and severity of water supply restrictions for both urban and agricultural areas. Flood protection performance measures were also developed. However, due to the coarse spatial resolution of the South Florida Water Management Model, these performance measures were simply used to identify areas of concern.

For each alternative plan, the South Florida Water Management Model produced information about the performance measures in the form of tables, graphs and maps. This information was useful for two reasons. First, the results could be compared against the performance measure targets to evaluate plan success at achieving the objectives. Second, the information was used to compare different conditions including: the Existing Condition (1995 Base), the Future "Without Plan" Condition (2050 Base), and any of the previously simulated alternative plans. For example, a graph may compare Alternative 1 with the Natural System Model (Historic Condition), the Existing Condition, and the Future without Plan Condition.

7.3.1.3.2 Across Trophic Level System Simulation Model

The Across Trophic Level System Simulation (ATLSS) model ***(Appendix D)*** is a set of computer models that integrates several approaches for different levels of the ecologic hierarchy. The model uses hydrologic information from the South Florida Water Management Model simulations of the alternative plans and predicts biological responses of several species and species groups. The basic models of ATLSS model included:

- Cape Sable Seaside Sparrow Breeding Potential Index
- Wading Bird Foraging Condition Index
- White-tailed Deer Breeding Potential Index
- Landscape Fish Model
- Cape Sable Seaside Sparrow Individual Based Model
- Snail Kite Breeding Potential Index

The nature and extent of ATLSS model results depended on the progress of each model's development and therefore varied among species and species groups. For example, detailed results were available for the Cape Sable seaside sparrow's western population and for fish abundance because development of these models was nearly complete at the time the alternative plans were evaluated. Less detailed results were available for foraging and breeding condition indices for the snail kite, wading birds, and others because these models were in earlier stages of development.

ATLSS model results for each alternative were compared with results for other alternatives, the 2050 Base, and in most cases, with 1995 Base. When results indicated that an alternative would improve species' biological responses as compared to the other conditions, the Restudy Team concluded that there was evidence to suggest that the alternative was beneficial for those species as compared to the other conditions.

7.3.1.3.3 Water Quality Models

The effects of alternative plans on water quality were evaluated using three analytical tools. The Lake Okeechobee Water Quality Model (James *et al.*, 1997) simulated lake eutrophication processes. The Everglades Water Quality Model (SFWMD, 1997h) simulated phosphorus transport in the Everglades Protection Area. In addition to these two models, an analysis (Walker, 1998) of the performance of the Everglades Construction Project and proposed reservoirs in reducing phosphorus was utilized.

7.3.1.4 Basis for Formulation and Tradeoffs for the Alternative Plans

In formulation for ecological restoration, the team agreed that it was important to make progress toward all the targets and that achieving a target in one area should not cause damage to another area. Recovery of an Everglades-like system is more likely to occur through recovery of a strong balance of all of the hydrological features that characterized the pre-drainage system. These features include spatial extent, duration of hydroperiods, sheet flow, flow volumes into estuaries and depth patterns.

Fundamentally different strategies for achieving Everglades restoration have been characterized as the "cookie cutter" and "Xerox reduction" approaches. Should the goal be "point-for-point" matches with pre-drainage characteristics in the remaining portions of the Everglades ("cookie cutter"), or should the goal be to recreate all the original community and landscape proportions in an Everglades that is now one-half its pre-drainage size ("Xerox reduction")? While this question prompted a healthy debate, most recent views have been (a) we should do neither, or (b) we should do some combination of the two.

Plan formulation for the Restudy was based on a variety of approaches. Alternative plans were formulated in an attempt to achieve pre-drainage targets, that is, a "cookie cutter" approach was followed. Additionally, a "Xerox reduction" approach was also achieved because the proportion of long-hydroperiod sloughs to short-hydroperiod prairies in the current Everglades is similar to the proportion between these two landscapes in the pre-drainage system.

The Restudy Team began formulation with the expectation that it would be possible to design a plan that would meet all of the performance measure targets. The team assumed that the targets could be met by increasing the amount of stored water, minimizing the amount of excess water to tide and re-distributing it.

As the process proceeded, it became increasingly apparent that, given the physical, operational, legal, and societal constraints in south Florida, it would not be possible to fully achieve every performance measure target. The constraints created situations where alternative plans could not meet all targets in all areas at all times resulting in the need to make tradeoffs among competing objectives. Tradeoff situations included cases where the volume of water was insufficient, or management options for local or sub-regional water supplies were sufficiently limited. Since it was not possible to reach all targets, the Restudy Team established the following guidelines for setting priorities among competing performance measure targets:

(1) The pre-drainage hydrological patterns shown by the Natural System Model are most likely to lead to the recovery of natural systems, and should be a priority for the natural wetlands of south Florida over other targets.

(2) Where not all pre-drainage hydrological parameters can be recovered, or where meeting these targets reduces the ability of a plan to meet pre-drainage targets in a different part of the system, the Conceptual Ecological Models (see ***Section 5*** of this report) set the priority for hydrological targets. Each Conceptual Ecological Model identifies critical ecological pathways which show the critical hydrological parameters related to ecological changes, and which should be given priority.

(3) Restoration should not cause additional, long-term ecological damage. However, the Restudy Team, recognizing that substantial changes in community structure and natural system boundaries have occurred over the past 100 years, is willing to see additional local community shifts (short-term "damage") occur if these would allow the realization of larger scale restoration targets. This view is consistent with the recognition by most Everglades ecologists that a successful Everglades restoration program will be one that recovers those ecological characteristics that defined the original system to a sufficient degree so that a "new" Everglades-type ecosystem is created (Davis and Ogden, 1994).

(4) Priorities for ecological targets may be based on criteria other than those shown by the pre-drainage model where there is a compelling technical basis for doing so. However, such targets may not have priority if, in meeting these targets, it becomes substantially more difficult to reach ecological targets in other regions.

7.3.2 Formulation and Evaluation Iterations

The formulation of alternative plans was generally an iterative process in which each plan was developed as a result of the evaluation of the previous alternative. Through the first three iterations, each alternative plan was developed in an attempt to improve upon the previous plan's performance. The iterative nature of this process allowed the team to learn more about particular components of the plans including how the components perform under a range of conditions. Through the last few alternative plans, a different approach to Everglades ecosystem restoration was explored, namely restoration through removal of the canals and levees within the remaining Everglades to restore connectivity and unrestricted sheetflow.

Each iteration began with an alternative plan. The components of that plan were built into the South Florida Water Management Model to simulate the plan's hydrologic effects. The model results were then posted on the Internet, and the Alternative Evaluation Team and others reviewed the results. These results were used as input into other models as described above to evaluate the plan's performance. Comments were provided to the Alternative Development Team, which in turn modified the alternative plan to improve performance shortfalls, thus creating the next alternative.

The iterative process to formulate and evaluate alternative plans began in September 1997 and was completed in June 1998.

7.3.2.1 Starting Point

The Starting Point was the first alternative plan formulated. It combined many of the features that were considered to solve system-wide problems. It was formulated by a Restudy sub-team with extensive experience in the C&SF Project and related studies such as the Lower East Coast Regional Water Supply Plan process and the Restudy Reconnaissance study.

The screening analysis provided the information needed to assemble the components into the Starting Point plan. Screening identified solutions for specific problems and the Starting Point integrated the individual solutions into a whole system-wide response. The components of the Starting Point are listed in ***Table 7-3***. The general philosophy of the Starting Point, and the first few alternatives, was to start small and build components with the intent to provide a clear justification as to why additional components were added in subsequent iterations.

The evaluation of the Starting Point showed the need for increased water storage throughout the system to meet ecological restoration and water supply objectives. In addition, the Starting Point included extensive seepage control components to keep more water in the natural system. However, the reduced seepage led to increased saltwater intrusion into the Biscayne Aquifer and urban wellfields. Therefore, formulation of Alternative 1 proceeded by increasing the storage capacity of the components proposed in the Starting Point and scaling back the rate of seepage management. It also included additional storage components and additional, more passive, seepage management components. The theme of adding additional storage continued throughout the plan formulation process.

TABLE 7-3
MAJOR COMPONENTS OF THE "STARTING POINT"

EAA Storage Reservoir
Caloosahatchee/C-43 Basin Storage Reservoir
St. Lucie/C-44 Basin Storage Reservoir
North of Lake Okeechobee Storage Reservoir
Everglades Rainfall-Driven Operations
Water Preserve Areas Components:
Site 1 Impoundment
Water Conservation Area-2B Seepage Management
C-11 Impoundment
Western C-9 Recharge Area
Central Lakebelt In-Ground Storage Reservoir
Bird Drive Impoundment
L-31N Seepage Management

7.3.2.2 Alternatives 1-6

Alternative 1 was formulated to overcome the water storage shortfalls identified in the Starting Point plan and to reduce the negative impacts of aggressive seepage management. ***Table 7-4*** lists the major features and design criteria used in Alternative 1 as well as the Starting Point and Alternatives 2-6. The evaluations of Alternative 1 and subsequently Alternative 2 continued to show the need for improved seepage management and greater storage throughout the system. However, it became evident that the remaining options to store additional water in surface reservoirs were more costly and other non-traditional storage options, such as aquifer storage and recovery (ASR, see ***Appendix C***), would have to be considered.

Alternative 3 substantially increased water storage capacity by including a series of aquifer storage and recovery components. However, the plan needed improvement in the timing and distribution of the water deliveries. Further, none of the plans had attempted to reestablish unrestricted sheetflow (connectivity) through the remaining Everglades.

Alternative 4 included partially decompartmentalizing the remaining natural system by removing physical barriers to flows. The alternative evolved from analyses of a series of South Florida Water Management Model computer simulations, called scenarios, that combined components of Alternative 3 with different amounts of levee and canal removal within the remaining Everglades. At a Restudy Team meeting on December 15, 1997 various approaches for modeling levee and canal removal within the natural areas of the Everglades were discussed. Three scenarios were formulated as a result of that discussion. Each scenario progressively removed more of the internal compartments between the Water Conservation Areas. The Alternative Evaluation Team evaluation of these scenarios showed that as levee and canal removal increased from south to north flows to Shark River Slough increased and some benefit was seen in the southern portion of Water Conservation Area 3A where extreme high water was greatly reduced -- because of removal of the L-29. However, removal of the levees and canals also resulted in extreme high water conditions in Water Conservation Area 3B and eastern Water Conservation Area-3A. With complete removal of the levees and canals from within the Water Conservation Areas, high water in Water Conservation Area 3B was the most extreme of any scenario or alternative considered by the Restudy Team. Further, drying conditions in Loxahatchee National Wildlife Refuge (WCA 1), Water Conservation Area 2A, and Northeast Shark River Slough were exacerbated, increasing the burden on Lake Okeechobee and impacting the littoral zone. Lower East Coast Region's dependence on the Lake for water supply increased as well.

Because one of the basic tenets of the Restudy is to do no harm to one part of the natural system in order to restore another, the team recommended taking a more moderate approach to levee and canal removal, understanding that if ways to mitigate the problems could be found, levee and canal removal of the upper part of the system could be reexamined at a later date.

Therefore, for Alternative 4 and each subsequent alternative, the barriers in the northern part of the system were retained. Specifically, the barriers between Loxahatchee National Wildlife Refuge and Water Conservation Area-2A and between Water Conservation Area-2A and Water Conservation Area-3A were kept to prevent excessive dry-downs in the Refuge and Water Conservation Area-2A and to protect Lake Okeechobee's littoral zone. The barrier between Water Conservation Area-2A and Water Conservation Area-2B was retained to prevent the excessive depths in Water Conservation Area-2B seen in the more extensive levee and canal removal scenarios.

The resulting alternative, Alternative 4, removed levees and canals within Water Conservation Area 3 and eliminated barriers between this Water Conservation Area and Everglades National Park. However, this alternative still produced unintended adverse consequences to Lake Okeechobee, water supply, and parts of the Water Conservation Areas.

Alternative 5 attempted to address problems created in Alternative 4. Many areas were substantially improved, but at this point it was clear that it would not be possible to precisely meet all targets. In addition, the timing and distribution of water in the Water Conservation Areas remained problematic.

Another plan, Alternative 6, was formulated to address the continuing problems identified from Alternative 5. This plan added additional high cost features including wastewater reuse. However, this plan was not evaluated in the same manner as the previous plans because the team recognized that the plans were no longer comparable. The formulation of the previous alternatives allowed the team to learn more about the individual plan components with each iteration. This led to component modifications and improvements in the later alternatives that were not included in the earlier alternatives. For example: excess flows in the Caloosahatchee Basin were identified and, as such, were available to store in the Caloosahatchee Basin or to backpump to Lake Okeechobee; and Biscayne Bay water demands were identified, resulting in degradation to the ecology of the Bay. Further, engineering designs of the components were improved upon with each iteration. For example, a stormwater treatment area was reduced in size from earlier plans because the land initially assumed to be available was not. An unintended consequence of these modifications and improvements was that the alternatives could not be fairly compared to each other. Therefore, the team decided to reformulate and redesign the alternative plans to place them on an equal footing for comparison.

7.3.2.3 Alternatives A-D

The next phase of plan formulation focused on developing a comparable array of alternative comprehensive plans. The team recognized that neither the Starting Point nor Alternatives 1 or 2 would achieve the planning objectives at levels that would be acceptable. Alternative 3, which had evolved from these first three plans, was clearly superior to its predecessors. Therefore, the Starting Point and Alternatives 1 and 2 were not considered further.

Next, the remaining alternatives were modified to reflect more current design assumptions that would make them comparable, and improve their performance. These changes fell into the following categories:

(1) Operational changes that would allow better performance of the alternatives (for example, climate forecasting for Lake Okeechobee operations and related reservoirs) or operational changes required due to a change to another component.

(2) Changes to the South Florida Water Management Model input data to account for better information (for example, runoff estimates from basins contributing inflow to the St. Lucie Estuary).

(3) Modifications to correct design deficiencies identified during formulation of Alternatives 1-5 (for example, canal design and location for backpumping water from C-17 to the West Palm Beach Water Catchment Area) or; design modifications to improve performance without an increase in cost (for example, relocating aquifer storage and recovery facilities from Hillsboro Canal to Site 1 Reservoir).

(4) Exclusion of components that were consistently poor performers (for example, North New River Regional Groundwater Aquifer Storage and Recovery).

(5) Inclusion of components that proved to be extremely good performers, but were omitted from earlier alternatives due to insufficient data (for example, Caloosahatchee Backpumping to Lake Okeechobee).

(6) Inclusion or exclusion of components as a result of changes to the base conditions (for example, inclusion of the C-4 Divide Structure that was previously believed to be implemented by the non-Federal sponsor but was subsequently proposed as an element of the Critical Projects Program).

In view of these changes, the team elected to rename the reformulated and redesigned alternative plans to clearly differentiate them from their earlier iterations. The final array of plans included:

- Alternative A, which was a reformulated and redesigned Alternative 3.
- Alternative B, which was a reformulated and redesigned Alternative 4.
- Alternative C, which was a reformulated and redesigned Alternative 5.
- Alternative D, which was Alternative 6.

Alternative A had the greatest number of changes from its original form, followed by Alternative B then C. ***Tables 7-5*** and ***7-6*** list the components in each alternative. Further, ***Figures 7-2, 7-3, 7-4, and 7-5*** display select features of Alternatives A – D, respectively. For a more complete description of the components included in Alternatives A – D, see ***Appendix A, Section 3***.

The reformulation provided an opportunity to make other modifications in the modeling including using the most recent version of the Natural Systems Model (NSM v4.5). Previous alternatives (Starting Point – Alternative 5) had been evaluated and compared to a provisional version of this model. This newer version of the Natural System Model became available in December 1997, so the team agreed to use this newer version for the evaluation of Alternatives A through D.

With the reformulation of the alternative plans, the final set of Alternatives A through D underwent a rigorous evaluation using a variety of analytical tools and processes. These included: River of Grass Evaluation Methodology, Summary Evaluation Criteria, Keystone and Endangered Species analysis, and Water Quality analysis. The results of these analyses were arrayed and compared to identify significant differences among plans.

7.3.2.4 River of Grass Evaluation Methodology, Alternatives A - D

The River of Grass Evaluation Methodology ***(Appendix D)*** was a tool used to determine the habitat quality of the alternative plans based on a subset of the performance measures. The methodology provided a process to select key performance measures, by sub-region, that are critical to achieving the ecologic objectives. Through mathematical equations and best professional judgement, each set of performance measures was normalized to generate a numeric score between 0 and 1.0. The result is a value that represents the habitat quality based on the relationship between hydrologic characteristics and habitat restoration targets. For water supply, a similar method of developing numerical output was followed to allow comparison of the plans relative to the water supply objectives.

The output from this analysis was used to compare the relative differences in habitat quality between alternative plans for each sub-region. It was not used to compare the habitat quality of one sub-region with the habitat quality of another sub-region. For example, it is appropriate to compare results for Shark River Slough to determine how well each alternative plan performed for that region. However, because different equations were used for each sub-region, it is not appropriate to make a comparison between Shark River Slough and Lake Okeechobee. The numeric scores are presented in ***Table 7-7*** and are explained in Appendix D, which includes a detailed interpretation of the effect of the alternative plans on the sub-regions. Alternative Plan D-13R which is included in this table is discussed in ***Section 7.3.3***.

7.3.2.4.1 Summary Evaluation Criteria, Alternatives A-D

The Alternative Evaluation Team made its final comparisons of the alternative plans by using three summary evaluation criteria:

- plan ranking
- plan grade
- plan color

These criteria were designed to convert the numerical scores from the River of Grass Evaluation Methodology into more qualitative descriptions of plan performance. Plan rankings compared relative performance among the plans, based on a tally of the ordinal scores created from the numerical scores. Plan grades were created by combining numerical scores, and converting these groupings of scores into letter grades, equivalent to the grading system in academic schools. Color schemes (green for successful, yellow for uncertain; red for unsuccessful) were used to express the team's best professional opinion of how likely each plan will result in the attainment of the long-term ecological or water supply objectives. A range of numerical scores could be given the same color evaluation, if the sub-team felt that the objectives could be realized within a range of hydrological conditions.

TABLE 7-7
RIVER OF GRASS EVALUATION METHODOLOGY
NUMERICAL SCORES
(0=lowest, 1=highest)

Lake Okeechobee Service Area	N/A	0.6	0.3	0.8	0.7	0.8	0.9	0.9
Lower East Coast Service Area	N/A	0.8	0.7	0.9	0.9	1.0	1.0	1.0

Ranking of the Alternative Plans: For each sub-region, the alternative plans and the Without Plan Condition were ranked from one through five. The best plan for each sub-region was awarded a one (1) and the worst plan a five (5). Ties were dealt with by averaging. For example, if two plans were tied for first place, they each received a score of 1.5, the average of 1 and 2. If three plans tied for first place, they each received a score of 2, the average of 1, 2, and 3. This system ensured that fifteen points for each sub-region were allocated across the alternatives, equalizing the contribution of each sub-region to the final sum of rankings. The results of this evaluation are included in ***Table 7-8***. The plan with the lowest cumulative score received the highest rank. For example, Plan D, the highest ranked plan, scored 44 points compared to the Without Plan condition which received 98 points.

Grading the Alternative Plans: Plan grades were created based on the numerical output from the River of Grass Evaluation Methodology for most sub-regions. All sub-regions except the Northern and Central Everglades, which developed letter grades independently, assigned letter grades (A, B, C, D, or F) based on the numerical scores (refer to ***Table 7-7***). The results of this evaluation are included in ***Table 7-9***. Letter grade A was best, or excellent at meeting the performance measures; and letter grade F was worst, or failed to meet the performance measure targets, just like the letter grading system used in academia. The letter grades indicate how well each alternative plan and the Without Plan Condition performed at meeting the performance measure targets. If two or more of the plans performed similarly for the performance measures for the sub-region, then more than one plan could receive a similar grade for a sub-region. For example, Loxahatchee National Wildlife Refuge earned a letter grade A for alternative plans A-D.

TABLE 7-9
PERFORMANCE OF THE WITHOUT PLAN CONDITION AND ALTERNATIVES

Color Assessment of the Alternative Plans: The alternative plans were also scored using colors (green, yellow, and red) by converting plan grades into a "best professional opinion" prediction of how likely each plan would achieve the long-term ecological or water supply objectives. The results are displayed in ***Table 7-10.*** Each color provides two kinds of information: (a) a prediction of how likely a plan will achieve the recovery and long-term sustainability objectives defined by the performance measure(s); and (b) a recommended priority for further improvement in the design and operation of the currently modeled plan. Green means that the current plan is likely to recover and sustain the ecological or water supply objective described by the performance measures. Yellow means that achievement of the long-term objectives is marginal or uncertain, and that improvement in the plan is a moderate priority. Red means that the recovery and long-term sustainability of the objectives are unlikely, and that the current plan requires improvement if these targets are met.

7.3.2.4.2 Keystone and Endangered Species Evaluation of Alternatives A-D

Evaluation of alternative plans' performance with regard to threatened, endangered and keystone species was accomplished through a combination of several methods. The Across Trophic Levels System Simulation model results provided information on expected biological responses of several species and species groups. Other methods to predict species response to the alternative plans included: (1) the additional Crocodile Habitat Suitability and Wood Stork Nesting Patterns performance measures; (2) information on known hydrological responses of species gleaned from Volume I of the *Multispecies Recovery Plan* for the Threatened and Endangered Species of south Florida, Technical/Agency Draft (U.S. Fish and Wildlife Service, 1998b); and (3) discussions with research biologists widely recognized as experts on particular species. These additional sources of information were considered along with results from the Across Trophic Level System Simulation model to form a "weight of the evidence" or "consensus" conclusion among members of the Restudy Team and species experts. The relative ranking of the plans for the keystone and endangered species are included in ***Table 7-11***.

TABLE 7-11

7.3.2.4.3 Water Quality Evaluation of Alternatives A - D

Model output from the South Florida Water Management Model and the water quality models were evaluated in the context of performance measures developed by the Restudy Water Quality Team. The Water Quality Team's empirical evaluation was conducted on a slightly different sub-regional basis than the Alternative Evaluation Team. The Water Quality Team did not develop an empirical evaluation of alternative plans on water quality conditions in the Big Cypress Basin or the Holey Land and Rotenberger Wildlife Management Areas. For those areas, a qualitative assessment was made based upon the proposed operation of the components contained in the alternatives.

From this evaluation, the Water Quality Team ranked the base conditions and alternative plans on a scale of 1 to 6, with higher scores indicating a more preferred condition from a water quality perspective. It should be noted that this method of ranking is reverse from the previous ranking evaluations, meaning a lower score indicates a more preferred condition. The rankings are included in ***Table 7-12***.

TABLE 7-12
WATER QUALITY RANKINGS
1=worse, 6=best[1]

Sub-Region	1995 Base	Alternatives				
		Without Plan	A	B	C	D
Lake Okeechobee	1.5	4.5	1.5	4.5	4.5	4.5
Everglades Agricultural Area and the Everglades Construction Project	1	2	6	5	3.5	3.5
Water Conservation Areas 2 & 3	1	2.5	5	2.5	5	5
St. Lucie Watershed	1	2	3.5	3.5	5	6
Caloosahatchee Watershed	1.5	1.5	3	4	5	6
Loxahatchee National Wildlife Refuge	1	2	4.5	4.5	4.5	4.5
Everglades National Park	1.5	5	3.5	6	1.5	3.5
Lower East Coast Service Area	6	3.5	1.5	1.5	5	3.5
Cumulative Score	*14.5*	*23*	*28*	*31.5*	*34.0*	*36.5*

[1] Care should be taken when comparing the water quality rankings with other evaluation rankings due to the differences in scale.

7.3.2.4.4 Evaluation Conclusions for Alternatives A - D

Results presented in the previous tables show that Alternative D is generally the best plan at achieving the ecologic, water supply, and water quality objectives. For these same criteria, Alternative C is the second best plan. ***Table 7-11*** shows that for Listed Species, Alternative D ranks slightly higher than the other alternatives, with Alternative C ranking second. All tables show that for most sub-regions, the plans provide substantial benefits (i.e., improvements) over the Without Plan Condition.

The Alternative Evaluation Team selected Alternative D, with the provision that steps be taken to correct specific weaknesses in the alternative. Overall, Alternative D performed best for:

- Lake Okeechobee Service Area
- Caloosahatchee Estuary

- Lake Okeechobee Service Area
- Lower East Coast Service Areas
- Loxahatchee National Wildlife Refuge
- Holey Land and Rotenberger Wildlife Management Areas
- Southern and southeastern Big Cypress Basin
- Southern Everglades Rocky Glades

Alternative D, was inadequate (reds in ***Table 7-10***) at meeting performance targets for:

- Portions of Water Conservation Areas 2 and 3
- Shark River Slough

Alternative D was moderately adequate (yellows in ***Table 7-10***) at meeting performance targets for:

- St. Lucie Estuary
- Florida Bay
- Lake Worth Lagoon
- South Dade Agricultural Region

From a water quality perspective, Alternatives C and D were preferred over Alternatives A and B. The Without Plan Condition was considered not acceptable. Due to a lack of model results (particularly the Everglades Landscape Model results), the alternative plans could not be ranked based upon water quality impacts or benefits in Big Cypress National Preserve and the Holey Land and Rotenberger Wildlife Management Areas.

The Alternative Evaluation Team recommended that ad hoc teams of ecologists, hydrologists and modelers be created to determine both the immediate and long-term strategy for improving the performance of Alternative D in the red and yellow scored areas.

The Alternative Evaluation Team also highlighted three specific strengths of Alternative B, which, if incorporated into Alternative D, would bring the different ecological strengths of these two plans together to form a more robust restoration plan. These included:

- Higher volumes of flow into the Florida Bay Estuary compared to other plans.
- Greater success at reestablishing system connectivity.
- Improved levels of sheet flow, compared to other plans.

These three features were a consequence of the greater extent of system-wide decompartmentalization, by the removal of levees and canals that create barriers between natural areas, which characterized Alternative B. The Alternative Evaluation Team recommended that the same ad hoc team explore the feasibility of merging these features of Alternative B into D.

At a Restudy Team meeting in early June 1998, the full team agreed with the conclusions of the Alternative Evaluation Team and selected Alternative D as the preferred alternative. The full team also accepted the Alternative Evaluation Team's recommendation that Alternative D should be refined to improve performance in five key areas: Water Conservation Areas 2 and 3, Shark River Slough, Florida Bay, and the St. Lucie Estuary.

7.3.3 Initial Draft Plan

In June 1998, a team of engineers and ecologists conducted an intense iterative process to improve the hydrologic performance of Alternative D in the five key areas. During the first seven iterations, the team attempted to achieve the improved performance by making only operational changes. However, such changes proved inadequate to meet the desired performance, and structural changes to the plan were considered. The next six iterations included both operational changes and structural changes to achieve the desired performance. The thirteenth and final iteration included component modifications and improvements to Alternative D that rectified performance inadequacies in portions of the Water Conservation Area, Everglades National Park, Florida Bay, and the St. Lucie Estuary. The plan that resulted was called Alternative D-13R. Alternative D-13R was designated as the Initial Draft Plan by the Restudy Team.

7.3.3.1 Features of Alternative D-13R

The most significant change between Alternative D and D-13R was the removal of additional levees and canals between Water Conservation Area 3A and Everglades National Park and Big Cypress National Preserve. Unlike Alternative B, Alternative D-13R left a barrier between Water Conservation Areas 3A and 3B. This barrier, a levee known as L-67, was modified in Alternative D-13R to include a conveyance canal and a series of passive weirs to promote high flows between these areas, in addition to allowing for managed flows during the dry season. Alternative D-13R also included several new operating rules for triggering when surface water is allowed to enter the Water Conservation Areas and Everglades National Park. Furthermore, additional surface water storage capacity was included for the C-23, C-24, Northfork and Southfork Basins in the Upper East Coast to further reduce damaging local basin runoff to the St. Lucie Estuary. The major features of Alternative D-13R are displayed in ***Figure 7-6***. For a complete description of this plan, refer to ***Appendix A, Section 4***.

7.3.3.2 Evaluation of Alternative D-13R

The modifications to Alternative D resulted in substantial improvements in the Water Conservation Areas and Everglades National Park without compromising Lake Okeechobee water levels or water supply to Lake Okeechobee and Lower East Coast Service Areas. The modifications relieved adverse high and low water conditions in the Water Conservation Areas. Flow volumes to Shark River Slough were increased while maintaining seasonal distribution of flows indicated by Natural System Model. The number of dry-downs in Shark River Slough was reduced to three events over the period of record compared to two events under Natural System Model. Salinity in Florida Bay coastal basins was improved as well. These improvements were achieved through partial decompartmentalization of Water Conservation Area 3 and Everglades National Park, which makes Alternative D-13R more like Alternative B as desired by the Alternative Evaluation Team and the Restudy Team. Additional storage acreage in the Upper East Coast basins reduced high volume local basin runoff to the St. Lucie Estuary. This enabled Alternative D-13R to come closer to meeting the performance measure target described by the number of times high local basin runoff occurred to the estuary.

Table 7-13 is a summary table of letter grades for the Without Plan Condition, and Initial Draft Plans D and D13R. ***Table 7-14*** shows the same by color ranking. ***Table 7-7*** includes the River of Grass Evaluation Methodology results for Alternative D-13R. A separate water quality evaluation was also conducted for Alternative D-13R (***see Appendix D***). From a water quality perspective, the performance of Alternative D-13R was improved when compared to Alternative D.

7.3.3.3 Uncertainty Analysis of D-13R Components

In selecting the components that are in Alternative D-13R, the Restudy Team recognized the high level of technical and implementability (due to high cost) uncertainties associated with some of the components. These uncertainties can be viewed as a question of whether an uncertain component will achieve the desired effect. If the component fails to achieve the desired effect, the feasibility of implementing an alternative component along with or as a replacement to the uncertain component may need to be considered to assure that the Comprehensive Plan meets its stated objectives.

ne – not evaluated

To understand the extent of these uncertainties, the team identified contingency plans to address potential performance deficiencies or cost-effectiveness problems related to these uncertain components. As a first step in identifying the scope of contingency plans, the Restudy Team identified the components with the highest degree of uncertainty and the most likely alternatives that could be implemented as partial or complete substitutes for the uncertain components. The team also identified the sources of the uncertainty as well as the contribution these components make to the overall system. The results of this investigation are included in ***Table 7-15.***

In addition, sensitivity analyses were conducted for the uncertain components using the South Florida Water Management Model. These computer simulations were evaluated to determine the extent of degraded performance. The results are documented in ***Section 7.3.3.4.***

7.3.3.4 Sensitivity Analysis of D-13R Components

Special investigations were undertaken to assess the sensitivity of Alternative D-13R (Appendix B). The analysis included removing components or reducing efficiency of components with the highest uncertainty from Alternative D-13R and then analyzing the simulated performance of D-13R under these conditions. These simulations were undertaken, in addition to other special investigations, at various stages in the alternative development process in order to assist in the design of alternatives or to investigate particular effects that could not be built into the alternatives. Although some of the sensitivity analyses indicate that the overall system performance does not change significantly when certain components are removed, this does not necessarily mean that the feature is not important or needed. No operational modifications or structural components were added to replace the function of the removed components. It was found that one or more of the remaining components was typically utilized more extensively to compensate for the removal of a component.

TABLE 7-15
COMPONENT UNCERTAINTY

Component	Key Performance Attributes of Component	Sources of Uncertainty	Potential Alternatives	Expected Downsides of Potential Alternatives
Lake Okeechobee ASR	A. Attenuates high Lake levels B. Keeps Lake levels up in dry periods C. Greatly reduces regulatory releases to Caloosahatchee and St. Lucie Estuaries D. Stores excess water for future use	1. High construction and O&M costs, especially potential treatment costs for water to be stored 2. Technical uncertainty, especially as regards how much water can ultimately be recovered	a) Increase storage by raising levels in Lake Okeechobee (B, C, D) (1, 2) b) Partition Lake into ecologically and water supply managed areas (A, B, C, D) (1, 2) c) Expand capacity of reservoirs in Alternative D13-R that can store Lake water, by making them larger and/or deeper (A, B, C, D) (2) d) New reservoir(s) (A, B, C, D) (2) Deep disposal wells (A, C) (1, 2)	• Increased evapotranspiration or loss of water to saline aquifers (c, d) • Negative ecological impact on Lake (a, b) • Higher Costs (c, d)
Lower East Coast ASR	A. Improves efficiency of reservoirs B. Reduces flows to tide (Lake Worth Lagoon) C. Stores water for future use	1. Technical uncertainty, especially as regards how much water can ultimately be recovered 2. High construction and O&M costs, especially potential treatment costs for water to be stored	a) Deepen surface storage reservoirs (B, C) (1) b) Construct new or expand reservoirs (include alternative location) (B, C) (1) c) Alternative water sources including reuse and Floridan aquifer water with membrane treatment (1)	• Higher costs (a, b, c) • Additional Land Required for Water Management (b)
Caloosahatchee ASR	A. Reduces excessive flows and helps meet minimum flows to Caloosahatchee Estuary B. Improves efficiency of reservoir C. Stores water for future use	1. Technical uncertainty, especially as regards how much water can ultimately be recovered	a) Deeper surface storage (A, C) (1) b) New expanded reservoirs (include alternative location) (A, C) (1) c) Deep disposal wells (A – excessive)	• Increased Evapo-transpiration or loss of water to saline aquifers (b) • Higher Costs (a, b) • Additional Land Required for Water Management (b)
North Lake Belt	A. Water supply to canal system B. Reduce deliveries from WCA/L C. Maintain canal stages (C-2, C-4, C-6, C-7, C-9) D. Flood protection	1. Ability to fluctuate levels in storage area may be limited by influx of poor quality water from deeper aquifers	a) Configure North Lake Belt Storage Reservoir with more above ground level storage capacity b) ASR if technical and cost uncertainties are successfully solved c) Alternative water supply/R.O./Reuse d) Store water in an alternative surface storage area which may be located locally or in the EAA	• Usable storage may still be reduced (a, c) • Costs per unit of storage capacity may be higher(b,d)

TABLE 7-15
COMPONENT UNCERTAINTY

Component	Key Performance Attributes of Component	Sources of Uncertainty	Potential Alternatives	Expected Downsides of Potential Alternatives
Central Lake Belt	A. Reduces high stages in WCAs and ENP B. Improves dry season flows to ENP	1. Ability to fluctuate levels in storage area may be limited by influx of poor quality water from deeper aquifers	a) Configure Central Lake Belt Storage Reservoir with more above ground level storage capacity b) Intercept water – store in EAA for later use c) Deepen above ground reservoirs in Alternative D13 such as C-9, C-11 and Bird Drive d) Increase delivery of water from west Dade to ENP	• Usable storage may still be reduced (a, c) • Costs per unit of storage capacity may be higher (a, b, c) • Coastal basin water shortages may be increased and flows to Biscayne Bay may be reduced (d)
Reuse – South Dade	A. Provides a base flow to Biscayne National Park B. Helps prevent saltwater intrusion by providing water to maintain canal and groundwater levels	1. Funding due to high costs related to treatment operations and maintenance 2. Treatment effectiveness and reliability	a) ASR if ASR technical and cost uncertainties are successfully solved (B) (1) b) In-ground storage (B) (1) c) Alternative water supply – R.O. Conservation (A, B) (1) d) Floridan Aquifer (A,B) e) Alternative surface water sources (A,B)	• Provides less water for Biscayne Bay when water is being placed into storage (a, b) • Quantity and quality of source water uncertainty(d,e)
Reuse – West Dade	A. Provides groundwater recharge for west wellfields B. Reduces deliveries from WCA/LO to Service Area 3 C. Provides flow to Biscayne National Park and to South Dade Conveyance system which helps recharge Taylor Slough D. Provides groundwater recharge to L-31N area from which water is withdrawn to deliver to ENP	1. Funding due to high costs related to treatment operations and maintenance 2. Treatment effectiveness and reliability	a) ASR if ASR technical and cost uncertainties are successfully solved (A, B, D) b) In-ground storage (A, B, D) (1) c) Alternative water supply – reverse osmosis and conservation (A, B, C, D) (1) d) Floridan Aquifer (C) e) Alternative surface water sources (C)	• Provides less water for uses when water is being placed into storage (a, b) • Quantity and quality of source water uncertainty(d,e)
L-31N Seepage Management	A. Provides ability to seasonally manage groundwater seepage out of ENP B. Protects water levels in ENP C. Protects necessary groundwater flows to coastal Miami-Dade County	1. Ability of pumping technology to seasonally manage groundwater seepage 2. Effectiveness and feasibility of the levee seepage barrier and resulting downstream impacts	a) Curtain wall with improved surface water deliveries to enhance coastal basin groundwater recharge b) Partial curtain wall with enhanced surface deliveries to ENP to mitigate for groundwater outflows. c) Seepage collection system	• Higher costs (a, b) • Reduced effectiveness (c)

(A, B, C, etc>) corresponds to key attributes of a component
(1, 2, 3, etc.) corresponds to the uncertainties related to a particular component
(a, b, c, etc.) corresponds to the potential alternative

Due to the high construction, operation and maintenance, and potential treatment costs for water stored in aquifers, and the technical uncertainty regarding the recovery efficiency of aquifer storage and recovery, two sensitivity modeling scenarios were run and evaluated. Modeling scenarios were run and evaluated for each of the aquifer storage and recovery components included in the Caloosahatchee Basin, the Lake Okeechobee area, and the Lower East Coast area. The two scenarios were evaluated against Alternative D-13R. The first scenario considered reduction in recovery efficiency of aquifer storage and recovery from 70 to 35 percent. The second scenario considered total removal of the aquifer storage and recovery component. These sensitivity analyses showed the following results. The scenarios with decreased aquifer storage and recovery efficiency at the Caloosahatchee and Lower East Coast Basins aquifer storage and recovery facilities required additional water from Lake Okeechobee and Water Conservation Area 1 to offset deficits. Scenarios with reduced efficiency for Lake Okeechobee and Lower East Coast Basins aquifer storage and recovery showed increased discharges to tide and more high flows to Lake Worth Lagoon. The scenario removing Lake Okeechobee aquifer storage and recovery more than tripled Lake Okeechobee Zone A regulatory discharges to the St. Lucie Estuary and doubled discharges to the Caloosahatchee Estuary. In addition, when Lake Okeechobee aquifer storage and recovery was removed southerly discharges from the lake to the Everglades Agricultural Storage Area and Water Conservation Areas increased.

In the North and Central Lake Belt Storage Areas, concern was expressed that the ability to fluctuate water levels within the storage areas may be limited due to the potential for introduction of poor quality water from deeper aquifers. Sensitivity analysis modeling scenarios were carried out to individually remove each of these storage components. The removal of the North Lake Belt Storage Area resulted in a significant increase in water deliveries from Lake Okeechobee and Water Conservation Area 3A to the Lower East Coast Service Area 3, to maintain water levels in the canals. As a result, lake stages were lower and there were increases in water restrictions in Lower East Coast Service Area 2 with the reduced ability to maintain coastal canals, and a redistribution of flows to Biscayne Bay. The removal of the Central Lake Belt Storage Area resulted in a significant increase in eastward diversions of excess water from Water Conservation Area 3A and 3B. This resulted in lowered stages in Water Conservation Area 3A and 3B and reduced flows south to Northeast Shark River Slough. Discharges to Biscayne Bay increased as a result of increased seepage from Water Conservation Area 3.

The wastewater reuse components were evaluated due to their high construction, operation and maintenance costs. Removal of the West Miami-Dade reuse component significantly lowered stages in the Bird Drive Recharge Area and in L-31N, decreased flows to Central Shark River Slough and Everglades National Park, lowered Lake Okeechobee stages during droughts, and increased Lake Okeechobee triggered water restrictions in the Lower East Coast Service Area.

Removal of the South Miami-Dade reuse component reduced discharges to Biscayne Bay and slightly increased locally triggered water restrictions in Lower East Coast Service Area 3. Water deliveries from Lake Okeechobee in particular increased to compensate for the removal of the reuse components.

Four Everglades Agricultural Area reservoir sensitivity scenarios were developed and resulting performance was compared to that of Alternative D13-R. Findings show that the 20,000 acre compartment dedicated to capturing Everglades Agricultural Area runoff and meeting Everglades Agricultural Area irrigation needs has a large region-wide benefit. The two-20,000 acre surge tank storage areas, dedicated to capturing excess Lake Okeechobee water and meeting Everglades water needs, are useful for reducing the dependence on Lake Okeechobee for meeting Everglades water needs. The analysis revealed that the adverse system-wide effects from removing the surge tanks were minimized by increased usage of the Lake Okeechobee aquifer storage and recovery component.

Component uncertainty for the L-31N Seepage Management results from concern regarding the effectiveness and feasibility of the levee seepage barrier and resulting downstream impacts and the ability of pumping technology to seasonally manage groundwater seepage. This sensitivity analysis was not modeled, however, the modeling results of the removal of the Central Lake Belt Storage Area and its perimeter seepage barrier could be extrapolated for general analysis. Wet season, groundwater seepage would be expected to raise the L-31N Borrow Canal levels, increase groundwater levels east of L-31N, flows to Biscayne Bay can be expected to increase due to seepage, and stages and hydroperiods in Everglades National Park west of L-31N can be expected to decrease.

7.3.4 Conclusions of Comprehensive Plan Formulation and Evaluation

The Restudy Team formulated and evaluated 10 alternative plans and in excess of 20 intermediate computer simulations (termed scenarios) that culminated in the selection of Alternative D-13R as the Initial Draft Plan. This plan was then further evaluated by identifying components that have a high degree of uncertainty and analyzing the sensitivity of these features. The results of these analyses suggest that Alternative D-13R, even with all of its uncertainties, is the plan that best achieves the planning objectives. However, a number of components had yet to be evaluated because they were outside the purview of the analytical tools being used to evaluate the alternative plans. Therefore, a subsequent analysis was initiated to evaluate these components, which the Restudy Team termed Other Project Elements.

7.4 OTHER PROJECT ELEMENTS

During the iterative plan formulation process, it became apparent that some components could not be evaluated using the South Florida Management Model because either they were outside the boundary of the model or they were too small to be simulated at the scale of the model. These components were termed Other Project Elements (OPEs) and underwent a separate evaluation (See ***Appendix A, Section 6***).

An initial list of Other Project Elements was developed by the Restudy Team from a number of sources including: the Critical Projects, the Restudy Plan Formulation document, and new proposals from Restudy Team members.

The Water Resources Development Act (WRDA) of 1996 authorizes the Secretary of the Army, subject to specific criteria, to proceed expeditiously with the implementation of restoration projects that are deemed critical to the restoration of the south Florida ecosystem (see ***Appendix A5***). These projects were termed "Critical Projects." This authority resulted in an expedited study to identify projects that would meet the criteria set forth in the authorizing legislation. A total of 35 projects were nominated as Critical Projects under this authority. However, the cumulative cost estimate for these projects exceeded the legislatively mandated limit. Therefore, it is anticipated that only a fraction of the projects will actually be implemented under the Critical Projects authority. Hence, to ensure that all of these projects received full consideration, the Restudy included the Critical Projects that had not yet been approved for construction in its planning process. Some of these Critical Projects are included in alternative plans such as the C-4 Divide Structure. The remainder of the Critical Projects were considered in this Other Project Element evaluation.

7.4.1 Evaluation of Other Project Elements

The first step in the evaluation of the Other Project Elements involved screening the initial list using the following criteria:

(1) The project element could not be evaluated using the South Florida Water Management Model.

(2) The project element must support and be consistent with the Restudy planning objectives.

(3) The project element must have a Federal interest.

(4) The project element should not be a stand alone research or data collection activity.

This screening resulted in 37 potential Other Project Elements. These were then evaluated by an interagency - interdisciplinary team in four benefit categories including: (1) ecological values based on hydrology, spatial extent, habitat quality, and improvement to native flora and fauna; (2) urban and agricultural water supply, (3) flood damage reduction; and (4) water quality. In addition, the team considered two other parameters including geographic extent and the significance to the Initial Draft Plan.

7.4.2 Conclusions of the Evaluation of the Other Project Elements

Of the 37 potential Other Project Elements, the team rated 26 of them (eleven of them were not rated due to lack of information). Of the 26 rated, 11 of them were recommended to be included with the Initial Draft Plan. Further, many of the other proposed Other Project Elements, including many of the lower-priority Critical Projects, were recommended for further study. However, in response to public and agency comments recommending the implementation of the Comprehensive Plan be accelerated to expedite ecologic restoration, many of these Critical Projects and additional Other Project Elements are now included in the final plan. Accordingly, 21 Other Project Elements are now recommended for inclusion in the Comprehensive Plan as displayed in ***Table 7-16***.

7.5 FINAL ARRAY OF ALTERNATIVE PLANS

Subsequent to the selection of Alternative D-13R as the Initial Draft Plan, an evaluation of the final array of alternative plans was conducted. This included an analysis of the economic benefits and impacts, an analysis of the environmental planning objectives, a cost effectiveness and incremental analysis, mitigation analysis, and an evaluation of the plans to meet various policy and regulatory requirements.

7.5.1 Economic Evaluation of the Alternative Plans

Many of the benefits afforded by the alternative plans are environmental in nature and were not converted to monetary units for evaluation. As a result, a major focus of the economic evaluation was on the cost effects of the alternatives. Such effects can result at both the national and regional levels.

TABLE 7-16
RECOMMENDED OTHER PROJECT ELEMENTS

Other Project Elements Title	CP[1] Rank
Melaleuca Eradication – Renovation of Existing Facility and Biological Agent Rearing components (CP)	3
Seminole Tribe Big Cypress Reservation Water Conservation Plan (CP)	6

[1]CP – Critical Project

Evaluation of economic effects of the alternatives was concerned with various aspects of the relationships between the economy and water. For example, water is necessary for agricultural and manufacturing processes, and individual survival. It is important for recreation and tourism. It is necessary for navigation. It plays a significant and obvious role in commercial and recreational fishing. The costs of transporting and treating water before and after its use, as well other costs associated with water use, are imbedded in the network of relationships and transactions of the economy. These interrelationships between the economic system and the ecosystem from which water is either consumed, or used in a non-consumptive way, by the economic system are the focal point for measuring some of the costs and benefits of the alternative plans.

The water-economy linkages briefly discussed above are perhaps the more obvious ones. There are also important linkages between the health of south Florida's natural ecosystem, and adequate amounts and timing of water, discussed elsewhere in this and other documents. The more elusive, hard-to-measure linkages, are those between the economic system and the natural ecosystem. This set of relationships is harder to see on a case-by-case basis (some polluted runoff here, some wildlife habitat lost there). In the aggregate, however, it is clear that a healthy functioning ecosystem is part of the requisite infrastructure for a healthy functioning economy. For purposes of this study, economic benefits were not used to "justify" ecosystem restoration plans.

The economic evaluation considered the effects on: agricultural water use, municipal and industrial water use, potential changes in flooding damages, navigation, recreation, and commercial fishing. A summary of the findings of this evaluation are displayed in ***Table 7-17*** and for a complete description of the evaluation, refer to ***Appendix E***.

Agricultural Water Supply – Since all plans involve some change in the management of water, the potential exists for changes in the amount and timing of water available for irrigation of crops, as well as changes in the water table. Such changes could in turn affect agricultural productivity (different productivity for existing crops, different crops, changes in crop practices, etc.). For the Everglades Agricultural Area and the Lower East Coast, changes in water deliveries to agriculture were converted to changes in agricultural crop yields, and in turn, to changes in net farm income. The agricultural water supply effects in the St. Lucie and Caloosahatchee Basins were measured by estimating the difference between the amount of irrigation water provided for a particular alternative and the demands of that basin. The result is a “demands-not-met” measurement that was compared to the Without Plan Condition. This analysis revealed that the alternative plans should result in a positive effect.

Municipal and Industrial Water Supply – Projections of future water demand were made using the IWR-MAIN Water Demand Forecasting software, and were used as input to the South Florida Water Management Model. Changes in water deliveries to the urban users were converted to estimated willingness to pay values. There is expected to be a positive effect for each of the alternative plans compared to the Without Plan Condition.

TABLE 7-17
ECONOMIC EFFECTS OF THE ALTERNATIVE PLANS
($Millions)

Economic Category	How Measured	Alternatives					
		Without Plan	A	B	C	D	D-13R
Agricultural Water Supply: Everglades Agricultural Area and Lower East Coast	Average Annual value of unmet demands (lower is better)	$2.6	$.58	$.88	$.66	$.74	$.71
St Lucie Basin	Percentage of Demands Not Met (lower is better)	22.4%	4.1%	6.5%	4.1%	3.1%	3.1%
Caloosahatchee Basin		31.6%	9.2%	14.9%	9.0%	7.5%	7.5%
Municipal and Industrial Water Supply	Average Annual Value of Unmet demand (lower is better)	$31.8	$10.2	$10.3	$6.4	$4.6	$4.6
Commercial Navigation	Percent of time Lake Okeechobee falls below critical stage (12 feet) (lower is better)	30%	16%	20%	16%	11%	11%
Recreation	See Appendix E	NQ	NQ	NQ	NQ	NQ	NQ
Commercial and Recreational Fishing	See Appendix E	NQ	NQ	NQ	NQ	NQ	NQ
Flood Control	See Appendix E	NQ	NQ	NQ	NQ	NQ	NQ
Regional Economic:	Expressed as percent of regional economy* (higher is better)						
Earnings		NA	.08%	.08%	.10%	.13%	.14%
Employment		NA	.06%	.07%	.07%	.10%	.11%
Output		NA	.08%	.09%	.08%	.12%	.14%

NQ – effects were not quantified
% - percent
* - Regional Economic effects for the alternatives are the difference between with and without a plan.

Commercial Navigation – Low lake levels affect the ability of commercial navigation traffic to safely navigate the Lake Okeechobee Waterway, and can also result in lock operation restrictions. Prior to this study, it was felt that changes in Lake Okeechobee water levels associated with some of the plans could impact navigation in Lake Okeechobee. However, for the alternative plans, this is not an issue. Lake level fluctuations appear to be moderated in the plans being considered compared to the Without Plan Condition. High levels are not as high as, and low levels are not as low as in the Without Plan Condition. The navigation effects could have been translated into monetary units, but the data uncertainty is such that the effects were evaluated by identifying when Lake Okeechobee stages fall below 12 feet.

Recreation – Recreation is a major industry in south Florida, and the natural ecosystems play a potentially important contributing role. Besides opportunities for ecosystem-related tourism (visitor centers, educational programs, etc.), there are potentially major implications for that part of the economy linked to the health of Florida Bay (mainly Monroe County, which includes the Florida Keys). While there is the possibility of a significant positive effect associated with any of the alternative plans being examined, but there is so much uncertainty at this stage of the planning process, that such effects were not monetized. ***Appendix E*** includes a lengthy discussion about this topic and the context within which possible changes will take place. However, the kind of detailed information that is necessary to estimate recreation effects of the different alternative plan was not available during this study.

Commercial Fishing – It is possible that economic commercial and recreational fishing benefits could result from the alternative plans. If fish stocks were to increase as a result of positive Florida Bay responses to Everglades ecosystem restoration, and commercial fish catch were to increase, then the difference in the value of fish catch would be an economic benefit. Some studies reveal strong evidence suggesting that such could be the case, particularly for pink shrimp. The potential exists for similar positive effects in the other affected areas of St. Lucie Estuary, Caloosahatchee Estuary, and Biscayne Bay. These effects could extend to offshore fisheries as well, due to the relationship between conditions in the bays and estuaries, which provide nursery functions for the offshore fisheries. Again, details necessary to identify monetary effects of each alternative plan were not available during this study. Similar to the recreation analysis, a discussion of the role commercial fishing plays in the economy is provided in ***Appendix E*** to highlight the relative significance of potential impacts in this area.

Flood Damage Reduction – A major justification for much of the existing C&SF Project was to control flooding. Modifications to achieve ecosystem restoration have the potential to change flood control. For example, alternative plans that increase canal capacities or include additional water storage capacity enhance flood control provided by the system. For this study, neither additional benefits nor costs (increased damages) have been quantified. This was because the South Florida Water Management Model, which was the primary tool used to simulate the alternative plans, did not have the spatial resolution, nor was it sufficiently calibrated in the urban areas to definitively evaluate flood damage changes expected to result from any of the alternative plans. However, known (existing) problem areas were defined and cross-compared with some of the South Florida Water Management Model output that identifies gross changes in annual peak stage. Further, during the engineering design of the plan components, steps were taken to minimize potential flooding that could result from any of the components. Therefore, the flood damage reduction analysis, which can be found in ***Appendix E***, identified areas which have a strong potential for follow-on flood damage reduction or mitigation analysis that may be needed in the more detailed implementation analyses which will follow the Restudy.

Regional Economic Development Effects – Regional economic impact effects were estimated for the alternative plans. This included the “multiplier” effects of project spending, as well as agricultural water supply changes, and the impact of agricultural land taken out of production due to project components (e.g., water storage facilities). In the context of the 12- county area of economic influence, the alternative plans would result in a relatively small positive effect on the regional earnings, sales, and employment. The analysis, which can be found in ***Appendix E***, showed that the positive effects associated with project spending and increased agricultural production due to fewer water restrictions would be greater than the negative effects of agricultural land removed from production for storage facilities.

7.5.2 Environmental Evaluation of the Alternative Plans

Two different methods were used to assess the ecological performance of the alternative plans. The color assessment scheme developed by the Alternative Evaluation Team was the first method of assessment. This provides information about the potential for achieving the long-term ecologic objectives. The team used "green" to indicate that an alternative plan will likely result in the recovery and long-term sustainablility of the ecologic and water supply objectives in the sub-region. The goal was to achieve a green assessment for all areas throughout the study area indicating potential system-wide restoration.

This assessment was used to quantify the spatial extent in meeting the planning objective by summing the acreage of each sub-region that was assessed as green. The result of this evaluation is displayed as "Green Acres" in ***Table 7-18.*** Alternative D-13R resulted in a substantially larger area of predicted sustainable ecosystems than any of the other plans evaluated. Had all sub-regions achieved this goal, approximately 2.7 million acres would be restored to levels capable of sustaining long term ecological objectives. The without plan condition has no areas assessed green; therefore, 0 acres.

A second evaluation was conducted to determine the success of alternative plans in meeting the planning objective for improving habitat quality of natural areas in south Florida. Habitat quality is critical to reestablishing sustainable populations of fish and wildlife resources in the central and south Florida ecosystem. To measure this objective, "Habitat Units" were calculated by multiplying the area of a sub-region (acres) by the numeric output from the River of Grass Evaluation Methodology. When summed, the habitat units provide an indication of the potential system-wide habitat quality. The result of this evaluation is displayed in ***Table 7-18***. If all sub-regions were restored, the result would be 2.7 million habitat units. Alternative D-13R resulted in 2.2 million habitat units, the most for any of the plans evaluated.

The Other Project Elements are not included within the domain of the South Florida Water Management Model; therefore, the environmental evaluations of these features were not included in the color assessment nor the River of Grass Evaluation Methodology. An estimate was prepared using principles similar to the River of Grass Methodology but at a more localized scale. The evaluation of the Other Project Elements included development of habitat units for the localized benefits produced within the “footprint” of the feature. No attempt was made to assess benefits that were expected to accrue offsite or benefits from Other Project Elements without a discrete footprint, such as the Biological Control for Melaleuca and Other Invasive Exotic Species project. The construction of this feature would have system-wide benefits but the assumptions necessary to make an estimate of habitat unit improvement would be overly gross and were not attempted. Accordingly, the estimate of Other Project Elements benefits is considered underestimated at 9,000 habitat units.

7.5.3 Cost Effectiveness and Incremental Cost Analyses

Cost effectiveness and incremental cost analyses reveal information about good financial investments given the dollar costs and non-dollar outputs (“benefits”) of alternative investment choices. The analyses are conducted in a series of steps that progressively identify alternatives that meet specified criteria and screen-out those that do not. Corps Engineer Regulation 1105-2-100 requires cost effectiveness and incremental cost analyses to support recommendations for ecosystem restoration.

Cost effectiveness analysis begins with a comparison of the costs and outputs of alternative plans to identify the least cost plan for every possible level of output. The resulting least cost alternative plans are then compared to identify those that will produce greater levels of output at the same cost, or at a lesser cost, as other alternative plans. Alternative plans identified through this comparison are the cost effective alternative plans. Next, the cost effective alternative plans are compared to identify the most economically efficient alternative plans, that is, the “best buy” alternative plans that will progressively produce the “biggest bang for the buck”. Finally, the additional costs for the additional amounts of output (“incremental cost”) produced by the best buy alternative plans are calculated. The results of all of the calculations and comparisons of costs and outputs provide a basis for addressing the decision question “Is it worth it?” In the case of the Restudy, the question is how much ecosystem restoration is worth the dollar cost? Additional information about the analyses is in *Evaluation of Environmental Investments Procedures Manual, Interim: Cost Effectiveness and Incremental Cost Analyses* by the U.S. Army Corps of Engineers, Institute for Water Resources (USACE, 1995).

NE-- Not Evaluated HU – Habitat Unit

This page is intentionally left blank.

In practice, Corps ecosystem restoration studies typically measure the ecosystem benefits of alternative plans in terms of physical dimensions (number of acres of wetlands, for example), or population counts (number of wading birds, for example), or various habitat-based scores ("habitat units" based on the U.S. Fish and Wildlife Service's *Habitat Evaluation Procedures*, or "HEP", for example). Any of these metrics may be used in conducting cost effectiveness and incremental cost analyses. For the purposes of the Restudy, the analyses were conducted using the "habitat unit" and "green acre (sustainable ecosystem)" measurements of plan outputs; see ***Section 7.5.2*** Environmental Evaluation of the Alternative Plans and ***Table 7-18*** for additional information about these metrics. Recognizing the cautions and limitations on using these metrics in a comparative manner and the uncertainties inherent in the metrics as well as the cost estimates, the habitat unit and green acre estimates were used in the analyses to illustrate the type of information they may reveal.

Cost effectiveness and incremental cost analyses were conducted for Alternatives A, B, C, D and D-13R. The analyses compared the alternative plans' average annual costs (over a 20-year construction period) against the habitat unit and green acre estimates. In preparation for the analyses, the effects of each alternative were calculated by subtracting the Without Plan Condition value from the with-alternative value ("with-and-without analysis") to determine the value of the alternative's change. ***Table 7-19*** displays the resulting scores for the habitat unit and green acre outputs, as well as costs, used in the cost effectiveness and incremental cost analyses.

The results of the cost effectiveness and incremental cost analyses for the final Restudy alternative plans are summarized in ***Table 7-20*** and ***Figure 7-7*** and provide the following information about the plans:

- In comparing costs against habitat units, Alternatives B, C and D would not be good choices because each would produce fewer habitat units at a greater cost compared to Alternative A. Therefore, if Alternatives B, C and D are set aside based on this reason, the remaining cost effective plans would be Alternatives A and D-13R. A subsequent analysis to identify the "best buy" plans indicated that Alternative A is the first best buy plan (with an incremental cost per habitat unit of $390), followed by Alternative D13R as the second and final best buy plan (with an incremental cost per habitat unit of $930).

- In comparing costs against green acres, Alternative B would not be a good choice because it would produce the same number of acres but at a greater cost compared to Alternative A. Therefore, if Alternative B is set aside based on this reason, the remaining cost effective plans would be Alternatives A, C, D and D-13R. A subsequent analysis to identify the "best buy" plans indicated that Alternative D-13R is the only best buy plan (with an incremental cost per green acre of $170).

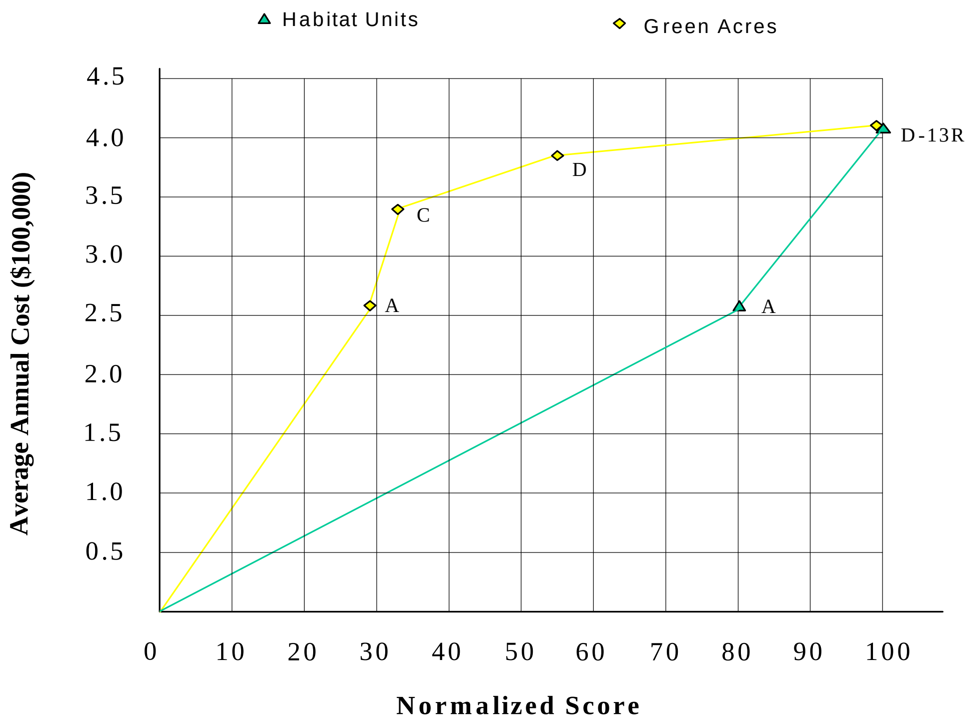
COST EFFECTIVE ALTERNATIVE PLANS



7.5.4 Fish and Wildlife Mitigation Analysis

Some of the components in the alternative plans have the potential to cause localized adverse environmental impacts. For example, the construction of levees, canals, reservoirs and stormwater treatment areas, could adversely impact wetlands and other aquatic sites as well as native upland habitats. The locations of many features are known, while others are only conceptually proposed within a study region or basin. As site-specific details for the components are developed during the Project Implementation Process, land suitability analyses will be utilized as part of the site selection process. Sites with extensive wetland and/or aquatic habitats and native upland habitats will be avoided to the greatest extent practicable. For selected sites where impacts to these habitats are unavoidable, impacts will be minimized through project design. Notwithstanding the current uncertainty regarding component siting and design, an analysis was conducted to determine the approximate extent of these potential impacts.

For the features that involve large areal extent like reservoirs, estimates were made for the affected wetland acreage. For the known sites, the acreage estimates were based on available information, such as existing studies, aerial photography and other physiographic data. Due to the variety of native upland habitats that could be encountered and the inability to discern them at the level this estimate was made, potential impacts to uplands were not included in this analysis. Furthermore, it is anticipated that the land suitability analyses to be utilized during the Project Implementation Report processes will minimize the potential effects on native habitat types in favor of disturbed sites. For sites that were only conceptually located, conservative estimates were made of the percent of wetland area expected to be encountered. For linear features such as canals and levees, the worst case scenario was used and it was assumed these features would be located entirely within wetlands.

In addition to the estimates of wetland acreage that could be affected, habitat quality estimates were made for both the existing and with-plan conditions. These wetland habitat quality estimates were made using a scale of zero to one, with 0.0 representing very poor habitat quality and 1.0 representing optimum habitat quality. For the existing condition estimates, habitat quality was based on available data for project features with known locations and best professional judgement was used for project features with conceptual locations. To estimate the habitat quality for the with-plan condition, operational details of the feature are needed. For example, the hydrologic operation and vegetative management of the Water Preserve Areas will dictate the effect on habitat quality as either beneficial or detrimental. Again, a conservative approach was taken and all features were assumed to produce an adverse impact. The total estimate of the potential adverse impacts of Alternative D-13R and the Other Project Elements is a loss of approximately 10,000 “wetland habitat units”. These units were derived by multiplying the estimated area of affected wetlands by the difference between the existing and with-plan habitat quality estimates.

7.5.5 Uncertainty Analysis

The primary purpose of the uncertainty analysis (see ***Appendix O***) was to identify which of the remaining uncertainties are most significant. That is, which have the most potential to affect the effectiveness of the project that will eventually be implemented. A secondary purpose of the analysis was to identify broad strategies that can be used to address or reduce the remaining uncertainties.

Much of the uncertainty that attends this study effort is considered routine uncertainty. Planning is an iterative process. The iterations are distinguished by an increasing quantity and quality of information and a corresponding decrease in uncertainty. In any planning study there are things that are unknown at one point in time that must and will be known before the project can be implemented. That includes such things as specifically where project elements will be located, how much they will cost, and who will pay for them, among many other issues. While there is a great deal of routine uncertainty attending the current iteration of this planning study, processes have been developed to ensure that they are resolved in due time.

Although much of the uncertainty that remains in the Restudy is routine and will be addressed in time, there are some uncertainties that are too unique to ignore. For example, although the basic workings of Aquifer Storage and Recovery (ASR) technology are a perceived uncertainty, there are some unique uncertainties associated with their application on a magnitude of this scale. Four key uncertainties were identified in the analysis that are unique enough to warrant special attention in the future. They include:

- Uncertainties about major Restudy models;
- Uncertainties about the linkage between hydrologic change and ecosystem restoration;
- Uncertainties about new technologies; and,
- Uncertainties about the risks associated with the Comprehensive Plan.

Appendix O includes the commitments that the Restudy Team has made to address these key uncertainty issues in subsequent planning and design activities and recommendations for additional studies to help resolve outstanding uncertainty issues including a qualitative risk assessment.

7.5.6 Planning Criteria

Performance of the alternative plans with respect to the planning objectives including ecologic, economic, and hydrologic criteria, is displayed in ***Table 7-22***.

7.5.7 Evaluation Accounts

Planning by Federal agencies for water resource development and management is guided by the requirements of the U.S. Water Resources Council's Principles and Guidelines. The Principles and Guidelines establish the Federal Objective for water projects, set forth a six-step planning and decision making process, and prescribe four accounts of evaluation.

TABLE 7-22
PLANNING CRITERIA EVALUATION

PLANNING CRITERIA	WITHOUT PLAN	A	B	C	D	D-13 R and OPEs
ECOLOGIC Increase the total spatial extent of natural areas (Acres of Sustainable Ecosystem, Green ranking)	0 acres	680,000 acres	680,000 acres	793,000 acres	1,295,000 acres	2,370,000 acres
Improve habitat and functional quality (ROGEM Numeric Score x effected acres) HU = Habitat Units	1,383,000 HU	2,025,000 HU	1,000,000 HU	1,940,000 HU	1,940,000 HU	2,186,000 HU
Improve native plant and animal species abundance and diversity (Number of Ecologic Landscape Types that are Sustainable, Green Ranking)	NA	58	58	58	56	58
ECONOMIC Increase availability of fresh water (volume of water restriction cutback for agricultural / urban, Acre-feet)	6,665,000	1,798,000	2,325,000	1,767,000	1,395,000	1,333,000
Reduce flood damages	Evaluation did not result in quantification of benefits and impacts since SFWMM is not designed for flood studies. Refer to Appendix E for description of the analysis.					
Provide recreational and navigation opportunities: Lake Okeechobee (percent time Lake Okeechobee falls below 12 feet)	30%	16%	20%	16%	11%	11%
Other recreational opportunities	Problematic to quantify effects of alternative plans; current expenditures $404 million (parks and preserves), $598 million (region); current consumer surplus $290 million (parks and preserves), $764 million (region)					
HYDROLOGIC Regain lost storage capacity (Additional Storage – total for 31 year period of record) (Coastal Discharges – water wasted to tide)	NA 1,774,000 ac-ft	44,016,000 ac-ft 67,000 ac-ft	48,315,000 ac-ft 138,000 ac-ft	48,369,000 ac-ft 383,000 ac-ft	52,469,000 ac-ft 311,000 ac-ft	52,005,000 ac-ft 311,000 ac-ft
Restore more natural hydropatterns (acres with improved ROGEM scores)	NA	2,725,358	2,656,188	2,344,142	1,669,263	2,777,045
Improve timing and quantities of fresh water deliveries to estuaries (Flood Discharge Volumes from Lake Okeechobee)	9,114,000 ac-ft	1,116,000 ac-ft	682,000 ac-ft	868,000 ac-ft	930,000 ac-ft	868,000 ac-ft
Restore water quality conditions (Cumulative Score from combined ranking matrix, higher = better)	27.0	32.5	35.5	30.5	40.5	45.5

The four accounts facilitate the evaluation, display, and comparison of the effects of alternative plans. These accounts are national economic development (NED), environmental quality (EQ), regional economic development (RED) and other social effects (OSE). The EQ account shows effects on ecological, cultural, and aesthetic attributes of significant natural and cultural resources that cannot be measured in monetary terms. The OSE account shows urban and community impacts and effects on life, health and safety. The NED account shows effects on the national economy. The RED account shows the regional incidence of NED effects, income transfers, and employment effects.

These four accounts encompass all significant effects of plan implementation, including economic, socioeconomic and environmental effects that must be considered in water resources planning as prescribed in the following Federal laws:

- The 1969 National Environmental Policy Act (Public Law 91-190);
- Section 122 of the 1970 Rivers and Harbors Act (Public Law 91-611);
- Sections 904 and 905 of the 1986 Water Resources Development Act (Public Law 99-662).

The 1969 National Environmental Policy Act (NEPA). Public Law 91-190 (42 USC 4321) requires assessment of alternative plan impacts on the human environment. NEPA also requires documentation of the planning process, alternative plan comparison and plan selection.

Section 122 of the Rivers and Harbors Act of 1970 (Public Law 91-611, 84 STAT. 1823) requires that consideration be given to possible adverse economic, social and environmental effects. It also requires that final decisions on the project be made in the best overall public interest, taking into consideration the need for flood control, navigation and associated purposes; and the associated costs of eliminating or minimizing the following adverse affects:

- Air, water and noise pollution;
- Destruction or disruption of man-made and natural resources, esthetic values, community cohesion, and availability of public facilities and services;
- Adverse employment effects;
- Tax and property value losses;
- Injurious displacement of people, businesses and farms;
- Disruption of desirable community and regional growth.

Section 904 of the 1986 Water Resources Development Act (Public Law 99-662, 100 STAT. 4185, 33 USC 2281)) describes additional requirements that must be addressed in the formulation and evaluation process for Federal water resources projects. These requirements are listed below. The formulation and evaluation process must consider the associated benefits and costs of these items, both quantifiable and unquantifiable, and must be displayed in the benefits and costs of such projects.

- Enhancing national economic development;
- Quality of the total environment;
- The well-being of the people;
- Prevention of loss of life;
- Preservation of cultural and historical values.

Section 905 of the 1986 Water Resources Development Act (Public Law 99-662 (100 STAT. 4185, 33 USC 2282) describes the requirements for feasibility reports for any water resources project or related study authorized to be undertaken by the Secretary. The feasibility report will describe, with reasonable certainty, the economic, environmental and social benefits and detriments of the recommended plan and alternative plans considered by the Secretary.

Effects of the alternative plans in the four evaluation accounts are displayed in ***Tables 7-23*** and ***Table 7-24.***

TABLE 7-23
EVALUATION ACCOUNTS LISTED IN THE "PRINCIPLES AND GUIDELINES"
(all dollar values in $ millions)

Evaluation Accounts	WITH- AND WITHOUT-PROJECT CONDITIONS					
	2050 Base Condition	Alternative A	Alternative B	Alternative C	Alternative D	Recommended Plan
National Economic Development Account						
Agricultural Water Supply: Avg. annual value of unmet demand*	$2.6	$0.6 (+$2.0)	$0.9 (+$1.7)	$0.7 (+$1.9)	$0.8 (+$1.8)	$0.7 (+$1.9)
M&I Water Supply: Avg. annual value of unmet demand*	$31.8	$10.2 (+$21.7)	$10.3 (+$21.5)	$6.4 (+$25.4)	$4.6 (+$27.2)	$4.6 (+$27.2)
Flood Control	• Limited evaluation of impacts, since SFWMM not designed for flood studies.					
Commercial Navigation	• No significant difference expected between with- and without-project conditions.					
Recreation	• Problematic to quantify effects of alternative plans. • Current Expenditures: $404 million (parks/preserves); $598 million (region). • Current Consumer Surplus: $290 million (parks/preserves); $764 million (region).					
Commercial/Recreational Fishing	• Annual revenues estimated for commercial and guided & recreational sportfishing in five areas: Lake Okeechobee, St. Lucie & Caloosahatchee estuaries, and Biscayne & Florida bays. • Significant positive economic impacts are expected to result from hydrologic modifications and consequent ecological impacts to all five areas with the exception of Biscayne Bay.					
Project Costs						
Total Construction & Real Estate Costs		$5,229	$6,023	$6,725	$7,335	$7,789
Annual Operations & Maintenance Costs		$70	$72	$126	$162	$165
Annual Monitoring Costs		$10	$10	$10	$10	$10
Annualized Costs		$254	$286	$341	$383	$402
Regional Economic Development Account						
Average annual effects (% of regional economy)						
Output		$173 (.08%)	$195 (.09%)	$192 (.09%)	$277 (.12%)	$307 (.14%)
Employment (jobs)		1,707 (.06%)	1,934 (.07%)	2,057 (.07%)	2,903 (.10%)	3,165 (.11%)
Earnings		$59 (.08%)	$65 (.08%)	$78 (.10%)	$103 (.13%)	$108 (.14%)
Environmental Quality Account	• Refer to Table 7-22 and 7-24 for a display of ecologic, cultural, and aesthetics attributes.					
Other Social Effects Account	• Potential community disruption from conversion of agricultural land to reservoirs.					

Note, A "+" indicates a reduction in unmet water demand.

TABLE 7-24
SUMMARY OF EFFECTS

CATEGORIES OF EFFECTS	EXISTING CONDITION	WITHOUT PLAN	A	B	C	D	Selected Plan
Air Quality	H	H	0	0	0	0	0

Existing and Without Plan Conditions display estimates of each resources relative values: H = high, M = moderate, L = low.
Plans' effects are estimates of net overall changes from the Without Plan Condition:

++ = very beneficial change
+ = beneficial change
0 = no change
- = adverse change
-- = very adverse change
N/A = not applicable

** During construction, localized
*** Unique Farmland will be taken out of production however no Prime Farmland will be impacted

7.6 PLAN FORMULATION PROCESS SUMMARY

The planning process used by the Restudy Team evolved over three years, ultimately resulting in selection of a recommended Comprehensive Plan. The team used an iterative decision making process to identify and evaluate the merits of individual components and the effects of combining these components into different comprehensive plans. The Restudy's major iterations are illustrated in **Figure 7.1**. ***Table 7-25*** highlights the purpose, decision criteria and results of the major iterations.

TABLE 7-25
PLAN FORMULATION MAJOR ITERATIONS

ITERATION We started with:	**PURPOSE Our intent was to:**	**CRITERIA We made decisions based on:**	**RESULT The iteration ended with:**
Goals and Objectives	Progressively identify components to meet the goals and objectives	Ideas from technical experts and the public	Components
Components	Comparatively array and screen components	• Lower East Coast Regional Water Supply Plan • Water Preserve Areas Land Suitability Analysis • Everglades Screening Model • Cost Effectiveness Analysis	Starting Point Alternative
Starting Point Alternative	Progressively formulate plans	Performance measures	Alternatives 1-6, which were screened to Alternatives A-D (3-6)
Alternatives A-D	Comparatively array and screen plans	• River of Grass Evaluation Methodology • Ranking Score • Grade Score • Color Score • Keystone and Endangered Species Evaluation • Water Quality	Alternative D
Alternative D	Progressively reformulate plans	Performance measures	Alternative D-13R
Alternatives A-D and D-13R (Final array)	Comparatively array and screen plans	• Economic Evaluation • Environmental Evaluation • Cost Effectiveness and Incremental Cost Analyses • Mitigation Analysis • Planning Criteria • Evaluation Accounts	D-13R plus Other Project Elements

As the Restudy planning iterations evolved, the criteria that were the basis for deciding the fate of solutions were refined and modified, but the planning objectives remained the same throughout. During the early iteration of screening components, it was possible to make such decisions using more qualitative information that was readily available from a limited number of analyses. This is in stark contrast to the final iteration in which new and more quantitative analyses were required to make more sophisticated judgments across a more extensive set of criteria. During each iteration, the decision criteria reflected the best available information that could be used to support decisions for dropping or retaining the solutions at hand.

This iterative planning process progressively eliminated inferior plans and carried superior plans forward for reformulation into even better plans. Subsequent iterations to improve the plans were based on criteria (and their related metrics) that had been refined and improved from criteria used in the previous iterations. Each iteration flowed from and built upon the decisions reached in the previous iterations. As such, the team did not carry along plans eliminated in previous iterations so that all plans are continually evaluated on an ever-evolving comparable basis. An iteration was not an opportunity to revisit previous decisions (although, on occasion, some iterations were indeed just that). Rather, each iteration sought to move decision making closer to a final recommendation.

7.7 SUBSEQUENT ITERATIONS OF THE RECOMMENDED PLAN

The U. S Department of Interior, and the Florida Game and Fresh Water Fish Commission listed a number of concerns about the draft Comprehensive Plan in the draft Fish and Wildlife Coordination Act Reports presented to the Corps of Engineers in August, 1998 (see ***Annex A***). Some of these issues were considered critical to acceptance of the Comprehensive Plan. While it was considered unreasonable to expect these issues could be completely resolved before completion of this report, the South Florida Ecosystem Restoration Working Group agreed they warranted additional attention and additional modeling, if possible.

The Alternative Evaluation Team agreed to develop a short-term issue identification and resolution process for addressing the outstanding issues associated with the Comprehensive Plan. Task teams were formed. The Everglades Basin task team combined the former Total Systems, Northern and Central Everglades, Southern Everglades and Florida Bay, and Big Cypress subteams. The Southeastern Estuaries task team combined the Biscayne Bay and Model Lands/C-111 Basin subteams. The Water Quality subteam was already in existence and a small Northern Estuaries team was formed.

The four teams identified all outstanding issues including, but not limited to, those coming from the two Coordination Act Reports. Some of the issues were plan formulation, evaluation, and modeling issues occurring in each Alternative Evaluation Team sub-region. These issues were considered to be within the scope of the Alternative Evaluation Team. Other agency concerns, such as policy issues, were listed, but because they were beyond the scope of the Alternative Evaluation Team, they were not pursued further during this process. The issue teams then agreed that six issues were exceptionally important and deserved additional attention prior to completion of the final report.

Team members drafted issue papers on each of the five most important issues following an agreed-upon outline developed by the Everglades Basin team and ratified by the others. The purpose of each issue paper was to better define the issues, propose a process for resolving the issue by creating a common understanding of the specific tasks that will be required and the information needed to resolve each issue either for the final report or during the future planning and implementation of the recommended Comprehensive Plan. Each paper was to propose a time line for reaching closure on each issue.

The six issues can be paraphrased as follows:

1. The plan needs to increase total overland flow to Florida Bay, Northeast Shark River Slough and Taylor Slough to fully meet Natural System Model depth and duration targets.

2. The plan needs to improve ecological performance in the Water Conservation Areas by eliminating damaging high and low water conditions.

3. The plan should improve ecological conditions in Biscayne Bay by restoring more natural freshwater inflows.

4. The risks and uncertainties associated with using wastewater reuse as a water source for Biscayne Bay should be closely examined.

5. Restoration targets in the St. Lucie Estuary should be more closely met.

6. The plan needs to improve ecological performance in the Model Lands and C-111 Basins by providing adequate freshwater to maintain target hydropatterns.

The Alternative Evaluation Team also undertook to draft a white paper to refine the team's working definition of restoration.

The Alternative Evaluation Team and its issue resolution task teams had an array of both short-term and long-term opportunities for addressing the remaining issues. Possible avenues included: optimization modeling, model refinements, technical peer review for questions of science, additional field studies and measures, refinement and creation of new performance measures, the development of review papers (white papers) on key issues, recommending operational and structural improvements during the detailed design phases, the use of an adaptive assessment strategy, and the design of a comprehensive ecological monitoring program.

The short-term strategy outlined above was an interim strategy intended to feed into and support the implementation and adaptive assessment strategies currently being developed for this report and to satisfy the recommendations of the U.S Fish and Wildlife Service and the Florida Game and Fresh Water Fish Commission Final Coordination Act Reports.

Four papers have been completed, reviewed by the Alternative Evaluation Team and accepted: the St. Lucie issue paper, the two Biscayne Bay issue papers, and the "defining restoration" white paper. The two Everglades basin teams combined and completed a draft issue paper. The issue papers can be found in the U.S. Fish and Wildlife Coordination Act Report (***Annex A***).

Understanding that two of the issues (numbers 1 and 3) would be resolved if the plan provided more water for Biscayne Bay and Shark River Slough, an initiative was begun to investigate the capture of additional water discharged to tide beyond the quantity captured in Alternative D-13R. This investigation included additional model runs of the SFWMM hydrologic model. These model runs were referred to as D-13R_x scenarios, with the $_x$ representing each of the additional scenarios. For example, the first scenario developed was called D-13R_1. The purpose of these scenarios was to increase the water supply to Northeast Shark River Slough and Biscayne Bay by capturing and directing water currently discharged to tide in previous alternative plans. An intense effort by the interagency Alternative Evaluation Team subteam chairs and hydrologic modelers involved daily meetings to view model outputs, evaluate them, and quickly suggest improvements for model runs to be made that night for review the following day. A total of four scenarios were developed during this process with scenario D-13R_4 producing the greatest additional water flow. Therefore, only alternative D-13R_4 is described further in this report. The description of the other scenarios can be found on the Restudy web site (*www.restudy.org*).

7.7.1 Scenario D-13R_4 Description

The components of D-13R_4 scenario were designed to provide peak flood attenuation, reduction of freshwater discharges to tide and increase flows to Northeast Shark River Slough, Water Conservation Area 2A and Biscayne Bay while recharging Miami-Dade County's coastal canals. This was accomplished by backpumping excess runoff from the C-51 Canal through the Lake Worth Drainage District's canal system (which will require conveyance improvements) and pumped into the Palm Beach County Agricultural Reserve Reservoir. From the Agricultural Reserve Reservoir, runoff will be discharged south into the Lake Worth Drainage District E-1W canal and routed into the Site 1 Impoundment. Further, the Site 1 Impoundment (Component M) had to be modified to accept the runoff routed south from the C-51 Canal. In addition, more runoff from the Hillsboro Canal was captured by increasing the inflow pump capacity. The Site 1 reservoir would be modified from the D13-R design (6 feet deep, 2,460-acre reservoir) to a 12 feet deep 300-acre reservoir and a 2,160-acre stormwater treatment area. This component modification also assumes that urban runoff that is pumped into the 300-acre reservoir provides recharge for the 30-5 MGD ASR wells proposed in D-13R. Further, water from the reservoir will gravity flow to the stormwater treatment area for treatment prior to discharging into the northeast corner of Water Conservation Area 2A. It is assumed that flood protection in all affected areas will be maintained.

Further, urban runoff from the C-14, C-13, North New River Canals and Water Conservation Area 2B levee seepage will be backpumped to the US 27 west borrow canal via C-42 and North New River Canals. This runoff will be directed south to the North Lake Belt Storage Area if storage is available in that facility. Discharges from the North Lake Belt Storage Area are described in Component XX. If storage is not available in North Lake Belt Storage Area, the backpumped water will be routed either to the Bird Drive Recharge Area or Biscayne Bay via the US 27 west borrow canal, the North Lake Belt Storage Area conveyance system improvements, and the C-1, C-2, C-4 and C-6 Canals. Deliveries will not be made during storm peaks to avoid impacting flood protection. If storage is not available in North Lake Belt Storage Area and conveyance capacities are also not available (without impact to flood protection), backpumping will not occur. Water quality of deliveries to Northeast Shark River Slough must be of acceptable quality for restoration or water will not be delivered. Additional types of water quality treatment may be required and it is assumed that flood protection in all affected areas will be maintained. Backpumping will not occur if the conveyance systems can not adequately pass flows to storage and/or treatment areas.

Finally, while the Everglades Construction Project is designed to backpump runoff from urban areas to the Water Conservation Areas after treatment within Stormwater Treatment Areas, this scenario denotes the first time the Restudy included a proposal to direct urban runoff into the Everglades Protection Area. These scenarios propose to direct water from C-51 into Water Conservation Area 2A after treatment and from North Lake Belt Storage Area, which receives runoff from C-6, C-9, C-11 and in this scenario C-14, C-13 and North New River to Northeast Shark River Slough after treatment. There are concerns about the level and practicality of treatment needed to provide water of appropriate quality to the

Everglades. Without completion of a pilot project, the quality of the water coming out of in-ground storage areas remains an unknown.

7.7.2 Evaluation of D-13R_4

The Alternative Evaluation Team conducted a preliminary evaluation of the D-13R_{1-4} scenarios during a meeting of the full Alternative Evaluation Team on 20 January 1999. The objective of these additional scenarios was to determine the feasibility of improving D-13R, by capturing additional surplus water from the amount discharged to tide each year, and conveying that "new" water (plus redistributing excessive water in the Water Conservation Areas) to better meet performance targets in the natural system. These scenarios were designed to convey urban runoff water into the natural system, an alternative water management scheme that had not been included in any previous comprehensive plan alternative due to the high cost and the risk associated with contamination of the Everglades from urban runoff. The D-13R_4 scenario was clearly the most successful of the four scenarios that were developed during this intensive, multi-agency planning and modeling process, which began in November 1998.

The Alternative Evaluation Team found that the overall performance of Scenario D-13R_4, as modeled included both gains and losses when measured against the existing and the future without plan conditions, and D-13R. D-13R_4 captured an average of 245,000 acre-feet/year of new water for the natural system from Palm Beach and Broward counties. This new water, when combined with excessive water from the Water Conservation Areas, provided an average of 271,000 acre-feet of new water each year to Everglades National Park and an average of 77,000 acre feet of new water to Biscayne Bay each year. The increased annual mean flows to the park and Biscayne Bay are expected to produce substantial improvements towards meeting the hydrological performance targets for these two areas. Although D-13R_4 also provided modest improvements in northeast Water Conservation Area 3A and northeast 2B, by reducing the number of undesirable high water events in these two subregions, this scenario increased the number of undesirable high water events in Water Conservation Areas 2A and 3B to a level greater than that predicted for the two base conditions and D-13R. Further, D-13R_4 created undesirable increases in the depth and duration of flooding in the Pennsuco wetlands. By delivering urban water to the natural system, this scenario raises a number of new water quality questions.

The Alternative Evaluation Team recognizes that much new information regarding the potential performance of D-13R was gained during the modeling of the four scenarios. The hydrological responses during the modeling of these four scenarios convincingly demonstrated the operational flexibility of D-13R, and offers encouraging documentation that additional improvements can be achieved during the detailed planning phases of the restoration program. The Alternative Evaluation Team recommended that the specific features of D-13R_4 that allowed for the capture and conveyance of substantial amounts of new water for the natural system be incorporated into the Recommended Plan, D-13R, contingent upon:

(1) Finding a way to reduce the number of damaging high water events in Water Conservation Area 2A and 3B and the Pennsuco Wetlands to a level at or below the level predicted for D-13R.

(2) Adequately treating the stormwater runoff from the C-51 east and C-13/14 basins directed into the Everglades Protection Area to meet all state and federal water quality standards to enable ecological restoration to be achieved.

It was agreed that these concerns can best be resolved during the finer scale modeling and planning, which will occur as a part of detail design work. The addition of these features should allow greater operational flexibility during future efforts to improve the overall performance of D-13R. Further, an issue paper is required from the Restudy's Water Quality Team, to more fully explore the questions being raised by the use of urban water to meet natural system targets in the Everglades.

Following the Alternative Evaluation Team's evaluation of D-13R_{1-4}, comments were received from Lake Worth Drainage District concerning the possible detrimental affects on flood protection that could be experienced within their system if the proposed modifications to their secondary canals are made. Lake Worth Drainage District recommended that the specific features of D-13R_4 not be incorporated into the recommended Comprehensive Plan until it can be demonstrated that the existing level of flood protection will not be compromised.

Finally, it should be noted that the Natural System Model topography in Northeast Shark River Slough is assumed to be the same as current topography, although recent data collected by the U.S. Environmental Protection Agency scientists indicate that substantial soil subsidence has occurred since the 1940's. This discrepancy in the topographic data in the model very likely affects the depth targets for Northeast Shark River Slough. Hence, if consistent topographic data assumptions were used for both Northeast Shark River Slough and Water Conservation Area 3B, target depths in Northeast Shark River Slough would be shallower, excess depths in Water Conservation Area 3B reduced and less water would be needed to meet Northeast Shark River Slough performance measure targets.

7.8 PLAN FORMULATION CONCLUSIONS

The initial screening effort identified the pressing need to capture more water in south Florida to restore the Everglades, protect the estuaries, and to provide for adequate water supply for urban and agriculture needs in the future. During the screening phase, the Restudy Team used modeling combined with an economic "best buy" approach to reduce to a workable number the vast array of components available for capturing and storing water and for conveying that water to the right parts of the system at the right time. Detailed plan formulation followed. In a nine-month period, representatives from every concerned agency - federal, state and local - worked closely together with other stakeholders to decide which features would be included in each alternative plan. Each alternative plan was modeled, the results reviewed by the team, and new alternative plans were formulated based on the improvements the team believed were needed. After looking at 10 alternative plans and over 25 modeling scenarios including D-13R$_4$, Alternative D-13R is by far the best of the alternative plans. This alternative, coupled with the 21 Other Project Elements, contains the array of components that has the most potential to achieve the Restudy's planning goals and objectives. Implementation of this plan will make restoration of healthy, sustainable south Florida ecosystems possible. Hence, Alternative D-13R, in combination with the Other Project Elements makes up the recommended Comprehensive Plan.

Economic and environmental evaluations of the plan show that the recommended plan is strongly justified. The environmental benefits are great and despite the scale of the project, it is extremely cost effective. The recommended plan appears to do what the varied participants in the study asked for it to do. More water has been captured and conveyed to areas where it is needed. Extreme events like regulatory releases to the estuaries, excessive flooding in the Water Conservation Areas and severe damaging dryouts in the marshes will be significantly reduced. Urban and agriculture areas will benefit from the extra water storage and be less dependent on the natural areas to meet their needs. Substantially more water makes its way into the large sloughs of Everglades National Park and the seasonal timing of flows throughout Everglades is more natural. In short, by balancing the needs of the natural system with the needs of urban areas and agriculture, a plan was developed which results in considerable benefits throughout the system. South Florida has clearly outgrown its old water management infrastructure and this plan provides sustainable solutions.

In response to comments made by the public and in the draft Fish and Wildlife Coordination Act reports the Alternative Evaluation Team produced a series of issue papers and developed additional modeling scenarios from D-13R. A major impetus for developing these scenarios was to determine if additional water could be captured in the Lower East Coast urban areas and used to better meet performance measure targets in the Water Conservation Areas and Everglades

National Park as well as for investigating alternative sources of water for Biscayne Bay. Preliminary evaluation by the Alternative Evaluation Team of scenarios $D13R_{1-4}$ indicate that additional captured water helps to meet hydrologic targets for Everglades National Park, Biscayne Bay and some areas within the Water Conservation Areas. However, in other areas of the Water Conservation Areas and the Pennsuco Wetlands, performance declines markedly relative to D-13R. In addition, issues relative to treating urban runoff prior to discharge into the Water Conservation Areas and the Everglades, and potential flooding impacts to secondary canals have not been resolved. These remaining areas of concern and the ultimate amount of additional water recaptured and its distribution will be determined in the subsequent more detailed design phase of individual components.

In summary, the recommended Comprehensive Plan contains the array of components that has the most potential to achieve the Restudy's planning goals and objectives. The subsequent detailed design phase of individual components will address the outstanding performance issues associated with the recommended Comprehensive Plan including:

1. The plan needs to increase total overland flow to Florida Bay, northeast Shark River Slough and Taylor Slough to fully meet Natural System Model depth and duration targets.

2. The plan needs to improve ecological performance in the Water Conservation Areas by eliminating damaging high and low water conditions.

3. The plan should improve ecological conditions in Biscayne Bay by restoring more natural freshwater inflows.

4. The risks and uncertainties associated with using wastewater reuse as a water source for Biscayne Bay should be closely examined.

5. Restoration targets in the St. Lucie Estuary should be more closely met.

6. The plan needs to improve ecological performance in the Model Lands and C-111 Basins by providing adequate freshwater to maintain target hydropatterns.

SECTION 8
ENVIRONMENTAL EFFECTS

This section includes a brief summary of the expected beneficial and adverse physical, ecological, and socio-economic effects on resources of regional concern within the study area. It does not attempt to provide comprehensive coverage of all effects or all resources; rather its purpose is to provide a summary account of effects on a "big picture" scale. In all instances the assessment of effects is based on a comparison between the recommended Comprehensive Plan and the Without Plan Condition (2050 Base).

Further information on effects on the regional system and the ten study regions is available in ***Appendix K***. Detailed analyses of effects on water quality are available in ***Appendix H,*** air quality in ***Appendix I,*** and to socio-economics in ***Appendix E***. Supporting information, including Fish and Wildlife Coordination Act Reports supplied by the Department of Interior and the Florida Game and Fresh Water Fish Commission, and a Programmatic Biological Opinion on effects on threatened and endangered species, supplied by the U.S. Fish and Wildlife Service, are provided in ***Annexes A*** and ***B***, respectively.

8.1. SOILS

Peat soils in the central Everglades marshes are expected to be positively affected by the Comprehensive Plan. With the recovery of multi-year hydroperiods, especially in many overdrained slough regions, peat accretion is likely. Any measurable affects to soils would probably occur over a medium to long-term time scale. The Restudy should include plans for close monitoring of soil accretion and possible loss, with a view to providing a more accurate, detailed assessment in the future.

For peat soils, an increase in hydroperiod will result in retardation of subsidence. A decrease in hydroperiod will accelerate soil oxidation, rate of subsidence and frequency of peat fires. Immediate effects of a shorter hydroperiod would be soil shrinkage, alteration of vegetation types, and reduction in productivity of current agriculture. On a regional scale, the Comprehensive Plan results in generally longer hydroperiods. Therefore, areas containing peat soils will experience reduced soil subsidence, and possibly reduced frequency of peat fires. Furthermore, retardation of soil subsidence in certain areas may result in conditions favorable for optimal productivity and maintenance of desired vegetation.

8.2. GEOLOGY

No significant effect is anticipated on the geology of the study area as a result of implementation of Comprehensive Plan. The only geologic resource exploited in the study area is limerock, and this activity will not be affected. The construction of a seepage barrier or curtain wall within the Central Lake Belt area may locally affect geology and groundwater flows.

8.3. CLIMATE

Overall, climate is not expected to be directly or indirectly affected by implementation of the Comprehensive Plan. Possible moderating effects on local micro-climates near large above ground storage reservoirs may occur due to the fairly extreme change in land use from some blend of terrestrial and wetland environment to an open water environment for up to several months or longer each year.

8.4. AIR QUALITY

Air quality is not expected to be permanently affected by implementation of the Comprehensive Plan. Small to moderate localized and temporal impacts are likely to occur due to the use of earth moving equipment for levee degradation, and other construction activities over the period of project construction. Detailed information on effects on air quality within the study area are in ***Appendix I.***

8.5. NOISE

Implementation, operation and maintenance of the proposed project will have little effect on ambient noise levels. Noise levels will be moderate in both scope and scale, and limited to construction areas. These localized impacts would likely occur for relatively brief periods at any one location. On a regional basis however, noise impacts due to construction activities may occur for an extended period of time, as the schedule for construction activities may last up to 20-30 years prior to project completion. Additional pumps associated with regional Aquifer Storage and Recovery facilities will introduce a new noise source into the region, but most will be located far from inhabited areas. Within the Lower East Coast region pump operations will likely represent a new noise source for inhabitants and visitors to areas near the ASR facilities.

8.6. VEGETATION

Implementation of the Comprehensive Plan is expected to have profound effects on native and exotic vegetation. More natural hydroperiods should assist in restoring natural plant communities. The reduction in persistent high water levels in some areas that are now “too wet”, and the provision of more and better-timed water to regions that are now “too dry”, should result in a more natural mosaic of plant communities. Restored hydroperiods, decompartmentalization of important interior areas of the Everglades Protection Area, restoration of more natural sheet flow, and the filling of several interior canals, it is believed, are all changes that will benefit native vegetation to the detriment of exotics. Native vegetation will further benefit through restored water quality conditions (see ***Appendix H***), and removal of interior canals such as the C-6 and the L-29 borrow canal, among others, which act as transportation corridors for nutrients, pesticides, and exotic plants and animals.

The Comprehensive Plan reduces dependence on water storage in Lake Okeechobee by increasing water storage in the regional system. In the past, this storage has resulted in extreme high lake water levels that damage the littoral zone. Restored, moderate lake levels will aid in maintaining a more healthy marsh and littoral vegetative community. Alternative storage areas, proposed under the Comprehensive Plan, also reduce and improve the timing of water releases to the Caloosahatchee River Estuary, and St. Lucie Estuary, and into the Everglades Protection Area. Regulatory flood releases, which in the past have negatively affected salinity and seagrass beds in the estuaries, will be substantially reduced. Extreme high and low water events in the central Everglades will no longer be as pervasive or as damaging to freshwater marsh vegetation. Although unnaturally long hydroperiods still remain a concern in portions of the central Everglades, their impact is less under the Comprehensive Plan than under either the existing condition or the Without Plan Condition. Further improvements should be addressed during detailed studies, by operational changes, monitoring, and adaptive management practices designed to address uncertain results for certain actions.

The northern and central Everglades constitute roughly 900,000 acres of Everglades landscape. The managed system caused widespread loss of peat soils from over-drainage, followed by microbial oxidation and muck fires. Tree island vegetation was destroyed by muck fires in over-drained regions and by prolonged high water in deeply ponded areas. The Comprehensive Plan appears to make major progress toward solving these two critical problems. Although all of the final alternatives developed by the Restudy Team helped relieve drought conditions and damage to peat soils, the Comprehensive Plan provides the best reduction in extreme high-water conditions that would flood tree island plant communities. Existing flows to the southern Everglades, Shark River Slough and estuaries of Florida Bay are believed to be a principal cause of seagrass die-off and expansion of woody vegetation into coastal marshes. The Comprehensive Plan produces greater overland flow and restored hydroperiods in the southern Everglades, which should result in restored conditions for seagrasses in Florida Bay and interstitial lakes, reduce the spread of mangroves into coastal marshes, and woody vegetation into marl prairies (J. Ogden, pers. comm.).

The Comprehensive Plan resulted in an overall decrease in surface water discharges to Biscayne Bay from Snake Creek. The projected discharges from Snake Creek would be expected to cause significant fluctuations in salinity, which may adversely affect existing vegetation. However, these impacts may be minimized through operational modifications to the Lake Belt reservoirs.

8.7. FISH AND WILDLIFE

Fish and wildlife and their habitat are expected to greatly benefit under conditions brought about under the Comprehensive Plan.

Lake Okeechobee will function more as a natural lake, rather than as a reservoir with prolonged high lake stages. This change should benefit fish reproduction and growth. Juvenile fish and other small aquatic species depend on a healthy, vegetated littoral zone for food and cover. Under the Comprehensive Plan, ecological conditions within the Lake marsh and littoral zone, valuable habitat for the fishery, would be enhanced. Heterogeneity of vegetation assemblages will be protected with less frequent prolonged flooding and extreme drydown events. There will be lower phosphorus loading to the littoral zone from the open water zone of the Lake.

In the northern and central Everglades, the Comprehensive Plan tends to reduce extreme high and low water events at the expense of increasing hydroperiod in several areas. Compared to the Without Plan Condition, the plan improves conditions in southern Water Conservation Area-3A by reducing high water and in northern Water Conservation Area-3A by reducing drydowns, but may affect conditions in northeastern Water Conservation Area-3A and Water Conservation Area 3B by increasing high water. Across Trophic Level Systems Simulation (ATLSS) model results predict higher average fish abundance under the Comprehensive Plan than the Without Plan Condition. Restoration of this important link in the food chain would enhance not only the fishery, but those animals such as wading birds, alligators *(Alligator mississippiensis*), otters (*Lutra canadensis*), minks (*Mustela vison evergladensis*), raccoons *(Procyon lotor*), and predatory fish, that prey upon them. Longer hydroperiods in sloughs also will improve habitats for limpkins (*Aramus guarauna*), mottled ducks (*Anas fulvigula*), pied-billed grebes (*Podilymbus podiceps*), pig frogs (*Rana grylio*), crayfish (*Procambarus alleni*), and other organisms.

The reduction of excessive high water conditions in many portions of the Water Conservation Areas should provide slightly better foraging conditions and reduce white-tailed deer mortality due to starvation and drowning. Conditions in Water Conservation Areas 2B and 3B are still wetter than optimal and do not result in improved foraging conditions as they do in Water Conservation Area 3A, particularly south of I-75. In Everglades National Park where deer habitat is already poor, the Natural System Model-like conditions in the plan would further reduce quality. For those few areas with high deer breeding potential (Long Pine Key, surrounding short hydroperiod marsh and northwest Big Cypress), there will be little impact.

In the southern Everglades and Florida Bay, the Comprehensive Plan approaches modeled natural hydropatterns. Improved timing and duration of freshwater flows to the Florida Bay estuaries and improved timing of fish-concentrating drydowns should lead to improved wading bird foraging and breeding conditions in the southern Everglades, when compared to existing conditions or the Without Plan Condition. Wetter conditions in marl prairies and greater flow into mainland estuaries (lower salinity) should substantially improve degraded alligator habitat. Improved freshwater flows are also expected to markedly improve conditions for pink shrimp (*Penaeus duorarum*), and a variety of fish and invertebrate species that inhabit the mangrove swamps and Florida Bay.

The rehydration of coastal wetlands and shifting of point source canal flow to distributed overland flow should provide more stable estuarine conditions along the western shoreline of southern Biscayne Bay. Stabilized estuarine conditions will result in enhanced nursery habitat for estuarine-dependent organisms.

Within those areas proposed for large-scale above-ground reservoirs, Stormwater Treatment Areas and regional scale Aquifer Storage and Recovery systems, a potentially large number of acres of uplands and wetlands may be permanently altered due to the need to site these facilities in the least sensitive areas. This would include existing uplands and wetlands around Lake Okeechobee, within the Everglades Agricultural Area, Water Preserve Area, and Caloosahatchee River and St. Lucie River Basins. Even though upland resources are valuable in and of themselves, particularly within the study area where wetland resources are abundant, and uplands are relatively fewer, avoidance of wetlands over uplands generally receives priority in planning. Many of these uplands support wildlife habitat of some value and adverse impacts to sensitive, rare or particularly valuable habitat needs to be avoided or minimized whenever possible.

8.8. THREATENED AND ENDANGERED SPECIES

Within the regional system, improved habitat conditions are anticipated for the West Indian manatee (*Trichechus manatus latirostris*), American crocodile (*Crocodylus acutus*), snail kite (*Rostrhamus sociabilis*), wood stork (*Mycteria americana*), Cape Sable seaside sparrow (*Ammospiza maritima mirabilis*), and the Okeechobee gourd (*Cucurbita okeechobeensis*). In the case of the manatee and crocodile, this is due to substantially enhanced freshwater flows to Florida Bay, and decreased salinities in the Florida Bay and Shark River Slough estuarine habitats relative to the Without Plan Condition. For the snail kite, wood stork, and Cape Sable seaside sparrow, improvements in restoring more natural hydroperiods, with Natural System Model-like conditions throughout much of their habitat, leads to an overall regional improvement in their populations. In some instances there may be local, minor negative impacts to habitat, caused by vegetation shifts over time, or increased ponding depths in relatively small areas currently serving as functional foraging or breeding grounds.

The endangered Okeechobee gourd is also expected to benefit due to a reduced occurrence of high water events and flooding of its habitat on the south shore of Lake Okeechobee.

Locally, the Florida scrub jay (*Aphelocoma coerulescens*), bald eagle (*Haliaeetus leucocephalus*), caracara (*Polyborus plancus*), and eastern indigo snake (*Drymarchon corais couperi*) may be negatively impacted by the Comprehensive Plan, primarily by the construction and operation of new water storage and treatment areas, mostly within the Kissimmee River and Caloosahatchee River regions. Filling in of canals is also likely to negatively impact some eastern indigo snake habitat, and may cause direct mortality of snakes, as they are known to utilize crab holes as refugia. The impacts to these animals are not likely to jeopardize their continued existence.

The opinion of the Department of Interior regarding impacts to Federally listed threatened and endangered species resulting from implementation of the Comprehensive Plan, is stated in their preliminary programmatic biological opinion, dated August 7, 1998 and confirmed by letter dated March 1, 1999 as the final biological opinion (see ***Annex B***). The Opinion states that the Comprehensive Plan is not likely to jeopardize any of the listed species or adversely affect critical habitat.

8.9. WATER MANAGEMENT

For the Kissimmee Basin, water managers will use a climate based inflow forecasting model, in conjunction with operational rules, which will help them in deciding when to pump water to the storage facilities outside Lake Okeechobee. Under the Comprehensive Plan, most of the water previously stored in the lake at prolonged and even extreme lake stages and/or sent to tide via the estuaries, will be pumped to storage north of the lake (127,000 acre-feet on a mean annual basis) or to other storage facilities in the Everglades Agricultural Area, Caloosahatchee River (C-43) Basin or the St. Lucie (C-44) Basin.

Changes to the existing Lake Okeechobee operation schedule (Run-25) include operational changes only, except for the project features designed to enhance water storage outside of the lake. Water storage facilities are expected to reduce the frequency and duration of flood control releases to the St. Lucie and Caloosahatchee Estuaries. Water from Lake Okeechobee will be pumped into Aquifer Storage and Recovery wells when the climate-based inflow forecasting model projects that the lake water level will rise significantly above those levels that are desirable for the littoral zone. Water management of the lake will rely on existing structures that will not require modification. In order to meet capacity requirements for water conveyance to Aquifer Storage and Recovery facilities, and storage reservoirs, additional canals, resizing existing canals, pumps and conveyance structures will be constructed outside of the immediate lake area.

The Caloosahatchee Basin storage reservoir and Aquifer Storage and Recovery system will capture local basin runoff and releases from Lake Okeechobee. Water from the reservoir will be used to provide environmental deliveries to the Caloosahatchee Estuary, to meet demands in the Caloosahatchee Basin, and to inject water into the Aquifer Storage and Recovery wellfield for long-term (multi-seasonal) storage. Lake Okeechobee water will also be used to meet any remaining local basin demands subject to supply-side management. The operation of project components in the Caloosahatchee Basin will significantly improve regional water managers' abilities to meet local basin agricultural/urban demands as well as the environmental needs of the downstream estuary. Water will be pumped to the storage facilities in the Everglades Agricultural Area with increased conveyance from Lake Okeechobee to the reservoir. The purposes are to improve timing of environmental deliveries to the Water Conservation Areas (including damaging flood releases from the Everglades Agricultural Area to the Water Conservation Areas) reduce Lake Okeechobee regulatory releases to the estuaries, meet supplemental agricultural irrigation demands, and increase flood protection within the Everglades Agricultural Area.

The proposed storage areas under the Comprehensive Plan will significantly improve water management on the Upper East Coast relative to the Without Plan Condition. Water storage sites will allow localized rainfall runoff to be captured and used for flow augmentation to the St. Lucie Estuary when needed during the dry season. The greatest benefit will come from storage of peak rainfall inside the basins, and reduced loss of this turbid, nutrient-laden water to tide. The

Comprehensive Plan reduced the frequency of high-flow discharges to the estuary by nearly 80 percent.

The Comprehensive Plan introduced operational changes in Water Conservation Area 2A that improved inundation patterns in the north, but in so doing increased the frequency of extreme drought conditions in the south. It appears that water management in Water Conservation Area 2A imposes tradeoffs involving improved marsh conditions in some areas but worse conditions in others. If rainfall based operational rules are adopted for Water Conservation Area 1 in the future, such unnatural fluctuations in depth in Water Conservation Area 2A may be alleviated. Rather than combining high water in the south with over-drainage in the north, as is currently the case in all of the Water Conservation Areas, the Comprehensive Plan predicts longer hydroperiods near Stormwater Treatment Area-2 input in the north, increased drying in the south, and accumulation of water at the southern end of in Water Conservation Area 2B.

A number of components in the Comprehensive Plan lead to significant predicted changes in hydrologic conditions in Water Conservation Area 3A. The Comprehensive Plan succeeded in limiting the frequency of extreme high water events within the overall bounds defined for the natural system by the Natural System Model. This performance can clearly be credited to the barrier provided by the L-67 levee, which prevents excess build up of water within the northern and central sections of the Water Conservation Areas. The Comprehensive Plan predicts a lower frequency of extreme high water events, and reduced flooding in Water Conservation Area 3B relative to the Without Plan Condition. The Without Plan Condition however, still predicts drier conditions than the ideal restoration target in Northeast Shark River Slough.

The principal changes in water management will be an increase in the number of structures (levees, pumps, weirs, and canals) associated with the storage areas and their operation. A fairly complex operation schedule will have to be designed and implemented to maximize the benefits of these storage sites. Water will be pumped into and out of the storage areas, requiring fuel and causing additional noise to nearby areas.

The Water Preserve Areas located adjacent to the eastern protective levee will function to prevent seepage out of the Water Conservation Areas and Everglades National Park, increase Everglades spatial extent by restoring existing quality wetlands, capture and store excess water that is currently lost to tide, buffer the urban developed areas from the natural areas, and treat water prior to returning it to the natural system. They are a critical element of the Comprehensive Plan, particularly in terms of re-routing flows from Water Conservation Area 2 south to the Central Lake Belt and into Biscayne Bay and Everglades National Park. They will be highly effective at reducing undesirable discharges to Lake Worth Lagoon, as well as conserving water originating from the natural system, currently lost to tide through the east coast canals.

The proposed changes in water management associated with southern and central Biscayne Bay will be due to the shifting of point source canal flow to distributed overland flow and to the transport of recycled water to the Bay from wastewater reuse plants. The backpumping from canals to the Lake Belt reservoirs resulted in significant decreases in freshwater flows to Biscayne Bay from Snake Creek and the Miami River. The Comprehensive Plan may enhance saltwater intrusion protection for the surficial aquifer in the south Miami-Dade area due to increased canal stages in the dry season. The effects of above ground storage on flood protection will be positive. The western C-4, C-9, and Hillsboro basins are currently flood prone basins. Available above ground storage areas should greatly reduce flooding in those areas during storm events.

Overall, the remaining Everglades will be managed as a whole, not as individual subcomponents of the regional system. A number of hydrologic benefits could be gained by construction of the Everglades Construction Project and implementation of rainfall-driven hydropattern targets within the Everglades. Rainfall-based delivery plans for Water Conservation Areas 2A and 3A based on antecedent rainfall and natural system hydropatterns should be developed. In addition, modifications should be made to the Everglades National Park’s current rainfall-based delivery plans in a manner that replicates natural system-like conditions. Model results showed that using the rainfall-driven targets significantly improved the quantity, timing, and distribution of water delivered to Water Conservation Area 2A, Water Conservation Area 3A, and Everglades National Park to closely match natural pre-drainage conditions.

8.10. WATER QUALITY

The Comprehensive Plan is expected to improve water quality conditions in the study area; however, water quality improvement in south Florida must be viewed as an integrated effort with several interdependent parts. As outlined below, these include: several components and other project elements of the Comprehensive Plan, with emphasis on a proposed Comprehensive Integrated Water Quality Plan (see ***Section 9.7.3***); the State of Florida’s Everglades Forever Act; Surface Water Improvement and Management (SWIM) Act planning efforts, including the development of pollutant load reduction goals (PLRGs); development of total maximum daily loads (TMDLs) under Section 303(d) of the Federal Clean Water Act; and the Florida Keys Water Quality Protection Program.

Water quality was a consideration in every aspect of the Comprehensive Plan. Major features include creation of approximately 181,270 acres of surface water storage area, totaling approximately 1.5 million-acre feet of additional storage volume. Surface water storage areas will reduce pollution loading into downstream receiving water bodies through the attenuation of surface flows and settling of attendant pollution loads prior to discharge. The Comprehensive Plan also includes a feasibility study to develop a Comprehensive Integrated Water Quality Plan, which will ensure that Comprehensive Plan facilities will be designed and operated to achieve maximum water quality benefits. More detailed descriptions of the positive water quality benefits that will be provided to waterbodies across the Restudy project area from construction and operation of the water storage areas are provided in ***Appendix H*** and ***Attachment F*** (Water Quality, Environmental Effects).

Additionally, many components and other project elements of the Comprehensive Plan include treatment features to ensure that water quality conditions are improved. Specifically, the Comprehensive Plan includes over 19 Stormwater Treatment Areas totaling approximately 35,550 acres of treatment area. These Stormwater Treatment Areas represent additional storage and treatment volume beyond that provided by the storage areas. More detailed descriptions of the positive water quality benefits that will be provided to waterbodies across the Restudy project area from construction and operation of the Stormwater Treatment Areas is provided in ***Appendix H*** and ***Attachment F*** (Water Quality, Environmental Effects). Those components of the Comprehensive Plan involving Aquifer Storage and Recovery and wastewater reuse also include treatment facilities to meet applicable State of Florida water quality standards.

Furthermore, implementation of the Comprehensive Plan according to the Implementation Plan (see ***Section 10***) will lead to the optimization of water quality benefits, above and beyond merely increasing surface water storage. Significant benefits to water quality conditions in waterbodies in the following study regions are anticipated through construction and operation of the above-discussed water storage areas and Stormwater Treatment Areas: Lower Kissimmee River, Lake Okeechobee, St. Lucie River/estuary, southern Indian River Lagoon, Lake Worth Lagoon, Caloosahatchee River/estuary, the Everglades Protection Area, Biscayne Bay, and Florida Bay.

However, water quality restoration in all water bodies within the study area depends on actions outside the scope of the Restudy. To fully achieve ecological restoration in all regions of the study area, pollution loads must be identified and quantified within each of the study area regions, and load reduction and concentration targets for pollutants of concern must be established. Concurrent with or prior to the proposed operation of components of the Comprehensive Plan, water quality improvement programs for degraded and/or designated use-impaired water bodies must be implemented by the responsible agencies in order to fully achieve ecological restoration objectives.

In its 1998 report to the U. S. Environmental Protection Agency, the Florida Department of Environmental Protection identified approximately 160 use-impaired waterbodies in the study area in accordance with the requirements of Section 303(d) of the Federal Clean Water Act. Section 303(d) listing is based on designated and actual uses of waterbodies, ambient monitoring data, and water quality standards. The South Florida Water Management District, Florida Department of Environmental Protection, and other agencies have developed water quality improvement strategies for several of the impaired waterbodies within the Restudy area. The most notable example is the Everglades Forever Act, which focuses on achieving adequate water quality in the Everglades. Other examples include Surface Water Improvement and Management Act (SWIM) planning efforts for the Indian River Lagoon, Lake Okeechobee, and Biscayne Bay, and the Florida Keys National Marine Sanctuary Water Quality Protection Program. However, there is not, presently, a comprehensive water quality strategy for the entire Restudy area, and implementation of some of the existing water quality improvement plans has been limited by lack of funding to complete assessment and planning activities. Watershed assessments are necessary to develop pollutant source reduction programs and to design and construct water quality treatment facilities, if necessary.

To address the lack of a comprehensive water quality strategy for south Florida, the recommended plan includes a feasibility study to develop a Comprehensive Integrated Water Quality Plan (see ***Section 9.7.3***). Development of this plan will involve an interagency effort to ensure that recommended plan facilities are designed and operated to achieve maximum water quality benefits in watersheds where Restudy facilities are located. An essential element of the Comprehensive Integrated Water Quality Plan is the development of total maximum daily loads (TMDLs) of pollutants for specific use-impaired waterbodies, and subsequent implementation of management programs to achieve TMDL pollution reduction targets. It is anticipated that the Comprehensive Integrated Water Quality Plan will expedite the process of developing TMDL pollution reduction targets and management plans for water quality impaired waterbodies in the study area.

8.11. WATER SUPPLY

The Comprehensive Plan will substantially improve water supplies for the Lake Okeechobee and Lower East Coast Service Areas when compared to the future Without Plan Condition. The Comprehensive Plan meets public water demands, minimizes the duration of water supply cutbacks, and maintains saltwater intrusion stages in the primary coastal canals in this region. Compared to the Without Plan Condition, it greatly improves the ability to meet public water supply demands and prevent saltwater intrusion. All of the alternative plans reduce the dependence of users on Lake Okeechobee and the Water Conservation Areas by providing regional water from new storage facilities. In the Comprehensive Plan, 23 percent less water will be delivered from the Water Conservation Areas and Lake Okeechobee through the structures to the Lower East Coast than in the Without Plan Condition. The future for urban and agricultural water supply shows significant problems in the Without Plan Condition even if the health of the environment were not a consideration. The urban areas will benefit from a sustainable system that supports their future water supply demands and restores the Everglades ecosystem.

8.12. SOCIO-ECONOMICS

The economic impact evaluation of the alternative restoration plans includes the following:

- Agricultural water supply,
- Municipal and industrial (M&I) water supply,
- Flooding potential,
- Commercial navigation,
- Recreation (Everglades-related),
- Commercial and recreational fishing,
- Costs,
- Regional economic effects, and
- Other social effects.

Four of the above are translated into monetary terms. Positive effects of the different alternatives on agricultural water supply range from about $1.7 to $2.0 million on an average annual basis. The effect for the Comprehensive Plan is $1.9 million per year. Positive effects on municipal and industrial water supply range from $21.5 to $27.2 million annually, the latter being the estimated impact associated with the Comprehensive Plan. Costs of the plans, on a uniform annual equivalent basis, range from $254 to $402 million for the Comprehensive Plan. The initial costs for construction and real estate range from $5.2 to $7.8 billion for the Comprehensive Plan. Recurring annual costs for operation and maintenance, and monitoring, range from $70 to $165 million per year. Average annual regional effects on total sales range from +$173 to +$307 million. Employment effects range from about +1,700 to +3,165 jobs. Impacts on earnings range from $59 to $108 million per year. While these are large numbers, they are small taken in the context of total economic activity within the study area, accounting for about 1/10th of one percent of total economic activity within the study area.

Flooding impacts of the alternatives are inconclusive at this time, due to the limitations of the analytical tools available within the scope and time frame of this study. It is possible that some areas will benefit from reduced flooding, and some areas will require more detailed analysis. Such an analysis will be done as a part of any plan implementation.

Very small positive effects on commercial navigation in Lake Okeechobee are expected to result from any of the alternative plans. These effects are due to decreased occurrence of low stages.

Plan implementation may cause some significant impact on recreation. Recreation and tourism are significant economic activities in Florida, and small incremental changes to this large activity base have the potential to be significant. Potential negative impacts on recreation include, among others, the filling in of canals and closure of points of access to established fisheries, most notably along the L-29 and L-67A canals. It is anticipated that existing fishery resources impacted within the Everglades Protection Area, would be offset, in the long term, by reservoir construction proposed as a part of the Comprehensive Plan. These effects have not been quantified or translated into monetary values due to uncertainties regarding the actual timing and effects of alternatives on recreation, and regarding plans and policies for recreational facilities and marketing. Such details will become known during implementation planning expected to follow this study. Lacking a clear vision of these pertinent factors at this time, it would be speculating to quantify recreational effects of the Comprehensive Plan or any of the other alternatives.

The alternative plans have the potential to affect recreational and commercial fishing throughout south Florida by modifying the hydrologic regime in the region’s waterways and estuaries. The linkage between hydrologic changes and ecological changes is expected to be positive, which would possibly result in positive economic implications for fishing. Not enough is known about the linkages between fishing and hydrological changes, which would be brought about by plan implementation, nor is enough known about the timing of the linkages between these changes, the resulting ecological changes, and ultimately the changes in the value of fishing, to estimate the economic effects on fishing in this study. All of the plans are expected to positively impact fishing, with the exception of Biscayne Bay, whose fishery would likely benefit only under Alternative D and the Comprehensive Plan.

The most potentially significant “other social effects” consideration for the alternative plans concerns the development of new storage reservoirs in the rural areas surrounding Lake Okeechobee, and the consequences for urban and community impacts and displacement of people. These project features would convert farm land to reservoirs. Their development could eliminate the jobs of the individuals who are employed in the affected area and have adverse effects on local communities and economies. The potential locations of the new reservoirs are not known at this time. However, the resilience of local economies and the cohesion of local communities to agricultural land conversion depend on a variety of factors, including the age, ethnic, and racial composition of the community and income, unemployment, and poverty levels. A social vulnerability index was developed using county-scale socio-economic characteristics, and this type of analysis could be replicated in more detail when and if new reservoir sites are proposed.

8.13. LAND USE

The most significant effect on land use will be the proposed creation of approximately 181,270 acres of storage reservoirs within the Caloosahatchee River Basin, St Lucie River Basin, Kissimmee River Basin, the Everglades Agricultural Area, and the Lower East Coast. It is anticipated that the majority of the storage needs will be met with agricultural lands, undeveloped lands and lands adjacent to the east coast protective levees. Therefore, implementation of these features in the Comprehensive Plan will likely have an effect on existing agricultural land use.

Storage reservoirs designed to augment the regional water supply system will occupy 25,000 acres in the Kissimmee River region and 60,000 acres in the Everglades Agricultural Area. There is also proposed a 20,000 acre storage reservoir in the Caloosahatchee River basin, a 5,000 acre Stormwater Treatment Area in the Kissimmee River region and 10,000 acres of storage in the St. Lucie Canal Basin, on mostly existing agricultural or vacant lands. In the remaining Upper East Coast region, additional storage facilities are planned for the C-23, C-24, C-25, North Fork and South Fork Basins totaling 35,550 acres. The acreage proposed for these project features is subject to change depending on design depths, which will be determined during final design and specifications. Proposed Aquifer Storage and Recovery facilities include 200 5-Million Gallon per Day wells located near the landside of the Herbert Hoover Dike, which surrounds the Lake. These Aquifer Storage and Recovery wells will require some land for construction, operation, and maintenance. Agricultural production may be compatible with Aquifer Storage and Recovery wells, as the structures are expected to take up minimal land above ground. It appears likely; however, that more than 120,000 acres of land in the northern portion of the study area will be taken out of existing or future agricultural production. Conversion of 60,000 acres of agricultural land in the Everglades Agricultural Area to create storage reservoirs would be approximately a nine percent reduction of the area farmed in this region, which is designated as unique farmland. Implementation of the Comprehensive Plan should have no negative effect on future urban land use around Lake Okeechobee. Urban lands surrounding the lake should benefit through a greater, more consistent source of water for urban and industrial use, including continued flood protection, beyond that projected in the Without Plan Condition.

Several thousand acres of land will be needed for water management facilities in the Lower East Coast region. The lands proposed for the Water Preserve Areas in the Lower East Coast are generally vacant or are in agricultural production. It is assumed that the majority of these lands would eventually be designated urban land, especially low density residential. These urban land uses can in general be accommodated on other vacant lands or by increasing the density of development. The lake belt reservoirs, which are in-ground facilities, are not expected to diminish the land use of rock mining or impinge on productive agricultural land. Seepage management should not cause changes to existing land use, as minimal land is required for the wells and physical barrier methods. Seepage control components along eastern Water Conservation Areas 3A and 3B are located on wetlands. These components will lengthen the hydroperiods of the wetlands involved.

Land use within the Big Cypress Basin will not likely be significantly affected by implementation of the Comprehensive Plan. The urban areas along the Lower West Coast, including the municipalities of Naples, Everglades City, and Marco Island, are outside the area of hydrologic influence of the Comprehensive Plan and land use will be unaffected by the project.

The Comprehensive Plan does not include construction features in the Florida Keys, therefore it will not affect land use. However, improvements in freshwater flow, and lower salinities in upper Florida Bay, may enhance the pink shrimp fishery in the Keys.

8.14. RECREATION RESOURCES

Some limited impacts to recreation may be assumed under the Comprehensive Plan. In an effort to restore more natural sheet flow and reduce negative ecological and hydrologic effects wrought by interior canals, miles of canals would be filled and levees degraded. Some of these canals currently support regionally important sport fisheries. New opportunities for recreation resource growth would become available with the implementation of the Comprehensive Plan. These include the restoration of existing national and regionally significant fisheries, including Lake Okeechobee, Indian River Lagoon and others, and the creation of tens of thousands of acres of reservoirs, which could function, in part, as recreation resources. If properly sequenced, fishery resources could be established within new project features, prior to impacting existing canals scheduled for filling in through levee degradation.

Restoration of the Everglades, a unique and internationally recognized wetland resource with huge spatial extent, and proven recreation potential in and of itself, should provide vast benefits to recreation resources. Native wildlife game and non-game populations are expected to increase in a sustained manner under improved ecological conditions resulting from the Comprehensive Plan. It is reasonable to conclude that overall, there is greater regional recreation resource potential under the Comprehensive Plan than either the existing condition or the Without Plan Condition.

As stated previously, the Comprehensive Plan may result in an initial localized decline in the mileage of canals available to fishermen, some of these are of state-wide importance. According to Corps design and cost estimates for the Comprehensive Plan, approximately 72 miles of canals are scheduled to be filled, while 74 miles of new canals will be constructed, and 100 miles of existing canals will be widened. The planned construction of the Water Preserve Areas, in Palm Beach, Broward and Miami-Dade Counties offers an important potential for new water based recreational areas.

8.15. AESTHETIC RESOURCES

Restoration of the south Florida ecosystem is expected to result in a healthier environment that will support vigorous plant communities, larger fish and aquatic animal populations, large numbers of wading birds, alligators, and sustainable populations of wide-ranging mammals in a natural setting, in perpetuity. Viewing wildlife, wetlands and open, relatively pristine spaces are valued by people, as tourism statistics for south Florida would seem to support. Regardless, the anticipated increase in native animals and native plants alone will probably not appreciably impact aesthetics to the casual observer. To the casual observer, the Everglades may already meet those criteria, as it is already a wilderness of pristine character to the casual viewer. Implementation of the Comprehensive Plan will not so much change the aesthetic as ensure that a truly healthy and sustainable ecosystem exists into perpetuity.

There are undoubtedly some areas where degradation of the natural environment has reached the point where restoration benefits may be seen and appreciated. Improvements to water quality and clarity should benefit important parts of the environment currently being impacted, including the waters of Lake Okeechobee, the Everglades Protection Area, the estuaries, and Florida Bay. Reducing damaging freshwater releases into the Caloosahatchee and St. Lucie Estuaries will improve water quality and clarity, reduce seasonal fish kills, restore important seagrass beds, oyster beds, and improve estuarine fisheries and wading bird foraging. Improvements in inflow water quality, and an overall reduction in exotic vegetation, should enhance conditions for a more natural heterogeneous assemblage of native vegetation, providing the necessary conditions to support optimal wildlife populations.

8.16. CULTURAL RESOURCES

Component features at this stage of planning are conceptual and feature locations are not precisely determined. Under the tiering concept of NEPA, specific effects on culturally significant sites will be addressed and coordinated with the State Historic Preservation Officer under Section 106 of the National Historic Preservation Act. In the future, separate Environmental Assessments or supplemental Environmental Impact Statements will be prepared for each project feature, and cultural resources assessments will be conducted in support of those documents, when necessary. Specific effects on historic period and pre-Columbian period archeological sites and standing structures, engineering structures and architectural features will be evaluated after individual project feature sites are provided. Effects from the proposed project are anticipated to come from project feature construction, operational changes, erosion, human disturbance, and changes in the hydrologic regime of the flood plain.

The State Historic Preservation Officer, in a letter dated August 14, 1998, reaffirmed the archeological and historical potential of the C&SF Project area. They also acknowledged our commitment to adhere to the procedures outlined in 36 CFR Part 800, and concurred that at this stage of project planning, the Restudy will have no adverse effect on historic properties listed or eligible for listing on the National Register.

8.17. HAZARDOUS, TOXIC, AND RADIOACTIVE WASTES

A Phase I Hazardous, Toxic and Radioactive Waste (HTRW) site assessment was conducted in the general vicinity of proposed project features or existing features proposed for significant modification for the entire area of the Restudy. Several site visits were conducted over the past few years, with the most recent survey having been performed in August 1998. The HTRW database search was performed on the entire area and it indicated that overall, the majority of the proposed new construction areas are free of hazardous and toxic waste. Most of these general features are proposed for remote and rural areas, and were farms, vacant land, or wildlife management areas. The most common type of HTRW being hydrocarbons, was found along state highways where the majority of the gasoline stations had leaking underground storage tanks.

Perusal of relevant databases also revealed that several locations are National Priority Listed. Most of these National Priority Listed sites are due to past landfill operations. These sites are located in Palm Beach County, the Lower East Coast Lake Belt area in the vicinity of the S-9 Structure and in Broward County south of Alligator Alley. Contaminated sites located on the perimeter of any proposed water storage area may experience migration or expansion of leachate or other pollutants into the study area. Any such sites would require further survey and specific evaluation prior to detailed design. Another feature of concern is the numerous landfills and waste handling facilities in the Lower East Coast region. To the extent feasible, water storage areas should not be sited immediately adjacent to these known sites.

These findings and conclusions are of existing conditions at this time. The project conditions assume that any HTRW found during any phase of the project would be remediated in accordance with local, state and federal laws. Therefore, it can be assumed that conditions at future construction sites will be contamination free or of low levels, which would include de minimis conditions that generally do not present a material risk of harm to the public health or the environment.

8.18. UNAVOIDABLE ADVERSE ENVIRONMENTAL EFFECTS

Land Use (Agriculture)

Cumulatively, a significant number of acres of agricultural lands will be permanently removed from production due to the construction of large above ground storage reservoirs and Stormwater Treatment Areas. Affected areas are north of Lake Okeechobee, in the Caloosahatchee River and St. Lucie River Basins, and Upper East Coast Basins, and within the Everglades Agricultural Area. Further agricultural land use will be permanently removed from Palm Beach, Broward and Miami-Dade Counties due to the construction of the Water Preserve Areas.

Wetlands

A limited number of acres of wetlands will be permanently altered within the boundaries of the large above-ground storage reservoirs and Stormwater Treatment Areas, and within the Water Preserve Areas.

Uplands

A potentially large number of acres of uplands may be permanently altered within the boundaries of the large above-ground storage reservoirs and Stormwater Treatment Areas, and within the Water Preserve Areas. Due to their relative value in a study area rich in wetland resources, upland resource impacts should also be studied carefully during detailed planning in order to avoid or minimize impacts to particularly valuable or sensitive upland areas.

Water quality

Temporary increases in turbidity of local waters are expected from the removal of canals and levees and by the construction of raised roadways and other structures.

Air quality

Fugitive dust from vehicular traffic and earth moving will be unavoidable but insignificant overall.

Soils

Temporary disruption of soils is expected from the removal of canals and levees and most construction activities.

Wildlife

Significant short-term disruption of wading bird colonies is expected from altering hydroperiods in the Water Conservation Areas. Localized disturbances to fish and wildlife are expected from removal of canals and levees and from the elevation of roadways and construction of other structures.

Recreation

Limited impacts to recreation resources (canal fisheries for example) are expected. However, project features proposed under the Comprehensive Plan, including restoration of existing natural resources, construction of new canals, deep water storage reservoirs and Stormwater Treatment Areas, all offer potentially important recreation benefits, which should offset existing resource loss.

Cultural Resources

An unknown number of historic and archeological sites may be affected. Studies will identify significant sites and necessary mitigation will be developed, on a project-specific basis.

8.19. RELATIONSHIP BETWEEN SHORT TERM USES AND LONG TERM PRODUCTIVITY

While regional conditions will improve, short-term or localized problems will undoubtedly occur. For example, in the process of improving wading bird nesting and foraging areas regionally, existing rookeries may be affected. Although overall restoration of the Everglades watershed is expected to improve habitat for nesting wading birds regionally over time, the transition period might adversely affect regional wading bird populations. Proper sequencing of project features should mitigate impacts to existing wildlife resources expected to be impacted by restoration activities within their vicinity. Further study and close monitoring will be critical to recovery and maintaining viable wading bird populations during the implementation of the Comprehensive Plan.

8.20. IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

Construction of the proposed project will include many features considered permanent, or modifications to existing C&SF Project features, which may be deemed irreversible. This would include, for example, construction of large reservoirs, degradation of levees and filling in of canals. Construction of regional Aquifer Storage and Recovery facilities, curtain walls, large storage reservoirs, Stormwater Treatment Areas, Water Preserve Areas, and waste water reuse facilities, are all necessary for the restoration of the natural ecosystem and maintenance of the urban and agricultural system. These features on the scale proposed in the Restudy, are probably of such a magnitude that these features would represent an irreversible and irretrievable commitment of resources. Resources committed would include state and Federal funding to purchase lands and labor, energy and project materials to build, operate, and maintain the project.

Fish and wildlife habitat will be permanently altered, (converted to open water particularly in the case of storage reservoirs and Stormwater Treatment Area facilities). These features would likely be inundated for much of the year.

8.21. CUMULATIVE EFFECTS

Large areas north of Lake Okeechobee, within the Everglades Agricultural Area, around the Lake, in the Caloosahatchee River Basin, and on the Upper East Coast will be used to increase water storage for the overall gain and long-term benefit of the regional system. These project features will provide important storage functions and are essential to the overall restoration of the freshwater marshes and the estuaries. Project features will cause some adverse consequences to agricultural land use, permanently removing tens of thousands of acres from agricultural production. These impacts may be felt locally and/or regionally as the economic base derived from agriculture is incrementally reduced relative to other sectors of the economy. The overall benefit to the regional system is expected to be far greater than the localized adverse effects. As these features occur disparately across the landscape within different hydrologic basins, and as distinct units rather than multiple features within a single watershed, they will not likely result in a significantly detrimental cumulative effect.

Overall, the Restudy project elements in the Water Preserve Areas may cumulatively affect the current rate of westward expansion of Lower East Coast cities and may increase the value of other residential or potentially residential lands. Restudy project components are not expected to result in a cumulative negative effect on the human environment of the Lower East Coast. Project components in the area, especially storage, seepage control, redirection of point source canal flows to overland flow, and water reuse plants, will act to restore more natural freshwater flows to Biscayne Bay, reduce seepage losses from the Everglades, improve recharge of the Biscayne aquifer, and should result in other beneficial environmental effects. In order to support the construction, maintenance and operation of project features contained in the Comprehensive Plan, the cost of water in urban areas may rise beyond that predicted by the Without Plan Condition.

SECTION 9
THE RECOMMENDED COMPREHENSIVE PLAN

The recommended Comprehensive Plan is the Initial Draft Plan, Alternative D-13R, together with the Other Project Elements. The plan consists of construction and operation features, real estate requirements, mitigation, a monitoring program, and operation and maintenance of the completed project. The individual features of the recommended Comprehensive Plan were designed at various levels of detail based on information available during the plan formulation and evaluation phase. The details of the recommended plan are conceptual and more site-specific analyses will be needed to optimize the design and operations of the plan. In addition, several studies are recommended to investigate additional improvements needed to support restoration, protection, and preservation of the south Florida ecosystem.

The following principles guided the development of the recommended Comprehensive Plan:

- The overarching objective of the Comprehensive Plan is the restoration, preservation and protection of the south Florida ecosystem while providing for other water related needs of the region;
- The Comprehensive Plan will be based on the best available science and independent scientific review will be an integral part of its development and implementation;
- The Comprehensive Plan will be developed through an inclusive and open process that engages all stakeholders;
- All applicable Federal, tribal, state, and local agencies will be full partners and their views will be considered fully; and
- The Comprehensive Plan must be a flexible plan that is based on the concept of adaptive assessment – recognizing that modifications will be made in the future based on new information.

9.1 CONSTRUCTION FEATURES

A large number of construction features have been identified in the recommended Comprehensive Plan. These features were designed at various levels of detail based on information available during the plan formulation and evaluation phase. As described in ***Section 7***, the engineering design of the Other Project Elements was very limited. Further, many of the design assumptions for components in the Initial Draft Plan were based solely on output from the South Florida Water Management Model (refer to ***Appendix B*** for more detailed description of this model), which averages hydrologic conditions across grid cells totaling four square miles. Consequently, the engineering details of the construction features, including the size and location, are conceptual. Conceptual planning of many of the construction and operation features did not involve detailed planning and design work necessary to optimize features to achieve all ecosystem restoration performance objectives, particularly on a smaller, local scale. In particular, conceptual planning work completed to date is not adequate to determine construction design features necessary to achieve basin-specific water quality performance objectives. Furthermore, water quality benefits of conceptual features of the recommended plan could not be fully evaluated for all regions of the study area during alternative plan formulation and evaluation because modeling and other predictive tools were not available. More site-specific analyses of the recommended plan features will be needed to determine the optimum size, location, depth and configuration in subsequent phases of this project. Subsequent site-specific analyses performed during the implementation phase will include collecting necessary physical and water quality data, finalizing hydrologic and water quality performance targets, conducting refined modeling and pilot projects, and resolving regulatory issues. In a number of cases, construction features, such as reservoirs, were not specifically sited in the Comprehensive Plan. In these cases, a cooperative effort with landowners in the areas where these features are proposed will be used to identify suitable sites in subsequent phases of this project.

The construction features in the recommended Comprehensive Plan are described in the following sub-sections by study region. In some cases, the construction features include multiple components. These components were grouped based on their dependency upon one another. For example, outlet conveyance improvements to Water Conservation Area 3 from the Central Lake Belt component were combined with the Central Lake Belt Storage Reservoir component. The component designation that was used during plan formulation is included in parentheses, e.g. (A). Other Project Elements are identified as (OPE).

9.1.1 Kissimmee River Region

9.1.1.1 North of Lake Okeechobee Storage Reservoir (A)

This feature includes an above-ground reservoir and a 2,500-acre stormwater treatment area. The total storage capacity of the reservoir is approximately 200,000 acre-feet and is located in the Kissimmee River Region, north of Lake Okeechobee. The specific location of this facility has not been identified, however, it is anticipated that the facility will be located in Glades, Highlands, or Okeechobee Counties. The initial design of this feature assumed a 20,000-acre facility (17,500-acre reservoir and 2,500-acre treatment area) with water levels in the reservoir fluctuating up to 11.5 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning, land suitability analyses, and design. Future detailed planning and design activities will also include an evaluation of degraded waterbodies within the watersheds of the storage/treatment facility to determine appropriate pollution load reduction targets, and other water quality restoration targets for the watershed.

The purpose of this facility is to detain water during wet periods for later use during dry periods and reduce nutrient loads flowing to the lower Kissimmee River and Lake Okeechobee. This increased storage capacity will reduce the duration and frequency of both high and low water levels in Lake Okeechobee that are stressful to the Lake's littoral ecosystems, and cause large discharges from the Lake that are damaging to the downstream estuary ecosystems. Depending upon the proposed location(s) of this water storage/treatment facility and pollutant loading conditions in the watershed(s), the facility could be designed to achieve significant water quality improvements, consistent with appropriate pollution load reduction targets.

The operation of this feature assumes that water from Lake Okeechobee, the Kissimmee River or the S-65E drainage basin will be pumped into the storage reservoir/stormwater treatment area when the climate-based inflow model (see ***Appendix B***) forecasts that the Lake water levels will rise significantly above desirable levels for the Lake littoral zone. Water held in the reservoir and stormwater treatment area will not be released until the lake levels decline to ecologically acceptable levels.

9.1.1.2 Taylor Creek/Nubbin Slough Storage and Treatment Area (W)

This feature includes an above-ground reservoir with a total storage capacity of approximately 50,000 acre-feet and a stormwater treatment area with a capacity of approximately 20,000 acre-feet in the Taylor Creek/Nubbin Slough Basin. The initial design of this feature assumed a reservoir of 5,000 acres with water levels fluctuating up to 10 feet above grade and a stormwater treatment facility of approximately 5,000 acres. The final size, depth and configuration of this feature will be determined through more detailed planning, land suitability analysis and design.

The purpose of this feature is to attenuate flows to Lake Okeechobee and reduce the amount of nutrients flowing to the Lake. The feature is designed to capture, store, and treat basin runoff during periods when levels in Lake Okeechobee are high or increasing. The water quality treatment element of this feature is consistent with the recommendations of the South Florida Ecosystem Restoration Working Group's Lake Okeechobee Issue Team and the Pollution Load Reduction Goals for Lake Okeechobee developed for the Lake Okeechobee Surface Water Improvement and Management Plan (SFWMD, 1997f). The water held in the reservoir would be released to Lake Okeechobee when lake levels decline to ecologically acceptable levels.

9.1.1.3 Lake Okeechobee Watershed Water Quality Treatment Facilities (OPE)

This feature includes two reservoir-assisted stormwater treatment areas and plugging of select local drainage ditches. The initial design of these reservoir-assisted stormwater treatment areas assumes a 1,775-acre facility in the S-154 Basin in Okeechobee County and a 2,600-acre facility in the S-65D sub-basin of the Kissimmee River Basin in Highlands and Okeechobee Counties. The plugged drainage ditches will result in restoration of approximately 3,500 acres of wetlands throughout the Lake Okeechobee watershed basin. This feature is also consistent with the recommendations of the South Florida Ecosystem Restoration Working Group's Lake Okeechobee Issue Team for achieving water quality restoration objectives in the Lake and should provide significant long-term water quality benefits for the Lake.

The other portion of this feature includes the purchase of conservation easements within four key basins of Lake Okeechobee to restore the hydrology of isolated wetlands by plugging the connection to drainage ditches and the diversion of canal flows to adjacent wetlands. The sites range in size from an individual wetland to an entire sub-basin and are located within the lower Kissimmee River Basins (S-65D, S-65E, and S-154) and Taylor Creek/Nubbin Slough Basin (S-191).

The purpose of this feature is to attenuate peak flows and retain phosphorus before flowing into Lake Okeechobee. Further, many of the wetlands in the Lake Okeechobee watershed have been ditched and drained for agriculture water supply and flood control. This feature will restore the hydrology of selected isolated and riverine wetlands in the region by plugging these drainage ditches.

The South Florida Ecosystem Restoration Working Group's Lake Okeechobee Issue Team identified six primary tributary basins (C-41 Basin, Fisheating Creek, Taylor Creek/Nubbin Slough, S-154 Basin, S-65D (Pool D) Basin, S-65E (Pool E) Basin) contributing significant phosphorus loads to the Lake. In order to further reduce nutrient loading to Lake Okeechobee in support of the water quality goals for the Lake, articulated in the Lake Okeechobee Surface Water Improvement Management Plan, there are potentially other reservoir-assisted stormwater treatment area facilities needed in the Lake Okeechobee watershed (such as in the C-41 and Fisheating Creek Basins) that are not included in this construction feature. Therefore, it is proposed that a comprehensive plan for the Lake Okeechobee watershed be developed before the final configuration of this construction feature is implemented. A comprehensive Lake Okeechobee watershed plan would include elements of the Lake Okeechobee Surface Water Management Plan and remediation programs developed to achieve appropriate pollution reduction targets established for the Lake.

9.1.1.4 Lake Okeechobee Tributary Sediment Dredging (OPE)

This feature includes the dredging of sediments from 10 miles of primary canals within an 8-basin area in the northern watershed of Lake Okeechobee. The initial design assumes that the dredged material will contain approximately 150 tons of phosphorus.

The purpose of this feature is to remove phosphorous in canals located in areas of the most intense agriculture in the Lake Okeechobee watershed. These sediments presently contribute to the excessive phosphorus loading to Lake Okeechobee. A partnership with local landowners will be pursued for the disposal of the dredged material on uplands. The South Florida Water Management District has programmed a demonstration project to be implemented in 1999. Findings from this demonstration project will be used for detailed planning and design of this construction feature. This feature is also consistent with the water quality restoration goals for the Lake included in the Lake Okeechobee Surface Water Management Plan and subsequently developed by the Lake Okeechobee Issue Team. Implementation of this feature will also complement other activities associated with pollution reduction for the Lake.

9.1.1.5 Lake Istokpoga Regulation Schedule (OPE)

This feature includes development of a plan to address water resource problems in the Lake Istokpoga Basin. Lake Istokpoga is a natural lake located in Highlands County, a tributary of Lake Okeechobee and the Kissimmee River. The major focus of this plan is to create a balance between the environmental needs, water supply and flood control in the Lake Istokpoga drainage basin.

The purpose of this plan is to examine the Lake Istokpoga Basin with a view towards enhancing fish and wildlife benefits and developing a long-term comprehensive management plan. It has been noted that operation of S-68, beginning in 1962, reduced the maximum annual fluctuation of the Lake (SFWMD, 1978). While the littoral zone expanded, the amount of quality habitat was reduced by this formation of extensive floating tussocks and dense cattail communities. Persistently lowered lake levels have reduced the natural frequency of seasonal drying and inundation. Without natural dewatering events, germination of diverse aquatic plant seeds is reduced, consolidation and compaction of organic sediments cannot occur, and the formation and expansion of floating mats of water hyacinths and other species common to tussock communities are promoted. These mats reduce overall productivity and diversity of the marsh.

The plan will also address the need for flood protection to the perimeter and upstream tributaries, and downstream areas west and east of C-41A. Water supply needs for agriculture and the Seminole Tribe of Florida will also be addressed.

9.1.2 Lake Okeechobee Region

9.1.2.1 Lake Okeechobee Aquifer Storage and Recovery (GG)

This feature includes a series of aquifer storage and recovery wells adjacent to Lake Okeechobee with a capacity of 1-billion gallons per day and associated pre- and post- water quality treatment in Glades and Okeechobee Counties. The initial design assumes 200 wells, each with the capacity of 5 million gallons per day with 8-ultrafiltration water quality pre-treatment facilities and aeration for post-treatment. Based on information for existing aquifer storage and recovery facilities, it is assumed that recovery of aquifer-stored water would have no adverse effects on water quality conditions in Lake Okeechobee. In fact, some level of nutrient load reduction may occur as a result of aquifer storage, which would be a long-term benefit to in-lake water quality conditions. The level and extent of treatment and number of the aquifer storage and recovery wells may be modified based on findings from a proposed aquifer storage and recovery pilot project (U.S. Environmental Protection Agency, 1999). The pilot project would also investigate changes to water chemistry resulting from aquifer storage and identify post-retrieval water quality treatment requirements, if any, necessary to implement aquifer storage and recovery facilities. The Implementation Plan (Section 10) includes pilot studies to investigate the proposed facilities, including water quality changes associated with aquifer storage and recovery.

The purpose of this feature is to: (1) provide additional regional storage while reducing both evaporation losses and the amount of land removed from current land use (e.g. agriculture) that would normally be associated with construction and operation of above-ground storage reservoirs; (2) increase the Lake's water storage capability to better meet regional water supply demands for agriculture, Lower East Coast urban areas, and the Everglades; (3) manage a portion of regulatory releases from the Lake primarily to improve Everglades hydropatterns and to meet supplemental water supply demands of the Lower East Coast; (4) reduce harmful regulatory discharges to the St. Lucie and Caloosahatchee Estuaries; and (5) maintain and enhance the existing level of flood protection.

The operation of this feature assumes that after treatment, water from Lake Okeechobee will be injected into the upper Floridan Aquifer when the climate-based inflow model forecasts that the Lake water level will rise significantly above those levels that are desirable for the Lake littoral zone. During the dry season, water stored in the Floridan Aquifer will be returned to the Lake after aeration either when the Lake water level is projected to fall to within three quarters of a foot of the supply-side management line or below an established water level during the dry season.

9.1.3 Caloosahatchee River Region

9.1.3.1 C-43 Basin Storage Reservoir and Aquifer Storage and Recovery (D)

This feature includes above-ground reservoir(s) with a total storage capacity of approximately 160,000 acre-feet and aquifer storage and recovery wells with a capacity of approximately 220 million gallons per day and associated pre- and post-water quality treatment located in the C-43 Basin in Hendry, Glades, or Lee Counties. The initial design of the reservoir(s) assumed 20,000 acres with water levels fluctuating up to 8 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design. The initial design of the wells assumed 44 wells, each with the capacity of 5 million gallons per day with chlorination for pre-treatment and aeration for post-treatment. The level and extent of treatment and number of the aquifer storage and recovery wells may be modified based on findings from a proposed aquifer storage and recovery pilot project (U.S. Environmental Protection Agency, 1999).

The purpose of this feature is to capture C-43 Basin runoff and releases from Lake Okeechobee. These facilities will be designed for water supply benefits, some flood attenuation, to provide environmental water supply deliveries to the Caloosahatchee Estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. It is assumed that, depending upon the location of the facility and pollutant loading conditions in the watershed, the facility could be designed to achieve significant water quality improvements, consistent with appropriate pollution load reduction targets.

Excess runoff from the C-43 Basin and Lake Okeechobee flood control discharges will be pumped into the proposed reservoir. Water from the reservoir will be injected into the aquifer storage and recovery wellfield for long-term (multi-season) storage. Any estuarine demands, not met by basin runoff and the aquifer storage and recovery wells, will be met by Lake Okeechobee as long as the lake stage is above a pre-determined level. Lake water is also used to meet the remaining basin demands subject to supply-side management. The C-43 reservoir is operated in conjunction with the Caloosahatchee Backpumping feature, which includes a stormwater treatment area for water quality treatment. If the level of water in the reservoir exceeds 6.5 feet and Lake Okeechobee is below a pre-determined level, then water is released and sent to the backpumping facility.

9.1.3.2 Caloosahatchee Backpumping with Stormwater Treatment (DDD)

This feature includes pump stations and a stormwater treatment area with a total capacity of approximately 20,000 acre-feet located in the C-43 Basin in Hendry and Glades Counties. The initial design of the stormwater treatment area assumed 5,000 acres with the water level fluctuating up to 4 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design.

The purpose of this feature is to capture excess C-43 Basin runoff, which will be used to augment regional system water supply.

This feature operates after estuary and agricultural/urban demands have been met in the basin and when water levels in the C-43 storage reservoir exceed 6.5 feet above grade. Lake Okeechobee must also be considered to have available storage. When these conditions are met, a series of pump stations will backpump excess water from the reservoir and the C-43 Basin to Lake Okeechobee after treatment through a stormwater treatment area. The stormwater treatment area will be designed to meet Lake Okeechobee phosphorus and other pollutant loading reduction targets consistent with the Surface Water Improvement and Management Plan for the Lake and future appropriate pollution load reduction targets which may be developed for the Lake and the watershed in which the facility is to be located.

9.1.4 Upper East Coast

9.1.4.1 C-44 Basin Storage Reservoir (B)

This feature includes an above-ground reservoir with a total storage capacity of approximately 40,000 acre-feet located in the C-44 Basin in Martin County. The initial design of the reservoir assumed 10,000 acres with the water levels fluctuating up to 4 feet above grade. The final location, size, depth and configuration of this facility will be determined through more detailed analysis to be completed as a part of the ongoing Indian River Lagoon Feasibility Study.

The purpose of the feature is to capture local runoff from the C-44 Basin, then return the stored water to the C-44 when there is a water supply demand. The reservoir will be designed for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to control salinity and reduce loading of nutrients, pesticides, and other pollutants contained in runoff presently discharged to the estuary.

9.1.4.2 C-23/C-24/C-25/Northfork and Southfork Storage Reservoirs (UU)

This feature includes above-ground reservoirs with a total storage capacity of approximately 349,400 acre-feet located in the C-23/C-24/C-25/Northfork and Southfork Basins in St. Lucie and Martin Counties. The initial design of the reservoirs assumed 39,000 acres with water levels fluctuating up to 8 feet above grade and 9,350 acres with water levels fluctuating up to 4 feet above grade. The final location, size, depth and configuration of these facilities will be determined through more detailed analysis to be completed as a part of the Indian River Lagoon

Feasibility Study. It is noted that experience from the Upper St. Johns Project reveals that greater variability of water levels are more desirable for the ecology and water quality.

The purpose of this feature is to capture local runoff from the C-23/C-24/C-25/Northfork and Southfork Basins for flood flow attenuation to the St. Lucie River Estuary. It is assumed that this feature can be designed to provide significant water quality improvement benefits to the Indian River Lagoon and St. Lucie River Estuary in terms of reduced loading of nutrients, pesticides, and suspended materials in stormwater runoff which is presently conveyed to those waterbodies. Interim Pollution Load Reduction Goals for total suspended material, total nitrogen, and total phosphorus have already been developed for the Indian River Lagoon Surface Water Improvement and Management Plan (SFWMD and SJRWMD, 1994). This water will then be used to provide both water supply and environmental water supply benefits.

9.1.5 Everglades Agricultural Area

9.1.5.1 Everglades Agricultural Storage Reservoirs (G)

This feature includes above-ground reservoir(s) with a total storage capacity of approximately 360,000 acre-feet located in the Everglades Agricultural Area in western Palm Beach County and conveyance capacity increases for the Miami, North New River, and Bolles and Cross Canals. The initial design for the reservoir(s) assumed 60,000 acres, divided into three, equally sized compartments (1, 2, and 3), with the water level fluctuating up to 6 feet above grade in each compartment. The final size, depth and configuration of this facility will be determined through more detailed planning and design.

The purpose of this feature is to improve the timing of environmental deliveries to the Water Conservation Areas, including reducing damaging flood releases from the Everglades Agricultural Area to the Water Conservation Areas, reducing Lake Okeechobee regulatory releases to the estuaries, meeting Everglades Agricultural Area irrigation and Everglades water demands, and increasing flood protection in the Everglades Agricultural Area.

Runoff from the Everglades Agricultural Area, Miami and North New River Canal Basins and regulatory releases from Lake Okeechobee will be pumped into the reservoirs. Compartment 1 discharges will be used to meet Everglades Agricultural Area irrigation demands only. Compartment 2 discharges will be used to meet environmental demands as a priority and can be used to supply a portion of agricultural demands if the environmental demands equal zero. Compartment 3 discharges will be used to meet environmental demands. The storage compartments can also be designed to provide a water quality treatment function, augmenting the performance of the Everglades Construction Project and ensuring protection of water quality in the Everglades Protection Area. Design of this feature for water quality performance will be based on water quality targets for the Everglades Construction Project and other water quality targets developed to protect designated uses in Everglades Agricultural Area waters.

9.1.6 Big Cypress Region

9.1.6.1 Big Cypress/L-28 Interceptor Modifications (CCC)

This feature includes modification of levees and canals, water control structures, pumps, and stormwater treatment areas with a total storage capacity of 7,600 acre-feet located within and adjacent to the Miccosukee and Seminole Indian Reservations in Collier and Hendry Counties. The initial design of the stormwater treatment areas assumed a total acreage of 1,900 acres with the water level fluctuating up to 4 feet above grade. Conceptual sizes of the stormwater treatment areas were based on interim phosphorus concentration targets in the conceptual plan for the Everglades Construction Project. The final size, depth and configuration of this facility, including the stormwater treatment areas, will be determined through more detailed planning and design. Design of the stormwater treatment areas will be based on water quality criteria of the Seminole Tribe and criteria applicable to Big Cypress National Preserve, as appropriate.

The purpose of this feature is to reestablish sheetflow from the West Feeder Canal across the Big Cypress Reservation and into the Big Cypress National Preserve, maintain flood protection on Seminole Tribal lands, and ensure that inflows to the North and West Feeder Canals meet applicable water quality standards. Consistency with the Seminole Tribe's Conceptual Water Conservation System master plan will be maintained.

Upstream flows entering the West and North Feeder Canals will be routed through two stormwater treatment areas to be located at the upstream ends of the canals. Sheetflow will be reestablished south of the West Feeder Canal by a system to be developed consistent with the Seminole Tribe's Conceptual Water Conservation System master plan. After conversion to a pump station, S-190 will also push flows south into the L-28 Interceptor Canal where sheetflow to the southwest will also be reestablished with backfilling of and degradation of the southwest levee of the canal.

9.1.6.2 Seminole Tribe Big Cypress Water Conservation Plan (OPE)

This feature includes construction of water control, management, and treatment facilities in the Big Cypress Reservation. The construction elements include conveyance systems, major canal bypass structures, irrigation storage cells, and water resource areas.

The purpose of this feature is to improve the quality of water and runoff from phosphorus generating agricultural sources within the Reservation. The area is traversed by the L-28 and L-28I Borrow Canals and the North and West Feeder Canals, all of which were constructed as part of the C&SF Project. This comprehensive watershed management system is designed to achieve environmental restoration on the Reservation, the Big Cypress Preserve, and the Everglades Protection Area. In addition, the project will reduce flood damage and promote water conservation.

The removal of pollutants will be achieved using natural treatment processes in pretreatment cells and water storage areas. A phosphorus level of 50 ppb is the goal, which is the current level to be achieved by the stormwater treatment areas of the Everglades Construction Project. Should design performance levels for phosphorus become more stringent, this project has sufficient flexibility to incorporate additional alternative technology.

9.1.7 Water Conservation Areas

9.1.7.1 Flow to Northwest and Central Water Conservation Area 3A (II and RR)

This feature includes relocation and modifications to pump stations and development of a spreader canal system located in the northwest corner and west-central portions of Water Conservation Area 3A in western Broward County.

The purpose of this feature is to increase environmental water supply availability, increase depths and extend wetland hydropatterns in the northwest corner and west-central portions of Water Conservation Area 3A.

Additional flows will be directed to the northwest corner and west central portions of Water Conservation Area 3A by increasing the capacity of the G-404 pump station, currently a part of the Everglades Construction Project, and increasing the capacity and relocating the S-140 pump station. A spreader canal system at S-140 will reestablish sheetflow to the west-central portion of Water Conservation Area 3A. Water quality treatment of flows is assumed to be provided by the Everglades Construction Project and water quality treatment strategies developed to fulfill the Non-Everglades Construction Project requirements of the Everglades Forever Act. If additional treatment is determined to be required as a result of future detailed planning and design work, those existing facilities would be modified to provide the necessary treatment.

9.1.7.2 Water Conservation Area 3 Decompartmentalization and Sheetflow Enhancement (AA, QQ and SS)

These features include the construction of new water control structures and the modification or removal of levees, canals, and water control structures in Water Conservation Area 3A and B located in western Broward County.

The purpose of these features is to reestablish the ecological and hydrological connection between Water Conservation Areas 3A and 3B, the Everglades National Park, and Big Cypress National Preserve.

Sheetflow obstructions will be removed with the backfilling of the Miami Canal and southern 7.5 miles of L-67A Borrow Canal, removal of the L-68A, L-67C, L-29, L-28, and L-28 Tieback Levees and Borrow Canals, and elevating of Tamiami Trail. Water supply deliveries to Miami-Dade County, previously made through the Miami Canal, will be rerouted through an expanded North New River Canal and southern conveyance system. Eight passive weir structures to be located along the entire length of L-67A will also promote sheetflow from Water Conservation Area 3A to 3B during high flow conditions.

9.1.7.3 Loxahatchee National Wildlife Refuge Internal Canal Structures (KK)

This feature includes two water control structures in the northern ends of the perimeter canals encircling the Loxahatchee National Wildlife Refuge (Water Conservation Area 1) located in Palm Beach County.

The purpose of this feature is to improve the timing and location of water depths within the Refuge. It is assumed that these structures will remained closed except to pass Stormwater Treatment Area 1 East and Stormwater Treatment Area 1 West outflows and water supply deliveries to the coastal canals.

9.1.7.4 Miccosukee Tribe Water Management Plan (OPE)

This feature includes construction of a 900-acre wetland retention/detention area on the Miccosukee Tribe's Alligator Alley Reservation. The feature includes a pump station, levees, trenches and culverts to create the inflow and outflow facilities for the retention/detention area.

The purpose of this feature is to provide water storage capacity and water quality enhancement for tribal reservation waters which discharge from tribal lands and downstream into the Everglades Protection Area.

9.1.8 Lower East Coast Region

9.1.8.1 Pal-Mar and J.W. Corbett Wildlife Management Area Hydropattern Restoration (OPE)

This feature includes water control structures, canal modifications and the acquisition of 3,000 acres located between Pal-Mar and the J.W. Corbett Wildlife Management Area in Palm Beach County.

The purpose of this feature is to provide hydrologic connections between the Corbett Wildlife Management Area and: (1) the Moss Property, (2) the C-18 Canal, (3) the Indian Trail Improvement District, and (4) the L-8 Borrow Canal, in addition to extending the spatial extent of protected natural areas. These connections would relieve the detrimental effects on native vegetation frequently experienced during the wet season and form an unbroken 126,000-acre greenbelt extending from the Dupuis Reserve near Lake Okeechobee across the J.W. Corbett Wildlife Management Area and south to Jonathan Dickinson State Park.

9.1.8.2 Water Preserve Areas / L-8 Basin (K and GGG)

This feature includes a combination above-ground and in-ground reservoir with a total storage capacity of approximately 48,000 acre-feet located immediately west of the L-8 Borrow Canal and north of the C-51 Canal in Palm Beach County. Other construction features include aquifer storage and recovery wells with a capacity of 50 million gallons per day and associated pre- and post- water quality treatment to be constructed in the City of West Palm Beach (Lake Mangonia), a series of pumps, water control structures, and canal capacity improvements in the M Canal. The initial design for the reservoir assumed a 1,800-acre reservoir with 1,200 usable acres with the water level fluctuating from 10 feet above grade to 30 feet below grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design. The initial design of the wells assumed 50 wells, each with a capacity of 5 million gallons per day with chlorination for pre-treatment and aeration for post-treatment. The level and extent of treatment and number of the aquifer storage and recovery wells may be modified based on findings from a proposed aquifer storage and recovery pilot project.

The purpose of this feature is to increase water supply availability and flood protection for northern Palm Beach County areas. It will also provide flows to enhance hydroperiods in the Loxahatchee Slough, increase base flows to the Northwest Fork of the Loxahatchee River, and reduce high discharges to the Lake Worth Lagoon.

Water will be pumped into the reservoir from the C-51 Canal and Southern L-8 Borrow Canal during the wet season, or periods when excess water is available, and returned to the C-51 and Southern L-8 during dry periods. Additional features will also direct excess water into the West Palm Beach Water Catchment Area. During periods when the West Palm Beach Water Catchment Area is above desirable stages, 50 million gallons per day will be diverted to Lake Mangonia for storage in the aquifer storage and recovery wells. The reservoir portion of this component may be implemented under a previous authorization

9.1.8.3 Acme Basin B Discharge (OPE)

This feature includes the construction of a wetland or chemical treatment area and a storage reservoir with a combined total storage capacity of 3,800 acre-feet located adjacent to the Loxahatchee National Wildlife Refuge in Palm Beach County. The initial design for the treatment area and reservoir assumed 310 acres with the water level fluctuating up to 4 feet above grade and 620 acres with the water level fluctuating up to 8 feet above grade. The final size, depth and configuration of these facilities will be determined through more detailed planning and design.

The purpose of this feature is to provide water quality treatment and stormwater attenuation for runoff from Acme Basin "B" prior to discharge to the Loxahatchee National Wildlife Refuge or alternative locations described below. Excess available water may be used to meet water supply demands in central and southern Palm Beach County.

Stormwater runoff from Acme Basin "B" will be pumped into the wetland treatment area and then into the storage reservoir until such time as the water can be discharged into the Loxahatchee National Wildlife Refuge if water quality treatment criteria is met or into the one of two alternative locations: the Palm Beach County Agricultural Reserve Reservoir (VV) or the combination above-ground and in-ground reservoir area located adjacent to the L-8 Borrow Canal and north of the C-51 Canal(GGG).

9.1.8.4 Lake Worth Lagoon Restoration (OPE)

This feature includes sediment removal and trapping within the C-51 Canal and sediment removal or trapping within a 2.5 mile area downstream of the confluence of the C-51 Canal and the Lake Worth Lagoon located in Palm Beach County. A prototype project will be conducted to determine if the Lagoon sediments will either be removed or trapped.

The purpose of this feature is to improve water quality and allow for the reestablishment of sea grasses and benthic communities. The elimination of the organically enriched sediment from the C-51 Canal discharge will provide for long term improvements to the Lagoon and enable success for additional habitat restoration and enhancement projects planned by Palm Beach County.

9.1.8.5 Winsburg Farms Wetland Restoration (OPE)

This feature includes the construction of a 175-acre wetland east of Loxahatchee Wildlife Preserve in Palm Beach County. The feature will reduce the amount of treated water from the Southern Region Water Reclamation Facility wasted in deep injection wells by further treating and recycling the water.

The purpose of this facility is to create a wetland from water, which would be normally lost to deep well injection and any future beneficial use. The wetland will reuse a valuable resource, recharge the local aquifer system, create a new ecologically significant wildlife habitat and extend the function of the nearby Wakodahatchee Wetland.

9.1.8.6 C-17 Backpumping and Treatment (X)

This feature includes backpumping facilities and a stormwater treatment area with a total storage capacity of approximately 2,200 acre-feet located in northeastern Palm Beach County. The initial design for the stormwater treatment area assumed 550 acres with the water level fluctuating up to 4 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design, and will address appropriate pollution load reduction targets necessary to protect receiving waters (West Palm Beach Water Catchment Area).

The purpose of this feature is to increase water supplies to the West Palm Beach Water Catchment Area and Loxahatchee Slough by capturing and storing excess flows currently discharged to the Lake Worth Lagoon from the C-17 Canal.

Excess C-17 Canal water will be backpumped through existing canals and proposed water control structures to the stormwater treatment area which will provide water quality treatment prior to discharge into the West Palm Beach Water Catchment Area.

9.1.8.7 C-51 Backpumping and Treatment (Y)

This feature includes backpumping facilities and a stormwater treatment area with a total storage capacity of approximately 2,400 acre-feet located in Palm Beach County. The initial design for the stormwater treatment area assumed 600 acres in size with the water level fluctuating up to 4 feet above grade. The final size, depth and configuration of this facility will be determined through more detailed planning and design, and will address appropriate pollution load reduction targets necessary to protect receiving waters (West Palm Beach Water Catchment Area).

The purpose of this feature is to increase water supplies to the West Palm Beach Water Catchment Area and Loxahatchee Slough by capturing and storing excess flows currently discharged to the Lake Worth Lagoon from the C-51 Canal.

Excess C-51 Canal water will be backpumped through existing and proposed water control structures and canals to the stormwater treatment area which will provide water quality treatment prior to discharge into the West Palm Beach Water Catchment Area.

9.1.8.8 C-51 Regional Groundwater Aquifer Storage and Recovery (LL)

This feature includes a series of aquifer storage and recovery wells with a capacity of 170 million gallons per day as well associated pre- and post- water quality treatment to be constructed along the C-51 Canal in Palm Beach County. The initial design of the wells assumed 34 well clusters, each with a capacity of 5 million gallons per day with chlorination for pre-treatment and aeration for post-treatment. The level and extent of treatment and number of the aquifer storage and recovery wells may be modified based on findings from a proposed aquifer storage and recovery pilot project.

The purpose of this feature is to capture and store excess flows from the C-51 Canal, currently discharged to the Lake Worth Lagoon, for later use during dry periods.

The aquifer storage and recovery facilities will be used to inject and store surficial aquifer ground water adjacent to the C-51 Canal into the upper Floridan Aquifer instead of discharging the canal water to tide. Water will be returned to the C-51 Canal to help maintain canal stages during the dry-season. If water is not available in the aquifer storage and recovery system, existing rules for water delivery to this region will be applied.

9.1.8.9 Palm Beach County Agricultural Reserve Reservoir and Aquifer Storage and Recovery (VV)

This feature includes an above-ground reservoir with a total storage capacity of approximately 20,000 acre-feet located in the western portion of the Palm Beach County Agricultural Reserve. Aquifer storage and recovery wells with a capacity of 75 million gallons per day and associated pre- and post- water quality treatment located adjacent to the reservoir will also be a part of this feature. The initial design for the reservoir assumed 1,660 acres with water levels fluctuating up to 12 feet above grade. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study. The initial design of the wells assumed 15 well clusters, each with a capacity of 5 million gallons per day as well as chlorination for pre-treatment and aeration for post-treatment. The source of water to be injected is surficial ground water adjacent to the reservoir. The level and extent of treatment and number of the aquifer storage and recovery wells may be modified based on findings from a proposed aquifer storage and recovery pilot project.

The purpose of this feature is to supplement water supplies for central and southern Palm Beach County by capturing and storing excess water currently discharged to the Lake Worth Lagoon. These supplemental deliveries will reduce demands on Lake Okeechobee and Loxahatchee National Wildlife Area. It is assumed that this facility could also be designed to achieve water quality improvements in downstream receiving waters, depending upon pollutant loading conditions in the watershed.

The facilities will be filled during the wet season with excess water from the western portions of the Lake Worth Drainage District and possibly from Acme Basin B. Water will be returned to the Lake Worth Drainage District Canals to help maintain canal stages during the dry-season. If water is not available in the reservoir or the aquifer storage and recovery wells, existing rules for water delivery to this region will be applied.

9.1.8.10 Protect and Enhance Existing Wetland Systems along Loxahatchee National Wildlife Refuge including the Strazzulla Tract (OPE)

This feature includes water control structures and the acquisition of 3,335 acres located in Palm Beach County.

The purpose of this feature is to provide a hydrological and ecological connection to the Loxahatchee National Wildlife Refuge and expand the spatial extent of protected natural areas. This land will act as a buffer between higher water stages to the west and lands to the east that must be drained. This increase in spatial extent will provide vital habitat connectivity for species that require large unfragmented tracts of land for survival. It also contains the only remaining cypress habitat in the eastern Everglades and one of the few remaining sawgrass marshes adjacent to the coastal ridge. This is a unique and endangered habitat that must be protected. This area provides an essential Everglades landscape heterogeneity function.

9.1.8.11 Site 1 Impoundment and Aquifer Storage and Recovery (M)

This feature includes an above-ground reservoir with a total storage capacity of approximately 15,000 acre-feet located in the Hillsboro Canal Basin in southern Palm Beach County. A series of aquifer storage and recovery wells with a total capacity of approximately 150 million gallons per day and associated pre- and post- water quality treatment will also be a part of this feature located adjacent to the reservoir or along the Hillsboro Canal. The initial design of the reservoir assumed 2,460 acres with water levels fluctuating up to 6 feet above grade. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study. The initial design of the aquifer storage and recovery facility assumed 30 well clusters, each with a capacity of 5 million gallons per day with chlorination for pre-treatment and aeration for post-treatment. The source of water to be injected is in the surficial ground water adjacent to the reservoir. The location, extent of treatment and number of the aquifer storage and recovery wells may be modified based on findings from a proposed aquifer storage and recovery pilot project.

The purpose of this feature is to supplement water deliveries to the Hillsboro Canal during dry periods thereby reducing demands on Lake Okeechobee and the Loxahatchee National Wildlife Refuge.

Water from the Hillsboro Canal will be pumped into the reservoir during the wet season or periods when excess water is available. Water will be released back to the Hillsboro Canal to help maintain canal stages during the dry-season.

9.1.8.12 Broward County Secondary Canal System (CC)

This feature includes a series of water control structures, pumps, and canal improvements located in the C-9, C-12 and C-13 Canal Basins and east basin of the North New River Canal in central and southern Broward County.

The purpose of this feature is to reduce water shortages by recharging local wellfields and stabilizing the saltwater interface. Excess water in the basins will be pumped into the coastal canal systems to maintain canal stages at optimum levels. When basin water is not sufficient to maintain canal stages, the canals will be maintained from other construction features such as the Site 1 Impoundment and the North Lake Belt Storage Area and then from Lake Okeechobee and the Water Conservation Areas.

9.1.8.13 Western C-11 Diversion Impoundment and Canal and Water Conservation Areas 3A and 3B Levee Seepage Management (O and Q)

This feature includes canals, levees, water control structures, and a stormwater treatment area/impoundment with a total storage capacity of 6,400 acre-feet located in western Broward County. The initial design of the stormwater treatment area/impoundment assumed 1,600 acres with the water level fluctuating up to 4 feet above grade. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study. Detailed design of this feature will address appropriate pollution load reduction targets necessary to protect receiving waters.

The purpose of this feature is to divert and treat runoff from the western C-11 Basin that is presently discharged into Water Conservation Area 3A, control seepage from Water Conservation Areas 3A and 3B by improving groundwater elevations, and provide flood protection for the western C-11 Basin.

Runoff in the western C-11 Canal Basin that was previously backpumped into Water Conservation Area 3A through the S-9 pump station will be diverted into the C-11 Stormwater Treatment Area/Impoundment and then into either the North Lake Belt Storage Area, the C-9 Stormwater Treatment Area/Impoundment, or Water Conservation Area 3A after treatment, as applicable.

9.1.8.14 C-9 Stormwater Treatment Area/Impoundment (R)

This feature includes canals, levees, water control structures and a stormwater treatment area/impoundment with a total capacity of approximately 10,000 acre-feet, located in the western C-9 Basin in Broward County. The initial design of the stormwater treatment area/impoundment assumed 2,500 acres with the water level fluctuating up to 4 feet above grade. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study and will address appropriate pollution load reduction targets necessary to protect receiving waters.

The purpose of this feature is to provide treatment of runoff stored in the North Lake Belt Storage Area, enhance groundwater recharge within the basin, provide seepage control for Water Conservation Area 3 and buffer areas to the west, and provide flood protection for the western C-9 Basin.

Seepage from the C-9 Stormwater Treatment Area/Impoundment will be collected and returned to the impoundment.

9.1.8.15 North Lake Belt Storage Area (XX)

This feature includes canals, pumps, water control structures, and an in-ground storage reservoir with a total capacity of approximately 90,000 acre-feet located in Miami-Dade County. The initial design of the reservoir assumed 4,500 acres with the water level fluctuating from ground level to 20 feet below grade. A subterranean seepage barrier will be constructed around the perimeter to enable drawdown during dry periods, to prevent seepage losses, and to prevent water quality impact due to the high transmissivity of the Biscayne Aquifer in the area. The reservoir will be located within an area proposed for rock mining. A pilot test of this component will be conducted prior to final design to determine construction technologies, storage efficiencies, impacts upon local hydrology, and water quality effects. The water quality assessment will include a determination as to whether the in-ground reservoir with perimeter seepage barrier will allow storage of untreated runoff without concerns of groundwater contamination. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study and will address appropriate pollution load reduction targets necessary to protect the adjacent surficial aquifer and downstream receiving surface waters.

The purpose of this feature is to capture and store a portion of the stormwater runoff from the C-6, western C-11 and C-9 Basins. The stored water will be used to maintain stages during the dry season in the C-9, C-6, C-7, C-4 and C-2 Canals and to provide water deliveries to Biscayne Bay to aid in meeting salinity targets.

Runoff is pumped and gravity fed into the in-ground reservoir from the C-6 (west of Florida's Turnpike), western C-11, and C-9 Basins. Outflows from the facility will be directed into the C-9 Stormwater Treatment Area/Impoundment for treatment prior to delivery to the C-9, C-7, C-6, C-4 and C-2 Canals. If necessary, additional stormwater treatment areas will be constructed adjacent to the in-ground reservoir.

9.1.8.16 Diverting Water Conservation Area 2 and 3 flows to Central Lake Belt Storage Area (YY and ZZ)

This feature includes pumps, water control structures, canals, and conveyance improvements located adjacent to Water Conservation Areas 2 and 3 in Broward County. The final size and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study.

The purpose of this feature is to attenuate high stages in Water Conservation Areas 2 and 3 and transport this excess water to the Central Lake Belt Storage Area where it will be stored to meet downstream demands in Shark River Slough, Water Conservation Area 3B or Biscayne Bay.

When stages in Water Conservation Areas 2B, 3A, and 3B exceed target depths, water will be diverted to the Central Lake Belt Storage Area through water control structures and conveyance features. Water supply deliveries will be made first to Northeast Shark River Slough, then to Water Conservation Area 3B, and, finally, to Biscayne Bay, if flows are available. It is assumed that the water to be diverted from Water Conservation Areas 2 and 3 is of adequate quality to return to the Everglades Protection Area and Biscayne Bay; however, the final size, depth and configuration of these facilities, including treatment requirements, will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study.

9.1.8.17 Central Lake Belt Storage Area (S and EEE)

This feature includes pumps, water control structures, a stormwater treatment area, and a combination above-ground and in-ground storage reservoir with a total storage capacity of approximately 190,000 acre-feet located in Miami-Dade County. The initial design of the reservoir assumed 5,200 acres with the water level fluctuating from 16 feet above grade to 20 feet below grade. A subterranean seepage barrier will be constructed around the perimeter to enable drawdown during dry periods and to prevent seepage losses. A pilot test of this technology will be conducted prior to final design of this component to determine construction technologies, storage efficiencies, impacts upon local hydrology, and water quality effects. Since this facility is to be located within the protection area of Miami-Dade County's Northwest Wellfield, the pilot test will also be designed to identify and address potential impacts to the County's wellfield which may occur during construction and/or operation. The stormwater treatment area was assumed to be 640 acres with the water level fluctuating up to 4 feet above grade. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study.

The purpose of the feature is to store excess water from Water Conservation Areas 2 and 3 and provide environmental water supply deliveries to: (1) Northeast Shark River Slough, (2) Water Conservation Area 3B, and (3) to Biscayne Bay, in that order, if available. Due to the source of the water (Water Conservation Areas 2 and 3), it is assumed that water stored in this facility is of adequate quality to return to the Everglades Protection Area and Biscayne Bay; however, the final size, depth and configuration of these facilities, including treatment requirements, will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study.

Excess water from Water Conservation Areas 2 and 3 will be diverted into the L-37, L-33, and L-30 Borrow Canals, which run along the eastern boundaries of the Water Conservation Areas, and pumped into the Central Lake Belt Storage Area. Water supply deliveries will be pumped through a stormwater treatment area prior to discharge to the Everglades via the L-30 Borrow Canal and a reconfigured L-31N Borrow Canal. If available, deliveries will be directed to Biscayne Bay through the Snapper Creek Canal at Florida's Turnpike. A structure will be provided on the Snapper Creek Canal to provide regional system deliveries when water from the Central Lake Belt Storage Area is not available.

9.1.8.18 Dade-Broward Levee/Pennsuco Wetlands (BB)

This feature includes water control structures and modifications to the Dade-Broward Levee and associated conveyance system located in Miami-Dade County. The final size and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study.

The purpose of this feature is to reduce seepage losses to the east from the

Pennsuco Wetlands and southern Water Conservation Area 3B, enhance hydroperiods in the Pennsuco Wetlands, and provide recharge to Miami-Dade County's Northwest Wellfield.

9.1.8.19 C-4 Control Structures (T)

This feature includes two water control structures located in the C-4 Canal in Miami-Dade County.

The purpose of this feature will be to enhance wetland hydroperiods and enhance recharge to Miami-Dade County's Northwest Wellfield.

The eastern structure will be operated to reduce regional system deliveries by diverting dry season stormwater flows to the C-2 Canal to provide salt water intrusion protection and recharge to downstream wellfields. A western structure, being implemented under the Critical Projects Program, will be operated to control water levels in the C-4 Canal at a higher elevation to reduce seepage losses from the Pennsuco Wetlands and areas to the west of the structure.

9.1.8.20 Bird Drive Recharge Area (U)

This feature includes pumps, water control structures, canals, and an above-ground recharge area with a total storage capacity of approximately 11,500 acre-feet located in western Miami-Dade County. The initial design of the recharge feature assumed 2,877 acres with the water level fluctuating up to 4 feet above grade. Final design will seek to enhance and maintain the continued viability of wetlands within the basin. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study and will address appropriate pollution load reduction targets necessary to protect downstream receiving surface waters.

The purpose of the feature is to recharge groundwater and reduce seepage from the Everglades National Park buffer areas by increasing water table elevations east of Krome Avenue. The facility will also provide C-4 flood peak attenuation and water supply deliveries to the South Dade Conveyance System and Northeast Shark River Slough.

Inflows from the western C-4 Canal Basin and from the proposed West Miami-Dade Wastewater Treatment Plant will be pumped into the Recharge Area. Inflows from the wastewater treatment plant will stop when the Recharge Area depth exceeds 3 feet above-ground and will be diverted to a deep well injection disposal system. Recharge area outflows will be prioritized to meet: (1) groundwater recharge demands, (2) South Dade Conveyance System demands, and (3) Northeast Shark River Slough demands, when supply is available. Regional system deliveries will be routed through the seepage collection canal system of the Bird Drive Recharge Area to the South Dade Conveyance system.

9.1.8.21 L-31N Improvements for Seepage Management and S-356 Structures (V and FF)

This feature includes relocating and enhancing L-31N, groundwater wells, and sheetflow delivery system adjacent to Everglades National Park located in Miami-Dade County. More detailed planning, design and pilot studies will be conducted to determine the appropriate technology to control seepage from Everglades National Park. These studies and tests will also determine the appropriate amount of wet season groundwater flow control that will minimize potential impacts to Miami-Dade County's West Wellfield and freshwater flows to Biscayne Bay.

The purpose of this feature is to improve water deliveries to Northeast Shark River Slough and restore wetland hydropatterns in Everglades National Park by reducing levee and groundwater seepage and increasing sheetflow.

This feature reduces levee seepage flow across L-31N adjacent to Everglades National Park via a levee cutoff wall (refer to ***Appendix C***). Groundwater flows during the wet season are captured by ground water wells adjacent to L-31N and pumped to Everglades National Park. Water from upstream natural areas will be diverted into a buffer area adjacent to Everglades National Park where sheetflow will be reestablished. Further, this feature includes relocation of the Modified Water Deliveries structure S-357 to provide more effective water deliveries to Everglades National Park. New discharges to Everglades National Park will be designed to meet applicable water quality criteria.

9.1.8.22 West Miami-Dade County Reuse (HHH)

This feature includes a wastewater treatment plant expansion to produce superior, advanced treatment of wastewater from a future West Miami-Dade Wastewater Treatment Plant to be located in the Bird Drive Basin in Miami-Dade County. The initial design assumed a potential discharge volume of 100 million gallons per day from the wastewater treatment plant. The final configuration of these facilities will be determined through more detailed planning and design to be completed in the ongoing West Dade Water Reuse Feasibility Study authorized in Section 413 of the Water Resources Development Act of 1996. Superior water quality treatment features will be based on appropriate pollution load reduction targets necessary to protect downstream receiving surface waters.

The purpose of the feature is to meet the demands for: (1) the Bird Drive Recharge Area; (2) the South Dade Conveyance System, and (3) the Northeast Shark River Slough. When all demands have been met, the plant will stop treatment beyond secondary treatment standards and will dispose of the secondary treated effluent into deep injection wells.

9.1.8.23 Biscayne Bay Coastal Wetlands (FFF and OPE)

The feature includes pump stations, spreader swales, stormwater treatment areas, flowways, levees, culverts, and backfilling canals located in southeast Miami-Dade County and covers 13,600 acres from the Deering Estate at C-100C, south to the Florida Power and Light Turkey Point power plant, generally along L-31E.

The purpose of this feature is to rehydrate wetlands and reduce point source discharge to Biscayne Bay. The proposed project will replace lost overland flow and partially compensate for the reduction in groundwater seepage by redistributing, through a spreader system, available surface water entering the area from regional canals. The proposed redistribution of freshwater flow across a broad front is expected to restore or enhance freshwater wetlands, tidal wetlands, and nearshore bay habitat. Sustained lower-than-seawater salinities are required in tidal wetlands and the nearshore bay to provide nursery habitat for fish and shellfish. This project is expected to create conditions that will be conducive to the reestablishment of oysters and other components of the oyster reef community. Diversion of canal discharges into coastal wetlands is expected not only to reestablish productive nursery habitat all along the shoreline but also to reduce the abrupt freshwater discharges that are physiologically stressful to fish and benthic invertebrates in the bay near canal outlets.

More detailed analyses will be required to define target freshwater flows for Biscayne Bay and the wetlands within the redistribution system.. The target(s) will be based upon the quality, quantity, timing and distribution of flows needed to provide and maintain sustainable biological communities in Biscayne Bay, Biscayne National Park and the coastal wetlands. Additionally, potential sources of water for providing freshwater flows to Biscayne Bay will be identified and evaluated to determine their ability to provide the target flows.

The component Biscayne Bay Coastal Canals as modeled in D-13R and the Critical Project on the L-31E Flowway Redistribution are smaller components of the Biscayne Bay Coastal Wetlands feature described above.

9.1.8.24 South Miami-Dade County Reuse (BBB)

This feature includes a plant expansion to produce superior, advanced treatment of wastewater from the existing South District Wastewater Treatment Plant located north of the C-1 Canal in Miami-Dade County. The initial design of this feature assumed that the plant will have a capacity of 131 million gallons per day. More detailed analyses will be required to determine the quality and quantity of water needed to meet the ecological goals and objectives of Biscayne Bay.

Additionally, due to the water quality issues associated with discharging reclaimed water into Biscayne National Park, an Outstanding Florida Water, such as potential failures of the treatment system and the limited ability to control contaminant inputs to the sanitary sewer system serving the treatment facility, other potential sources of water to provide required freshwater flows to southern and central Biscayne Bay should be investigated before pursuing the reuse facility as a source. If it is determined that other, more appropriate sources are not available, the reuse project will be initiated by determining the parameters of concern, the necessary wastewater treatment requirements, and the appropriate treatment technology to be implemented.

The purpose of this feature is to provide additional water supply to the South Biscayne Bay and Coastal Wetlands Enhancement Project. In order to attain the superior level of treatment, construction of an add-on pretreatment and membrane treatment system to the existing secondary treatment facility will be necessary. Superior water quality treatment features will be based on appropriate pollution load reduction targets necessary to protect downstream receiving surface waters (Biscayne Bay).

9.1.8.25 Restoration of Pineland & Hardwood Hammocks in C-111 Basin (OPE)

This feature includes restoring south Florida slash pine and hardwood hammock species on a 200-foot wide strip on each side of two miles of SR 9336 from the C-111 Canal to the L-31W Borrow Canal (approximately 50 acres) and the establishment of 2, one-acre hammocks in low-lying areas on each side of the road located in Miami-Dade County.

The purpose of this feature is to restore hammocks to a portion of the Frog Pond which has been purchased by the South Florida Water Management District as part of the C-111 Project to restore the Taylor Slough portion of the Everglades. This feature will provide some water quality treatment for runoff passing through the hammocks and will demonstrate the techniques required to re-establish native conifer and hardwood forests on land that has been rock plowed.

9.1.8.26 C-111N Spreader Canal (WW)

This feature includes levees, canals, pumps, water control structures, and a stormwater treatment area to be constructed, modified or removed in the Model Lands and Southern Glades (C-111 Basin) area of Miami-Dade County. This feature enhances the C-111 Project design for the C-111N Spreader Canal with the construction of a stormwater treatment area, the enlarging of pump station S-332E and the extension of the canal under U.S. Highway 1 and Card Sound Road into the Model Lands. The initial design of this feature pumps water from the C-111 and the C-111E Canals into a stormwater treatment area prior to discharging to Southern Everglades and Model Lands. This features also calls for filling in the southern reach of the C-111 Canal and removal of structures S-18C and S-197. The final size, depth, location and configuration of this feature will be determined through more detailed planning and design.

The purpose of this feature is to improve deliveries and enhance the connectivity and sheetflow in the Model Lands and Southern Glades areas, reduce wet season flows in C-111, and decrease potential flood risk in the lower south Miami-Dade County area.

9.1.9 Southwest Florida Region

9.1.9.1 Southern Golden Gate Estates Restoration (OPE)

This feature includes a combination of spreader channels, canal plugs, road removal and pump stations in the Western Basin and Big Cypress, Collier County, south of I-75 and north of U.S. 41 between the Belle Meade Area and the Fakahatchee Strand State Preserve.

The purpose of this feature is to restore and enhance the wetlands in Golden Gate Estates and in adjacent public lands by reducing over-drainage. Implementation of the restoration plan would also improve the water quality of coastal estuaries by moderating the large salinity fluctuations caused by freshwater point discharge of the Fahka Union Canal. The plan would also aid in protecting the City of Naples' eastern Golden Gate wellfield by improving groundwater recharge.

9.1.9.2 Southern Corkscrew Regional Ecosystem Watershed Project Addition (OPE)

This feature includes the acquisition and restoration of 4,670 acres of land, replacement of the Imperial Bonita Estates bridge on the Imperial River, and replacement of the Kehl Canal Weir in southern Lee County, adjacent to Corkscrew Sanctuary.

The purpose of this feature is to: (1) re-establish historic flow patterns and hydroperiods on the project lands, as well as Corkscrew Regional Ecosystem Watershed and Corkscrew Sanctuary wetlands to the east; (2) restore historical storage potential of the Southern Corkscrew Regional Ecosystem Watershed lands; (3) reduce excessive freshwater discharges to Estero Bay during the rainy season; (4) decrease saltwater intrusion during the dry season; (5) reduce loading of nutrients and other pollutants to the Imperial River and Estero Bay; (6) increase aquifer recharge and water supply for an area frequently facing water restrictions during dry years; and (7) reduce flooding of homes and private lands west of the project area.

Hydrologic restoration of this land will include the following modifications: removal of existing road beds, removal of single family homes, removal of junk debris, filling of ditches, and removal of agricultural canals and berms. Other components within the plan include: replacement of the Kehl Canal weir, clearing and snagging on Imperial River, Estero River and Halfway Creek, reconnection of Spring Creek and Halfway Creek under U.S. Interstate 75, and replacement of the Imperial Bonita Estates bridge.

9.1.9.3 Lake Trafford Restoration (OPE)

This feature includes a lake-wide organic sediment removal to Lake Trafford near Ft. Myers, Florida. Lake Trafford has poor water quality, extensive muck accumulations, loss of native submergent plant communities, periodic aquatic weed infestations, and numerous moderate fish kills. Poor water quality is attributed to internal nutrient cycling from extensive organic much deposits throughout the Lake's basin.

The purpose of this feature is to preserve the headwaters of the Corkscrew Swamp and Camp Keais Strand. The water quality of the Lake affects these wetland resources that have been targeted for protection. These wetlands drain into important estuarine systems such as Estero Bay and Cape Ramono. Lake Trafford is an integral contributor to the sheet flow that traverses such areas as the Corkscrew Regional Ecosystem Watershed and the Southern Golden Gates Estates area. The quality of the Lake and the associated watershed affects important wildlife species and offers a sanctuary for migrating birds. As the only major lake in southwest Florida, Lake Trafford provides a sanctuary during the dry season.

9.1.9.4 Henderson Creek/Belle Meade Restoration (OPE)

This feature combines multiple individual elements to complement each other to form a larger-scale combined effect. This feature includes a 10-acre stormwater lake/marsh filtering system; four culverts under State Road 951; hydrologic restoration around Manatee Basin including culverts, ditching, removal of some roadbed; invasive, exotic plant removal; a public access point and interpretive boardwalk; construction of a swale and spreader system; and removal of the Road-to-Nowhere. This southwest Florida feature is located in Collier County. The area known locally as Belle Meade is the primary drainage basin for the Henderson Creek Estuary, which drains into Rookery Bay.

The purpose of this feature is to restore historic sheetflow to the estuary, treatment of stormwater, improvement of water quality and increase in habitat value and wetland functions.

9.1.9.5 Lakes Park Restoration (OPE)

This feature includes the construction of a 40-acre marsh/flowway in an abandoned rock mine, removal of exotic vegetation, and planting native vegetation on 11 acres of uplands and 9 acres of littoral zone. This feature is located in the Lee County Lakes Regional Park, upstream of Estero Bay.

The purpose of this feature is to enhance surface water runoff quality by creating a meandering flowway with shallow littoral zones to enhance pollution removal and oxygen content, removing aquatic and upland exotic infestation while allowing public access into upland areas of improved native habitat. The restoration will provide immediate habitat and water quality benefits at Lakes Park and improve downstream conditions in Hendry County and the Estero Bay Aquatic Preserve.

9.1.10 Florida Bay and Keys

9.1.10.1 Florida Keys Tidal Restoration (OPE)

This feature includes the use of bridges or culverts to restore the tidal connection between Florida Bay and the Atlantic Ocean in Monroe County. The four locations are as follows: (1) Tarpon Creek, just south of Mile Marker 54 on Fat Deer Key (width 150 feet); (2) unnamed creek between Fat Deer Key and Long Point Key, south of Mile Marker 56 (width 450 feet); (3) tidal connection adjacent to Little Crawl Key (width 300 feet); and (4) tidal connection between Florida Bay and Atlantic Ocean at Mile Marker 57 (width 2,400 feet).

The purpose of this feature is to restore the tidal connection that was eliminated in the early 1900's during the construction of Flagler's railroad. Restoring the circulation to areas of surface water that have been impeded and stagnant for decades will significantly improve water quality, benthic floral and faunal communities, larval distribution of both recreational and commercial species (i.e. spiney lobster), and the overall hydrology of Florida Bay.

9.1.11 System-wide

9.1.11.1 Melaleuca Eradication Project and other Exotic Plants (OPE)

This feature includes: 1) upgrading and retrofitting the current quarantine facility in Gainesville, and 2) large-scale rearing of approved biological control organisms for release at multiple sites within the south Florida ecosystem.

The purpose of this feature is to increase the effectiveness of biological control technologies to manage Melaleuca and other invasive exotic species.

9.2 OPERATIONAL FEATURES

A number of operational components have been identified in the recommended Comprehensive Plan. These components have been evaluated on a regional scale using the South Florida Water Management Model, which as noted earlier is an effective tool for analyzing regional hydrologic effects. These operational components have been evaluated along with the construction components previously described. More detailed planning and analyses will be necessary to develop the optimum operational modifications that will be implemented for the Central and Southern Florida Project.

The costs to implement these operational features are not explicitly presented in this report. Most of the operational features will be implemented in association with related construction features described previously and, as such the costs are included in those features. However, in the case of Coastal Wellfield Operations (***Section 9.2.5.1***) the magnitude and uncertainties of implementing the feature have necessitated that no cost estimates be developed. Additionally, it is assumed that the costs will be borne by the appropriate affected utilities.

9.2.1 Lake Okeechobee Region

9.2.1.1 Lake Okeechobee Regulation Schedule (F)

The Lake Okeechobee Regulation Schedule will be modified in order to take advantage of the additional storage facilities identified in the construction features. Two additional zones will be added to the schedule. The first zone will trigger discharges to the north of Lake Okeechobee reservoir and the Everglades Agricultural Area reservoir. The second higher zone will trigger the Lake Okeechobee aquifer storage and recovery facilities to begin injecting water from the Lake. Climate based forecasting will be used to guide management decisions regarding releases to the storage facilities.

It is anticipated that all flood control releases through the C-43 and C-44 Canals will be eliminated with the exception of emergency zone A. Zone A levels are expected to be similar to the levels that occur in the current regulation schedule Run 25, however, the number of times that the Lake is above zone A is expected to be dramatically reduced.

9.2.2 Caloosahatchee Region

9.2.2.1 Environmental Water Supply Deliveries to the Caloosahatchee Estuary (E)

Freshwater deliveries to the Caloosahatchee Estuary will be provided to protect and restore more natural estuarine conditions. Minimum and maximum flows were identified which would cause poor water quality conditions for the estuary. This feature includes the development of a series of operational rules for storage features in the C-43 Basin along with modifications to Lake Okeechobee operations in order to maintain the salinity conditions in the estuary to support a range of aquatic vegetation, seagrass, invertebrates, and fish communities.

9.2.3 Upper East Coast Region

9.2.3.1 Environmental Water Supply Deliveries to St. Lucie Estuary (C)

Freshwater deliveries to the St. Lucie Estuary will be provided to protect and restore more natural estuarine conditions. Minimum and maximum flows were identified which would cause poor water quality conditions for the estuary. This feature includes the development of a series of operational rules for storage features in the C-23, C-24, C-25, C-44, Northfork and Southfork Basins along with modifications to Lake Okeechobee operations in order to maintain the salinity conditions in the estuary to support a range of aquatic vegetation, seagrass, invertebrates, and fish communities.

9.2.4 Water Conservation Areas and Everglades Regions

9.2.4.1 Everglades Rain-Driven Operations (H)

Modifications to the regulation schedules for Water Conservation Areas 2A, 2B, 3A, 3B and the current Rainfall Delivery Formula for Everglades National Park will be made to implement rain-driven operations for all of these areas. These new operational rules are intended to improve timing and location of water depths in the Water Conservation Areas and Everglades National Park and to restore more natural hydropatterns.

The rain-driven operational concept is a basic shift from the current operational practice, which uses calendar-based regulation schedules for the Water Conservation Areas. Regulation schedules, also referred to as flood-control schedules, typically specify the release rules for a Water Conservation Area based on the water level at one or more key gages. Regulation schedules do not typically contain rules for importing water from an upstream source. The schedules also repeat every year and make no allowance for inter-annual variability. The rain-driven operational concept includes rules for importing and exporting water from the Water Conservation Areas in order to mimic a desired target stage hydrograph at key locations within the Everglades system. The target stage hydrographs mimic an estimate of the more natural (pre-drainage Everglades) water level response to rainfall.

9.2.4.2 Modified Holey Land Wildlife Management Area Operation Plan (DD)

Modification to the current operating plan for Holey Land Wildlife Management Area will be made to implement rain-driven operations for this area. Water deliveries are made to Holey Land from the Rotenberger Wildlife Management Area or from Stormwater Treatment Area 3 & 4 if Rotenberger flows are insufficient. The deliveries are assumed to be of acceptable water quality. These new operational rules are intended to improve the timing and location of water depths within the Holey Land Wildlife Management Area.

9.2.4.3 Modified Rotenberger Wildlife Management Area Operation Plan (EE)

Modification to the current operating plan for Rotenberger Wildlife Management Area will be made to implement rain-driven operations for this area. Water deliveries are made to Rotenberger from Stormwater Treatment Area 5. Discharges from Rotenberger are made to the Holey Land Wildlife Management Area. The deliveries are assumed to be of acceptable water quality. These new operational rules are intended to improve the timing and location of water depths within the Rotenberger Wildlife Management Area.

9.2.5 Lower East Coast Region

9.2.5.1 Change Coastal Wellfield Operations (L)

For coastal public water supply utilities in the Lower East Coast Service Area, which are expected to experience an increased threat of saltwater intrusion, demands will be shifted from eastern facilities to western facilities away from the saltwater interface. The following utilities have a portion of their demands shifted inland: Riviera Beach, Lake Worth, Lantana, Manapalan, Boca Raton, and Florida City. The volume shifted is dependent upon the degree of saltwater intrusion, but is generally proportional to the increase in demands between the 1995 existing conditions and the 2050 future without plan conditions. Eastern wellfields at Miramar, Hollywood, Broward County 3A, 3B and 3C, Dania and Hallandale are assumed to be on standby with the entire demand met from western facilities.

9.2.5.2 Lower East Coast Utility Water Conservation (AAA)

This feature reduces the Lower East Coast public water supply demands through the full implementation of the South Florida Water Management District's current mandatory water conservation program. Full implementation of the conservation program over the next 50 years is projected to decrease public water supply demand by approximately 6 percent more than conservation incorporated in the future without project public water supply demands.

The regional effect from the implementation of this additional conservation would be more efficient utilization of water resources by the public and a reduction of the volume of water delivered from Lake Okeechobee, the Water Conservation Areas, and other regional storage facilities to recharge coastal canals and wellfields.

9.2.5.3 Operational Modification to Southern Portion of L-31N and C-111 (OO)

Modifications to the operations of the C-111 Project, currently under construction, will be made to the southern portion of L-31N Borrow Canal and C-111. These operational modifications will be made to improve deliveries to Everglades National Park and decrease flood risk of adjacent agricultural areas in the Lower East Coast Service Area.

9.3 PILOT PROJECTS

In addition to the construction and operational features previously discussed, a series of pilot projects have been recommended. These pilot projects are needed to address uncertainties associated with some of the physical facilities that are proposed in the recommended plan. The pilot projects will be designed to determine the feasibility, as well as optimum design, of a facility prior to embarking upon full scale implementation of a new facility.

9.3.1 Lake Okeechobee Aquifer Storage and Recovery – Pilot Project (GG)

This feature is multi-purpose and provides benefit to environmental, urban and agricultural users (see ***Section 9.1.2.1***). The pilot project is necessary to identify the most suitable sites for the aquifer storage and recovery wells in the vicinity of Lake Okeechobee and to identify the optimum configuration of those wells. Additionally, the pilot project will determine the specific water quality characteristics of waters to be injected, the specific water quality characteristics and amount of water recovered from the aquifer, and the water quality characteristics of the receiving aquifer. Further information from the pilot project will provide the hydrogeological and geotechnical characteristics of the upper Floridan Aquifer System within the region, and the ability of the upper Floridan Aquifer System to maintain injected water for future recovery.

9.3.2 Caloosahatchee River (C-43) Basin Aquifer Storage and Recovery – Pilot Project (D)

Aquifer Storage and Recovery wells are proposed in order to maximize the benefits associated with the Caloosahatchee River Storage Reservoir (see ***Section 9.1.3.1***). A pilot project for these wells is necessary to identify the most suitable sites for the aquifer storage and recovery wells in the vicinity of the reservoir and to determine the optimum configuration of those wells. The pilot project will provide information regarding the characteristics of the aquifer system within the Caloosahatchee River Basin as well as determine the hydrogeological and geotechnical characteristics of the upper Floridan Aquifer. The pilot project will also determine the specific water quality characteristics of waters to be injected, the specific water quality characteristics and the amount of water recovered from the aquifer, and the water quality characteristics of water within the receiving aquifer.

9.3.3 Site 1 Impoundment and Aquifer Storage and Recovery – Pilot Project (M)

The Site 1 above-ground impoundment is proposed to be operated in conjunction with multiple aquifer storage and recovery wells in order to maximize the benefits of the reservoir. A pilot project for these wells is necessary to determine the most suitable sites for the aquifer storage and recovery wells in the vicinity of the reservoir and to determine the optimum configuration of those wells. The identification of the hydrogeological and geotechnical characteristics of the soils and aquifer will also be determined. The pilot project will also determine the specific water quality characteristics of water within the aquifer as well as the quality of water proposed for injection and the water quality characteristics of water recovered from the aquifer.

9.3.4 In-Ground Reservoir Technology – Pilot Project

Several features recommend the use of areas where lime rock mining will have occurred (see ***Sections 9.1.8.2, 9.1.8.15 and 9.1.8.17***). The initial design of these reservoirs includes subterranean seepage barriers around their perimeter in order to enable drawdown during dry periods, prevent seepage losses, and prevent water quality impacts due to transmissivity of the aquifer in these areas.

The pilot project is required to determine construction technologies, storage efficiencies, impacts on local hydrology, and water quality effects. Water quality assessments will include a determination as to whether the in-ground reservoirs and seepage barriers will allow for storage of untreated waters without concerns of groundwater contamination.

9.3.5 L-31N Seepage Management – Pilot Project (V)

The purpose of this feature is to reduce levee seepage flow across L-31N adjacent to Everglades National Park via a levee cutoff wall (see ***Section 9.1.8.21***). Additionally, the feature was designed to reduce groundwater flows during the wet season by capturing groundwater flows with a series of groundwater wells adjacent to L-31N, then backpumping those flows to Everglades National Park. The pilot project is necessary to determine the appropriate technology to control seepage from Everglades National Park. The pilot project will also provide necessary information to determine the appropriate amount of wet season groundwater flow to return that will minimize potential impacts to Miami-Dade County's West Wellfield and freshwater flows to Biscayne Bay.

9.3.6 Wastewater Reuse Technology – Pilot Project (HHH, BBB, and OPE)

Currently, two features involve the advanced treatment of wastewater (see ***Sections 9.1.8.22 and 9.1.8.24***). This pilot project will address water quality issues associated with discharging reclaimed water into natural areas such as the West Palm Beach Water Catchment Area, Biscayne National Park, and the Bird Drive Basin as well as determine the level of superior treatment and the appropriate methodologies for that treatment. A series of studies will be conducted to help determine the level of treatment needed.

Pilot facilities will be constructed to determine the ecological effects of using superior, advanced treated reuse water to replace and augment freshwater flows to Biscayne Bay and to determine the level of superior, advanced treatment required to prevent degradation of freshwater and estuarine wetlands and Biscayne Bay. The constituents of concern in wastewater will be identified and the ability of superior, advanced treatment to remove those constituents will be determined.

In addition, a pilot facility will be constructed to treat wastewater from the East Central Regional Wastewater Treatment Facility using advanced and superior wastewater treatment processes to remove nitrogen and phosphorus. After treatment, the wastewater will be used to restore 1500 acres of wetlands and to recharge wetlands surrounding the City of West Palm Beach's wellfield. A portion of the treated wastewater will be used to recharge a residential lake system surrounding the City's wellfield and a Palm Beach County wellfield.

Besides serving as a pilot project for wetlands based water reclamation this feature will reduce a portion of the City's dependence on surface water from Lake Okeechobee during dry or drought events. In addition, approximately 2,000 acres of wetlands would be created or restored. Other benefits include aquifer recharge and replenishment, reduction of water disposed in deep injection wells and a reduction of stormwater discharge to tide.

9.4 REAL ESTATE

The real estate requirements for the recommended Comprehensive Plan are discussed in ***Appendix F***. The land requirements are based on an analysis of the land that would be needed for the construction features described in ***Section 9.1***. Based on this analysis, an estimated cost for land acquisition was developed. More detailed planning and analyses will be necessary to develop the optimum real estate requirements in the recommended Comprehensive Plan.

9.4.1 Land Acquisition

For the construction features identified in ***Section 9.1***, the total estimated land requirement is approximately 220,000 acres as displayed in ***Table 9-1***. These lands were estimated based on the engineering assumptions made during the formulation of alternative plans. For example, in the case of a storage reservoir north of Lake Okeechobee, the Restudy Team used a conceptual reservoir and treatment area design that encompassed approximately 20,000 acres located somewhere north of Lake Okeechobee. As discussed in ***Section 9.1***, the specific areal extent and location of this feature was not critical to analyzing the regional water resources effects of the Comprehensive Plan and that specific design criteria for the features will be addressed in subsequent planning phases of this project. Consequently, the estimated land requirements will likely change as the result of more detailed analysis. However, these assumptions were used for the purpose of estimating the total real estate requirements for the Comprehensive Plan. Further, contingency costs were escalated above normal levels to address this uncertainty.

A cooperative effort, with landowners in the areas where construction features are proposed, should be used to identify suitable sites in subsequent planning phases of this project.

9.4.2 Relocation Assistance (Public Law 91-646)

In accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended (Public Law 91-646), relocation assistance will be provided to affected residents and businesses. However, due to the magnitude of the study area and the uncertainty in the location of many of the construction features, the number of residences, farms, and businesses were not estimated. These will be determined during more detailed planning and design of the construction features. For this level of planning, the unknown relocation assistance cost estimate is covered in a higher than usual contingency cost added to each construction feature.

TABLE 9-1
ESTIMATED REAL ESTATE LAND REQUIREMENTS

Report Section	Real Estate Land Requirement	Estimated Acreage	Counties
9.1.1	**Kissimmee River Region**		
9.1.1.1	North of Lake Okeechobee Storage Reservoir	20,000	Glades, Highlands, and Okeechobee,
9.1.1.2	Taylor Creek/Nubbin Slough Storage and Treatment Area	10,000	Okeechobee and St Lucie
9.1.1.3	Lake Okeechobee Watershed Water Quality Treatment Facilities	4,515	Glades, Highlands and Okeechobee
9.1.1.4	Lake Okeechobee Tributary Sediment Dredging	320	Hendry, Glades and Lee
9.1.1.5	Lake Istokpoga Regulation Schedule	0	Highlands
9.1.2.1	Lake Okeechobee Aquifer Storage and Recovery	300	Glades and Okeechobee
9.1.3	**Caloosahatchee River Region**		
9.1.3.1	C-43 Basin Storage Reservoir and Aquifer Storage and Recovery	20,000	Hendry, Glades and Lee
9.1.3.2	Caloosahatchee Backpumping with Stormwater Treatment	5,000	Glades
9.1.4	**Upper East Coast**		
9.1.4.1	C-44 Basin Storage Reservoir	10,000	Martin
9.1.4.2	C-23/C-24/C-25/Northfork and Southfork Storage Reservoirs	48,350	Martin and St Lucie
9.1.5	**Everglades Agricultural Area**		
9.1.5.1	Everglades Agricultural Storage Reservoirs	17,500	Palm Beach
9.1.6	**Big Cypress Region**		
9.1.6.1	Big Cypress/L-28 Interceptor Modifications	1,900	Hendry and Broward
9.1.6.2	Seminole Tribe Big Cypress Water Conservation Plan - East & West	3,800	Hendry and Collier
9.1.7	**Water Conservation Areas Region**		
9.1.7.1	Flow to Northwest and Central Water Conservation Area 3A	0	Broward and Miami-Dade
9.1.7.2	Water Conservation Area 3 Decompartmentalization and Sheetflow Enhancement	255	Palm Beach, Broward and Miami-Dade
9.1.7.3	Loxahatchee National Wildlife Refugee Internal Canal Structures	5	Palm Beach
9.1.7.4	Miccosukee Water Management Plan	900	Broward
9.1.8	**Lower East Coast Region**		
9.1.8.1	Pal-Mar and J.W. Corbett Wildlife Management Area Hydropattern Restoration	3,000	Palm Beach and Martin
9.1.8.2	Water Preserve Areas / L-8 Basin	2,180	Palm Beach
9.1.8.3	Acme Basin B Discharge	930	Palm Beach
9.1.8.4	Lake Worth Lagoon Restoration	0	Palm Beach
9.1.8.5	Winsburg Farms Wetland Restoration	175	Palm Beach
9.3.6	Palm Beach County Wetlands Based Water Reclamation	2,000	Palm Beach
9.1.8.6	C-17 Backpumping and Treatment	550	Palm Beach

Report Section	Real Estate Land Requirement	Estimated Acreage	Counties
9.1.8.7	C-51 Backpumping and Treatment	710	Palm Beach
9.1.8.8	C-51 Regional Groundwater Aquifer Storage and Recovery	34	Palm Beach and Broward
9.1.8.9	Palm Beach County Agricultural Reserve Reservoir and Aquifer Storage and Recovery	1,660	Palm Beach
9.1.8.10	Protect and Enhance Existing Wetland Systems along Loxahatchee National Wildlife Refuge including the Strazzulla Tract	3,335	Palm Beach
9.1.8.11	Site 1 Impoundment and Aquifer Storage and Recovery	2,458	Palm Beach
9.1.8.12	Broward County Secondary Canal System	245	Broward
9.1.8.13	Western C-11 Diversion Impoundment and Canal and Water Conservation Areas 3A and 3B Levee Seepage Management	5,887	Broward and Miami-Dade
9.1.8.14	C-9 Stormwater Treatment Area/Impoundment	2,500	Broward
9.1.8.15	North Lake Belt Storage Area	5,861	Miami-Dade
9.1.8.16	Diverting Water Conservation Area 2 and 3 flows to Central Lake Belt Storage	837	Broward and Miami-Dade
9.1.8.17	Central Lake Belt Storage Area	5,770	Miami-Dade
9.1.8.18	Dade-Broward Levee/Pennsuco Wetlands	384	Miami-Dade
9.1.8.19	C-4 Control Structures	2	Miami-Dade
9.1.8.20	Bird Drive Recharge Area	2,877	Miami-Dade
9.1.8.21	L-31N Levee Improvements for Seepage Management and S-356 Structures	3,947	Miami-Dade
9.1.8.22	West Miami-Dade County Reuse	100	Miami-Dade
9.1.8.23	Biscayne Bay Coastal Wetlands	13,950	Miami-Dade
9.1.8.24	South Miami-Dade County Reuse	200	Miami Dade
9.1.8.25	Restoration of Pineland & Hardwood Hammocks in C-111 Basin	0	Miami-Dade

	TOTAL	**220,141**	

9.5 ADAPTIVE ASSESSMENT AND MONITORING PROGRAM

An extensive Adaptive Assessment Program which includes a system-wide monitoring program will be conducted to support the goals and objectives of the Comprehensive Plan. This program will provide an opportunity to continue investigating concepts and issues relative to the overall Comprehensive Plan while implementation of the initial project features are underway. The Adaptive Assessment Program will include continued system-wide evaluation and analysis among other planning activities. The monitoring program will have a dual focus on the biological (including water quality) and hydrological restoration objectives in the natural systems, and the water supply and flood protection objectives in the urban and agricultural regions.

9.5.1 Adaptive Assessment Program

Adaptive assessment is a process for evaluating how well the phases of the Comprehensive Plan achieve their expected objectives, and for using these evaluations as a basis for refining future phases of the program. To be successful, an adaptive assessment process requires that the Comprehensive Plan be implemented iteratively, that a pre-determined set of targets be appropriately monitored, that it be possible to make changes in the design and sequencing of the plan in response to information learned from the monitoring program and from new research and modeling, and that a specific protocol for conducting the adaptive assessment process be in place throughout the life of the program.

Adaptive assessment provides an organized process for confronting and reducing the levels of uncertainty caused when there is insufficient information for knowing how the natural and human systems in south Florida will respond to the long-term implementation of the Comprehensive Plan. These uncertainties are inevitable, in that we are dealing with systems that are tremendously complex, not thoroughly understood, and difficult to predict. The systems are complex in their detail (i.e., in the number of different variables to consider), and in their dynamics (i.e., the number and scales of relationships that drive responses).

In addition to the inevitable uncertainties, natural and human systems will at times respond in totally unexpected ways (i.e., in ways that are not anticipated or predicted by any existing hypotheses). It is these unexpected responses, when they result in negative changes, which often are the stimuli for “crises” at political and management levels. Adaptive assessment should moderate these crisis responses, by providing an in-place process for early detection and interpretation of the unexpected, and for maximizing the learning opportunities associated with these events.

Adaptive assessment is a process for learning, and for incorporating new information into the planning and evaluation phases of the restoration program.

Adaptive assessment is valuable in that it treats all responses, expected or not, as major learning opportunities. An unexpected response does not represent a failure for the program if it can be used to substantially improve our understanding of a complex system. Much of the design of the Comprehensive Plan, including the selection of performance measures and targets, is based on a set of causal hypotheses derived from a set of conceptual ecological models for the major landscapes of south Florida. Implementation of the Comprehensive Plan provides opportunities for loosely "testing" these hypotheses (without replications), by comparing actual system responses to those predicted by the hypotheses. Actual responses, in combination with information obtained from ongoing research and modeling, can lead to refinements in the conceptual models and hypotheses, and to reduced levels of uncertainty regarding future iterations of the Comprehensive Plan.

Adaptive assessment provides a stimulus for the development and long-term operation of a regionally comprehensive monitoring program. The application of an adaptive process requires that a monitoring program be in place that provides measures of a spatially, temporally and hierarchially appropriate set of pre-determined performance targets (indicators, endpoints). The design of such a monitoring program provides a valuable opportunity for a healthy review of existing monitoring programs for their coverages, protocols, and data management adequacies, relative to the needs of adaptive assessment.

Overall, adaptive assessment provides a much needed framework for: (1) strengthening coordination across agency and disciplinary lines by establishing a commonly accepted evaluation process and set of performance targets, (2) validating the performance of each iteration in a long-term restoration program, and (3) encouraging agencies to be flexible about the design and implementation of the Comprehensive Plan. The bottom line is that adaptive assessment substantially improves the probability that a complex, regional Comprehensive Plan will be successful, by providing a structured, well-focused process for evaluating and refining the design and performance of that program on a continuing basis throughout its implementation.

9.5.2 Monitoring Program

A fundamental component of adaptive assessment is a monitoring program that is based on the goals and objectives of the project. There must be agreement on performance targets, and on the ecological changes that constitute improvements, as a prerequisite for determining which parameters in the system must be monitored. Because of the uncertainties inherent in any effort to restore such a complex and altered ecosystem, the performance targets and the interim measures of success can only be broadly stated. Nevertheless, these targets and measures need definition to design a monitoring program that is well focused and efficient; thus, to assure that it provides the kind of information required for the implementation of an adaptive management strategy. In the following two sections, the objectives and components that should be considered for a regional monitoring program are reviewed.

A regional monitoring program should provide data for meeting several, essential objectives of the Comprehensive Plan. Although these objectives may be overlapping, each makes a discrete contribution toward the realization of the goals of the Comprehensive Plan. Monitoring will:

1. Determine problem areas as a basis for designing and setting priorities for components of the Comprehensive Plan. Knowledge of water quality, water supply and flood protection issues, which species and ecologic communities are having problems, and when and where in the system these problems are occurring, is essential information for designing a Comprehensive Plan that is well focused for correcting those problems.

2. Determine the hydrological, physical, water quality and ecological responses to each incremental step in the Comprehensive Plan, as a basis for designing and/or fine tuning subsequent steps. If each incremental step in the plan is viewed as an experiment, accompanied by one or more hypotheses that predict how that step will improve the system, monitoring will provide the measure of how well the hypotheses and the experiment achieve the expected results. This information, in turn, becomes the basis for improving the design of the experiment and the hypotheses for the next step in the program.

3. Determine the responses to each incremental step, as a means for continuing the all important process of enhancing existing knowledge of the functions and relationships in the south Florida ecosystem, and how these processes respond to alterations in the spatial temporal and hydrologic patterns in the system. Much of the uncertainty about how the overall system will respond during implementation of the Comprehensive Plan is caused by the current, incomplete knowledge of ecological and hydrological processes in the south Florida ecosystem. This is compounded by the fact that these processes have changed in ways that are not fully predictable.

4. Measure the status and trends of a wide range of hydrological, ecological, water quality and physical components of the south Florida ecosystem. A strong, ongoing monitoring program will provide a regional overview of how well the ecosystem and water management systems are functioning. This includes the status of endangered and indicator species; the range and frequencies of interannual response patterns; the effectiveness of implemented components in achieving anticipated performance; long-term effects of modified hydrological conditions on estuarine salinity gradients, saltwater intrusion protection, and on regional plant communities; and other parameters that enhance current understanding of broad trends across the ecosystem. It will determine responses

and trends at appropriate spatial and temporal scales, and from among a taxonomically representative array of components of the natural systems.

5. Contribute to an improved focus, and consensus, regarding the water quality, physical and biological elements which, collectively, will constitute a “restored” natural system, and determine when the Comprehensive Plan goals have been reached. A large number of performance targets including “ecological endpoints” for restoration have been used in the evaluation of the alternative plans and subsequent selection of the recommended plan. A regional monitoring program will reveal when and under what conditions these performance targets and endpoints have been reached and are sustainable.

9.5.3 Monitoring Program Planning Guidelines

Comprehensive, integrated ecological and water resource monitoring to measure the effects of the Comprehensive Plan components and the success of the overall Comprehensive Plan will involve coordination with the South Florida Ecosystem Restoration Working Group including it’s Science Coordination Team. The general guidelines for the monitoring program include the following:

1. A single, regionally comprehensive, and integrated multi-agency monitoring program, which will operate over the entire south Florida ecosystem, with clear assignment of lead and cooperating agency responsibilities. The program will be managed by a standing, interagency coordinating team. The geographic boundaries of the monitoring program will be consistent with the outer limits of the region that is predicted to be influenced by the Comprehensive Plan.

2. Contain adequate coverage at all trophic levels, spatial and temporal scales, among hydrological, ecological, water quality and physical components, to measure both regional and local responses to the Comprehensive Plan and the overall south Florida ecosystem restoration effort. An independent peer-review process will provide recommendations on the design and coverage of the monitoring program.

3. Be designed at scales and with objectives that are proportional to the design of each sub-regional or local, component of the Comprehensive Plan. Additional, specific elements will be added to a regional monitoring program to measure more local responses to the incremental scale steps in the Comprehensive Plan.

4. Focus on those hydrological, ecological water quality, and physical parameters that can be readily and quantitatively measured, and which are understood well enough so that the monitoring data can be adequately interpreted.

5. Collection and analysis of monitoring data at temporal scales that are appropriate to the nature of the data and the design of each component of the

Comprehensive Plan. Depending upon what is being monitored, these time scales may range from hourly for hydrological parameters (such as water stage or discharge), to daily for physical parameters (such as urban flood protection levels or saltwater intrusion), to once every several years (such as for soil thickness).

6. A formally established program for sharing and managing monitoring data and reports, among the agencies, other participants and interested parties.

7. Be in place sufficiently prior to the implementation of features of the Comprehensive Plan, so that baseline information on pre-project conditions and patterns can be established, before changes occur as a result of the projects. For elements of the natural system which typically operate on multi-year cycles, or which have relatively slow response times, monitoring to establish base-line conditions must begin years prior to the implementation of Comprehensive Plan features.

8. Develop standardized monitoring protocols at the initiation of the monitoring program. The program includes resources to maintain these monitoring protocols for the life of the program and avoid problems of data interpretation, which occur when the quality and quantity of these data vary over time and space.

9. Build on existing monitoring programs by the participating agencies, including reassessing monitoring priorities and protocols by each agency, within the context of a single, integrated regional program.

10. Finally, and most importantly, the program will measure the water quality, hydrological, physical and ecological parameters that are appropriate to the ecological restoration goals and measures of success that have been set for the program.

An essential component of this regional monitoring program is the creation of a single, integrated data management system (items 6 and 8 above). The South Florida Water Management District's Kissimmee River Restoration Evaluation Program, the U. S. Environmental Protection Agency's Environmental Monitoring and Assessment Program (EMAP), and the National Oceanic and Atmospheric Administration and Florida Department of Environmental Protection's Integrated Marine Monitoring Program are examples of the organization and implementation of such a program.

The Kissimmee program is both multi-agency and multi-disciplinary. Its overall purposes are to organize all monitoring data as a basis for quantifying and qualifying ecosystem responses to the restoration projects, and for evaluating the success of the restoration effort. To meet these purposes, the Kissimmee program provides a holistic and integrated picture of all monitoring data to ensure the proper definition of relationships among these data, and provides a database structure for efficiently storing and managing these data to ensure efficient and timely access to restoration monitoring data. The data management system has a central location, and a single, senior program manager responsible for overall quality of the system.

The Environmental Protection Agency's EMAP has been developed based on a stratified random sampling approach, which is essential for a meaningful interpretation of landscape-scale ecological monitoring. EMAP includes a statistical survey design, which allows for ecological analysis of the effects of the Comprehensive Plan components on restoration across the entire C & SF region, not just at or near specific sampling regions.

Beginning in 1995, scientists from Federal, state and local agencies have worked together to integrate the many environmental monitoring projects taking place in south Florida's marine and estuarine waters. Led by the National Oceanic and Atmospheric Administration and Florida Department of Environmental Protection, an inventory was conducted of planned, ongoing, and completed projects in coastal waters, and information on more than 200 projects was entered into a database. Many other agencies came together to review and prioritize the major issues affecting coastal areas, determine information needs, and develop a comprehensive monitoring plan. A geographic information system for sampling sites throughout the region is now being constructed, and gaps in data collection are being filled. This extensive multi-agency coordination will help to document change at the ecosystem level, measure the effectiveness of management actions, reduce monitoring gaps and overlaps, and improve existing monitoring capabilities.

9.5.3.1 Natural Systems Monitoring

There are several major reasons, with direct applications to the restoration effort, for conducting an extensive natural systems monitoring program: construction impact assessments, adaptive assessments, and for evaluating applications to other restoration efforts.

Construction impact assessments ensure that temporary or incidental environmental impacts are documented and minimized during construction. Because of the phased construction approach, this aspect of the monitoring program could prove to be particularly valuable in reducing effects of construction-related disturbance, including potential effects on endangered species and downstream effects that could affect subsequent restoration phases.

Ecological monitoring provides a basis for adaptive assessment measures that almost certainly will be needed to facilitate early recovery, as well as, subsequent persistence of the full complement of natural resource values. Although restoration of the study area's resources will occur primarily through natural processes, the restored system will have one significant management component - inflow regulation. Modeling studies have shown that the proposed restoration features will produce hydrologic and water quality characteristics that are within the required range of variability of the ecological restoration criteria. However, to achieve restoration and persistence of all biological components, some hydrologic characteristics, particularly discharge and flood inundation characteristics, must vary over the established historic range. Moreover, early recovery of some biological components could be slowed or inhibited if management of the regional hydrology produces hydrologic and water quality characteristics that are perhaps at one end of the spectrum of required variability. Comprehensive ecological monitoring will track restoration progress and provide the necessary data to effectively modify or adjust operation and management schemes to meet restoration objectives.

The potential that the restoration program planning and implementation principles and guidelines developed by the Restudy will be applicable to other regional restoration endeavors is another reason to conduct extensive ecological monitoring studies. One approach to evaluating the broader applicability of these principles and guidelines will be through measures of the effectiveness of the Restudy process, as demonstrated by system responses. Monitoring will provide a means for demonstrating the effectiveness of the regional planning and adaptive assessment protocols developed by the Restudy. The principles of ecosystem restoration that are being employed by the Restudy are pioneering at such vast temporal and spatial scales. The adaptive assessment strategy proposed in this process may be the most environmentally sound approach to restoration, and, over the long term, the most cost effective means of restoring the natural resource values of damaged ecosystems. It is important to demonstrate whether these planning principles and guidelines are applicable to other regions.

9.5.3.1.1 Natural System Elements to be Monitored

In order for the regional monitoring program to be both effective and efficient, substantial thought must be given to the choice of the components of the natural systems that should be monitored. Some guidelines for making these selections are presented in the Monitoring Planning Program Guidelines presented above. Additionally, it is highly important to select the most parsimonious set of components which will reveal the major (i.e., most significant) responses that are relevant to the issues being addressed by the restoration program. A major failing of many monitoring programs is that they attempt to monitor too large a number of system elements, more than are needed to evaluate how well a project meets its objectives, and more than can be adequately and consistently monitored over the time frames needed to evaluate these programs. Uncertainties in long-term funding and personnel which so commonly characterize large government programs require that excessive, and perhaps ecologically unnecessary, monitoring not be made a part of essential, long-term monitoring programs.

The Restudy is using a set of conceptual ecological models of the major physiographic and landscape features in south Florida (Ogden and Davis, in prep.) to identify a parsimonious set of natural system elements for inclusion in a regional monitoring program. The conceptual models show the major hydrological stressors in these systems, and how these stressors link, ecologically, with a set of attributes, which can be used to characterize the ecological health of these systems. The hydrological stressors identified by these models include both the water quantity and water quality impacts, which have been the major sources of ecological change in the natural systems. Because of the links (major ecological pathways) between the stressors and attributes, it is assumed that measures of change among the attributes will reflect the levels of success of the restoration projects at correcting the problems caused by the stressors. Teams of regional natural resource specialists selected the ecological attributes shown in each model. These attributes were selected because they directly reflect impacts from the major stressors, they are measurable and reasonably well understood, and they represent responses that are expected to occur over a range of spatial, temporal and hierarchical scales in the natural systems.

Because the restoration projects should cause changes (improvements) to both the stressors and the attributes in the models, both should be included in a monitoring program. An understanding of responses by both stressors and attributes not only is necessary to measure effects from the restoration projects, but also to evaluate ("test") the hypotheses which were used to create the models and to set priorities during restoration planning.

The hydrological stressors and attributes for the landscapes of the central and southern Everglades and Florida Bay were reported by Ogden et al. 1997. The four conceptual models contained in this report, for the central and southern Everglades sloughs, the southern Everglades marl prairies and rocky glades, the mainland mangrove estuaries downstream from the southern Everglades, and Florida Bay, serve to illustrate the stressors and attributes which should be monitored to determine restoration effects in these regions.

For the central and southern Everglades sloughs, the conceptual model shows the major hydrological stressors to be: annual and multi-year hydroperiods, wet season surface-water depths dry-season ground water depths, wet season regulatory releases, impoundments created by levees, and phosphorus and mercury loadings. The ecological attributes which reflect the effects from these stressors are: peat soil accretion rates; flood, fire and exotic plant conditions on tree islands; the distribution, composition and structure of marsh communities; species composition and production rates in periphyton communities; composition and size structure and abundance of marsh fishes and aquatic invertebrates; the abundance and density of alligator nests and active alligator ponds; and the size, timing and location of wading bird nesting colonies (including recovery of "super" colonies).

For southern Everglades marl prairies and rocky glades, the conceptual model suggests the stressors to be monitored should include duration of annual hydroperiods, dry-season minimum water levels, and dry-season recession patterns.

Monitored attributes are: marl accretion; vegetation community mosaics and composition; abundance and species composition of fishes, crayfish and the herpetofauna; abundance and density of alligator nests and active alligator ponds; Cape Sable seaside sparrow nesting distribution and abundance; seasonal abundance and distribution of foraging wading birds; and mercury and toxin loads in vertebrates.

For the southern mangrove estuaries, the stressors are the volume and duration of freshwater flows into the estuaries. The indicator attributes are: the species composition of submerged aquatic plants and the species and abundance of waterfowl in the coastal lakes: primary production and sediment accretion in the mangrove communities; the distribution and cover of vegetation communities; the production and survival of resident mangrove fishes; recruitment rates of juvenile sport fishes; growth and survival of juvenile crocodiles; and the patterns and success of wood stork and roseate spoonbill nesting colonies.

For Florida Bay, the hydrologically related stressors shown in the conceptual model are freshwater influences on salinity patterns, and nitrogen and phosphorus inputs. The indicator attributes for these stressors are: species composition; density and productivity in the seagrass communities; water chemistry and turbidity; species composition of mollusc communities; pink shrimp abundance; species composition of sport fishes; and the abundance and distribution of fish-eating birds (brown pelican, osprey, cormorant).

Stressors and attributes for Lake Okeechobee are shown in a conceptual model reported by K. Havens (Havens, 1998). For the Lake, the hydrologically related stressors are; elevated levels of contaminants, nutrients and sediments: prolonged extreme high water levels; and prolonged extreme low water levels. Attributes for the Lake are: the quality and quantity of urban and agriculture water supply; sport and commercial fisheries; spatial extent and composition of marsh communities; abundance and nesting success of snail kites; and the population size and nesting success of water birds.

Stressors and attributes for the Caloosahatchee and St. Lucie Estuaries have been shown in a conceptual model reported by S. Gray and D. Haunert (Gray and Haunert, 1998). The major hydrologically related stressors on these estuaries are, flood control releases from Lake Okeechobee, the seasonal timing and magnitude of freshwater flows, increased loads of nutrient and dissolved organics, and agricultural toxins. Attributes for these stressors are, benthic invertebrate community structure, submerged aquatic vegetation distribution and abundance, seagrass community structure, abundance and biomass of larval, juvenile fishes, fish catch rates, nesting success and abundance of fish-eating water birds, and abundance and recruitment of manatee.

Stressors and attributes for the Big Cypress Basin are shown in a conceptual model reported by M. Duever (Duever, 1998). Hydrologically related stressors are: the bioaccumulation of mercury and other toxins; inflows of drainage water with high nutrient and mineral content; and lowered water tables and shortened hydroperiods. Attributes of these stressors are: mercury and toxin body burdens in vertebrates; composition, structure and distribution of vegetation communities; abundance and distribution of fishes, crayfish and amphibians; size, distribution and success of wood stork nesting colonies; and population size, reproductive success and mercury body burdens for Florida panther.

A written performance measure is prepared for each stressor and attribute (indicator) to be monitored. The performance measure identifies the restoration target and the specific parameters to be measured, as a basis for determining how each stressor and attribute responds to the restoration projects. A set of hydrological performance measures which covers the major stressors from the conceptual models was prepared by the Restudy, Alternative Plan Evaluation Team, and is described in **Section 7** of this report. Performance measures for the attributes in the models still remain to be created.

9.5.3.2 Hydrologic Monitoring

The current hydrologic monitoring system was devised primarily to support the current operations of the Central and Southern Florida Project. The design and implementation of the Restudy components necessitates the need for modifications to the current monitoring system. The need comes from: (1) new data requirements for modeling in the detail design phase; (2) the development of new components that dramatically modify the existing hydrologic patterns and conditions; and (3) changes needed in traditional monitoring programs to correctly monitor new features such as sheetflow. Traditional data collection sites may not be consistent with areas being targeted for specific hydrologic changes. Furthermore, new “trigger” points for future operational purposes may also require new monitoring sites.

In addition to identifying several areas that will require special operations, new monitoring techniques, and new monitoring sites, the Restudy process also identified significant data gaps in some areas. For example, during the development of performance measures by the Alternative Evaluation Team, data necessary for evaluation were not available for a number of ecologically sensitive areas. Vast areas within the Big Cypress National Preserve were ungaged; thus conclusive ecological evaluations dependent upon hydropatterns were not possible.

Development of a new hydrologic monitoring program will require a multi-disciplinary team to ensure the hydrologic factors needed for ecological evaluations, as well as operational input needs, are developed. Monitoring for ecological assessments will be different from sampling for operational purposes. New monitoring programs for ecological assessments will be especially critical in areas undergoing extensive hydrologic modification. The monitoring program will be crucial to the success of adaptive management for the ecological restoration of the Everglades.

9.5.3.3 Water Quality Monitoring

Numerous water quality monitoring programs are currently being conducted by federal, state, tribal and local governments across south Florida. The location, sampling frequency and water parameters monitored associated with these existing water quality monitoring programs relate to existing regulatory, non-regulatory, and research programs. Development of an integrated, system-wide water quality monitoring program linked to hydrological and physical process monitoring programs will be a primary objective of the recommended feasibility study supporting the creation of a Comprehensive Integrated Water Quality Plan feasibility study (see ***Section 9.7.3***).

Design of a water quality monitoring program will be driven by the need to measure appropriate water quality parameters in watersheds that will be affected by the operation and construction of Comprehensive Recommended Plan components and Other Project Elements. The Restudy monitoring program should focus on developing sufficient baseline information to characterize watersheds in order to complete detailed planning and design work necessary to construct and operate recommended plan features to achieve pollutant load reduction targets. Nutrient (e.g., nitrates, phosphorus) concentrations and loads are of particular concern in south Florida water bodies. The majority of use-impaired water bodies are impaired due to elevated nutrient levels. Water quality monitoring will be also developed to obtain critical water quality information relating to ecological performance measures and ecological responses associated with the conceptual ecological models (see ***Section 9.5.3.1***) and supporting existing and future water quality models.

The Comprehensive Integrated Water Quality Plan will be crucial to the development of the Restudy water quality monitoring program since it will address issues of fragmented, uncoordinated water quality sampling, data quality, and climatological effects and trends. The Comprehensive Integrated Water Quality Plan will also include recommendations for oversight and support of improved water quality modeling efforts in south Florida, recommendations for development of additional water quality restoration targets and appropriate pollution load reduction targets, where needed, and recommendations for remediation programs to achieve water quality restoration targets. This additional information will support changes and improvements to the Restudy water quality monitoring program consistent with the adaptive assessment monitoring process described in ***Section 5***.

9.5.3.4 Physical Process Monitoring

Physical process monitoring will encompass a number of activities in the south Florida ecosystem. These activities include saltwater intrusion, flood level protection, urban and agricultural water use, sea level rise, soil subsidence/accretion, soil genesis due to restoration, and the ability of implemented components to achieve their anticipated performance. The majority of these activities are currently underway but will require a coordinated approach with long-term commitment if they are to be successful. Saltwater intrusion monitoring will allow the interagency monitoring coordination team the ability to evaluate the implementation of the recommended plan on urban areas, detect movement of the saltwater/ freshwater interface and make changes under the adaptive management strategy of the C&SF Comprehensive Review Study Implementation Plan, to counter unwanted movement. A successful monitoring program coupled with an adaptive management strategy will ensure the long-term health and integrity of the water supply wellfields of the region.

Flood level protection monitoring will ensure that the existing level of protection is not compromised as a result of implementation of the recommended plan. Coupled with an adaptive assessment strategy any unforeseen effects of the plan could be corrected.

Urban and agricultural water use monitoring will ensure that any significant deviation from forecasts of urban consumption and estimates of agricultural consumption that were included in the assumption base for this plan will be accounted for. Periodic comparisons (e.g., every three to five years) of actual consumption with that used in the Comprehensive Plan will allow for plan adjustments through time.

Sea level rise will need to be continuously monitored so that both saltwater intrusion protection and flood protection levels within the south Florida urban areas is not compromised as a result of this global process. Sea level rise will also affect the south Florida ecosystem in ways that are not fully anticipated or understood. Monitoring in the natural system will help resource managers understand how the ecosystem is evolving in response to the changing conditions and to better understand the relative contribution that sea level rise and changes in freshwater flow into the estuaries have on vegetation composition in the coastal zones.

Soil subsidence/ accretion and soil genesis monitoring will be used as another indicator metrics to determine if the recommended plan is moving the restoration process in the predicted direction of success. A major success measure for the slough system is the recovery of organic soils. Where portions of the slough systems currently are losing organic soils through increased fire frequencies and increased soil subsidence, restoration should result in soil accretion. Longer, more natural hydroperiods are expected to recover the processes that build organic soils. A long-term monitoring program will need to be institutionalized, to provide regional measures of rates of change in soil depths.

Post-construction monitoring of the recommended components, such as reservoirs and aquifer storage and recovery facilities, will be needed to determine whether their performance is achieving that anticipated in the planning process. This monitoring is necessary to evaluate the plan's overall effectiveness in providing the water needs of the south Florida ecosystem.

9.6 FISH AND WILDLIFE MITIGATION

During subsequent phases of this project, the construction features of the Comprehensive Plan will be designed to first avoid and then minimize unavoidable impacts to wetlands or other aquatic sites and natural upland habitats. Unavoidable impacts to these habitats are expected to be offset by the ecological improvement throughout the south Florida ecosystem that results from the overall restoration achieved by the Comprehensive Plan. Accordingly, separate compensatory mitigation features are not included in the recommended Comprehensive Plan for these impacts.

However, in certain wetland or upland areas, the construction and operation of Comprehensive Plan features may adversely affect unique or scarce habitats. In such cases, the project components will be sited and engineered to be environmentally compatible when possible. As site-specific details for the components are developed during the Project Implementation Report process, land suitability analyses will be utilized as part of the site selection process. Sites with extensive unique or scarce habitats will be avoided to the greatest extent practicable. For selected sites where impacts to these habitats are unavoidable, impacts will be minimized through project design. If impacts to unique or scarce habitats can not be avoided, a separable compensatory mitigation plan may be needed.

There also could be impacts to existing wetland compensatory mitigation sites that were established by authorized regulatory permits. These compensatory mitigation sites were established as permit requirements in order to offset the adverse environmental impacts of permitted development projects and the attendant reduction of the spatial extent of wetlands at the development sites. Subsequent elimination or reduction of these environmental benefits due to Restudy activities may require reevaluation of the mitigation analysis used in the original permit decision by the District Engineer.

Furthermore, one of the Restudy goals is to increase the spatial extent of wetlands within the study area. Adverse effects to regulatory-derived mitigation sites, which were intended to offset losses in the spatial extent wetlands, could result in the Restudy contributing to losses in spatial extent. Accordingly, adverse impacts to regulatory-derived compensatory mitigation sites attributable to construction of a Comprehensive Plan component or its operation will be offset as part of Restudy implementation. This compensatory mitigation requirement for the Restudy must be derived from sources other than the benefits claimed by the Comprehensive Plan itself. Therefore, a separable compensatory mitigation plan for these impacts may be needed. The type and extent of the mitigation requirement will be determined in subsequent phases of this project on a case by case basis.

9.7 NEW FEASIBILITY STUDIES

The time frame of this feasibility study did not permit a thorough investigation of all the regional water resource problems of south Florida. Therefore, subsequent to the completion of this feasibility study, a number of new feasibility studies are proposed. They include a Florida Bay and the Florida Keys Feasibility Study, a Southwest Florida Feasibility Study, and a Comprehensive Integrated Water Quality Plan. These studies will be conducted under the authority of the Water Resources Development Act of 1996 that allows for the continuation of studies and analyses that are necessary to further the Comprehensive Plan.

9.7.1 Florida Bay and the Florida Keys Feasibility Study

Construction of Flagler's railroad to Key West and subsequent conversion into U.S. Highway 1 (US-1) involved the placement of fill material in wetlands and open water for the numerous causeways between keys. These causeways altered tidal flows between Florida Bay and the Atlantic Ocean, resulting in adverse water quality and fish and wildlife habitat impacts. One of the House of Representatives Committee on Public Works and Transportation resolutions of September 24, 1992 requested that the Corps of Engineers conduct a study of Florida Bay, including a comprehensive, coordinated ecosystem study with hydrodynamic modeling of Florida Bay and its connections to the Everglades, the Gulf of Mexico, and the Florida Keys Coral Reef ecosystem. Hydrodynamic and water quality models currently under development for Florida Bay will provide the tools necessary for evaluation of the problem in a holistic manner. A feasibility study is recommended to comprehensively evaluate Florida Bay and to determine the types of modifications that are needed to successfully restore water quality and ecological conditions of the Bay.

9.7.2 Southwest Florida Feasibility Study

The Caloosahatchee River is the only portion of the C&SF Project that lies in southwest Florida. The river serves as an outlet from Lake Okeechobee to the Gulf of

Mexico and is the major source of surface water supply for the Lower West Coast region. It provides agricultural and lawn irrigation, public water supplies and is used to recharge shallow wellfields. The river also provides drainage for private drainage systems and local drainage districts.

The facilities included in the Comprehensive Plan for the Caloosahatchee River Basin will help meet the needs of the basin. However, there are additional water resources problems and opportunities in southwest Florida that require studies that are beyond the scope of the Comprehensive Plan. For example, primary water quality and hydrologic data do not exist for much of the region. This lack of information, assessments and monitoring data is a fundamental gap for this region of the state and greatly hinders its long-term water resources management opportunities.

The Southwest Florida Feasibility Study will include Collier, Lee, Charlotte, Glades, and Hendry Counties; and provide a framework to address the health of aquatic ecosystems; water flows; water quality (including appropriate pollution reduction targets), water supply; flood protection, wildlife, and biological diversity and natural habitat. The study will also investigate non-structural alternatives.

9.7.3 Comprehensive Integrated Water Quality Plan

The recommended Comprehensive Plan includes a number of construction features, such as stormwater treatment areas, specifically designed to improve water quality conditions for the purpose of south Florida ecosystem restoration. Further, the plan includes other construction features, such as water storage reservoirs that could be designed to maximize water quality benefits to downstream water bodies. Optimizing the design and operation of construction features of the recommended plan to achieve water quality restoration targets is essential for achieving overall ecosystem restoration goals for south Florida.

Degradation of water quality throughout the study area is extensive, particularly in agricultural and urban coastal areas. The Florida Department of Environmental Protection listed approximately 160 use-impaired water bodies in south Florida in its 1998 Section 303(d) list (see ***Section 5.3***). Although there are several ongoing water quality restoration programs in the study area (e.g. National Pollutant Discharge Elimination System (NPDES) point and non-point source regulatory programs, total maximum daily loads (TMDLs) development and remediation programs, Surface Water Improvement and Management planning efforts), there is no comprehensive plan for achieving water quality restoration in south Florida which links together water quality restoration programs in the context of comprehensive planning for ecosystem restoration. It is also recognized that achieving all of the water quality goals for ecosystem restoration in all use-impaired water bodies within the study area will depend on actions outside the scope of the Restudy. The South Florida Water Management District, Florida Department of Environmental Protection, U.S. Environmental Protection Agency and other agencies have developed or are developing water quality improvement programs for several of the impaired water bodies within the Restudy area. The most notable example is the Everglades Forever Act, which focuses on achieving adequate water quality in the Everglades. Other examples include the Surface Water Improvement and Management Act planning efforts for the Indian River Lagoon, Lake Okeechobee, and Biscayne Bay, and the Florida Keys National Marine Sanctuary Water Quality Protection Program. However, the degree to which some of the existing water quality improvement programs have been implemented has been limited. To ensure that south Florida ecosystem restoration objectives are achieved, a Comprehensive Integrated Water Quality Plan that links water quality restoration targets and remediation programs to the hydrologic restoration objectives of the recommended plan must be developed for the entire study area.

Development of a comprehensive integrated water quality plan for south Florida is consistent with recommendations of the South Florida Ecosystem Restoration Task Force and the Florida Governor's Commission for a Sustainable South Florida. In its July, 1998 Interim Report on the C&SF Project Restudy (GCSSF, 1998), the Governor's Commission recommended that a water quality implementation plan for the Restudy be developed with Florida Department of Environmental Protection as the lead agency, in cooperation with the U.S. Environmental Protection Agency, U.S. Army Corps of Engineers, South Florida Water Management District, the Seminole and Miccosukee Native American Tribes, and local governments. In order to resolve water quality problems on an ecosystem wide basis, the Governor's Commission recommended that a comprehensive water quality plan be initiated as a feature of the Restudy.

The Comprehensive Integrated Water Quality Plan for south Florida would involve identifying pollution-impaired water bodies, quantifying types and sources of pollution, establishing interim and final pollution load reduction targets necessary to achieve ecosystem restoration, recommendations for development of potential source reduction programs, recommendations for baseline and future water quality monitoring programs to assess ecological responses to water quality changes, and recommendations for designing and constructing water quality treatment facilities, if necessary. Although the scope of the feasibility study has not yet been developed, it is envisioned that the feasibility study would also address issues of fragmented, uncoordinated water quality sampling, data quality, and climatological effects and trends; recommendations for oversight and support of improved water quality modeling efforts in south Florida; development of additional water quality restoration targets, where needed; recommendations for remediation programs to achieve those targets; recommendations for Best Management Practices in specific agricultural and urban areas where appropriate (including identifying those urban areas where participation in the NPDES municipal stormwater program is needed); and, recommendations for synchronizing water quality restoration programs with the implementation schedule for the components of the recommended plan. The Comprehensive Integrated Water Quality Plan would also include recommendations for locations of water storage and treatment areas and design features for optimizing recommended plan components to achieve water quality restoration targets. The comprehensive integrated water quality plan may also lead to recommendations for additional features (e.g., polishing cells, operational features) for recommended plan components currently lacking specific water quality performance elements.

A discrete task which has already been identified to be performed as part or the Comprehensive Integrated Water Quality Plan study is further evaluating the feasibility of dredging phosphorus-enriched sediments in Lake Okeechobee. For other regions of the study area, the extent of water quality problems and key water quality restoration targets are less well known. Particular regions where establishment of pollutant load reduction targets needs to be accelerated to enable optimization of recommended Comprehensive Plan components for water quality benefits are: the lower Kissimmee River region; the Lake Okeechobee watershed; the St. Lucie River and estuary and Indian River Lagoon, the Caloosahatchee River and estuary, the Lake Worth Lagoon, Biscayne Bay, Florida Bay, and the Florida Keys.

For the Florida Keys particularly, the Comprehensive Integrated Water Quality Plan would ensure that the Florida Keys Water Quality Protection Program is integrated with the recommended Comprehensive Plan and with water quality improvement activities in the Keys. The Comprehensive Integrated Water Quality Plan would also expedite development of salinity based water quality criteria for Florida Bay and appropriate pollution load reduction targets for pollutants causing impairment in nearshore waters of the Florida Keys.

9.8 FUTURE IMPROVEMENTS TO THE COMPREHENSIVE PLAN

In response to comments made by the public and in the draft Fish and Wildlife Coordination Act report, the Study Team identified a process by which key ecosystem restoration features could be further improved through optimization and adaptation of the draft comprehensive plan (D-13R). Most notably since November 1998, the Study Team has developed and run several modeling “scenarios” (described in ***Section 7***) in which the draft comprehensive plan was modified in an effort to improve restoration in key areas of the south Florida ecosystem. These scenarios were vital in demonstrating the robust and flexible nature of the recommended comprehensive plan and its ability to be manipulated to further improve performance.

A major impetus for developing these scenarios was to determine if additional water could be captured in the Lower East Coast urban areas and used to better meet performance measure targets in the Water Conservation Areas and Everglades National Park, as well as for investigating alternative sources of water for Biscayne Bay. The importance of improving the performance of the draft plan in these areas is fully understood. Also, consistent with the Governor’s Commission for a Sustainable South Florida's long held principle that no part of the ecosystem will be harmed during the implementation phase of the Restudy, such improvements cannot be undertaken at the ecological expense of the Water Conservation Areas. These efforts ultimately resulted in scenario runs D-13R$_{1-4}$. Preliminary evaluation by the interagency Alternative Evaluation Team indicates that additional captured water (about 245,000 acre-feet) helps to meet hydrologic targets for Everglades National Park, Biscayne Bay and some areas within the Water Conservation Areas. In other areas of the Water Conservation Areas and the Pennsuco Wetlands, performance declines markedly relative to D-13R. In addition, issues relative to treating urban runoff prior to discharge into the Water Conservation Areas and the Everglades, and impacts to secondary canals have not been resolved.

The Restudy is committed to implementing the final plan in a manner that provides improvements to the operation of the Water Conservation Areas as well as providing more water for Everglades National Park and Biscayne Bay. In addition, the Restudy is committed to solving the remaining operational problems of the Water Conservation Areas associated with the Comprehensive Plan. The final comprehensive plan that is implemented will provide for an improved capability for delivery of additional water to Everglades National Park and Biscayne Bay by capturing additional runoff from urban areas. The Implementation Plan (***Section 10***) includes a phased approach to provide for substantial improvements and the maximum ecological benefits to the Water Conservation Areas, Everglades National Park, Biscayne Bay, and those other natural areas that have been adversely affected by the C&SF Project. The ultimate amount of additional water recaptured and its distribution will be determined based on this phased approach and the ability to obtain the maximum ecological benefits in each of these areas. While some implementation scenarios indicate a reduction of fresh water flows to Biscayne Bay, the Comprehensive Plan will be implemented in a way that avoids such results. Scientists, including scientists from Biscayne National Park, are reviewing the performance measures for Biscayne Bay and it is possible that there will be a consensus conclusion that alternative fresh water flow patterns may be beneficial to Biscayne Bay. Only in that event would reducing flows below the 1995 base to Biscayne Bay during the implementation phase of the Restudy be considered.

Many of the issues that have been raised regarding the Restudy performance in natural areas will be addressed during the development of the Project Implementation Report for each component. The ideal restoration solution for the remnant natural areas would be one without control structures. For that reason, where control structures are required, a preference for the use of passive control structures will be established. For example, in those cases where structural controls within natural areas are unavoidable for water management, the detailed design for project components will include passive control features to the maximum extent practicable. Further, the Implementation Plan (***Section 10***) will commit to limiting the use of active features, such as pumps and gates, to those situations where passive controls are not adequate.

9.9 COST ESTIMATE

The estimated cost estimate for the Comprehensive Plan include construction and real estate costs which have been termed Initial Costs; Adaptive Assessment and Monitoring Program costs, and Operation and Maintenance Costs.

9.9.1 Initial Costs

The total estimated cost of the recommended Comprehensive Plan is $7,800,000,000 (rounded) at October 1999 price levels. The cost estimate is shown in ***Table 9-2***. This estimate is the "base line" estimate, and does not account for future price escalation.

9.9.2 Adaptive Assessment and Monitoring Costs

The adaptive assessment and monitoring program for the Comprehensive Plan is still under development. Given the conceptual nature of plan and the need to integrate the monitoring program with other ongoing efforts, it is difficult to prepare a detailed estimate of its cost at the present time. However, based on other ongoing monitoring programs such as the Kissimmee River and the C-111 Project, the annual monitoring cost was estimated to be $10,000,000 during the period of construction.

9.9.3 Operation, Maintenance, Repair, Replacement, and Rehabilitation (OMRR&R) Costs

Annual operation and maintenance costs were estimated for the construction features of the recommended Comprehensive Plan. The operation and maintenance costs were determined by extrapolating from operational cost histories supplied by the South Florida Water Management District. The costs reflect projected values based on past trends encountered and represent the difference between with versus without the Comprehensive Plan. Replacement costs were calculated for culverts and mechanical and electrical equipment related to pump plants and spillway structures. The annual OMRR&R costs are estimated to be $172,000,000 (rounded) and are provided in ***Table 9-3***.

TABLE 9-2
ESTIMATED INITIAL COST FOR CONSTRUCTION FEATURES
($1,000, October 1999 Price Levels)

Report Section	CONSTRUCTION FEATURES	Construction	Real Estate	Total Initial Cost
9.1.1	**Kissimmee River Region**			
9.1.1.1	North of Lake Okeechobee Storage Reservoir	$95,134	$189,720	$284,854
9.1.1.2	Taylor Creek/Nubbin Slough Storage and Treatment Area	$74,326	$29,700	$104,026
9.1.1.3	Lake Okeechobee Watershed Water Quality Treatment Facilities	$47,800	$14,448	$62,248
9.1.1.4	Lake Okeechobee Tributary Sediment Dredging	$3,800	$900	$4,700
9.1.1.5	Lake Istokpoga Regulation Schedule	$50	$0	$50
9.1.2.1	Lake Okeechobee Aquifer Storage and Recovery	$1,108,797	$7,515	$1,116,312
9.1.3	**Caloosahatchee River Region**			
9.1.3.1	C-43 Basin Storage Reservoir and Aquifer Storage and Recovery	$313,574	$132,621	$446,195
9.1.3.2	Caloosahatchee Backpumping with Stormwater Treatment	$69,715	$13,179	$82,894
9.1.4	**Upper East Coast**			
9.1.4.1	C-44 Basin Storage Reservoir	$21,888	$90,675	$112,563
9.1.4.2	C-23/C-24/C-25/Northfork and Southfork Storage Reservoirs	$281,175	$429,048	$710,223
9.1.5	**Everglades Agricultural Area**			
9.1.5.1	Everglades Agricultural Storage Reservoirs	$350,112	$86,536	$436,648
9.1.6	**Big Cypress Region**			
9.1.6.1	Big Cypress/L-28 Interceptor Modifications	$36,051	$6,700	$42,751
9.1.6.2	Seminole Tribe Big Cypress Water Conservation Plan - (East & West)	$69,553	$5,735	$75,288
9.1.7	**Water Conservation Areas Region**			
9.1.7.1	Flow to Northwest and Central Water Conservation Area 3A	$30,877	$0	$30,877
9.1.7.2	Water Conservation Area 3 Decompartmentalization and Sheetflow Enhancement	$185,408	$26,279	$211,687
9.1.7.3	Loxahatchee National Wildlife Refugee Internal Canal Structures	$7,324	$345	$7,669
9.1.7.4	Miccosukee Water Management Plan	$22,741	$1,718	$24,459
9.1.8	**Lower East Coast Region**			
9.1.8.1	Pal-Mar and J.W. Corbett Wildlife Management Area Hydropattern Restoration	$2,500	$8,000	$10,500
9.1.8.2	Water Preserve Areas / L-8 Basin	$383,541	$31,641	$415,182
9.1.8.3	Acme Basin B Discharge	$11,600	$8,500	$20,100
9.1.8.4	Lake Worth Lagoon Restoration	$2,000	$300	$2,300
9.1.8.5	Winsburg Farms Wetland Restoration	$10,000	$4,140	$14,140
9.3.6	Palm Beach County Wetlands Based Water Reclamation	$24,900	$2,800	$27,700
9.1.8.6	C-17 Backpumping and Treatment	$9,824	$10,367	$20,191
9.1.8.7	C-51 Backpumping and Treatment	$19,156	$13,475	$32,631

Report Section	CONSTRUCTION FEATURES	Construction	Real Estate	Total Initial Cost
9.1.8.8	C-51 Regional Groundwater Aquifer Storage and Recovery	$122,391	$9,945	$132,336
9.1.8.9	Palm Beach County Agricultural Reserve Reservoir and Aquifer Storage and Recovery	$66,442	$57,657	$124,099
9.1.8.10	Protect and Enhance Existing Wetland Systems along Loxahatchee National Wildlife Refuge including the Strazzulla Tract	$3,800	$48,972	$52,772
9.1.8.11	Site 1 Impoundment and Aquifer Storage and Recovery	$116,792	$23,587	$140,379
9.1.8.12	Broward County Secondary Canal System	$10,978	$1,920	$12,898
9.1.8.13	Western C-11 Diversion Impoundment and Canal and Water Conservation Areas 3A and 3B Levee Seepage Management	$57,526	$167,646	$225,172
9.1.8.14	C-9 Stormwater Treatment Area/Impoundment	$26,207	$62,939	$89,146
9.1.8.15	North Lake Belt Storage Area	$381,193	$154,868	$536,061
9.1.8.16	Diverting Water Conservation Area 2 and 3 flows to Central Lake Belt Storage	$66,336	$13,321	$79,657
9.1.8.17	Central Lake Belt Storage Area	$402,502	$100,359	$502,861
9.1.8.18	Dade-Broward Levee/Pennsuco Wetlands	$10,103	$8,676	$18,779
9.1.8.19	C-4 Control Structures	$1,834	$495	$2,329
9.1.8.20	Bird Drive Recharge Area	$52,459	$71,625	$124,084

TABLE 9-3
OPERATIONS, MAINTENANCE, REPAIR, REPLACEMENT AND REHABILITATION COSTS

Report Section	Operations and Maintenance	Cost
9.1.1	**Kissimmee River Region**	
9.1.1.1	North of Lake Okeechobee Storage Reservoir	$1,515,245
9.1.1.2	Taylor Creek/Nubbin Slough Storage and Treatment Area	$2,164,114
9.1.1.3	Lake Okeechobee Watershed Water Quality Treatment Facilities	$2,602,000
9.1.1.4	Lake Okeechobee Tributary Sediment Dredging	$0
9.1.1.5	Lake Istokpoga Regulation Schedule	$0
9.1.2.1	Lake Okeechobee Aquifer Storage and Recovery	$25,000,000
9.1.3	**Caloosahatchee River Region**	
9.1.3.1	C-43 Basin Storage Reservoir and Aquifer Storage and Recovery	$6,707,889
9.1.3.2	Caloosahatchee Backpumping with Stormwater Treatment	$2,273,076
9.1.4	**Upper East Coast**	
9.1.4.1	C-44 Basin Storage Reservoir	$759,953
9.1.4.2	C-23/C-24/C-25/Northfork and Southfork Storage Reservoirs	$4,832,774
9.1.5	**Everglades Agricultural Area**	
9.1.5.1	Everglades Agricultural Storage Reservoirs	$14,458,409
9.1.6	**Big Cypress Region**	
9.1.6.1	Big Cypress/L-28 Interceptor Modifications	$404,457
9.1.6.2	Seminole Tribe Big Cypress Water Conservation Plan	$775,000
9.1.7	**Water Conservation Areas Region**	
9.1.7.1	Flow to Northwest and Central Water Conservation Area 3A	$1,102,327
9.1.7.2	Water Conservation Area 3 Decompartmentalization and Sheetflow Enhancement	$740,111
9.1.7.3	Loxahatchee National Wildlife Refugee Internal Canal Structures	$42,045
9.1.7.4	Miccosukee Water Management Plan	$540,000
9.1.8	**Lower East Coast Region**	
9.1.8.1	Pal-Mar and J.W. Corbett Wildlife Management Area Hydropattern Restoration	$60,000
9.1.8.2	Water Preserve Areas / L-8 Basin	$2,273,929
9.1.8.3	Acme Basin B Discharge	$594,000
9.1.8.4	Lake Worth Lagoon Restoration	$0
9.1.8.5	Winsburg Farms Wetland Restoration	$200,000
9.3.6	Palm Beach County Wetlands Based Water Reclamation	$2,500,000
9.1.8.6	C-17 Backpumping and Treatment	$752,435

Report Section	Operations and Maintenance	Cost
9.1.8.7	C-51 Backpumping and Treatment	$1,089,682
9.1.8.8	C-51 Regional Groundwater Aquifer Storage and Recovery	$1,496,000
9.1.8.9	Palm Beach County Agricultural Reserve Reservoir and Aquifer Storage and Recovery	$1,019,500
9.1.8.10	Protect and Enhance Existing Wetland Systems along Loxahatchee National Wildlife Refuge including the Strazzulla Tract	$90,000
9.1.8.11	Site 1 Impoundment and Aquifer Storage and Recovery	$2,052,608
9.1.8.12	Broward County Secondary Canal System	$418,017
9.1.8.13	Western C-11 Diversion Impoundment and Canal and Water Conservation Areas 3A and 3B Levee Seepage Management	$783,432
9.1.8.14	C-9 Stormwater Treatment Area/Impoundment	$615,743
9.1.8.15	North Lake Belt Storage Area	$1,241,234
9.1.8.16	Diverting Water Conservation Area 2 and 3 flows to Central Lake Belt Storage	$146,635
9.1.8.17	Central Lake Belt Storage Area	$1,964,519
9.1.8.18	Dade-Broward Levee/Pennsuco Wetlands	$105,871
9.1.8.19	C-4 Control Structures	$30,015
9.1.8.20	Bird Drive Recharge Area	$1,470,869
9.1.8.21	L-31N Levee Improvements for Seepage Management and S-356 Structures	$4,647,234
9.1.8.22	West Miami-Dade County Reuse	$36,500,000
9.1.8.23	Biscayne Bay Coastal Wetlands	$923,300
9.1.8.24	South Miami-Dade County Reuse	$47,815,000
9.1.8.25	Restoration of Pineland & Hardwood Hammocks in C-111 Basin	$0
9.1.8.26	C-111N Spreader Canal	$59,586
9.1.9	**Southwest Florida Region**	
9.1.9.1	Southern Golden Gates Hydrologic Restoration	$93,000
9.1.9.2	Southern CREW Project Addition	$160,000
9.1.9.3	Lake Trafford Restoration	$0
9.1.9.4	Henderson Creek/Belle Meade Restoration	$41,000
9.1.9.5	Lake Park Restoration	$62,000
9.1.10	**Florida Bay and Keys**	
9.1.10.1	Florida Keys Tidal Restoration	$0
9.1.11	**System-wide**	
9.1.11.1	Melaleuca Eradication Project and other Exotic Plants	$5,000
	TOTAL	$172,404,805
	Rounded	**172,000,000**

9.9.4 Annual Costs

Investment costs were converted to annual costs using an interest rate of 6 7/8 percent and a project life of 50 years to compute interest and amortization. Annual operation and maintenance costs were then added to the interest and amortization costs to determine the average annual cost, which is $404,946,000 for the recommended Comprehensive Plan.

9.9.5 Cost Estimate Uncertainties

The current estimated cost of the recommended Comprehensive Plan is based on the best available information. Appropriate contingency factors were used in developing the cost estimates to reflect the uncertainties inherent at this stage of project development. It is anticipated that the cost of the plan will be modified in the future as pilot projects and individual Project Implementation Reports are completed. As more site specific analysis is completed the contingency factors will be revised to reflect the greater levels of certainty. Value engineering will be used to optimize the design of facilities in the detailed planning and design phases of implementation for individual projects. During the detailed design phases, opportunities will be sought that reduce the number of control structures as well as using more passive control structures wherever feasible, which could result in reduced construction and OMRR&R costs of projects.

In addition there are other factors which may reduce the cost of the recommended plan. For instance, the aquifer storage and recovery pilot projects will evaluate the water quality of the source water to be used for aquifer storage and recovery and help identify the level of treatment necessary as defined by the U. S. Environmental Protection Agency and Florida Department of Environmental Protection. ***Appendix C*** provides a more detailed discussion of aquifer storage and recovery treatment methods. However, preliminary water quality information and correspondence from the U.S. Environmental Protection Agency indicates that the high level of treatment for aquifer storage and recovery facilities included in the recommended Comprehensive Plan may not be required and a reduction in treatment costs up to $500,000,000 may be possible (U.S. Environmental Protection Agency, 1999). Information derived from the pilot projects will be used to conduct a risk-based analysis of treatment requirements. Reducing the requirements of treating water for aquifer storage and recovery may also result in a reduction in the OMRR&R costs for these facilities.

Further, wastewater reuse facilities included in the recommended Comprehensive Plan which provide additional water flows to Biscayne Bay is another area where project cost estimates may be modified. Refinement of ecological goals and objectives for Biscayne Bay along with evaluation of alternative sources of water for Biscayne Bay may result in a reduction in the need for superior, advanced wastewater facilities and a subsequent reduction in project costs. The two wastewater reuse facilities account for an estimated $84,000,000 (rounded) of the total OMRR&R costs. As noted previously, the evaluation of alternative water supply sources for Biscayne Bay may reduce the need for advanced treatment or the need for all or a part of the volume of wastewater that is currently identified in the recommended Comprehensive Plan.

9.10 COST SHARING

Responsibilities for implementing the recommended Comprehensive Plan will be shared by the Corps of Engineers, on behalf of the Federal government, and the non-Federal sponsor, the South Florida Water Management District. The Corps will design the project and administer construction contracts to build the project. The South Florida Water Management District will be involved in the project design; will share the design and construction costs; furnish necessary lands, easements, rights of way, relocation, and disposal areas (collectively referred to as LERRD); and operate and maintain the completed project. Rules, which determine how project responsibilities are shared, are established in Federal law and related Administration implementing policies.

9.10.1 Cost Sharing of Water Quality Features

Section 528 of the Water Resources Development Act of 1996 requires that the Comprehensive Plan include water quality features necessary to provide water to restore, preserve, and protect the south Florida ecosystem. The Act further states that if the Secretary of the Army determines that a project feature to improve water quality is essential to Everglades restoration, the non-Federal cost of the feature shall be 50 percent. This provision does not apply to any feature of the Everglades Construction Project being constructed by the State of Florida.

Ecosystem restoration in south Florida depends, in part, on improving the timing and increasing the amount of water entering the Everglades to levels more typical of pre-drainage conditions. The source of this water is stormwater now sent to the coast in drainage canals, and diversions from Lake Okeechobee and other water storage facilities.

The State of Florida has water quality standards and regulatory programs in place that include protection of natural flora and fauna. However, requisite water quality characteristics (even for the same use classification) can vary depending on the type of natural flora and fauna present, or desired to be present. For example, while the water quality for the stormwater now discharged to the coast or Lake Okeechobee through drainage canals generally meets State standards, the Comprehensive Plan will result in delivering this water to areas that have a different water quality need. Therefore, the Comprehensive Plan was formulated to clean up this water before sending it to areas for ecosystem restoration purposes.

For the purpose of analyzing Federal participation in these water quality features, it is assumed that the Clean Water Act and State/Tribal water quality standards are being met for the existing use classification. This assumes that all reasonable measures within watersheds are in place to assure that the waters being received by the C&SF Project canal system are of sufficient quality to meet published standards. If these measures did not provide water of adequate quality for south Florida ecosystem needs, then additional features for water quality improvement were deemed essential for Everglades restoration and formulated and included in the Comprehensive Plan with 50-50 cost sharing. These features were formulated as either water reuse or water reclamation projects and are list in ***Table 9-4.***

Water reclamation includes modifying the C&SF Project system so that the stormwater that was once released to coastal waters or disposed of in some other way will be pumped back into the C&SF Project system to increase the volume of water available for ecosystem restoration. An example of reclaiming water includes the authorized C-51 Project which involves diverting stormwater that was formerly discharged to the Lake Worth Lagoon into the Loxahatchee National Wildlife Refuge (WCA-1) for restoration purposes. Given the change in discharge locations from the original canal design, the water will require additional treatment in a stormwater treatment area (STA-1E) prior to discharge into the Everglades. The Water Preserve Areas features of the Comprehensive Plan are another case of reclaiming waters that are presently discharged to coastal waters. The new locations of the proposed discharges will require water quality treatment prior to diverting the water into the wetlands adjacent to the Everglades. In these cases, the modification of the C&SF Project would warrant Federal participation in Comprehensive Plan water quality features due to the diversion of stormwater for Everglades restoration.

Water reuse involves changing the final use of the water for ecosystem restoration. Water that was originally discharged for flood control or used for water supply purposes will require treatment prior to being used for Everglades restoration. For example, proposed operational changes for Lake Okeechobee include water supply deliveries to the Water Conservation Areas for Everglades restoration. Water quality standards for nutrient concentrations in Lake Okeechobee are much less stringent than those for the Everglades. Therefore, any water delivered from Lake Okeechobee must be treated prior to direct use in the Everglades for ecosystem restoration purposes. These projects include modifying the final use classification of the water for the sole purpose of ecosystem restoration. Hence, all the features in the recommended plan are essential to Everglades restoration and 50-50 cost sharing applies.

TABLE 9-4

9.1.9.1	Southern Golden Gates Hydrologic Restoration		✓

9.10.2 Cost Sharing of Construction and Land Costs

Section 528 of the Water Resources Development Act of 1996 and U.S. Army Corps of Engineers policy requires that:

- LERRD will be provided by the non-Federal sponsor.

- The total first cost of the project, including the value of LERRD and pre-construction engineering and design costs, will be shared equally between the Federal government and the non-Federal sponsor. The non-Federal sponsor will provide cash as necessary during project construction to meet its 50 percent share of the total first cost of the project.

Table 9-5 contains an apportionment of project costs between the Federal government and the non-Federal sponsor based on these cost sharing provisions.

TABLE 9-5
COST APPORTIONMENT OF RECOMMENDED PLAN
(First Costs - rounded)

ITEM	TOTAL	FEDERAL	NON-FEDERAL
Construction	$5,500,000,000	$3,900,000,000	$1,600,000,000
LERRD	$2,300,000,000	$0	$2,300,000,000
Total	$7,800,000,000	$3,900,000,000	$3,900,000,000

9.10.3 Cost Sharing of Adaptive Assessment and Monitoring

The Adaptive Assessment Program that includes a system-wide monitoring program has been developed as described in ***Section 9.5.*** This program is needed to provide essential information that supports the development and the implementation of the recommended Comprehensive Plan. Continued system-wide planning data collected as part of the monitoring program is critical to the continuing development of the components of the plan by providing the basis for adjustments to design and operation criteria as needed. The monitoring program is a necessary component for assuring that ecosystem benefits are achieved in Everglades National Park, Biscayne Bay National Park, Big Cypress National Preserve, and the Loxahatchee Wildlife Refuge, as well as other natural areas. Consequently, it would be appropriate that these costs be shared between the Federal government and the non-Federal sponsor and that the costs be shared the same as the construction costs (50-50). It should be noted that monitoring cost associated with the Kissimmee River Restoration Project are cost shared 50 percent Federal and 50 percent non-Federal under the Corps of Engineers Construction Program.

9.10.4 Cost Sharing of Operations and Maintenance

Section 528 of the Water Resources Development Act of 1996 specifies that operation and maintenance of the Comprehensive Plan shall be a non-Federal responsibility. However, this provision is not consistent with previous C&SF Project authorizations. Some Operations, Maintenance, Repair, Replacement and Rehabilitation (OMRR&R) costs for the existing C&SF Project are cost shared between the South Florida Water Management District and the Corps of Engineers. The Corps, under the provision of the 1948 Flood Control Act (House Document 80-643) is responsible for the operation and maintenance of the levees, channels, locks, and control works of the St. Lucie Canal, Lake Okeechobee, and Caloosahatchee River and main spillways of the conservation areas. The SFWMD is responsible for operation and maintenance of the remainder (except for the Upper St. Johns Basin) of the C&SF Project Works in accordance with regulations prescribed by the Secretary of the Army.

The Flood Control Act of 1968 (Senate Document 90-369, Paragraph 119) states the following: "The cost of the project works for providing water to Everglades National Park is considered to be a wholly Federal responsibility…It was considered that the Federal Government would share in the major pumping costs for water supplies on the basis of 60 percent Federal and 40 percent non-Federal, which approximates the ratio of pumped water delivered to the Everglades National Park and the non-park users."

As a result of the Everglades National Park Expansion and Protection Act of 1989, OMRR&R costs of all proposed structure modifications of the C&SF project associated with Modified Water Deliveries to Everglades National Park are cost shared with the non-Federal sponsor. That cost sharing is set at 75 percent Federal and 25 percent non-Federal. The C-111 project is another project for which cost sharing was established on OMRR&R costs. The Flood Control Act of 1968 and Section 316 of the Water Resources Development Act of 1996 established this cost sharing at 60 percent Federal and 40 percent non-Federal for water supply to Taylor Slough and Everglades National Park. Cost sharing for both of these projects was established on the basis of benefits to Everglades National Park.

The recommended Comprehensive Plan contains a large number of components that together accomplish restoration of the south Florida ecosystem and directly benefit Everglades National Park, Biscayne National Park, Big Cypress National Preserve, and the Loxahatchee National Wildlife Refuge. The recommended Comprehensive Plan includes storage features such as in-ground and above-ground reservoirs as well as aquifer storage and recovery wells that are located outside the remaining natural Everglades. These storage facilities capture wet season excess flows that would normally be discharged into the coastal waters through the C&SF Project canals and retains them in the system until they are needed. This storage provides benefits to both the natural system (including Everglades National Park, Biscayne National Park, Big Cypress National Preserve, and the Loxahatchee National Wildlife Refuge) as well as the urban or agricultural users. The stored water that is returned to the Everglades directly benefits the natural system to achieve the goals of restoration. Further, the operation of these features of the Comprehensive Plan provides direct benefits to threatened and endangered species. These benefits will be experienced on Federal lands including Everglades National Park, Biscayne National Park, Big Cypress National Preserve, and the Loxahatchee National Wildlife Refuge, but they will also be experienced on non-Federal lands which threatened and endangered species utilize in south Florida.

The comprehensive plan contains a number of components that together accomplish restoration of the south Florida ecosystem and consequently benefit

Everglades National Park, Biscayne National Park, Big Cypress National Preserve, and the Loxahatchee National Wildlife Refuge. The Plan works as a whole to provide environmental restoration to the south Florida ecosystem. Given the multi-objective nature of these components and the difficulty of determining separable benefits for the components of the Comprehensive plan, it is appropriate that the costs for OMRR&R associated with the Comprehensive Plan be shared equally between the Federal government and the non-Federal sponsor.

SECTION 10
IMPLEMENTATION PLAN

The ultimate success of the Comprehensive Plan described in ***Section 9*** will be a reflection of its implementation over a period of more than 20 years. Simply stated, the hard work lies ahead in terms of restoring this important ecosystem. It will take a well coordinated strategy that, like the plan itself, is based on a set of principles that recognize that first and foremost, ecosystem restoration is the overarching objective. This objective will in turn be the principle driving force behind the sequence and pace at which we undertake the specific project features.

This Implementation Plan will begin to reverse, in a relatively short time, the pattern of ecological degradation that has been occurring in the natural system for many decades. As a result, the natural wetland systems of south Florida will be ecologically healthier by the year 2010.

Implementation of the recommended Comprehensive Plan will require integration of many related projects and tasks. The Comprehensive Plan is comprised of more than sixty major components representing literally hundreds of small projects that all need to be coordinated with each other and with other Federal, state and local programs and projects. Implementation will require an intense and innovative project management effort. This Section describes the project implementation process and the schedule developed to implement the recommended Comprehensive Plan described in ***Section 9***.

10.1. INTRODUCTION

Development of the Implementation Plan began after selection of the Initial Draft Plan in June 1998. Due to the complexity of this effort, an Implementation Plan Team was formed to address the development of the Implementation Plan. Invitations to participate on the Implementation Plan Team were extended to Federal agencies, state agencies, local governments, and tribal representatives. In addition to team meetings, five public workshops specific to the development of the Implementation Plan have been held with stakeholders. The first four workshops took place on July 29, 1998, August 27, 1998, November 23, 1998, and December 11, 1998. Public participants together with Implementation Plan Team members brainstormed ideas regarding: decision making guidelines for project prioritization; Implementation Plan principles; and the process that would be used to further develop the Implementation Plan. At each subsequent public meeting, an overview of the implementation planning process to date was presented. The status of the development of initial authorization options was also shared with the public from whom comments and suggestions were solicited.

During the public comment period on the draft report, the public expressed a desire to have the opportunity to review and comment on the revised Implementation Plan prior to its inclusion in this final report. Accordingly, the revised draft Implementation Plan was released for public review on January 25, 1999. A fifth Implementation Plan public workshop was held on February 1, 1999, to present the revised Implementation Plan and solicit comment. The public comment period on the draft Implementation Plan ended February 5, 1999. All public comments were considered while the Implementation Plan was finalized.

The Implementation Plan consists of a set of guidelines, the identification of a process for developing project components beyond this study, a schedule of project level activities, and an implementation program that includes pilot projects and other components recommended for initial authorization.

Because of the large number of complex features that will be developed over a long period of time and the benefits that will be gained in the south Florida ecosystem, the strategy for implementation of the recommended Comprehensive Plan will be pursued as a program. Approaching implementation as a program will allow flexibility in the management of the schedule and funding. Using a programmatic approach will allow for a structured management strategy. This strategy will allow the flexibility to continuously monitor implementation (both physical and operational) and will allow managers to take advantage of new information as well as provide for the refinement of the Implementation Plan to account for new and/or emerging information and technologies.

The magnitude of the effort involved in the implementation of the Comprehensive Plan does not lend itself to the traditional Corps of Engineers methodology for implementing water resources projects. This is due to the need to integrate many related features contained within the sixty plus components with each other as well as integrating the components with numerous ongoing Federal, State, tribal and local efforts. The need for an intense and innovative project management effort is clearly necessary to achieve the Restudy's goals and objectives within the timeframe laid out in this Implementation Plan. To meet this need, each component or group of components will be implemented as a project itself, but will additionally be linked to the overall Comprehensive Plan. As part of the next step of component development, a Project Management Plan will be developed and provide a detailed schedule of activities necessary to complete each portion of the project. The Project Management Plan will identify resource requirements and outline the management strategy for the completion of the related work. This programmatic approach will provide the flexibility to holistically manage the cost sharing in a manner equitable to the Federal government and the local sponsor.

10.2. GUIDELINES FOR IMPLEMENTING THE COMPREHENSIVE PLAN

The Implementation Plan Team created a set of basic principles called guidelines. The guidelines include management strategies for ensuring that the comprehensive plan is implemented in a manner consistent with the goals and objectives of the Restudy effort. Further, the Implementation Plan Team used these guidelines as they developed the implementation schedule for the Comprehensive Plan. The guidelines are presented in ***Table 10-1*** and discussed in detail in the following sub-sections.

TABLE 10-1
IMPLEMENTATION PLAN GUIDELINES

Utilize Interdisciplinary and Interagency Teams
Incorporate Outreach and Public Involvement
Maintain Regional System Focus
Integration with Ongoing and Future Projects
Integrate Contingency Planning
Address Water Quality Needs
Plan Evaluation Through Adaptive Assessment
Addressing Uncertainties
Assurances to Water Users
Development and Refinement of Models and Tools

10.2.1. Utilize Interdisciplinary and Interagency Teams

The Restudy effort has been an open, collaborative process involving Federal and state agencies, local governments and tribal participation. Use of the Internet has allowed Restudy Team members to interact and review information in real-time, thus reducing evaluation turn-around time and making meetings more productive. This interagency process was, and still is very effective, efficient and successful. The Restudy interagency team approach will continue throughout the implementation period to review, evaluate and adaptively manage the design, construction, monitoring, and implementation of the Comprehensive Plan. This interagency approach will be utilized for the development of pilot projects as well.

10.2.2. Incorporate Outreach and Public Involvement

The Restudy outreach and public involvement efforts have been integral parts of the process used to develop the Comprehensive Plan and will continue throughout the planning, design, construction, monitoring, and implementation of the Comprehensive Plan. The objective of all outreach activities is to ensure that the public is informed about the Restudy and that the plan that is implemented is reflective of the input received from stakeholders and the public throughout the project's implementation. ***Section 11*** of this report describes the outreach and public involvement efforts on the Restudy.

10.2.3. Maintain Regional System Focus

The Comprehensive Plan was developed and evaluated with respect to its contribution to the system-wide goals and objectives of the Restudy. Due to the size and complexity of the Comprehensive Plan, implementation of the plan will require that it be divided into smaller implementable packages of components. As these packages are further planned and designed, analyses and evaluations that measure the package's overall contribution to system-wide goals will be conducted in order to determine, and thus assure, that the system-wide goals and benefits of the Comprehensive Plan are being realized. This process will allow the Comprehensive Plan to be refined and revised as necessary as part of the adaptive assessment process described in a later sub-section.

10.2.4. Integration With Ongoing And Future Projects And Programs

There are a number of Federal, state, tribal and local water resources projects presently underway or authorized in the study area, including:

- Kissimmee River Restoration;
- C-111 Project;
- Modified Water Deliveries to Everglades National Park;
- Approved Critical Projects; and
- Everglades Construction Project.

The Comprehensive Plan includes modifications or additions to some of these projects. Consequently, implementation of all ongoing projects must be closely coordinated, and thus linked, with ongoing implementation of the Comprehensive Plan. The basic strategy will be to identify common features between the Comprehensive Plan and these projects. A review of the ongoing project's plan will then occur to ensure that all the ongoing projects and the Comprehensive Plan are consistent. It is important that these ongoing restoration projects be implemented in an expeditious manner.

In addition to these ongoing projects in the study area, there are numerous water resources planning and/or study efforts underway that are expected to affect implementation of the Comprehensive Plan. Some of the major planning efforts at the state and Federal level are:

- Lower East Coast Regional Water Supply Plan
- Lake Okeechobee Regulation Schedule Study
- Caloosahatchee Water Management Plan
- Lower West Coast Water Supply Plan
- Charlotte Harbor National Estuary Program
- Indian River Lagoon National Estuary Program

- Biscayne Bay Feasibility Study
- The Critical Project "Studies" (e.g., Florida Keys Carry Capacity Study)
- SW Florida Environmental Impact Statement (Corps wetland permitting)
- Indian River Lagoon Feasibility Study
- Water Preserve Areas Feasibility Study
- Florida Keys National Marine Sanctuary Management Plan and Water Quality Protection Program

Water Supply Plans under development by the South Florida Water Management District address the District's statutory responsibility to provide for water supplies to meet the reasonable beneficial needs of the region and form a critical connection with the Restudy. These plans are linked directly to the District's capital improvement funding process, the regulatory program for consumptive use permitting and operational protocols for C&SF Project facilities. The plans will evaluate the benefits from the existing C&SF Project and new C&SF Project facilities proposed in the Restudy with respect to the availability of water for allocation to human uses or reservation from use for protection of natural systems. Thus, the processes for developing the water supply plans is a critical element in addressing the issues related to assurances for existing legal users, discussed in ***Section 10.2.9***. The South Florida Water Management District has four regional water supply plans. The boundaries of the largest plan, the Lower East Coast Regional Water Supply Plan, have extensive overlap with C&SF Project boundaries.

To avoid duplication of effort, in 1997, the South Florida Water Management District merged its Lower East Coast Regional Water Supply Plan analysis of major proposed water supply storage facilities into the Restudy. The water supply plan process will now incorporate appropriate Restudy features into the state planning process to determine how much water can be made available from the modified regional system for human users and the natural system through the state regulatory program. The state water supply planning process will verify the construction sequencing of the proposed Restudy elements through a year 2020 time frame in order to protect existing reasonable and beneficial water users, protect the water resources and environment from harm, and balance the future water needs of the region. Likewise, the other water supply plans (Lower West Coast, Upper East Coast and the Kissimmee Valley) will consider the potential benefits from proposed Restudy projects in their current and future planning efforts and determine the availability of water for allocation and reservation under the appropriate state processes.

In addition to these studies, the Comprehensive Plan proposes several new feasibility studies for the planning area. These are:

- Florida Bay and the Keys Feasibility Study
- Southwest Florida Feasibility Study

- Comprehensive Integrated Water Quality Plan

A concerted coordination effort of all those involved is needed to ensure that information flowing from these studies is efficiently integrated on a system-wide basis into Comprehensive Plan component development. The strategies to ensure coordination and provide system-wide feedback are proposed in the Project Implementation Process described later in this section.

10.2.5. Integrate Contingency Planning

The Restudy Team recognized that there were technical and cost uncertainties associated with some of the major components included in the recommended Comprehensive Plan. As each component proceeds towards actual implementation, technical uncertainties will be addressed. The question of whether a component performs at the level anticipated within the context of the overall Comprehensive Plan is a most important consideration. For this reason, contingency plans have been explored and will be developed for all appropriate components and technologies.

In order to determine whether or not certain technologies will perform as anticipated, six pilot projects are recommended for immediate implementation. The results of these pilot projects will be used to help determine if alternatives are needed to achieve the same level of performance. The proposed pilot projects are: Lake Okeechobee Aquifer Storage and Recovery; Caloosahatchee River Aquifer Storage and Recovery; Site 1 Aquifer Storage and Recovery; L-31 Seepage Management; Lake Belt (curtain wall) Technology; and Natural Systems Reuse Technology. These pilot projects are described in greater detail in ***Section 9*** of this report.

Contingency plans will address performance deficiencies and cost-effectiveness issues that may arise as pilot projects and detailed design studies are implemented and completed. Contingency plans for uncertain technologies are described in greater detail in ***Section 7*** and ***Table 7-14*** "*Component Uncertainty*" in this report.

10.2.6. Address Water Quality Needs

One of the principal guidelines of the Implementation Plan is to ensure that the components are located, designed, and operated consistently with existing and future water quality protection criteria and restoration targets. The Comprehensive Plan includes a number of features (e.g., stormwater runoff treatment areas, treatment for water to be stored in aquifers by Aquifer Storage and Recovery facilities) to protect and improve the quality of water in receiving water bodies related to the operation of specific plan components. In addition, regional-scale surface storage reservoirs included in the Comprehensive Plan present an opportunity to improve water quality when those reservoirs are located in basins with impaired water bodies (water bodies not meeting designated uses and/or water quality criteria contained in water quality standards). Future detailed planning and engineering activities will consider water quality protection criteria for water bodies when plan components are to be located and designed with operational features necessary to achieve water quality restoration targets.

Other water quality protection efforts by state, tribal, and local agencies (e.g., National Pollutant Discharge Elimination System point and non-point source regulatory programs, routine monitoring activities, development and implementation of Total Maximum Daily Loads and Pollutant Load Reduction Goals) will compliment the implementation of the Comprehensive Plan components and the development of the comprehensive integrated water quality plan. The integration of water quality protection targets into the implementation process, together with monitoring and adaptive assessment of project components and ongoing state, tribal, and local efforts, will ensure that water quality protection is achieved and sustained for the natural and managed environments of the south Florida ecosystem.

10.2.7. Plan Evaluation Through Adaptive Assessment

It is expected that implementation of the Comprehensive Plan components will move restoration in a predicted direction. However, due to the uncertainties inherent in ecosystem restoration, adaptive assessment is an essential strategy.

The adaptive assessment strategy requires incremental implementation of plan components. Each increment will be planned and designed to carry the program one step closer to the ultimate goal of ecosystem restoration. Conceptual models were developed for each natural landscape within the greater south Florida ecosystem (e.g. Lake Okeechobee, Marl Prairies, etc.) to identify the stressors on the natural systems and the attributes that are expected to respond to the restoration plan. The hypotheses generated by the conceptual models, in conjunction with hypotheses about water quality and hydrology, reflect current understanding of how natural and managed systems in south Florida will likely respond to the improvements in hydrological patterns resulting from each increment. After modeling each increment, scientific review of the results will determine whether expectations will be met and whether they are reasonable. Either the hypotheses or the project can be altered at that time. Once a component is implemented, monitoring will confirm whether expectations have been achieved, and again, the opportunity exists to alter either the hypotheses or revisit the plan, as necessary.

Incremental implementation allows testing of hypotheses, thus providing an essential means for learning more about ecological cause and effect relationships with much greater certainty than is possible with ecological models. Incremental implementation also provides opportunities to refine plans to more effectively meet overall program objectives. An incremental process is required for the south Florida ecosystem restoration program because of the large and complex nature of the ecosystem and its problems, and because of the uncertainties regarding the ecological responses that will occur as more natural hydrological conditions are established. These uncertainties are inherent where major alterations in the region's spatial scale and landscape have substantially changed ecological relationships among species, habitats, and communities throughout the region. If an unexpected response occurs, it becomes the basis for reviewing and revising the operating set of hypotheses, which results in an ever-improving focus on the actions required to meet the ultimate restoration objectives.

A schematic flow chart showing how the adaptive assessment process is expected to function during the implementation of the Comprehensive Plan is presented in ***Figure 10-1***. The flow chart shows that each phased iteration in the overall restoration plan is modeled within the context of existing conditions, as a basis for predicting the expected ecological responses. During and following implementation of each phase of the projects, a regional monitoring program will provide the means of measuring actual hydrological and ecological responses. Expected and actual responses will be compared with overall project objectives as a means for evaluating the success of that phase. These comparisons provide opportunities for revising the conceptual ecological models and hypotheses being used to predict ecological responses within the plan and to revise either the content or sequencing of future projects within the plan.

For adaptive assessment to be successful, certain specific tasks and responsibilities for actually managing the process must be identified. ***Figure 10-1*** shows several places of assessment "feed-back" loops where design or sequencing of phases of a plan may be altered, depending on the nature of the responses. The three basic components in the feed-back loop of the adaptive assessment process are shown in ***Figure 10-2***. These basic components might require that teams be formed to: (a) review and interpret annual monitoring results in the context of the performance measure targets, and (b) use the annual assessments as a basis for designing and recommending revisions in future phases of the plan. The first of these tasks might be conducted primarily by experienced Everglades and wetland ecologists, and hydrologists; and the second task primarily by modelers and senior management personnel. The products of this internal evaluation and plan formulation process will subsequently be reviewed on a regular basis by the Science Advisory and Review Panel (See ***Section 10.4.3.1***). This panel of scientists, to be appointed by the South Florida Ecosystem Restoration Task Force and representing a broad range of expertise including biology, ecology, toxicology, hydrology, agronomy, economics, and other disciplinary backgrounds, will review any revisions to conceptual models and working hypotheses, as well as any recommended plan modifications. The current need is to decide how these tasks will be performed, and to make certain that they are adequately integrated into the overall implementation strategy, ensuring that they are routinely conducted over time. These may be tasks that can best be coordinated through the RECOVER team, described later in this section.

**FIGURE 10-1
ADAPTIVE ASSESSMENT FLOW DIAGRAM**

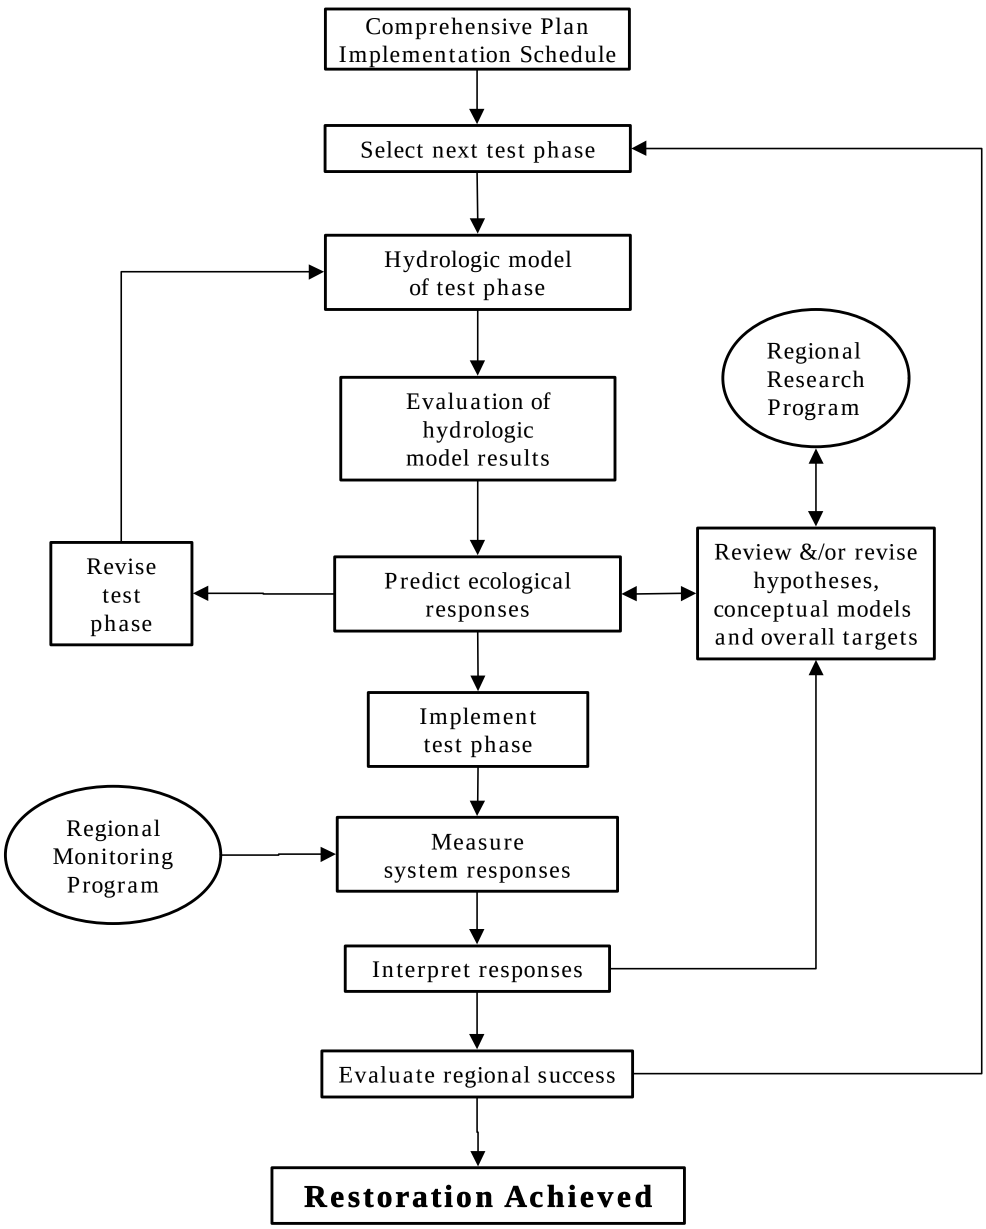

FIGURE 10-2
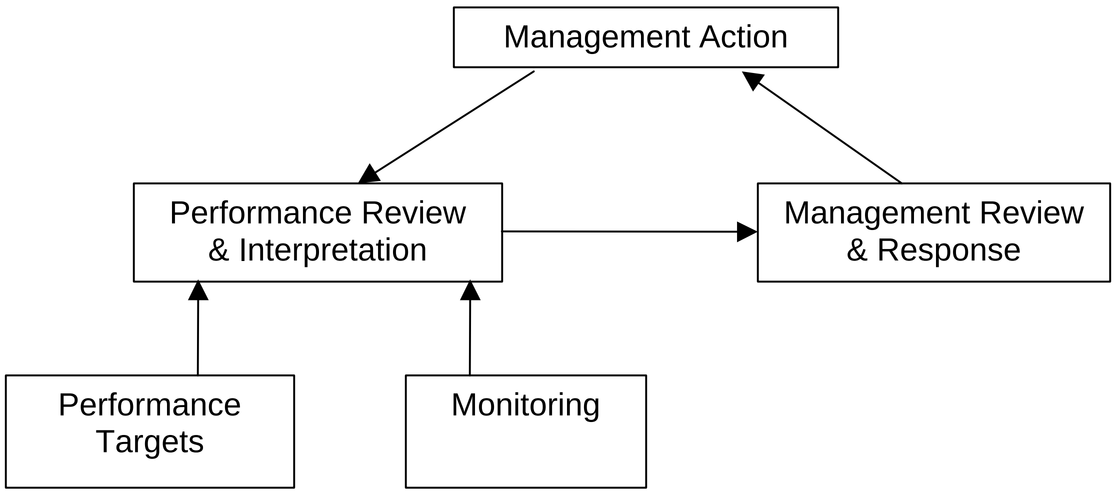
ADAPTIVE ASSESSMENT

Basic Components



To fully evaluate the success of a restoration program, the monitoring program must measure responses over a wide range of scales, including broad temporal scales. For a number of reasons, some significant system responses may not become apparent until several years after the project specifically responsible for these ecological changes has been completed. The time required for detectable responses may be longer than the intervals between plan iterations. In these cases, detection of cause and effect relationships, and evaluations of separate plan iterations, becomes obscured as a result of the necessary pace of the overall restoration program.

Even when system responses seem to be occurring on shorter time scales, relative to the implementation of discreet components, it may still be difficult to determine specific cause and effect relationships. These complications in the adaptive assessment process, caused by the pace of the overall program and uncertainties in causal relationships, can be substantially moderated in two ways. First, by maintaining strong ecological research and modeling programs concurrently with the implementation of the restoration program, new information necessary to better interpret system responses will consistently be accumulating. And second, by creating the recommended team of senior scientists, the best professional opinions can be focused on the adaptive assessment process. This team would be responsible for reviewing and interpreting system responses, integrating new science into the assessment process, and revising the conceptual models and working hypotheses.

10.2.8. Uncertainties

There are uncertainties associated with some of the technologies proposed in the Comprehensive Plan. Pilot projects and additional studies offer the best way to address the concerns that these uncertainties present prior to full implementation of these project components.

Further specific studies will be developed to provide additional information needed for detailed design and "value engineering" of specific components of the Comprehensive Plan. These studies could potentially include additional or revised estuary targets, flood impacts, ecological effects of reuse water and data collection.

It is likely that new technologies will emerge during the implementation process. New technologies offer the possibility of improving the Comprehensive Plan. The implementation process will allow flexibility to consider and include new technologies as they emerge.

10.2.9. Assurances To Water Users

The concept of "assurances" is key to the successful implementation of the Comprehensive Plan. Assurances can be defined in part as protecting, during the implementation phases of the Comprehensive Plan, the current level(s) of service for water supply and flood protection that exist within the current applicable Florida permitting statutes. Assurances also involve protection of the natural system.

The current C&SF Project has generally provided most urban and agricultural water users with a level of water supply and flood protection adequate to satisfy their needs. Florida law requires that all reasonable beneficial water uses and natural system demands be met. However, the C&SF Project, or regional system, is just one source of water for south Florida to be used in concert with other traditional and alternative water supplies.

The Governor's Commission for a Sustainable South Florida developed a consensus-based set of recommendations concerning assurances to existing users, including the natural system (GCFSSF, 1999). The following text is taken from the Commission's *Restudy Plan Report*, which was adopted on January 20, 1999:

> *"Assurances are needed for existing legal users during the period of plan implementation. It is an important principle that has helped gain consensus for the Restudy that human users will not suffer from the environmental restoration provided by the Restudy. At the same time, assurances are needed that, once restored, South Florida's natural environment will not again be negatively impacted by water management activities. Getting 'from here to there' is a challenge. The*

implementation plan will be the key to assuring predictability and fairness in the process.

<u>Protecting Current Levels of Service (Water Supply and Flood Protection) during the Transition from the Old to the New C&SF Project.</u>

The goal of a sustainable South Florida is to have a healthy Everglades ecosystem that can coexist with a vibrant economy and quality communities. The current C&SF Project has generally provided most urban and agricultural water users with a level of water supply and flood protection adequate to satisfy their needs. In fact, if properly managed, enough water exists within the South Florida system to meet restoration and future water supply needs for the region. However, past water management activities in South Florida, geared predominantly toward satisfying urban and agricultural demands, have often ignored the many needs of the natural system (GCSSF, 1995; transmittal letter to Governor Chiles, p. 2). Specifically, water managers of the C&SF Project historically discharged vast amounts of water to tide to satisfy their mandate to provide flood protection for South Florida residents, oftentimes adversely impacting the region's estuarine communities.

The Commission recommended that in the Restudy, the SFWMD and the Corps should ensure that the redesign of the system allows for a resilient and healthy natural system (GCSSF, 1995; p. 51) and ensure an adequate water supply and flood protection for urban, natural, and agricultural needs (GCSSF, 1996a; p.14). In response to the need to restore South Florida's ecosystem, and in light of the expected future increase of urban and agricultural water demands, the Restudy aims to capture a large percentage of water wasted to tide or lost through evapotranspiration for use by both the built and natural systems. In order to maximize water storage, the Restudy intends to use a variety of technologies located throughout the South Florida region so that no one single area bears a disproportionate share of the storage burden. This direction reinforces the Commission's recommendation that water storage must be achieved in all areas of the South Florida system using every practical option (GCSSF, 1996a; p. 25).

However, concerns have been expressed that a water user would be forced to rely on a new water storage technology before that technology is capable of fully providing a water supply source or that existing supplies would otherwise be transferred or limited, and that the user would thereby experience a loss of their current legal water supply level of service. Any widespread use of a new technology certainly has potential limitations; however, the Restudy should address technical uncertainties prior to project authorization and resolve them before implementation in the new C&SF Project. With the addition of increased water storage capabilities, water managers will likely shift many current water users to different water sources.

Additionally, stakeholders are concerned that a preservation of the current level of service for legal uses would not encompass all the urban uses, some of which are not incorporated in the term 'legal' and covered by permit. Specifically, an adequate water supply is needed to address urban environmental preservation efforts as well as water level maintenance to reduce the impact of salt water intrusion.

The Commission believes that in connection with the Restudy, the SFWMD should not transfer existing legal water users from their present sources of supply of water to alternative sources until the new sources can reliably supply the existing legal uses. The SFWMD should implement full use of the capabilities of the new sources, as they become available, while continuing to provide legal water users as needed from current sources. It is the Commission's intent that existing legal water users be protected from the potential loss of existing levels of service resulting from the implementation of the Restudy, to the extent permitted by law.

The Commission also recognizes that the SFWMD cannot transfer the Seminole Tribe of Florida from its current sources of water supply without first obtaining the Tribe's consent. This condition exists pursuant to the Seminole Tribe's Water Rights Compact, authorized by Federal (P.L. 100-228) and State Law (Section 285.165, F.S.).

However, the issues surrounding the development of specific assurances to water users are exceedingly complex and will require substantial additional effort to resolve.

RECOMMENDATION

- *The SFWMD and the Corps should work with all stakeholders to develop appropriate water user assurances to be incorporated as part of the Restudy authorizations. These water user assurances should be based on the following principles:*

  A. Physical or operational modifications to the C&SF Project by the federal government or the SFWMD will not interfere with existing legal uses and will not adversely impact existing levels of service for flood management or water use, consistent with State and federal law.

  B. Environmental and other water supply initiatives contained in the Restudy shall be implemented through appropriate State (Chapter 373 F.S.) processes.

  C. In its role as local sponsor for the Restudy, the SFWMD will comply with its responsibilities under State water law (Chapter 373 F.S.).

  D. Existing Chapter 373 F.S. authority for the SFWMD to manage and protect the water resources shall be preserved.

Water Supply for Natural Systems

Concerns have been raised about long term protection of the Everglades ecosystem. According to WRDA 1996, the C&SF Project is to be rebuilt 'for the purpose of restoring, preserving, and protecting the South Florida ecosystem' and 'to provide for all the water-related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the C&SF Project.'

Environmental benefits achieved by the Restudy must not be lost to future water demands. When project implementation is complete, there must be ways to protect the *natural environment so that the gains of the Restudy are not lost and the natural systems, on which South Florida depends, remain sustainable.*

A proactive approach which includes early identification of future environmental water supplies and ways to protect those supplies under Chapter 373 F.S. will minimize future conflict. Reservations for protection of fish and wildlife or public health and safety can be adopted early in the process and conditioned on completion and testing of components to assure that replacement sources for existing users are on line and dependable. The SFWMD should use all available tools, consistent with Florida Statutes, to plan for a fair and predictable transition and long term protection of water resources for the natural and human systems.

Apart from the more general goals of the Restudy, there are specific expectations on the part of the joint sponsors - the State and the federal government. The more discussion that goes into an early agreement on expected outcomes, the less conflict there will be throughout the project construction and operation.

RECOMMENDATIONS

- *The SFWMD should use the tools in Chapter 373 F.S. to protect water supplies necessary for a sustainable Everglades ecosystem. This should include early planning and adoption of reservations. These reservations for the natural system should be conditioned on providing a replacement water source for existing legal users which are consistent with the public interest. Such replacement sources should be determined to be on line and dependable before users are required to transfer.*

- *The SFWMD should expeditiously develop a 'recovery plan' that identifies timely alternative water supply sources for existing legal water users. The recovery plan should consist of water supply sources that can reliably supply existing uses and whose development will not result in a loss of current levels of service, to the extent permitted by law. To assure that long term goals are met, the State and federal governments should agree on specific benefits to water users, including the natural system, that will be maintained during the recovery.*

- *In the short term, the Restudy should minimize adverse effects of implementation on critical and/or imperiled habitats and populations of State and federally listed threatened and/or endangered species. In the long term, the Restudy should contribute to the recovery of threatened species and their habitats.*

Protecting Urban Natural Systems and Water Levels

Water supply for the urban environment is connected to water supply for the Everglades and other natural areas targeted for restoration and preservation under the Restudy.

It is essential that the Restudy projects proposed to restore and preserve the environment of the Everglades do not reduce the availability of water to such an extent in urban areas that the maintenance of water levels and the preservation of natural areas becomes physically or economically infeasible.

The successful restoration of Everglades functions is dependent not only upon the establishment of correct hydropatterns within the remaining Everglades, but also upon the preservation and expansion of wetlands, including those within urban natural areas that once formed the eastern Everglades. Some of the westernmost of these areas have been incorporated in the Restudy as components of the WPAs. However, the on-going preservation efforts of local governments have acquired hundreds of millions of dollars worth of additional natural areas for protection both inside and outside of the WPA footprint.

Water supplies for these urban wetlands are not covered by existing permits or reservations and are therefore, not adequately protected. Efforts are underway at both the SFWMD and the local level to preserve these vital areas and assure their continuing function as natural areas and in ecosystem restoration.

Detailed design for the Restudy, in particular the detailed modeling associated with the WPA Feasibility Study, will make possible plans to protect these urban wetlands from damage and to assure maximum integration with Restudy components.

RECOMMENDATIONS

- *The SFWMD and the Corps should acknowledge the important role of urban natural areas as an integral part in the restoration of a functional Everglades system. As a part of the implementation plan, the SFWMD and the Corps should develop an assurance methodology in conjunction with the detailed design and modeling processes, such as the WPA Feasibility Study, to provide the availability of a water supply adequate for urban natural systems and water level maintenance during both implementation and long term operations.*

- *Expand and accelerate implementation of the WPAs. Accelerate the acquisition of all lands within the WPA footprint to restore hydrologic functions in the Everglades ecosystem, and ensure hydrologic connectivity within the WPA footprint. The WPA Feasibility Study process should be given a high priority. The WPA concept should be expanded into other SFWMD planning areas such as the Upper East Coast.*

- *The Restudy should assure that the ecological functions of the Pennsuco wetlands are preserved and enhanced."*

There is a substantial body of law that relates to the operation of Federal flood control projects, both at the state and Federal level. Much of the Governor's Commission language is directed to the South Florida Water Management District and matters of state law. To the extent that the Governor's Commission's guidance applies to the Corps' actions, the Corps will give it the highest consideration as

Restudy planning proceeds and as plan components are constructed and brought on-line consistent with state and Federal law. The recommended Comprehensive Plan does not address or recommend the creation or restriction of new legal entitlements to water supplies or flood control benefits.

10.2.10. Development And Refinement Of Models And Tools

As implementation of the Comprehensive Plan proceeds, additional models and tools or refinements to existing models and tools will be needed both at the system-wide level as well as at more localized, site-specific levels. For example, the South Florida Water Management Model with its four square mile grid size is not an appropriate tool for the analysis of flooding at a local level. More site-specific models with a much finer grid size will be needed as implementation proceeds. Additionally, the existing tools and models will be refined in order to improve their applicability and usefulness.

An example of more finite model development is depicted in the ongoing Water Preserve Areas Feasibility Study. The South Florida Water Management District is currently developing five hydrologic models in Palm Beach, Broward, and Miami-Dade Counties. These models are known as the North Palm Beach, South Palm Beach, Broward, North Miami-Dade and South Miami Dade groundwater models. Further, numerous other modeling tools have been identified that will promote a better understanding of the ecologic response of the Comprehensive Plan. These include the Everglades Landscape Model, Lake Okeechobee Water Quality Model, Florida Bay Circulation Model, Biscayne Bay Hydrodynamic Model, and Everglades Water Quality Model.

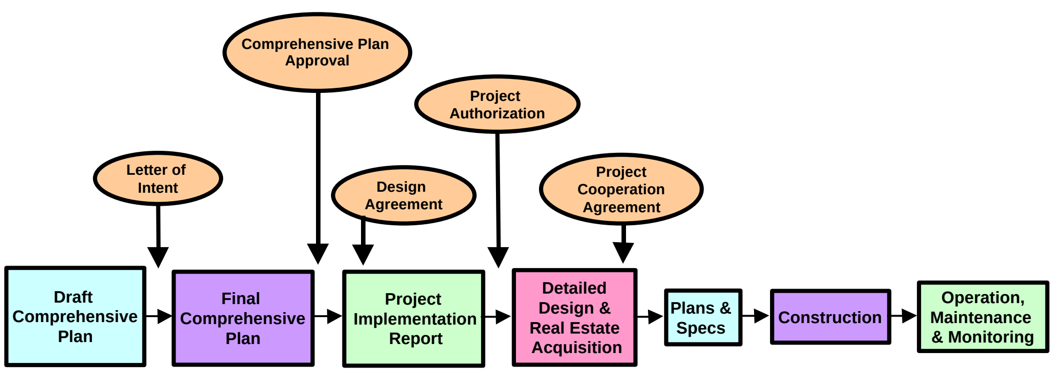
Additional data will need to be collected to further design the “next” tools needed to implement the Comprehensive Plan. These data will include items such as topographic and geologic data. The southern portion of Florida has unique features such as a very flat topography; a large, highly concentrated human population; and a very unique and fragile ecosystem. Because of this flat topography, a slight change in ground level at one location can significantly impact a large geographic area. The current lack of precision in existing vertical control can result in erroneous estimates to important hydrologic variables. There is an anticipated effort to increase the accuracy of vertical measurement called the Geodetic Vertical Control Survey, which involves second-order class I vertical control over a four-year period.

10.3. PROJECT IMPLEMENTATION PROCESS

To ensure continued progress in implementing the Comprehensive Plan, a project implementation process is needed to allow for additional studies that would support project development, and future Congressional authorizations. Further, a process is needed to reevaluate the Comprehensive Plan, as necessary, using new information that is developed during the component development and design process. This section of the Implementation Plan describes key steps that are necessary to implement the Comprehensive Plan.

Generally, implementation of the Comprehensive Plan will follow the steps shown in ***Figure 10-3***. Subsequent to the submittal of this report to Congress, a detailed planning effort in the form of a Project Implementation Report will be developed for each component or a logical group of components. Except for those projects recommended for initial authorization or accomplished under the proposed programmatic authority (described later in this section), each Project Implementation Report will be submitted to Congress for project authorization. Following completion of the Project Implementation Report, detailed design and real estate activities would commence followed by construction and operation of the project.

FIGURE 10-3
GENERALIZED PROJECT DEVELOPMENT PROCESS



Components that are authorized for construction prior to the development of a Project Implementation Report (i.e. initially authorized components and programmatic authority components) will still require completion of a Project Implementation Report. For these components, the Project Implementation Report will be completed and submitted to Corps higher authority for approval and the Project Implementation Report will not be submitted to Congress.

10.3.1. Project Implementation Reports

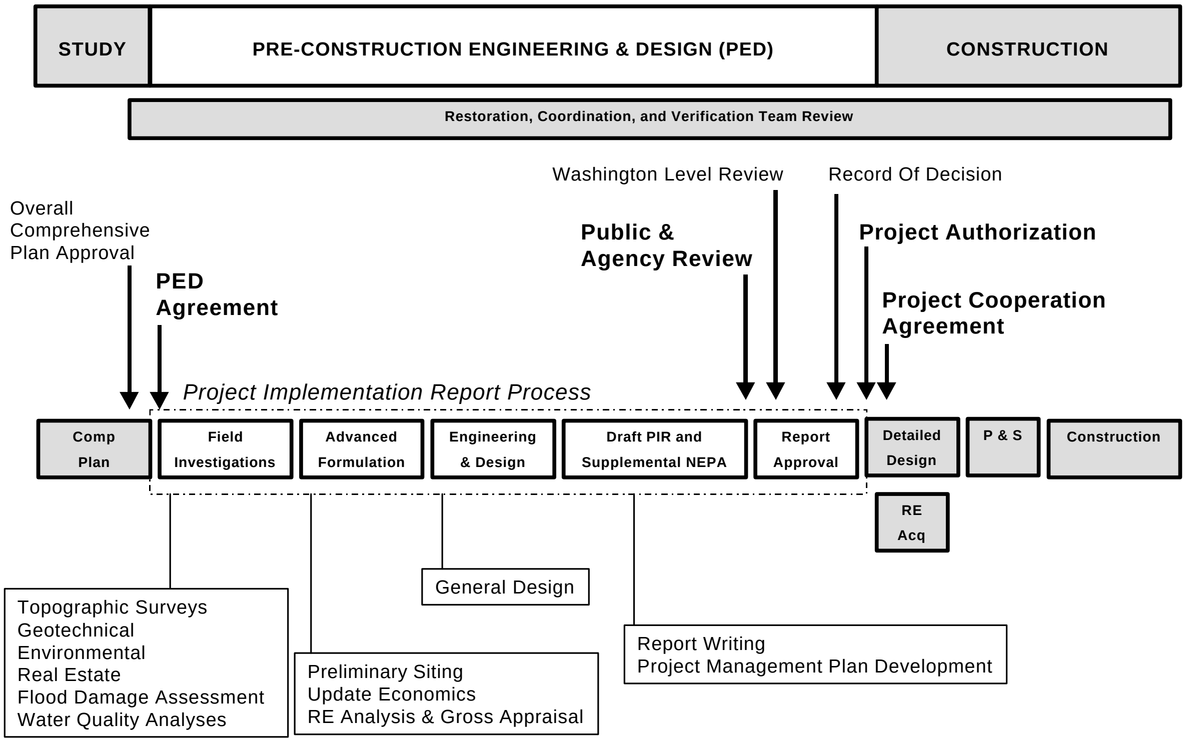
The recommended Comprehensive Plan described in ***Section 9*** has a level of detail and analysis sufficient for plan selection and cost estimation, but it is not as refined as traditional Corps of Engineers' feasibility report recommendations submitted to Congress for construction authorization. To continue project implementation, additional efforts are needed to develop the detailed technical information to implement the project. These additional efforts include:

- Additional Plan Formulation
- Engineering and Design to General Design Memorandum Levels
- Environmental Analyses
- Flood Protection Analyses
- Water Quality Analyses
- Economic Analyses
- Siting and Real Estate Analyses
- Contribution to Comprehensive Plan Performance
- Refinements/Modifications to the Comprehensive Plan
- Supplemental NEPA Document

The results of these additional efforts will be documented in a Project Implementation Report. The Project Implementation Report will bridge the gap between the conceptual design contained in the Comprehensive Plan and the detailed design necessary to proceed to construction. The steps for these future detailed studies are displayed in ***Figure 10-4***.

The Project Implementation Report is a new type of reporting document. The Project Implementation Report will be similar to a General Reevaluation Report in that it will contain additional plan formulation and evaluation, and will optimize the components. It will also contain General Design Memorandum level, or higher, engineering and design. Some of the tasks associated with the preparation of the Project Implementation Report will include surveys and mapping, geotechnical investigations, site analyses, design optimization, economics, environmental analyses, flood damage assessment, real estate analyses and preparation of supplemental National Environmental Policy Act documents. Further, each Project Implementation Report will be accompanied by a Project Management Plan. The Project Management Plan will detail schedules, funding requirements, and identify resource needs for final design and construction of the project.

FIGURE 10-4
PROJECT IMPLEMENTATION REPORT PROCESS



The objectives of Project Implementation Report are to: (1) more thoroughly investigate water resource solutions identified in the Comprehensive Plan, and (2) recommend appropriate actions. The Project Implementation Report will typically be completed in 18 to 36 months. The Project Implementation Report will document the analyses and results of the studies, and provide the basis for a final decision on the project. The Project Implementation Report will include supplemental National Environmental Policy Act (NEPA) documentation (either an Environmental Assessment or an Environmental Impact Statement). The Project Implementation Report will also contain the results of coordination activities such as the Fish and Wildlife Coordination Act Report and consultation under the Endangered Species Act. As necessary, the Comprehensive Plan will be modified as components are refined and additional information is obtained during the process.

The purpose of the Project Implementation Report is to affirm, reformulate or modify a component, or group of components, in the recommended Comprehensive Plan. All planning analyses, including economic, environmental, water quality, flood protection, real estate, and plan formulation, conducted during pre-construction design studies will be documented and included in the Project Implementation Report. The Project Implementation Report will be the vehicle to identify, quantify and attempt to resolve the uncertainties surrounding the cost or performance of each major component. These uncertainties are not limited to hydrologic performance of the specific structure component, but also include the uncertainties surrounding the expected ecosystem response to the component. A clear description of the expected environmental outcome of each component will be included in the Project Implementation Report.

The real estate analysis performed as part of the Project Implementation Report process will include siting of specific project features and a gross appraisal for all lands, easements and rights-of-way necessary for component(s) construction and operation. Field investigations will be required to provide needed information for the real estate analysis, as well as for the engineering and design analysis and advance plan formulation. These activities will typically include geotechnical and environmental investigations and topographic surveys.

The supplemental National Environmental Policy Act document prepared as a result of the Project Implementation Report will supplement this Final Programmatic Environmental Impact Statement, which is necessary for compliance with the National Environmental Policy Act. This document would be either an Environmental Assessment or an Environmental Impact Statement.

Each Project Implementation Report will also contain an analysis of the Comprehensive Plan and recommended modifications. The RECOVER team, described later in this section, will play a key role in this analysis.

The studies and preparation of the Project Implementation Report will be accomplished by an interagency interdisciplinary study team, similar to the type of team that developed the Comprehensive Plan.

10.3.2. Restoration, Coordination, And Verification Process

Throughout the project implementation process, system-wide analyses will continue. A feedback loop will be established so that each Project Implementation Report is evaluated for its contribution to the overall system and that the Comprehensive Plan is revised as necessary to reflect new information developed during the project development process.

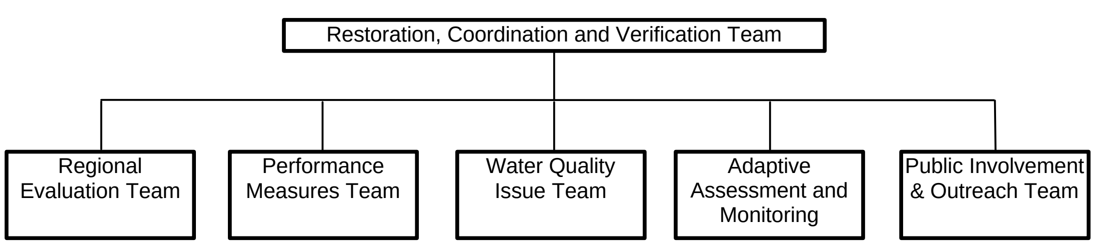
As part of this effort, a Restoration, Coordination and Verification (RECOVER) Team will be established to provide system-wide evaluations and analyses. The RECOVER Team represents the evolution of the multi-disciplinary interagency Restudy Team that was used to formulate the Comprehensive Plan. It is a system-wide evaluation and analysis team that will be responsible for helping to determine the overall regional contributions provided by individual projects and whether or not revisions to the Comprehensive Plan are necessary. The RECOVER

Team is not an oversight or management group. The RECOVER Team responsibilities will include, but not limited to, the following activities and respective coordination thereof:

- Development and Refinement of System Level Analytical Models Tools
- Continuing Re-Analysis of the Comprehensive Plan
- Development of an Information Needs Program
- Coordination of Peer Review of all Science
- Modeling Effects of Project Elements on the Comprehensive Plan
- Development and Implementation of Adaptive Assessment Protocols
- Coordination of Monitoring Program
- Interpretation of Monitoring Results as a Basis for Conducting the Adaptive Assessment Process
- Further Development and Refinement of Performance Measures and Targets
- Linkage and Coordination with Other Ongoing Projects.
- Public Involvement and Outreach
- Issue Resolution Process

The RECOVER Team will form sub-teams for specific technical evaluations as needed. Examples of currently anticipated sub-teams include: Regional Evaluation; Performance Measure Refinement and Development; Implementation Plan; Water Quality; Adaptive Assessment and Monitoring; and Public Involvement and Outreach (See ***Figure 10-5***). All RECOVER sub-teams will report status and findings to the overall RECOVER Team, and then as a team, recommendations will be developed. RECOVER Team responsibilities will not replace normal agency roles or required coordination. For example, Fish and Wildlife Coordination Act responsibilities, consultations under the Endangered Species Act, and other National Environmental Policy Act activities will not be replaced or duplicated by the RECOVER Team.

FIGURE 10-5
RECOVER TEAM COMPOSITION



The RECOVER Team is responsible for addressing system-wide issues through evaluations and analyses. These evaluations include, but not limited to addressing, hydrologic, ecological, water quality, flood protection, water supply and interim operations. This coordination activity will require the RECOVER Team, or its delegated sub-team, to provide specific input to each on-going project team regarding the linkages and affects that projects and designs have on each other.

It is envisioned that during and throughout the project development process the RECOVER Team will interactively work with the respective project team to evaluate system-wide performance and regional contributions that will be realized from full implementation of specific projects. RECOVER will utilize the most current system-wide models and evaluation tools together with the most recent performance measure information for each region. A resulting product from this effort will be a Comprehensive Plan update, which will be included within each Project Implementation Report. This update will include recommendations for Comprehensive Plan modifications if needed. This report will also act to document any changes that occurred to the project(s) formulation and design as a result of the system-wide evaluations.

In a sense the RECOVER Team will be building the system-wide incremental model by adding projects in their time-phased sequence (as they occur in the planning process) and evaluating their system-wide contribution to overall ecosystem restoration. This incremental system-wide approach will assist the adaptive assessment and monitoring sub-teams by enabling them to use the incremental information to formulate their assessments and recommendations.

10.3.3. Independent Scientific Peer Review

Sound science has always served as the basis for restoration of the south Florida ecosystem. At the heart of preserving the integrity of the science, peer review has been used to provide independent review of the science being applied to restoration efforts and to solicit advice on difficult issues.

In past years, independent panels have been formed to: (a) provide annual reviews of the overall Florida Bay science program (the Boesch panel); (b) review and advise on specific issues, such as the perceived conflict among endangered species restoration objectives (kites vs. storks), the overall high water research program, and the Cape Sable seaside sparrow research program; and (c) provide guidance and review for the Kissimmee River restoration program's ecological objectives and research and monitoring protocols.

10.3.3.1. Peer Review Previously Conducted

Fundamental documents used by the Everglades restoration planners have also received independent review. For example, the 31 chapters in *Everglades: The Ecosystem and Its Restoration* (Davis & Ogden, 1994) are a primary source for the basic hypotheses and technical understandings of the Everglades system. Each of the 31 chapters was anonymously refereed by three or more outside reviewers. Additionally, much of the natural systems research conducted by the state and federal land management agencies is published in peer-reviewed journals.

The process for developing conceptual ecological models and the models themselves have been reviewed. A team of scientists from the Restudy's participating agencies and the University of Miami's Rosenstiel School for Marine and Atmospheric Science jointly developed and managed the process of organizing existing facts and hypotheses into a format that would support the planning and evaluation of the restoration programs. The process was designed specifically to support the development of performance measures and restoration targets to guide the Everglades restoration program. The Restudy's Alternative Evaluation Team used these conceptual ecological models as a basis for developing conceptual hydrologic and biological performance measures and targets during the plan formulation and selection process. The University of Miami scientists provided the initial training and review for the conceptual models. The conceptual models were fully reported in an invited session of the 1997 annual Conference of the Society for Ecological Restoration.

The South Florida Water Management District has an "Expert Assistance" program for bringing outside experts to advise and review the scientific work of District staff. This process was used to review the River of Grass Evaluation Methodology (ROGEM). ROGEM was used during the plan formulation, evaluation, and selection process to determine the relative ecological value of different alternative plans.

The models used in the conceptual planning stage have been reviewed both to certify their integrity and to determine if they are being used appropriately. The South Florida Water Management Model has been documented (MacVicar et al., 1984 and SFWMD, 1997i) and the documentation peer reviewed (Loucks et al., 1998.). Likewise, the Natural Systems Model, Version 4.3 was reviewed by the Department of Interior, U. S. Geological Survey (Bales et al., 1997). Modifications to the Natural System Model recommended as a result of the U.S. Geological Survey review were incorporated in the version of the model that the Comprehensive Plan development process used.

10.3.3.2. Future Peer Review

The adaptive assessment protocol proposed for evaluating ecosystem responses during implementation of the restoration program includes a team of senior Everglades and wetland ecologists and hydrologists, charged with the responsibility of reviewing and interpreting system responses, revising conceptual models and working hypotheses, and recommending plan modifications. The products of this internal review process will be subsequently reviewed on a regular basis by the Science Advisory and Review Panel (SARP).

The SARP will be appointed by and provide independent scientific advice to the South Florida Ecosystem Restoration Task Force, chaired by the Secretary of the Interior. To help ensure the success of the adaptive assessment process, the SARP will at the request of the Task Force, review the science associated with the south Florida ecosystem restoration effort, including the implementation of the Comprehensive Plan on an ongoing basis. Since the Comprehensive Plan is the central component of the south Florida ecosystem restoration, the SARP will take into account the broad objectives of the Restudy as defined in the Water Resources Development Act of 1996:

> *The Secretary [of the Army] shall develop, as expeditiously as practicable, a proposed comprehensive plan for the purpose of restoring, preserving, and protecting the South Florida ecosystem. The comprehensive plan shall include such features as are necessary to provide for the water-related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the Central and Southern Florida Project. (Public law 104-303, October 12, 1996).*

The SARP will be comprised of scientists representing a broad range of expertise, including biology, ecology, toxicology, hydrology, agronomy, economics, and other disciplinary backgrounds necessary to evaluate the full range of scientific issues associated with implementation of the Comprehensive Plan and the restoration of the south Florida ecosystem.

Members of the SARP will be individuals who are not personally involved in south Florida research and monitoring activities. Members will be expected to serve three to four years, rotating off the Panel at intervals that ensure sufficient continuity of activities.

The SARP will be a key element of the adaptive assessment process. The restoration of a large and complex ecosystem such as that in south Florida is a dynamic process that is continually influenced by the results of research and monitoring activities. The Science Coordination Team assists the Task Force by managing the broad range of scientific activities being undertaken by university, and Federal, state, tribal, and local governments. The SARP will evaluate the effectiveness of this scientific effort and ensure that the restoration of the south Florida ecosystem is based on the highest quality of scientific standards.

In addition to its responsibilities for providing broad scientific review during the implementation of the Comprehensive Plan, the SARP may periodically undertake special reviews or provide science advice on future directions of the program at the request of the Task Force. This may include evaluating the quality of specific research, modeling, and monitoring activities, as well as providing guidance on the significance of research results and their implications for management and restoration of the ecosystem. In addition, the SARP may be asked to identify individuals who might participate in peer review and advisory activities in specialized subject areas.

10.3.4. Water Quality Considerations

The initial authorization request includes plan components expected to provide significant regional water quality benefits (e.g., C-44 Basin Storage Area, Taylor Creek/Nubbin Slough Storage and Treatment Area, etc.). Subsequent detailed planning, engineering and design, and review by the interagency RECOVER Team, as part of the implementation process, ensures that the construction and design of initially authorized components will maximize water quality benefits to the maximum extent possible consistent with the overall performance objectives for those components.

The Project Implementation Report process described in this section includes several steps in which water quality considerations can be integrated into the overall implementation process (pre-construction, engineering and design; advanced formulation; RECOVER Team review; detailed planning and engineering; National Environmental Policy Act analyses). This will assure that water quality problems do not impede overall implementation and it will maximize opportunities to protect and restore water quality through the implementation process.

10.3.5. Flood Protection

Due to the conceptual nature of the Comprehensive Plan and the modeling tools used for the alternative analyses, detailed flood damage assessment was not performed for the Comprehensive Plan. However, maintaining levels of flood protection remains an important purpose of the C&SF Project and an objective of the Comprehensive Plan. Project Implementation Reports for individual or groups of components will include a detailed review of flood protection for the area affected by the components. Opportunities for enhancing flood protection in conjunction with other design objectives will be investigated.

10.3.6. Project Management

The magnitude of the effort involved with the implementation of the Comprehensive Plan presents a unique opportunity to utilize Federal, state, local, and tribal resources to achieve the Restudy's goals and objectives. Further, the comprehensive nature of the Restudy does not lend itself to the traditional Corps of Engineers methodology for implementing water resource projects. This is due to the need to integrate many related features contained within the sixty-plus recommended components that constitute dozens of separable project elements, as well as integrating the components with numerous ongoing Federal, State, tribal, regional and local efforts. Implementation of the Comprehensive Plan may involve multiple sponsors and numerous funding mechanisms. Coupled with a significant increase in the Jacksonville District and the South Florida Water Management District's annual programs, the need for an intense and innovative project management strategy will be necessary to complete implementation of the recommended Comprehensive Plan in a timely manner.

The scope of the recommended Comprehensive Plan warrants a management approach that is programmatic in nature. This "program" will require a management structure that is integrated into both the Corps and the local sponsor's executive, managerial, and technical staffs. The program's resources must be based on a sound strategy for implementation that includes identification of system-wide efforts, assigns responsibility for component development, and provides a projection of funding and manpower requirements supported by appropriate agreements for local cooperation. This management strategy will provide the conceptual framework for Federal, State, local, tribal, and private efforts to protect and restore the south Florida ecosystem.

The implementation process will continue to be open to the public in a manner that maximizes agency and stakeholder review and input. This Implementation Plan and the associated schedule are considered to be a "living" document. Changes to the Implementation Plan will be made when necessary by future information that is gained from pilot projects and additional studies, and other factors such as actual funding, real estate acquisition and certification, and opportunities to re-sequence portions of the project for various reasons.

10.4. SCHEDULE DEVELOPMENT

Development of the Comprehensive Plan implementation schedule was based on guidelines established by the interagency Implementation Plan Team. With these guidelines, a set of rules and assumptions were developed to form the sequencing and scheduling for components of the Comprehensive Plan. The schedule that has been developed for the Implementation Plan is consistent with the level of detail contained in the Comprehensive Plan. That is, the Implementation Plan provides a conceptual level schedule for the Comprehensive Plan. To trouble-shoot the Implementation Plan Team's sequencing of components a quality assurance and quality control modeling analysis was incorporated into the Implementation Plan Schedule development process. The results of this analysis are discussed in more detail in a later part of this section.

10.4.1. Assumptions And Rules

There are three major assumptions made in the preparation of the Implementation Plan prepared for this report. They are related to: project authorization, pilot projects and additional studies, and funding and manpower resources. These are described in the following sections. A set of factors and rules were also developed to guide development of the Implementation Plan. These factors and rules are also described in more detail in the following sections.

10.4.1.1. Project Authorization

In order to expeditiously realize the benefits of the Comprehensive Plan, implementation will be structured so that the work is not subject to institutional delays. Development and approval processes will be streamlined and time between phases will be minimized. Accordingly, it is assumed that Congressional authorizations for project elements will occur so as not to impact project sequencing and scheduling.

10.4.1.2. Pilot Projects and Additional Studies

For the purpose of developing the Implementation Plan, it is assumed that the pilot projects and needed additional studies will not substantially change the recommended Comprehensive Plan. This assumption was made in order to avoid unnecessary complexities in scheduling and sequencing of project components at the conceptual level. This alleviates the need to build every conceivable alternative solution into the network of activities. Such a level of complexity would be problematic in developing the Implementation Plan. This assumption does not negate the need to address contingency or assurance planning in this or any follow-on project document. The Implementation Plan is expected to be revised as the pilot projects and further studies are completed.

10.4.1.3. Funding and Manpower Resources

For planning purposes, the schedule for implementing the Comprehensive Plan uses an annual funding guideline of approximately $400,000,000. This annual funding guideline reflects the best professional judgement of the Implementation Plan Team. Furthermore, this guideline was coordinated between the Corps and the South Florida Water Management District to insure consistency between the potential cost sharing partners and the capability of both organizations to execute a program of this size. It is recognized that this level of funding is viewed by some as being very aggressive, and by others as not being aggressive enough. The schedule developed for this plan should be considered a model that provides scheduling data (start and completion dates) for the generalized activities associated with component development identified in the Implementation Plan, as well as projecting funding requirements by distributing the estimated activity's cost over the projected activity's duration. The Implementation Plan's schedule has been developed in a manner that provides the ability to be adjusted for different funding levels.

It is assumed that adequate manpower resources will be available to implement the Comprehensive Plan components at this funding level. Further, it is also assumed that management responsibilities for the construction of projects would be shared by the Corps and the South Florida Water Management District.

10.4.1.4. Sequencing Rules

In order for the Implementation Plan Team to develop the project implementation schedule, it first identified a series of factors and rules to consider in developing the sequence of project implementation. Factors that could expedite component implementation include:

- Components that have physiographic and functional connectivity
- Components that can provide immediate benefits
- Components that contribute to the overall system
- Components that can be implemented through ongoing projects
- Components that need to be implemented to avoid lost opportunity potential

Factors that would typically limit the ability to implement component(s) include:

- Components that have operational limitations
- Components that are dependent on other components
- Components that have land acquisition constraints

As stated previously, the implementation of the recommended Comprehensive Plan will require the integration of many related projects and tasks. The identification of component dependencies and the linking of various activities are complex tasks. The set of general sequencing rules developed by the Implementation Plan Team helped develop a sequence order for all of the components contained in the Comprehensive Plan. These rules provided the Implementation Plan Team with a starting point for establishing the overall project implementation schedule and are as follows:

- Consider earlier sequencing of components according to when the need occurs.
- Consider earlier sequencing of components that are prerequisites to other components.
- Consider earlier sequencing of components that provide replacement function.
- Consider earlier sequencing of components that provide significant benefits.

- Consider earlier sequencing of components that are most likely to provide multiple system-wide benefits.
- Consider earlier sequencing of components whose costs are expected to escalate if implementation is delayed.
- Consider earlier sequencing of tests, studies and pilot projects for components whose technical and permitting feasibility are needed to implement components at a full scale.
- Consider earlier sequencing of components that solve acute problems (i.e., degraded water quality).
- Consider earlier sequencing of components that can be implemented under existing authorizations and appropriations.
- Consider earlier sequencing of components, which if delayed, means "Loss of Opportunity."
- Consider earlier sequencing of components that have design already initiated.
- Consider earlier sequencing of components that provide definite benefits and resolve the existing conditions currently degrading the natural systems.
- Consider earlier sequencing of components that reduce losses of water from the regional system.
- Consider later sequencing of components that primarily serve to meet targets having the greatest level of uncertainty and whose revision may indicate that the component should be eliminated.

10.4.1.5. Integration With Ongoing Projects and Programs

The development of south Florida's water management system has been continuous since the original C&SF Project's authorization. Numerous efforts are currently underway to modify the project. Ongoing efforts within the planning area that are sufficiently developed to be considered in the Comprehensive Plan implementation schedule are:

- C-111 Project
- Modified Water Deliveries to Everglades National Park
- Everglades Construction Project
- Lower East Coast Regional Water Supply Plan
- Kissimmee River Restoration
- Minimum Flows and Levels
- SWIM Plans

Integration of these efforts with implementation of the Comprehensive Plan is critical. Components or features that have been identified in the Comprehensive Plan and are consistent with the authorization of other ongoing efforts will be pursued under the ongoing effort. To accomplish this, additional coordination with the ongoing Project Team will occur during the detailed planning efforts. For the purposes of this Implementation Plan, when a Comprehensive Plan component or feature will be implemented by an ongoing effort, the completion of this action will be represented as a milestone and will mark the completion of the event. No time or funding will be associated with this component or feature in the Comprehensive Plan Implementation Plan.

10.4.1.6. Modeling Preliminary Implementation Schedule

A modeling analysis for the purpose of trouble-shooting the Implementation Plan Team's preliminary sequencing of components was performed and evaluated. The results of the analysis, the 2010 Case Study, were used to aid in the development of the Implementation Plan schedule. The purpose of the analysis was to make sure that the implementation sequencing would not cause any detrimental or unanticipated adverse effects. As a result, the sequencing of some components were modified to correct identified problem areas.

This analysis consisted of identifying the components that were scheduled to be complete and fully operational by the end of year 2010. Those components were then modeled to evaluate whether the sequencing would cause ecological or water supply conditions worse than the 1995 Base Case or the 2050 future without project condition to any area or user. The modeling analysis and evaluation of the components utilized the same performance measures as the alternative plan formulation process. This analysis was used to identify problem areas and validate that the schedule was constructed in a logical order that furthered the project's goals and objectives. It is anticipated that this method will be used during further component development to identify interim solutions that will minimize further degradation of the existing system and maximize interim construction configurations and operations in the most beneficial manner as individual components are brought on-line.

10.4.2. Implementation Schedule

The implementation schedule depicted in ***Figure 10-6*** represents scheduling of the components contained in the Comprehensive Plan. This schedule represents the Implementation Plan Team's best professional judgement and technical implementation solution for the scheduling of components using the guidelines, assumptions, and rules described earlier in this section. This Gantt chart shows the relative timeline, depicted as a "rolled-up" time scaled bars, for each component recommended in the Comprehensive Plan using the $400,000,000 annual funding guideline. A more detailed task Gantt schedule is presented in ***Appendix M – Implementation Plan Scheduling and Sequencing***.

Page 3 of 3

As noted previously, $400,000,000 per year served as an approximate annual funding guideline. When this guideline was applied to the component sequencing and the estimated duration associated with more detailed planning, design, real estate acquisitions, land availability and construction, all plan components, except for the Lake Belt elements, are fully implemented by the year 2020. Additionally, there are a number of years that annual funding requirements will exceed $400,000,000 in order to achieve this schedule. The North and Central Lake Belt storage components will not be fully constructed until the year 2037 due to rock mining in the area, which will not be completed for a number of years. An analysis of the project schedule that removed the $400,000,000 guideline resulted in no significant savings in time to complete implementation of the Comprehensive Plan when compared to the schedule in this report

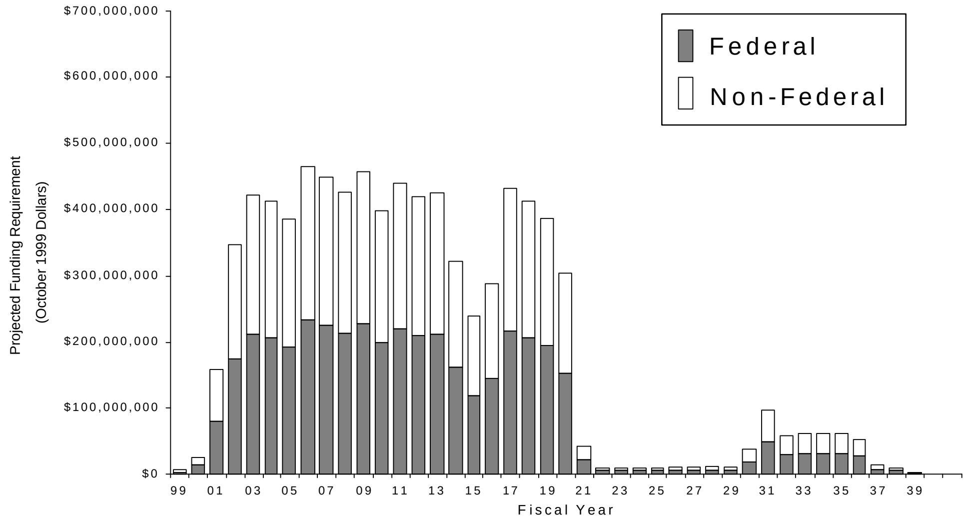
Modifications to the implementation schedule will be made as more information concerning factors that may affect future implementation are identified. Such factors would include, but not limited to future authorizations and actual funding levels. As implementation progresses, adjustments to the schedule will be made as necessary to adjust for the current situation and provide opportunities to advance work consistent with the project's purposes.

10.4.3. Funding Stream

To establish a projected annual funding requirement, the estimated cost of a given activity (Project Implementation Report preparation, Detailed Design, Plans and Specifications, Real Estate Acquisition, Construction, etc.) required to implement a component was evenly distributed over the estimated duration of that activity. It is recognized that a prorated distribution may differ from historical expenditures for construction and other types of activities. The software was limited in distribution technique: therefore, a straight-line distribution was used to establish the funding stream of the schedule developed using the $400,000,000/year funding guideline. The resulting annual funding projections are depicted in ***Figure 10-7***.

Figure 10-7 shows the annual distribution of estimated project costs for the project schedule reflected in October 1999 dollars. These annual costs will be adjusted on an annual basis as implementation progresses past the final report date. Adjustments will be based on further analyses that will be performed by the respective Project Implementation Teams during the more detailed planning and design phases.

FIGURE 10-7
C&SF RESTUDY IMPLEMENTATION PROJECTED ANNUAL COST



10.4.4. Evaluation Of The Project Schedule

This section discusses the conditions that may exist in the natural system of south Florida at approximately the half-way point in the implementation of the Comprehensive Plan, about the year 2010. Because restoration of the natural system is the principle goal of the Comprehensive Plan, this discussion uses ecological and biological criteria as measures of natural system conditions in 2010. The accuracy of predictions of system conditions for any given period in the future is substantially influenced by the quality of the models used for this purpose, and by understandings of how systems are likely to respond to specific combinations of features in the plan. These predictions will be difficult to make for any specific time-period prior to the completion of the full plan. System responses will be occurring at many different temporal scales, including some that will occur over multi-year time-frames, and some that may initially exhibit response lags. In addition, we understand less about how natural systems will respond to subsets of the total package of features in the complete plan, than we do about responses to the total package of features. Conceptually, it is agreed that the recovery of NSM-like hydrological patterns throughout the remaining natural system is likely to maximally recover the health of these systems. However, because of the weak understandings of ecological thresholds in the south Florida systems, the degree of recovery towards what are considered to be healthy systems are difficult to predict for different stages prior to full implementation.

Nevertheless, it is worthwhile to attempt to predict what these systems will be like at key stages during the implementation of the plan. This will be a useful contribution to an on-going process of plan re-evaluation and adaptive assessment. The following narrative offers an entirely conceptual and qualitative view of 2010 conditions. Just as the details of the plans will continue to be improved throughout the life of this restoration program, so too will the predictions of system responses be improved. These early predictions should be treated as guidelines for on-going evaluations of an evolving Implementation Plan, and not as concrete descriptions of conditions at a specific time in the future.

10.4.4.1. Reasonable Expectations

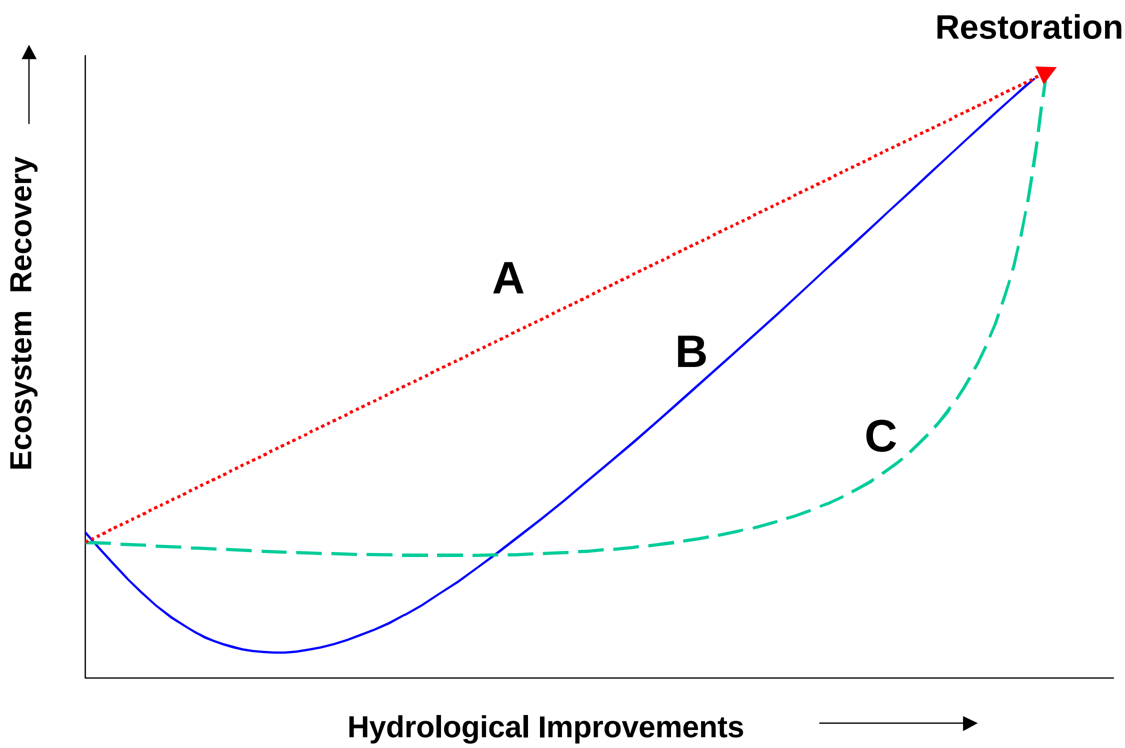
In general, the large scale hydrological improvements that will be necessary to stimulate large scale ecological improvements will only come once the features of the Comprehensive Plan which substantially increase water storage capacities of the regional system and the infrastructure needed to move this water, are in place. To the extent that certain features of the Comprehensive Plan must be in place before the additional storage and distribution components can be constructed and operated, some of the major ecological improvements anticipated by the Plan will not occur in the short-term. This unfortunate "reality" should not be viewed with surprise, when one realizes how substantially altered and degraded the south Florida ecosystem has become.

The features of the Comprehensive Plan currently proposed to be fully implemented by 2010 include the components (e.g., seepage control, land acquisition, reservoir construction, development of water preserve areas) that must be in place to set the stage for the addition of substantial amounts of clean water into the natural system. For example, in order to bring water from the urban east coast into the natural system and avoid additional water quality problems, the features required to clean that water must be in place. In order to decompartmentalize the interior Everglades and avoid additional over-drainage problems in Lake Okeechobee and the northern Everglades, the features required to substantially increase the regional storage capacity must be in place. Overall, the strategy of the Comprehensive Plan is to substantially improve hydrological performance within the remaining natural system while at the same time removing water control structures from within the natural areas. The structures that must be relocated outside of the natural system in order to make these internal improvements must be completed before the full benefits of the restoration plan will be achieved.

10.4.4.2. Ecological Responses

Notwithstanding the above considerations, the recovery of healthy ecosystems is most likely to occur in one of three ways (***Figure 10-8***). The simple, conceptual models shown in this figure depict three hypothetical ways that wetland ecosystems and the biological components within these systems can respond to improvements in hydrological conditions. Model "A" suggests that recovery can have a linear relationship with hydrological improvements. Model "B" suggests that changes in hydrological patterns can cause an initial, short-term negative response, followed by recovery. The third model "C," accounts for the effects of ecological thresholds and lag responses in the recovery process.

FIGURE 10-8
CONCEPTUAL ECOSYSTEM RECOVERY MODELS



Current understandings of organisms in the Everglades suggest that while responses to improvements in hydrological conditions may occur in all three ways, depending on the scales and the organisms measured, most response patterns will resemble "C." It is widely believed that much of the ecological recovery in the south Florida wetland systems will lag behind hydrological improvements, at a wide range of mostly unknown temporal scales. Some responses may occur within months (short-term responses, e.g., shifts in periphyton species composition), some may require one to several years (mid-term responses, e.g., recovery of fish biomass), and some may require decades (long-term responses, e.g., recovery of pre-drainage soil and plant community patterns). The expected hydrological conditions at year 2010 should result in ecological recovery at local spatial scales (e.g., at the scale of alligator holes) and at short-term temporal scales, but is unlikely to show substantial recovery for the mid-term and long-term elements of the systems.

Patterns of recovery resembling the "B" model may occur where hydrological change is more rapid than ecological responses, to the extent that the change can cause relatively short-term but reversible degradation in habitat conditions for specific organisms. A possible example might be in the first one or two years after increased flows reach the mainland mangrove estuaries below Shark Slough, resulting in reduced densities of the large sized fishes preferred by foraging wood storks. Longer periods of high flows will eventually result in increases in prey fish above current average levels. The status of organisms showing this recovery pattern, at any given point in the process of improving hydrological conditions, will depend on whether these organisms are on the early or late portions of the recovery "curve."

Model "A" patterns of recovery may be rare in the real world. It is possible that average rates of recovery over multiple years of good habitat conditions may produce recovery patterns similar to "A." Such recovery rates might be possible in populations of small fishes or aquatic invertebrates. 2010 conditions could produce hydrological patterns conducive to this type of recovery at local spatial scales.

10.4.4.3. Summary

In summary, the natural wetland systems of south Florida will be ecologically healthier by the year 2010 than they are today. This improvement reverses a pattern of ecological degradation in the natural systems that have been occurring for many decades. Most of the improvements will be at comparatively local spatial scales and among the ecological components that exhibit short-term response times. For example, alligator holes in certain regions will be healthier than today, wading birds will have a larger area of favorable feeding habitat, and estuarine conditions in such areas as the St. Lucie system will be substantially improved. The magnitude of hydrological improvements expected by 2010, and the longer time-frames required for responses by many organisms and communities in the greater Everglades basin, mean that many of the ecological benefits of the Comprehensive Plan will be realized during the second half of the project.

10.5. IMPLEMENTATION PROGRAM

Implementation of the Comprehensive Plan will require both a long-term program, which will take place over the next several decades, as well as a commitment of resources from the Federal, State, South Florida Water Management District, and local governments in the region. The recommendations for the implementation program are based on input from the Implementation Plan Team, public meetings, state and agency review, local sponsors, South Florida Water Management District's Letter-of-Intent, Governors Commission for a Sustainable South Florida, South Florida Ecosystem Restoration Task Force and Working Group.

The implementation program was developed based on an analysis of the scheduling of plan features and ongoing Federal and State programs, such as the C-111 Project and the Everglades Construction Project. This implementation program assumes:

1. Congressional approval of the Comprehensive Plan as a framework and guide for authorization;
2. initial authorization of a specific set of key components and pilot projects in the Water Resources Development Act (WRDA) of 2000;
3. a programmatic authority similar to the existing Critical Projects authority contained in WRDA 1996;
4. future Congressional authorization of components in subsequent WRDAs;
5. implementation of some components without further Congressional action;
6. completion of additional feasibility studies.

10.5.1. Approval of the Comprehensive Plan

Upon transmitting this report to the Commander of the South Atlantic Division in Atlanta, Georgia, and a favorable review by the Division office, the Division Engineer will issue a “Division Engineer’s Notice.” This notice announces the completion of this feasibility report by the Jacksonville District Engineer. Concurrently with the notice, the Division Engineer will transmit the report to Corps Headquarters in Washington D.C. This feasibility report will receive a final policy compliance review by Headquarters’ staff prior to releasing the report for final 30-day Federal agency review. A copy will also be provided to the State of Florida (via the Governor’s office) for final State review and comment. Corps headquarters will file the Programmatic Environmental Impact Statement with the Council on Environmental Quality. This will result in a mandatory 30-day review of the Programmatic Environmental Impact Statement. These mandatory review periods will run simultaneously. After addressing comments that are provided through the final review and making any necessary changes to the report, a “Chief of Engineer’s Report” will be issued. This report along with the Chief of Engineer’s Report will be transmitted to the Assistant Secretary of the Army for Civil Works (ASA(CW)) for review and transmittal to Congress (typically for inclusion in a Water Resources Development Act). By Congressional direction on the Restudy, this must occur by July 1, 1999. Congressional hearings may be held on the plan prior to Congressional action. It is currently anticipated that Congress, through enactment of a Water Resources Development Act of 2000, will approve the Comprehensive Plan as a framework and guide for authorization and implementation and will authorize construction of certain components.

10.5.2. Initial Authorization

Careful attention was given to developing an initial authorization recommendation for pilot projects and key specific components. A number of factors where considered when considering which components should be recommended for initial authorization. Consideration was given to include projects that will provide immediate system-wide water quality and flow distribution benefits to the ecosystem. Initial authorization of components associated with ongoing Federal, state and local programs will allow for integration of components from the Comprehensive Plan with these ongoing projects as soon as possible. For example, immediate authorization will allow development of comprehensive solutions to ongoing Federal and state projects such as the Modified Water Deliveries Project and the Everglades Construction Project that otherwise could not be pursued under existing authorities. Further, it is anticipated that there may be substantial cost savings by integrating the Comprehensive Plan components with these ongoing programs. The South Florida Water Management and U.S. Department of the Interior have purchased lands associated with a number of components of the Comprehensive Plan. Immediate authorization of the components that utilize these lands will ensure timely and efficient utilization and crediting of these lands.

10.5.2.1. Pilot Projects

Pilot projects are needed to address many of the technical uncertainties of the components. The Implementation Plan Team agreed early in the process that the following pilot projects should be recommended for immediate implementation. ***Table 10-2*** includes the list of the pilot projects to be recommended for authorization and the estimated cost and completion dates of these projects.

10.5.2.2. Initially Authorized Project Components

As stated previously, careful attention was given to developing an initial authorization recommendation for specific project components. The purpose of seeking authorization of select components of the Comprehensive Plan is to maximize the opportunity to integrate these features with ongoing Federal and state programs. The specific components that are recommended for this initial authorization are displayed in ***Table 10-3***.

TABLE 10-2
PILOT PROJECTS

Project	Cost	Completion Date
Lake Okeechobee ASR	$19,000,000	2004
Caloosahatchee River ASR	$6,000,000	2005
Site 1/Hillsboro ASR	$9,000,000	2002

Seepage Management	$10,000,000	2003
Reuse Technology	$30,000,000	2007
TOTAL	$97,000,000	

TABLE 10-3
CONSTRUCTION FEATURES FOR INITIAL AUTHORIZATION

Component	Report Section [1]	Project	Cost	Construction Dates
B	9.1.4.1	C-44 Basin Storage Reservoir	$112,562,000	6/04 - 6/07
G (Phase 1)	9.1.5.1	Everglades Agricultural Area Storage Reservoirs - Phase I	$233,408,000	9/05 – 9/09
M[3] (Phase 1)	9.1.8.11	Site 1 Impoundment	$38,535,000	9/04 - 9/07
O[2a]	9.1.8.13	WCA 3A/3B Levee Seepage Management	$100,335,000	9/04 - 9/08
Q[2a]	9.1.8.13	C-11 Impoundment & Stormwater Treatment Area	$124,837,000	9/04-9/08
R[2a]	9.1.8.14	C-9 Impoundment/Stormwater Treatment Area	$89,146,000	9/04-9/07
W	9.1.1.2	Taylor Creek/Nubbin Slough Storage and Treatment Area	$104,027,000	1/05-1/09
QQ[2b,3] (Phase 1)	9.1.7.2	Raise and Bridge East Portion of Tamiami Trail and Fill Miami Canal within WCA 3	$26,946,000	1/05-1/10
SS[2b]	9.1.7.2	North New River Improvements	$77,087,000	1/05 - 1/09
WW	9.1.8.26	C-111 N Spreader Canal	$94,035,000	7/05 – 7/08
	9.5	Adaptive Assessment and Monitoring Program (10 years)	$100,000,000	
		TOTAL	$1,100,918,000	

[1] Refer to the appropriate section in this Feasibility Report for a description of these features
[2a,2b] Project components are dependent upon each other and would be implemented as a single project
[3] Although the initial phase of this project component is within the cost limits of the proposed Programmatic Authority, the total cost for the component exceeds that authority and therefore is included with these recommended construction features

10.5.2.3. Implementation of Initially Authorized Projects

Due to the scope of this feasibility report, it is proposed that individual Project Implementation Reports be developed subsequent to authorization for each of the components included in the initial authorization. These Project

Implementation Reports will document advanced planning; engineering and design; real estate analyses; and supplemental requirements under the National Environmental Policy Act. It is anticipated that these reports will be approved by the Secretary of the Army without need for further Congressional action unless major changes to the Comprehensive Plan are recommended. Subsequent to the approval of the Project Implementation Report, recommended features will progress to detailed design and construction. The implementation of the initially authorized features will utilize the process depicted in ***Figure 10-9***.

10.5.3. Programmatic Authority

The Water Resources Development Act of 1996 provided authorization (see **Appendix A5**) for Everglades Ecosystem Restoration Projects (Critical Projects). These projects were defined as those projects which would *"produce independent, immediate, and substantial restoration, preservation, and protection benefits."* A similar programmatic authority is recommended to help expedite implementation of certain components in the Comprehensive Plan. It is proposed that projects included under the programmatic authority will be those components that are part of the Comprehensive Plan and have a total project cost up to $70,000,000 with a maximum Federal cost of $35,000,000. The timing of the implementation of projects receiving programmatic authority will be consistent with the schedule that has been developed for implementing the overall Comprehensive Plan. In addition, the process for project development and implementation will be consistent with the implementation of other Comprehensive Plan components recommended for authorization in Water Resource Development Act of 2000 including the development of Project Implementation Reports. The components that could be implemented under this authority are displayed in ***Table 10-4***.

FIGURE 10-9
PROCESS FOR IMPLEMENTING INITIALLY AUTHORIZED COMPONENTS

		TOTAL	$489,885,000	

10.5.4. Future Water Resources Development Acts

The recommended components of the Comprehensive Plan that are not initially authorized or eligible for the proposed programmatic authority will be submitted to Congress for construction authorization (as scheduled) in future Water Resources Development Acts. Project Implementation Reports that are completed by April of a Water Resources Development Act year (assumed to be biennial) will be submitted for Congressional action. Based on an analysis of the current Comprehensive Plan schedule, components will have Project Implementation Reports completed and ready to submit to Congress through fiscal year 2016. The components that will be contained in future authorization acts are contained in ***Table 10-5***.

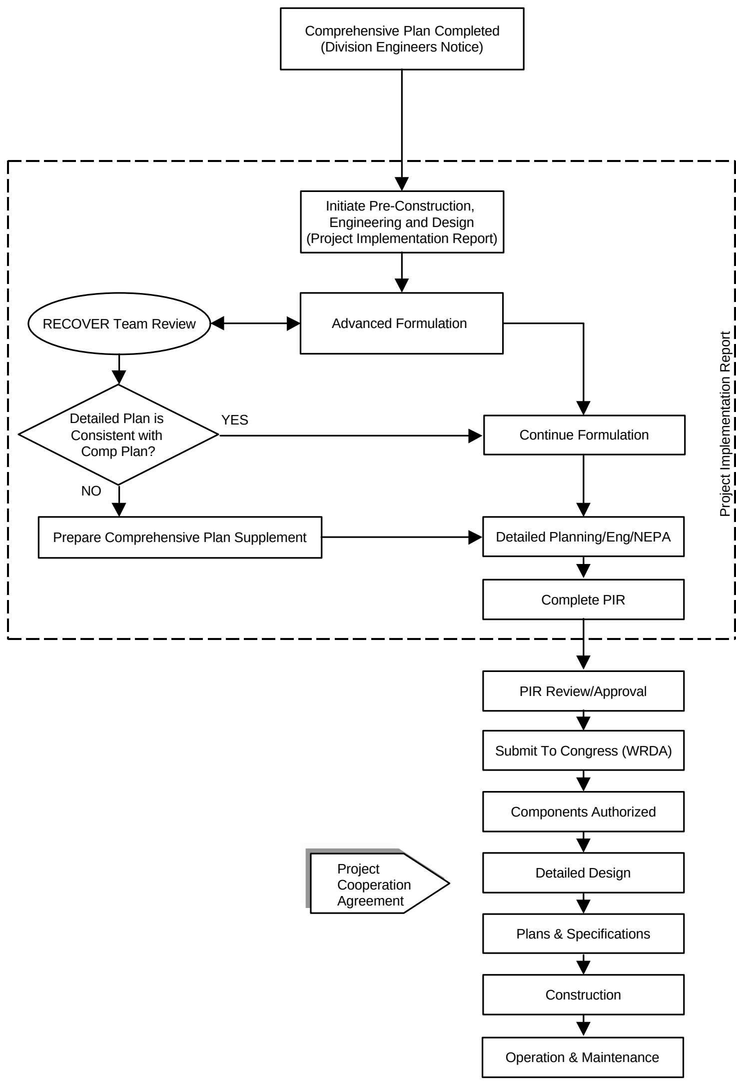
BBB	9.1.8.24	South Miami-Dade County Reuse	$363,024,000	2014	6/16-6/20
		TOTAL	$6,211,396,000		

[1] For determining projects for future WRDA authorizations, certain components were combined to form functional component packages for construction features that were clearly dependent
[2] The reservoir in component GGG may be implemented under a previous authorization

10.5.4.1. Implementation of Projects in Future WRDAs

The implementation of these components would require congressional authorization before construction could commence. Hence, implementation of these components would utilize the process depicted in ***Figure 10-10***. Based on the current scheduling, there are occasions when more than one Project Implementation Report will be completed and ready to be submitted to Congress for construction authorization. In this case, multiple components may be packaged together in a Project Implementation Report for a single decision document.

FIGURE 10-10
PROCESS FOR COMPONENTS TO BE AUTHORIZED IN FUTURE WRDAs



10.5.5. Components Not Needing Congressional Authorizations

There are several components that do not require additional congressional action to implement. These components are integral to the overall success of the project, but for various reasons (covered under a separate authorization, locally implemented program, etc.) will not require congressional action prior to design and implementation. A list of these components is provided in ***Table 10-6***.

TABLE 10-6
PROJECTS NOT REQUIRING CONGRESSIONAL ACTION

Item	Report Section	Project	Explanation
F	9.2.1.1	Lake Okeechobee Regulation Schedule	Operational change only; implement when appropriate as other facilities come on line
E	9.2.2.1	Environmental Water Supply Deliveries to the Caloosahatchee Estuary	Operational change only; implement when appropriate as other facilities come on line
C	9.2.3.1	Environmental Water Supply Deliveries to the St. Lucie Estuary	Operational change only; implement when appropriate as other facilities come on line
H	9.2.4.1	Everglades Rain Driven Operations	Operational change only; implement when appropriate as other facilities come on line
L	9.2.5.1	Change Coastal Wellfield Operations	Operational change only
DD	9.2.4.2	Modified Holey Land Wildlife Management Area Operation Plan	Implement under existing state process
EE	9.2.4.3	Modified Rotenberger Wildlife Management Area Operation Plan	Implement under existing state process
AAA	9.2.5.2	Lower East Coast Utility Water Conservation	Implement under existing state process
OO	9.2.5.3	Operational Modifications to Southern Portion of L-31N and C-111	Operational change only; implement as part of C-111 Project

10.5.6. Feasibility Studies

Three new feasibility studies – the Florida Bay and the Florida Keys Feasibility Study, Southwest Florida Feasibility Study, and Comprehensive Integrated Water Quality Plan have been identified for initiation. These studies will be conducted under the authority of the Water Resources Development Act of 1996 that allows for the continuation of studies and analyses that are necessary to further the Comprehensive Plan. For a description of these studies, refer to ***Section 9.7***.

10.6. RECOMMENDED FEATURES FOR INITIAL AUTHORIZATION

The features of the Comprehensive Plan which are recommended for initial authorization include those projects that are necessary to expedite ecological restoration of the south Florida ecosystems. Implementing these features will ensure maximum integration with ongoing Federal, State, and local ecological restoration and water quality improvement programs. The features, which are shown in ***Figure 10-11***, consist of pilot projects, initial construction features and an adaptive assessment and monitoring program. This section describes the projects recommended for initial authorization.

Subsequent to Comprehensive Plan, advanced planning and engineering design will be accomplished for each of the major features included in this recommendation. These studies will be conducted over the next few years and will result in Project Implementation Reports as previously described. These reports will document advance planning, engineering design, real estate analyses, and supplemental National Environmental Policy Act documents associated with the construction and operation of these features.

10.6.1. Pilot Projects

Pilot projects are needed to address uncertainties associated with some of the physical features that are proposed in the Comprehensive Plan. To ensure that the Comprehensive Plan is implemented in a timely manner, it is necessary to expedite the pilot projects to resolve issues before further detailed design of these facilities can be initiated. The design and analysis of the pilot projects will be coordinated through the multi-agency RECOVER Team. These pilot projects are designed to determine the feasibility, as well as optimum design, of the features prior to embarking on the full-scale development of these features. These projects include:

- Aquifer Storage and Recovery in each geographic region that the technology is proposed,
- In-ground Reservoir technology in the Lake Belt region of Miami-Dade County,
- Levee Seepage Management technology adjacent to Everglades National Park, and
- Advanced Wastewater Treatment technology to determine the feasibility of using reuse water for ecologic restoration.

10.6.1.1. Aquifer Storage and Recovery Pilot Projects

Aquifer Storage and Recovery is a major element in several components of the Comprehensive Plan. Due to the difference in the geomorphology and the potential for different raw water sources (i.e., surficial ground water or surface water), multiple aquifer storage and recovery pilot projects are proposed. These aquifer storage and recovery pilot projects are necessary to identify the most suitable sites for the aquifer storage and recovery wells in three areas:

- Adjacent to Lake Okeechobee
- Caloosahatchee River Basin
- the Lower East Coast area adjacent to the Site 1 and the Hillsboro Canal

In December 1998, an Aquifer Storage and Recovery Issue Team was formed by the South Florida Ecosystem Restoration Working Group to develop an action plan and identify projects to address the surface water, hydrogeological and geochemical uncertainties associated with regional aquifer storage and recovery facilities (SFERWG, 1998a). This report will serve as the basis for developing the aquifer storage and recovery pilot projects which will determine the specific water quality characteristics of waters to be injected and the water quality characteristics of the receiving aquifer. In addition, the pilot projects will provide information on the hydrogeological and geotechnical characteristics of the upper Floridan Aquifer System within the regions, and the ability of the upper Floridan Aquifer System to store injected water for future recovery.

10.6.1.2. In-Ground Reservoir Technology Pilot Project

Several components use areas where lime rock mining will have occurred (see ***Sections 9.1.8.2, 9.1.8.15 and 9.1.8.17***). The initial design of these reservoirs includes subterranean seepage barriers around their perimeter in order to enable drawdown during dry periods, prevent seepage losses and prevent water quality impacts due to transmissivity of the aquifer in these areas.

The In-ground Reservoir Technology Pilot Project is required to determine construction technologies, storage efficiencies, impacts on local hydrology and water quality effects. Water quality assessments will include a determination as to whether the in-ground reservoirs and seepage barriers will allow for storage of untreated waters without concerns of ground water contamination.

10.6.1.3. L-31N Seepage Management Pilot Project

Hydrologic modeling results have shown that controlling seepage from the Everglades produces desirable hydrologic conditions within the Everglades. However, the proposed technologies to control the seepage may have unintended consequences that must be investigated before full-scale implementation of the proposed project features. These features included reducing levee seepage flow across L-31N adjacent to Everglades National Park via a levee cutoff wall (see ***Section 9.1.8.21***). This feature was designed to reduce groundwater flows during the wet season by capturing groundwater flows with a series of ground water wells adjacent to L-31N, then backpumping those flows to Everglades National Park.

The purpose of the L-31N Seepage Management Technologies Pilot Project is to investigate seepage management technologies technology to control seepage from Everglades National Park. The pilot project will provide necessary information to determine the appropriate amount of wet season groundwater flow to return to the Park while minimizing potential impacts to Miami-Dade County's West Wellfield and freshwater flows to Biscayne Bay.

10.6.1.4. Wastewater Reuse Technology Pilot Project

The Comprehensive Plan includes two advance wastewater treatment facilities (see ***Sections 9.1.8.22 and 9.1.8.24***) to increase the quantity of water available for ecological restoration. However, the high cost and the issues concerning the quality of the water must be further investigated through a pilot project.

This pilot project will address water quality issues associated with discharging reclaimed water into natural areas such as the West Palm Beach's Catchment Area, Biscayne National Park, and the Bird Drive Basin, as well as determine the level of superior treatment and the appropriate methodologies for that treatment. A series of studies will be conducted to help determine the level of treatment needed. In addition, a small advanced wastewater treatment facility that was previously included as a Critical Project will be constructed to treat wastewater that is presently disposed by deep well injection from the East Central Regional Wastewater Treatment Facility. This treatment will be accomplished by using advanced and superior wastewater treatment processes to remove nitrogen and phosphorus. After treatment the wastewater will be used to restore 1,500 acres of wetlands and to recharge wetlands surrounding the City of West Palm Beach's wellfield. A portion of the treated wastewater will be used to recharge a residential lake system surrounding the City's wellfield and a Palm Beach County wellfield.

Besides serving as a pilot project, this project will reduce the City's dependence on surface water from Lake Okeechobee during dry or drought events. In addition, approximately 2,000 acres of wetlands would be created or restored. Other benefits include aquifer recharge and replenishment, reduction of water disposed in deep injection wells and a reduction of stormwater discharge to tide.

10.6.1.5. Pilot Project Costs

The total estimated cost of the Pilot Projects is $97,000,000, at October 1999 price levels. These costs include $9,411,000 for planning, engineering and design; $9,800,000 for real estate; and $77,789,000 for construction and associated monitoring. ***Table 10-7*** displays the total cost for the proposed pilot projects. The long-term operation cost of the pilot projects are accounted for in the operation and maintenance cost of the full-scale project feature.

10.6.2. Initial Features for Authorization

This section identifies the major features recommended for initial authorization including location, the need for early authorization, the project description, the benefits of these features, the costs of each feature and the need for additional studies as needed.

10.6.2.1. C-44 Basin Storage Reservoir

This feature is located in the Upper East Coast region of south Florida in southern Martin County and is shown in ***Figure 10-12***. The storage reservoir will be constructed in close proximity to the C-44 Canal within the C-44 Basin. The exact location of the reservoir has not been identified at this time. The location will be determined during detailed design as a result of recommendations of the Indian River Lagoon Feasibility Study.

This feature is included in the initial authorization for a number of reasons. Preliminary analyses has shown that the majority of the Restudy benefits to the natural areas will not be realized until most of the major storage features, such as reservoirs like this, are in place. Early authorization of this component is expected to provide significant regional water quality benefits, specifically to the St. Lucie River and Estuary and the Indian River Lagoon, in the form of nutrient reduction. In addition, early authorization will provide the opportunity to moderate damaging releases to St. Lucie estuary from Lake Okeechobee and the surrounding basin as soon as possible. The Indian River Lagoon and the St. Lucie Estuary experienced significant impact as a result of releases made from the lake during the spring of 1998. In addition, Martin County has shown strong support for the Restudy passing a resolution in late 1998 to generate a funding source for land acquisition for environmental restoration in the county.

This feature includes an above ground reservoir with a total storage capacity of approximately 40,000 acre-feet located in the C-44 Basin in Martin County. The initial design of the reservoir assumes 10,000 acres with the water levels fluctuating up to 4 feet above grade. The final location, size, depth and configuration of this facility will be determined through more detailed analysis to be completed as a part of the ongoing Indian River Lagoon Feasibility Study.

The purpose of the feature is to capture local runoff from the C-44 Basin, then return the stored water to the C-44 Canal when there is a water supply demand. The reservoir will be designed for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary.

During the wet season, this large storage component will aid in the prevention of damaging regulatory releases to the estuary while reducing basin flooding by capturing and storing excess stormwater runoff. Subsequently, during the dry season, water supply, including environmental water supply to the estuary, will be enhanced, as stored water is metered out to the system as needed. Inflows to the storage facility include local basin runoff and releases from Lake Okeechobee when the lake stage is greater than 14.5 feet NGVD. The initial design includes inflow pump capacity of 1,000 cfs and outflow structure capacity of 800 cfs. This feature is currently scheduled for construction initiation in June 2004 with completion in June 2007.

Regulatory releases were made from Lake Okeechobee through the C-44 Canal from December 1997 until late April 1998. These regulatory releases ranged from 2,500 cfs to 7,000 cfs for most of the duration. The St. Lucie River and Estuary and the Indian River Lagoon experienced reduced salinity concentrations outside the range of the established minimums for a healthy ecosystem. During this release event, approximately 33 species of lesioned fish were discovered by local fisherman, 450 individual lesioned fish were sent to the Florida Marine Research Institute for analysis, local citizens became concerned for human health related to water quality in surrounding waters, and in addition, silting of the offshore reef system was discovered. The actual cause of the epidemic of lesioned fish is still unknown, but scientists are working from the theory that the heavy freshwater discharges and the associated water quality are connected (SFERWG, 1998).

By capturing excess stormwater runoff and storing it, harmful wet season regulatory releases will be reduced, protecting oysters, seagrasses and other estuarine organisms. Water quality benefits include protecting the estuary from excessive freshwater pulses that drastically reduce salinities, and protecting the estuary from the nutrients inherent in stormwater runoff. Controlled releases of the stored water during the dry season will protect the estuary from high salinities during the dry season as well. These freshwater deliveries to the St. Lucie Estuary will protect and restore more natural estuarine conditions. The stored water will also be returned to the C-44 Canal when needed to meet agricultural water supply demands.

Minimum and maximum flows were identified which would cause poor water quality conditions for the estuary. This feature, in combination with component UU (storage features in the C-23, C-24, C-25, Northfork and Southfork Basins) and modifications to the Lake Okeechobee operation schedule, will require development of a series of operational rules for all associated facilities. These rules will help to maintain optimal salinity conditions in the estuary in order to support a range of aquatic vegetation, seagrass, invertebrates, and fish communities.

There are other ongoing efforts in the areas affected by this feature of the Comprehensive Plan. They are the South Florida Water Management District's Upper East Coast Water Supply Plan, the Indian River Lagoon Surface Water Improvement and Management Plan and the Indian River Lagoon Feasibility Study.

The total initial cost for construction of the C-44 Basin Storage Reservoir is $112,563,000 at October 1999 price levels. This includes planning costs of $902,000, engineering and design costs of $602,000, real estate costs of $90,675,000 and construction costs of $20,384,000. The annual operations, maintenance, repair, replacement and rehabilitation costs are $760,000. The real estate land requirement for the C-44 Basin Storage Reservoir is estimated at 10,000 acres in Martin county.

Operation and maintenance costs for the C-44 Reservoir are based upon the following: levee mowing on a regular basis; routine maintenance and equipment replacement based upon an annual investment for control structures; canal maintenance that includes removal of floating and submerged vegetation plus shoreline spraying; and maintenance, operation and replacement costs for an unmanned electric inflow pump station and seepage pumps.

10.6.2.2. Everglades Agricultural Area Storage Reservoirs Phase-1

This feature is located on lands in the Everglades Agricultural Area in western Palm Beach County on lands being purchased with Department of Interior Farm Bill funds, with South Florida Water Management District funds, and through a series of exchanges for lands being purchased with these funds. The location of the Phase 1 lands, which includes both the Talisman Land purchase (including exchanges) and the Carroll Property, are shown in ***Figure 10-13.*** The area presently consists of land that is mostly under sugar cane cultivation. This feature will be implemented consistent with the Farm Bill land acquisition agreements.

This feature is included in the initial authorization for three reasons: 1) lands needed for the project have been or will be acquired by the U.S. Department of Interior and the South Florida Water Management District, 2) it provides the opportunity to construct the facility in a manner that is mutually beneficial for the Comprehensive Plan and the sponsor's Everglades Construction Project, 3) expedites construction of this facility which provides multiple environmental, water supply, and flood protection benefits. This feature will improve timing of environmental deliveries to the Water Conservation Areas including reducing damaging flood releases from the Everglades Agricultural Area to the Water Conservation Areas, reduce Lake Okeechobee regulatory releases to estuaries, meet supplemental agricultural irrigation demands, and increase flood protection within the Everglades Agricultural Area.

This feature includes above ground reservoir(s) with a total storage capacity of approximately 240,000 acre-feet located on land associated with the Talisman Land purchase in the Everglades Agricultural Area. Conveyance capacity increases for the Miami, North New River, Bolles and Cross Canals are also included in the design of this feature. The initial design for the reservoir(s) assumed 40,000 acres, divided into two, equally sized compartments with the water level fluctuating up to 6 feet above grade in each compartment. As originally envisioned, Compartment 1 would be a 20,000-acre reservoir at 6 feet maximum depth with inflow pumps with a capacity of 2,700 cfs from the Miami Canal Basin and 2,300 cfs from the North New River Canal Basin for diversion of Everglades Agricultural Area runoff. Outflow to the Everglades Agricultural Area would be through a 3,000 cfs structure to Miami Canal Basin and a 4,400 cfs structure to North New River and Hillsboro Basins. Compartment 2 would be a 20,000-acre reservoir at 6 feet maximum depth with inflow pumps with a capacity of 4,500 cfs from the Miami Canal Basin and 3,000 cfs from the North New River Canal Basin for diversion of Lake Okeechobee regulatory releases. Outflow to the Everglades Construction Project's Stormwater Treatment Areas 3 and 4 would be through a 3,600 cubic foot per second structure. Canal conveyance capacities would be increased by 200 percent for the Miami, North New River and Bolles and Cross Canal in order to direct Lake Okeechobee regulatory releases to the reservoir. The Project Implementation Report for the project will address the specific location and sizing of the facility as well as more site-specific design of levees and pump stations. In addition, the extent of conveyance improvements for the North New River Canal, the Miami Canal, and the Bolles and Cross Canal will be identified.

As originally designed, Compartment 1 of the reservoir would be used to meet Everglades Agricultural Area irrigation demands. The source of water is excess Everglades Agricultural Area runoff. Overflows to Compartment 2 could occur when Compartment 1 reaches capacity and Lake Okeechobee regulatory discharges are not occurring or impending. Compartment 2 would be used to meet environmental demands as a priority, but could supply a portion of Everglades Agricultural Area irrigation demands if environmental demands equal zero. Flows will be delivered to the Water Conservation Areas through Stormwater Treatment Areas 3 and 4. The sources of water are overflow from Compartment 1 and Lake Okeechobee regulatory releases. Compartment 2 will be operated as a dry storage reservoir and discharges made down to 18 inches below ground level.

Operation and maintenance costs are based upon levee mowing on a regular basis; control structure maintenance and annualized equipment replacement; canal maintenance including removal of floating and submerged vegetation and shoreline spraying; unmanned seepage control pump maintenance, power and annualized equipment replacement; and manned diesel pump station maintenance and operation costs including direct labor, fuel and power, annualized equipment replacement and overhaul and structural maintenance and repair.

The benefits to the project derived from this feature include improved storage and conveyance features that will enhance the water supply to the natural areas and support better timing of water deliveries to the Water Conservation Areas by capturing and managing flood releases from the Everglades Agricultural Area to the Water Conservation Areas. This component will reduce the need to make damaging regulatory releases from Lake Okeechobee to the St. Lucie and Caloosahatchee estuaries and will help meet Everglades Agricultural Area irrigation needs while increasing flood protection in the area.

The total initial cost for this feature is $233,408,000, which includes planning costs of $9,621,000, engineering and design costs of $6,414,000, no real estate costs and construction costs of $217,373,000. No real estate costs are included in the initial cost for this feature, as the land being purchased with Department of Interior Farm Bill funds, with South Florida Water Management District funds, and through a series of exchanges for lands being purchased with these funds. Cost sharing allocations between the Federal government and the South Florida Water Management District for this will be determined during the Project Implementation Report. The annual operation costs are $14,458,000.

10.6.2.3. Water Conservation Area 3 Decompartmentalization and Sheetflow Phase - 1

These project modifications will occur within the Water Conservation Areas and Everglades National Park in Broward and Miami-Dade Counties and is shown in ***Figure 10-14***.

This project is included in the initial authorization for two reasons; 1) to provide immediate opportunities for enhanced sheetflow within Water Conservation Area 3 and between Water Conservation Area 3 and Everglades National Park and 2) to integrate with ongoing modifications that are being made in the detailed design and construction of the Modified Water Deliveries to Everglades National Park project.

This project as originally envisioned includes backfilling the Miami Canal in Water Conservation Area 3 from one to two miles south of the S-8 pump station down to east coast protective levee. To make up for the loss of water supply conveyance to the Lower East Coast urban areas from the Miami Canal, the capacity of the North New River Canal south of the proposed Everglades

Agricultural Area Storage Reservoir will be doubled to convey additional water supply deliveries to Miami-Dade County as necessary. The capacities of S-351 and S-150 to pass additional water supply deliveries down the North New River Canal to Miami-Dade County will be doubled. In addition, the conveyance of the L-33 and L-37 borrow canals on the west side of US 27 between L-38W and the Miami Canal will be increased as necessary to pass the additional flows. Modifications will also be made to the eastern section of Tamiami Trail which includes elevating the roadway through the installation of a series of bridges between L-31N Levee and the L-67 Levees. The eastern portion of L-29 Levee and Canal will also be degraded in the same area as Tamiami Trail modifications. The Project Implementation Report will address the scope and method to be used for Miami Canal backfilling, conveyance improvements to the North New River Canal and, the bridging of Tamiami Trail, and L-29 modifications that are necessary to enable unrestricted flow from Water Conservation Area 3 into Everglades National Park. The sequencing of these modifications will also be addressed in the Project Implementation Report. These project modifications will be coordinated with the existing Modified Water Deliveries to Everglades National Park Project as well as the development of rainfall driven operational schedules for Water Conservation Area 3 and Everglades National Park.

The modifications described above will provide the initial increment of more integrated passive management of Water Conservation Area 3 and Everglades National Park. It is anticipated that these modifications will be made in association with the implementation of rainfall driven operational schedules for both Water Conservation Area 3 and Everglades National Park.

Operation and maintenance costs are based upon control structure maintenance and annualized equipment replacement and canal maintenance including removal of floating and submerged vegetation.

The benefits to the project from this feature are that restoring sheet flow will reduce the unnatural discontinuities in the landscape. Depth patterns will be more gradual, aquatic organisms will be able to move more freely, exotic species will not have the advantage of deep water canals that provide thermal refuge or dry levees on which to grow. Normal proportions of predators/prey species in fish populations will be undisturbed. Natural interspersions of different marsh habitats will replace the current system of upstream pools and downstream dry area on either side of barriers. The result will be better quality and more easily accessible habitat for wading birds and other Everglades species.

The total initial cost for this feature is $104,033,000, which includes planning costs of $3,205,000, engineering and design costs of $2,137,000, real estate costs of $26,279,000 and construction costs of $72,412,000. The annual operation costs are $650,000.

10.6.2.4. Site 1 Impoundment

This feature is located in southern Palm Beach County adjacent to the Hillsboro Canal and Loxahatchee National Wildlife Refuge and Water Conservation Area 2A and is shown in ***Figure 10-15.***

This feature is included in the initial authorization for several reasons: 1) a large portion of the lands required for the feature have already been acquired by the sponsor, 2) benefits to the ecosystem will be gained from this feature by capturing water that is normally sent to tide and returning it to the system early in the process, and 3) uncertainty in constructing this feature is minimized by postponing the construction of the aquifer storage and recovery portion until after the pilot project for this site is completed. The purpose of this feature is to supplement water deliveries to the Hillsboro Canal during dry periods thereby reducing demands on Lake Okeechobee and Loxahatchee National Wildlife Refuge.

This feature includes an above ground reservoir with a total storage capacity of approximately 15,000 acre-feet. The initial design of the reservoir assumed 2,460 acres with water levels fluctuating up to 6 feet above grade. An inflow pump station with a capacity of 700 cfs, an outflow structure with a capacity of 200 cfs and an emergency outflow structure with a capacity of 700 cfs are proposed. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study.

The reservoir will be filled during the wet-season from excess water pumped from the Hillsboro Canal. Water will be released back to the Hillsboro Canal to help maintain canal stages during the dry-season. If water is not available in the reservoir, existing rules for water delivery to this region will be applied.

Operation and maintenance costs are based upon levee mowing on a regular basis; control structure maintenance and annualized equipment replacement; canal maintenance including removal of floating and submerged vegetation; shoreline spraying; unmanned pump station and seepage control pump maintenance, power and annualized equipment replacement.

The benefits to the project will be a reduction in demands on the Loxahatchee National Wildlife Refuge and Lake Okeechobee during the early dry season as well as a reduction in the amount of water discharged to tide. By reducing the demands on Lake Okeechobee the littoral zone of the Lake and the marshes in the Refuge will suffer fewer damaging low levels.

There are additional studies planned for this site. They include a small ongoing reservoir pilot project performed by the South Florida Water Management

District and as part of this initial authorization, a pilot project for aquifer storage and recovery to address the uncertainty regarding applying the technology at this feature location.

The total initial cost for this feature is $38,535,000, which includes planning costs of $616,000, engineering and design costs of $411,000, real estate costs of $23,587,000 and construction costs of $13,921,000. The annual operation costs are $733,000.

10.6.2.5. Western C-11 Diversion Impoundment and Canal and Water Conservation Areas 3A and 3B Levee Seepage Management

This feature is located in western Broward County east of Water Conservation Area 3A and 3B and is shown in ***Figure 10-16***. The diversion canal is located west of US-27 between C-11 and C-9 Canals. The C-11 stormwater treatment area/impoundment is located northeast of the intersection of U.S. Highway 27 and C-11 Canal.

Initial authorization is necessary due to the existing operation of the S-9 pump station. The original C&SF Project design provides for Western C-11 Basin drainage to be pumped into Water Conservation Area 3. This feature will provide the necessary facilities to maintain flood protection within the basin, while reducing flows through the S-9 to Water Conservation Area 3. Other factors supporting initial authorization include: 1) lands were identified as suitable by both the East Coast Buffer Feasibility Analysis and the Water Preserve Areas Land Suitability Analysis; 2) lands are being actively acquired by sponsor; 3) this feature is consistent with ongoing programs such as the Water Preserve Areas Feasibility Study and the Everglades Stormwater Program; and 4) acquisition and utilization of land which is suitable for storage and water quality treatment are rapidly being lost to urbanization.

This feature includes canals, levees, water control structures, and a stormwater treatment area/impoundment with a total storage capacity of 6,400 acre-feet. The initial design of the stormwater treatment area/impoundment assumed 1,600 acres with the water level fluctuating up to 4 feet above grade. The initial design of the diversion canal west of U.S. Highway 27 is for a conveyance capacity of 2,500 cfs. A 2,500 cfs conveyance capacity improvement is envisioned to the C-9 canal between S-30 and the C-9 Impoundment. An intermediate 2,500 cfs pump station in the C-11 canal will be used to direct runoff to the C-11 stormwater treatment area/impoundment. A seepage collection canal and inflow pump station will also be used on the C-11 stormwater treatment area/impoundment. A 2,200 cfs outflow structure is envisioned to discharge from the impoundment to C-11 west of U.S. 27 to the diversion canal. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study.

Runoff in the western C-11 Canal Basin that was previously backpumped into Water Conservation Area 3A through the S-9 pump station will be diverted into the C-11 Stormwater Treatment Area/Impoundment and then into either the North Lake Belt Storage Area, the C-9 Stormwater Treatment Area/Impoundment, or Water Conservation Area 3A after treatment, as applicable.

Operation and maintenance costs are based upon regular mowing of levee surfaces; control structure maintenance and annualized equipment replacement; manned diesel pump station maintenance and operation costs including direct labor, fuel and power, annualized equipment replacement and overhaul, structural maintenance and repair; canal maintenance including removal of floating and submerged vegetation; and shoreline spraying.

The benefit to the project from this feature is that Water Conservation Area 3A water quality will improve when the poor quality runoff from the western C-11 Canal basin is no longer being backpumped into it through the S-9 pump station. This component diverts that water into the C-11 Stormwater Treatment Area/Impoundment where it then becomes available for either the C-9 Stormwater Treatment Area/Impoundment, the North Lake Belt Storage Area after it is operational or Water Conservation Area 3A after treatment, as applicable. In addition, this feature will help control seepage from Water Conservation Areas 3A and 3B by increasing groundwater elevations directly east of the east coast protective levee.

The C-11 Critical Project is currently under construction at this site and is fully compatible with this feature.

The total initial cost for this feature is $225,172,000, which includes planning costs of $2,371,000, engineering and design costs of $1,581,000, real estate costs of $167,646,000 and construction costs of $53,574,000. The annual operation costs are $783,000.

10.6.2.6. C-9 Stormwater Treatment Area/Impoundment

This feature is located in the western C-9 Basin in Broward County and is shown in ***Figure 10-17***.

This feature is included in the initial authorization due to its interaction with the C-11 Stormwater Treatment Area and Impoundment. Other factors supporting initial authorization of this feature include: 1) lands were identified as suitable by both the East Coast Buffer Feasibility Analysis and the Water Preserve Areas Land Suitability Analysis; 2) lands are being actively acquired by sponsor; 3) this feature is consistent with ongoing programs such as the Water Preserve Areas Feasibility Study and the Everglades Stormwater Program; and 4) acquisition and utilization of land which is suitable for storage and water quality treatment are rapidly being lost to urbanization; 5) this area is necessary for diversion of C-11 Basin flows prior to the completion of the North Lake Belt Storage Area which is later in the implementation schedule; 6) improved flood protection in the Western C-9 Basin.

This feature includes canals, levees, water control structures and a stormwater treatment area/impoundment with a total capacity of approximately 10,000 acre-feet. The initial design of the stormwater treatment area/impoundment assumed 2,500 acres with the water level fluctuating up to 4 feet above grade. An inflow pump station with a capacity of 1,000 cfs and an outflow gravity structure with a capacity of 1,000 cfs are also envisioned for the impoundment. A seepage collection canal and pump station with a capacity of 200 cfs are needed to prevent impact to private adjacent land. The final size, depth and configuration of these facilities will be determined through more detailed planning and design to be completed as a part of the Water Preserve Areas Feasibility Study.

Operationally, excess stormwater runoff from the C-11 Basin and Western C-9 Basin will be pumped into the C-9 Stormwater Treatment Area/Impoundment for storage and water quality treatment prior to making water supply deliveries to the C-9, or C-6/C-7 Canals. Seepage from C-9 Stormwater Treatment Area/Impoundment will be collected and returned to the impoundment.

Operation and maintenance costs are based upon levee mowing on a regular basis; canal maintenance including removal of floating and submerged vegetation and shoreline spraying; unmanned seepage control pump maintenance, power and annualized equipment replacement; and manned diesel pump station maintenance and operation costs including direct labor, fuel and power, annualized equipment replacement and overhaul and structural maintenance and repair.

The benefits from this feature will include enhancing groundwater recharge within the basin, provide seepage control for Water Conservation Area 3 and buffer areas to the west thereby keeping more of the natural system's water in the natural system. In addition flood protection for the western C-9 Basin will be enhanced.

The total initial cost for this feature is $89,146,000, which includes planning costs of $1,080,000, engineering and design costs of $720,000, real estate costs of $62,939,000 and construction costs of $24,407,000. The annual operation costs are $616,000.

10.6.2.7. C-111N Spreader Canal

This feature is located in south Miami-Dade County in the Southern Glades and Model Lands areas as shown in ***Figure 10-18***

This feature is included in the initial authorization for several reasons: 1) early authorization will allow for inclusion into the ongoing detailed design and construction of the C-111 project, and 2) inclusion of a stormwater treatment area to provide water quality treatment of agricultural runoff prior to distributing water through the C-111N spreader canal. This feature will improve deliveries and enhance the connectivity and sheetflow in the Model Lands and Southern Glades areas, reduce wet season flows in C-111, and decrease potential flood risk in the lower south Miami-Dade County area.

This feature includes construction, modification or removal of levees, canals, pumps, water control structures, culverts and a stormwater treatment area. This feature enhances the C-111 Project design for the C-111N Spreader Canal with: the construction of a 3,200 acre stormwater treatment area; the enlarging of pump station S-332E from 50 cfs to 500 cfs; increasing the capacity of C-111N for the higher capacity of flow and the extension of the canal approximately two miles under U.S. Highway 1 and Card Sound Road into the Model Lands; and culverts under U.S. Highway 1 and Card Sound Road. The initial design of this feature pumps water from the C-111 and the C-111E Canals through two 250 cfs pump stations into a stormwater treatment area prior to discharging through S-332E to the Southern Glades and the Model Lands through the C-111N Canal. This feature also fills in the southern reach of the C-111 Canal below C-111N to S-197; removal of structures S-18C and S-197; completely backfilling C-110; and removal of adjacent levees and roads. The final size, depth, location and configuration of this feature will be determined through more detailed planning and design.

Operation and maintenance costs are based upon regular mowing of levee surfaces; canal maintenance including removal of floating and submerged vegetation and shoreline spraying; unmanned seepage control pump maintenance, power and annualized equipment replacement; and unmanned electric pump station maintenance and operation costs including power, annualized equipment replacement and overhaul and structural maintenance and repair.

This feature improves deliveries and enhances the connectivity and sheetflow in the Model Lands and Southern Glades areas, reduces wet season flows in C-111, and decreases potential flood risk in the lower south Miami-Dade County area while improving the quality of water discharged into the Model Lands and Southern Glades areas.

The total initial cost for this feature is $94,034,000, which includes planning costs of $1,990,000, engineering and design costs of $1,326,000, real estate costs of $45,766,000 and construction costs of $44,952,000. The annual operation costs are $60,000.

10.6.2.8. Taylor Creek/Nubbin Slough Storage and Treatment Area

This feature is located northeast of Lake Okeechobee in the Taylor Creek/Nubbin Slough (S-191) Basin. This basin is located in Okeechobee, St. Lucie and Martin Counties. An initial site for a portion of the facilities is located near the northeastern shores of Lake Okeechobee and at the base of Nubbin Slough shown in ***Figure 10-19***. The site consists of large areas of improved pasture and hayfields of an existing dairy operation.

This feature is included in the initial authorization for three reasons: 1) a portion of the lands needed for the project have been identified by the sponsor; 2) flows to Lake Okeechobee will be attenuated when lake levels are high or rising and 3) water quality treatment will be provided for flows from the Taylor Creek/Nubbin Slough basin which currently contribute the highest phosphorus inflow concentrations to Lake Okeechobee.

This feature includes an above-ground reservoir with a total storage capacity of approximately 50,000 acre-feet and a stormwater treatment area with a capacity of approximately 20,000 acre-feet in the Taylor Creek/Nubbin Slough Basin. The initial design of this feature assumed a reservoir of 5,000 acres with water levels fluctuating up to 10 feet above grade and a stormwater treatment facility of approximately 5,000 acres. It is anticipated that there will be a series of reservoir and stormwater treatment facilities located throughout the basin. The Project Implementation Report will address the location and sizing of the facilities as well as the design of levees and pump stations for the reservoirs and stormwater treatment areas.

Local runoff from the Taylor Creek/Nubbin Slough Basin will be pumped into the reservoir then into an adjacent stormwater treatment area. The stormwater treatment area will reduce phosphorus concentrations in the runoff from approximately 0.58 mg/l to 0.117 mg/l. Treated water will be pumped into Lake Okeechobee when the lake stage is falling and is at least 0.5 feet below the bottom pulse release zone.

Operation and maintenance costs are based upon levee mowing on a regular basis; canal maintenance including removal of floating and submerged vegetation and shoreline spraying; unmanned seepage control pump maintenance, power and annualized equipment replacement; and manned diesel pump station maintenance and operation including direct labor, fuel and power, annualized equipment replacement and overhaul and structural maintenance and repair.

This feature will benefit the project by protecting Lake Okeechobee from excessive high levels that impact the littoral zone as well help reduce regulatory releases from the lake to the St. Lucie and Caloosahatchee estuaries. Lake Okeechobee will also benefit from receiving the water when lake levels decline, providing protection from damaging low levels. Water quality treatment will reduce the nutrient load on the lake to the benefit of all of the Lake's native organisms including the substantial fishery.

The total initial cost for this feature is $104,026,000, which includes planning costs of $3,064,000, engineering and design costs of $2,042,000, real estate costs of $29,700,000 and construction costs of $69,220,000. The annual operation costs are $2,164,000.

10.6.3. Adaptive Assessment and Construction Monitoring Program

An extensive Adaptive Assessment Program, which includes a system-wide monitoring program will be conducted to support the ecosystem restoration objectives of the Comprehensive Plan as described in ***Section 9.5***. This program will provide an opportunity to continue investigating concepts and issues relative to the overall Comprehensive Plan while implementation of the initial project features are underway. The Adaptive Assessment Program, which will be implemented through the RECOVER Team described in ***Section 10.3.3***, will include continued system-wide evaluation and analysis among other planning activities. The construction and regional monitoring program will have a dual focus on the biological and hydrological restoration objectives in the natural systems, and the water supply and flood protection objectives in the urban and agricultural regions.

This Adaptive Assessment Program for the Comprehensive Plan is still under development. Given the conceptual nature of the Comprehensive Plan and the need to integrate the monitoring program portion with other ongoing efforts, it is difficult to prepare a detailed estimate of its cost at the present time. However, based on other ongoing programs including this feasibility study and other ecologic restoration monitoring programs such as the Kissimmee River Restoration Project, the total estimated annual cost for this program is estimated to be $10,000,000. For Corps of Engineers programming purposes, this cost is assumed to be a "Construction" cost as opposed to Operation and Maintenance cost since it is required to advance the project to completion.

10.6.4. Total Cost for Features Included in this Recommendation

The total cost includes the initial cost of planning, engineering and design, and construction as well the annual operation and maintenance costs of the features recommended for initial authorization.

10.6.4.1. Implementation Cost

The total estimated cost of the initial authorization of the recommended Comprehensive Plan is $1,198,000,000 (rounded) at October 1999 price levels. The cost estimate is shown in ***Table 10-7.*** This estimate is the "base line" estimate, and does not account for future price escalation.

TABLE 10-7
IMPLEMENTATION COST OF INITIAL AUTHORIZATION

Project		IMPLEMENTATION COSTS					Operation & Maintenance
		Planning	Engineering and Design	Real Estate	Construction	Total	
B	C-44 Basin Storage Reservoir	$902,000	$602,000	$90,675,000	$20,384,000	$112,563,000	$760,000
G (Phase 1)	Everglades Agricultural Area Storage Reservoirs – (Phase 1)	$9,621,000	$6,414,000	$0	$217,373,000	$233,408,000	$14,458,000
QQ (Phase 1) and SS	Water Conservation Area 3 Decompartmentalization and Sheetflow (Phase 1)	$3,205,000	$2,137,000	$26,279,000	$72,412,000	$104,033,000	$650,000
M (Phase 1)	Site 1 Impoundment	$616,000	$411,000	$23,587,000	$13,921,000	$38,535,000	$733,000
Q & O	Western C-11 Diversion and Impoundment and WCA 3A & B Levee Seepage Management	$2,371,000	$1,581,000	$167,646,000	$53,574,000	$225,172,000	$783,000
R	C-9 Impoundment/Stormwater Treatment Area	$1,080,000	$720,000	$62,939,000	$24,407,000	$89,146,000	$616,000
WW	C-111N Spreader Canal	$1,990,000	$1,326,000	$45,766,000	$44,952,000	$94,034,000	$60,000
W	Taylor Creek/Nubbin Slough Storage and Treatment Area	$3,064,000	$2,042,000	$29,700,000	$69,220,000	$104,026,000	$2,164,000
	Pilot Projects	$2,225,000	$7,186,000	$9,800,000	$77,789,000	$97,000,000	
	Adaptive Assessment and Monitoring (10 years)	$100,000,000				$100,000,000	
	TOTALS	**$125,074,000**	**$22,419,000**	**$456,392,000**	**$594,032,000**	**$1,197,917,000**	**$20,224,000**

10.6.4.2. Operation, Maintenance, Repair, Replacement, and Rehabilitation (OMRR&R) Costs

Annual operation and maintenance costs were estimated for the initial construction features of the recommended Comprehensive Plan. The operation and maintenance costs were determined by extrapolating from operational cost histories supplied by the South Florida Water Management District. The costs reflect projected values based on past trends encountered and represent the difference between with versus without the Comprehensive Plan. Replacement costs were calculated for culverts and mechanical and electrical equipment related to pump plants and spillway structures. The OMRR&R costs are estimated to be $20,000,000 (rounded).

10.6.5. Cost Sharing

Table 10-8 contains an apportionment of project costs between the Federal government and the non-Federal sponsor based on the cost sharing provisions described in ***Section 9.9***.

Annual operation and maintenance costs for the initial features will also be shared equally between the Federal Government and the non-Federal sponsor as described in ***Section 9.9.4***. The estimated annual Federal cost is $10,112,000 and the estimated non-Federal cost is $10,112,000.

TABLE 10-8
COST APPORTIONMENT

	Total	Federal	Non-Federal
Construction[1]	$741,525,000	$598,958,500	$142,566,500
Lands, Easements, Rights-of-way	$456,392,000	$0	$456,392,000
Total	$1,197,917,000	$598,958,500	$598,958,500
Rounded	$1,198,000,000	$599,000,000	$599,000,000

[1] Includes Planning; Preconstruction, Engineering and Design; and Construction Management.

10.6.6. Financial Analysis

It is expected that the South Florida Water Management District will have the capability to provide the required local cooperation for the recommended features identified in this Section. The South Florida Water Management District has provided a statement of financial capability which is included in ***Appendix G, Local Cooperation and Financial Analysis.***

10.6.7. Local Cooperation

The project's non-Federal sponsor must provide its share of project costs, including LERRD and cash for construction and later OMRR&R costs, as described above. LERRD are to be furnished to the Federal government prior to the advertisement of any construction contract, which involves those LERRD. In providing LERRD, the sponsor must comply with the provisions of the Uniform Relocations Assistance and Real Property Acquisition Policies Act of 1970 (Public Law 91-646), as amended. Any required cash payments for project construction costs are to be made during construction at a rate proportional to Federal expenditures. The sponsor's share of pre-construction engineering and design costs will be repaid during the first year of construction.

A project may be initiated only after the sponsor has entered into a binding Project Cooperation Agreement with the Department of the Army, which are normally negotiated during the pre-construction engineering and design phase. Project Cooperation Agreements will be developed for each separable project that is implemented. The Project Cooperation Agreement assigns Federal and non-Federal responsibilities, which, for the Comprehensive Plan, will include as a minimum the following items of local cooperation:

a. Provide 50 percent of the total project costs as further specified below:

1. Enter into an agreement, which provides, prior to construction, 25 percent of pre-construction engineering and design (PED) costs;

2. Provide, during construction, any additional funds needed to cover the non-Federal share of pre-construction engineering and design costs;

3. Provide all lands, easements, and rights-of-way, including suitable borrow and dredged or excavated material disposal areas, and perform or assure the performance of all relocations determined by the Government to be necessary for the construction, operation, and maintenance of the project;

4. Provide or pay to the Government the cost of providing all retaining dikes, wasteweirs, bulkheads, and embankments, including all monitoring features and stilling basins, that may be required at any dredged or excavated material disposal areas required for the construction, operation, and maintenance of the project; and

5. Provide, during construction, any additional costs as necessary to make its total contribution equal to 50 percent of total project costs.

b. Grant the Government a right to enter, at reasonable times and in a reasonable manner, upon land which the local sponsor owns or controls for access to the project for the purpose of inspection, and, if necessary, for the purpose of completing, operating, maintaining, repairing, replacing, or rehabilitating the project.

c. For so long as the project remains authorized assume responsibility for operating, maintaining, replacing, repairing, and rehabilitating (OMRR&R) the project or completed functional portions of the project, including mitigation features, with 50 percent of the funding provided by the Federal government, in a manner compatible with the project's authorized purposes and in accordance with applicable Federal and State laws and specific directions prescribed by the Government in the OMRR&R manual and any subsequent amendments thereto.

d. Comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended, and Section 103 of the Water Resources Development Act of 1986, Public Law 99-662, as amended, which provides that the Secretary of the Army shall not commence the construction of any water resources project or separable element thereof, until the non-Federal sponsor has entered into a written agreement to furnish its required cooperation for the project or separable element.

e. Hold and save the Government free from all damages arising for the construction, operation, maintenance, repair, replacement, and rehabilitation of the project and any project-related betterments, except for damages due to the fault or negligence of the Government or the Government's contractors.

f. Keep and maintain books, records, documents, and other evidence pertaining to costs and expenses incurred pursuant to the project to the extent and in such detail as will properly reflect total project costs.

g. Perform, or cause to be performed, any investigations for hazardous substances that are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 USC 9601-9675, that may exist in, on, or under lands, easements or rights-of-way necessary for the construction, operation, and maintenance of the project; except that the non-Federal sponsor shall not perform such investigations on lands, easements, or rights-of-way that the Government determines to be subject to the navigation servitude without prior specific written direction by the Government.

h. Assume complete financial responsibility for all necessary cleanup and response costs of any CERCLA regulated materials located in, on, or under lands, easements, or rights-of-way that the Government determines necessary for the construction, operation, or maintenance of the project.

i. To the maximum extent possible, operate, maintain, repair, replace, and rehabilitate the project in a manner that will not cause liability to arise under CERCLA.

j. Participate in and comply with applicable flood plain management and flood plain insurance programs in accordance with section 402 of Public Law 99-662, as amended.

k. Not less than once each year, inform affected interests of the limitations of the protection afforded by the project.

l. Publicize flood plain information in the area concerned and provide this information to zoning and other regulatory agencies for their use in preventing unwise future development in the flood plain, and in adopting regulations as may be necessary to prevent unwise future development and to ensure compatibility with protection levels provided by the project.

m. As between the Federal Government and the non-Federal sponsor, the non-Federal sponsor shall be considered the operator of the project for the purpose of CERCLA liability. To the maximum extent practicable, operate, maintain, repair, replace, and rehabilitate the project in a manner that will not cause liability to arise under CERCLA.

n. Prescribe and enforce regulations to prevent obstruction of or encroachment on the Project that would reduce the level of protection it affords or that would hinder operation or maintenance of the Project.

o. Comply with the applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public law 91-646, as amended by title IV of the Surface Transportation and Uniform Relocation Assistance Act of 1987 (Public Law 100-17), and the Uniform Regulations contained in 49 CFR part 24, in acquiring lands, easements, and rights-of-way, and performing relocations for construction, operation, and maintenance of the project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said act.

p. Comply with all applicable Federal and State laws and regulations, including Section 601 of the Civil Rights Act of 1964, Public Law 88-352, and Department of Defense Directive 5500.11 issued pursuant thereto, as well as Army Regulation 600-7, entitled “Nondiscrimination on the Basis of Handicap in Programs and Activities Assisted or Conducted by the Department of the Army.”

q. Provide 50 percent of that portion of total cultural resource preservation mitigation and data recovery costs attributable to the project that are in excess of one percent of the total amount authorized to be appropriated for the project.

r. Do not use Federal funds to meet the non-Federal sponsor’s share of total project costs unless the Federal granting agency verifies in writing that the expenditure of such funds is expressly authorized by statute.

10.6.8. Sponsor’s Views

As the non-Federal sponsor of this feasibility study, the South Florida Water Management District has worked very closely in partnership with the Corps to ensure that the study and this report fairly and accurately reflected its views. On February 10, 1999, the South Florida Water Management District provided a Letter of Intent, which indicated their strong support for the Comprehensive Plan and the processes described in this report to implement the plan. This included the initial construction features proposed for authorization in the Water Resource Development Act of 2000 as described in this Section. In addition, the Letter of Intent notes that ensuring strong support from the Governor and the State Legislature continues to remain a key goal. The South Florida Water Management District’s letter is included in ***Appendix G, Local Cooperation and Financial Analysis***.

The South Florida Water Management District’s Letter of Intent states that “as the implementation plan crystallizes, several outstanding issues of great importance” to the District and the State of Florida will need to be adequately addressed. These are: (1) capital projects cost share; (2) operation, maintenance and monitoring cost share; (3) permitting of Comprehensive Plan components and projects; (4) assurances to existing legal users; (5) provision of flood protection; (6) impacts on ongoing projects; (7) water quality; and (8) scientific peer review. A more detailed discussion of these issues was developed as an attachment to the Letter of Intent (included in ***Appendix G, Local Cooperation and Financial Analysis***).

10.7. CONCLUSION

The Comprehensive Plan recommended in this report is a roadmap that provides critical direction and organizational structure for restoring and protecting the south Florida ecosystem. The comprehensive, system-wide nature of the plan and the linkage of the elements of the plan to each other must be preserved during implementation. Implementation of the plan must proceed using the principles of adaptive assessment as outlined in this Implementation Plan. Appropriate independent scientific peer review is an integral part of the implementation process. This Implementation Plan recognizes fully the need to ensure that once restored, south Florida's natural environment will not again be negatively impacted by water management activities. Consistent with Federal and State law, the requirement to protect existing legal users of water from adverse impacts caused by implementation of the Comprehensive Plan is recognized.

The Comprehensive Plan incorporates a number of technologies such as aquifer storage and recovery, seepage management, and wastewater reuse that have not been implemented on such a large scale. The pilot projects, as described in the Implementation Plan, should be undertaken in order to resolve uncertainties associated with the use of these technologies in the Comprehensive Plan and that their performance be evaluated before full-scale implementation of these technologies is undertaken.

The aquifer storage and recovery wells fall under the provisions of the Safe Drinking Water Act and are regulated by the Underground Injection Control Program. As a result, facilities utilized for treating surface and surficial waters to meet the standards of the Underground Injection Control Program are included in the cost estimate for the Comprehensive Plan. Recently, the U. S. Environmental Protection Agency has indicated their willingness to consider a flexible approach to constructing and permitting the aquifer storage and recovery wells proposed in the Restudy. This approach involves "risk-based" analyses to confirm that this flexible approach is appropriate. If the results of water quality testing and analyses conducted as part of the aquifer storage and recovery pilot projects confirm the appropriateness of this approach, then it is possible that the total cost of the recommended comprehensive plan could be reduced by $500,000,000 and annual operation and maintenance costs could be reduced significantly as well.

The Comprehensive Plan includes a wastewater reuse facility in south Miami-Dade County. Given its high cost and the uncertainties associated with using reuse to meet the ecological goals and objectives for Biscayne Bay, other potential sources of water to provide freshwater flows to central and southern Biscayne Bay will be investigated before pursuing the reuse facility.

Contingency plans will address performance deficiencies and cost-effectiveness issues that may arise as pilot projects are implemented and detailed design studies are completed as part of the implementation process.

One of the principal guidelines of the Implementation Plan is to ensure that the components are located, designed, and operated consistently with existing and future water quality protection criteria and restoration targets. The Comprehensive Plan includes a number of features (e.g., stormwater treatment areas, treatment for water to be stored in aquifers by aquifer storage and recovery facilities, advanced wastewater treatment by reverse osmosis at wastewater reuse plants) to protect and improve the quality of water in receiving water bodies related to the operation of specific plan components. In addition, regional-scale surface storage reservoirs included in the Comprehensive Plan present an opportunity to improve water quality where those reservoirs are located in basins with degraded water bodies (water bodies not meeting designated uses and/or water quality criteria contained in water quality standards). Future detailed planning and engineering activities will consider water quality protection criteria for water bodies in which plan components are to be located and designed with operational features necessary to achieve water quality restoration targets. Integration of water quality protection targets into the implementation process, together with monitoring and the adaptive assessment process will ensure that water quality protection is achieved and sustained for the natural and built environments of the south Florida ecosystem.

Water quality in the Keys is critical to ecosystem restoration. The Florida Keys Water Quality Protection Plan includes measures for improving wastewater and stormwater treatment within the Keys. Implementation of this plan is critical for restoration of the south Florida ecosystem.

There are a number of Federal, state, tribal, and local water resources projects presently underway or authorized in the study area such as the Kissimmee River Restoration, Modified Water Deliveries to Everglades National Park, C-111, and Everglades Construction Projects. The Comprehensive Plan includes modifications or additions to some of these projects. Consequently, implementation of all ongoing projects must be closely coordinated, and thus linked with ongoing implementation of the Comprehensive Plan.

Since 1993, with the creation of the South Florida Ecosystem Restoration Task Force, the Federal government has been working in partnership with State, tribal, and local governments, the private sector, and individual citizens to accomplish ecosystem restoration and protection objectives. It is important for the long-term restoration of the ecosystem that these efforts be continued and strengthened. Furthermore, we believe that in order for this effort to be successful, the State of Florida must be a full partner with the Federal government. It is anticipated that the Governor and Legislature will define the role of the State in the implementation process.

SECTION 11
PUBLIC INVOLVEMENT AND COORDINATION

Due to the intense public, political, and media interest in restoration of the south Florida ecosystem, public involvement is a critical component of the Restudy effort. This section describes the public involvement and coordination activities conducted during the Restudy.

11.1 PUBLIC INVOLVEMENT PROGRAM

Public involvement is a process by which interested and affected individuals, organizations, agencies, and governmental entities are consulted with and participate in a decision-making process. Public involvement in the Restudy had two main functions: to inform the public about the Restudy and to generate their input on key issues and concerns. This dialogue helped guide the Restudy, making it inclusive, balanced, and comprehensive. Public involvement activities also facilitated open and frank discussions that enhanced efforts to develop consensus on important issues. Supporting an exchange of ideas and information among interested individuals and groups has been critical to resolving the challenges involved in performing the Restudy.

Due to the large geographic area the Restudy encompasses, issues were complex and diversity of interests great. In recognition of these factors, the Corps of Engineers and the South Florida Water Management District as the non-Federal sponsor of the C&SF Project, intensified public involvement activities during the feasibility phase that were begun in the reconnaissance phase of the Restudy. A public involvement program was developed that was inclusive of all interests and concerns and balanced the sometimes-competing interests of this diverse region. This program was based upon a two-way communication and collaborative problem-solving model with the goal of reaching better, more informed decisions.

Public involvement activities ranged from workshops, focus group meetings, educational and technical briefings, presentations to interested parties, public meetings, fact sheets, and newsletters, to having the results of alternative plan formulation efforts available on a web site for comment back to the Restudy Team. Stakeholders and other interested parties were also invited to participate in the development of the Project Study Plan, which was the blueprint the Restudy Team used to perform the work necessary to accomplish the feasibility study.

Public involvement and coordination were identified as critical components of the feasibility study effort, due to the concentrated public, political, and media interest in the objectives of the Restudy. A public participation / public outreach plan was formulated to 1) inform the public, 2) gather information, 3) identify public concerns, 4) develop consensus, and 5) develop and maintain credibility. The overall objective of all outreach activities was to ensure that the south Florida community was informed about the Restudy and that the recommended Comprehensive Plan was reflective of the input received from stakeholders and the public.

Three additional objectives for public involvement were identified:

- Gather input from the diverse groups outside of the Restudy Team to assist in problem identification and the formulation and evaluation of alternative plans;

- Develop relationships critical to the success of the Restudy and the implementation of the recommendations of the Restudy; and

- Promote realistic expectations within an atmosphere where there is widespread public interest about the health of south Florida ecosystems, but a lack of awareness about the Corps' study.

Further, it was the obligation of the Restudy Team to:

- Keep people informed so that they could make educated choices;

- Provide visible ways to participate in the process; and

- Provide equal access to information and decision-makers regardless of viewpoint.

11.2 SCOPING

A Notice of Intent to prepare a Programmatic Environmental Impact Statement for the study was published in the Federal Register, Volume 61, No. 19, on January 29, 1996. The Notice of Intent outlined in summary form the project purpose and objective; described the study area; project features and scope; and laid out the Scoping process utilized to involve Federal, state, and local agencies; affected Native American Tribes; and interested private organizations and parties.

A Scoping Letter, dated February 7, 1996, was sent out by the Corps to over 5,000 recipients, including Federal, state, and local agencies; Native American Tribes; and private organizations and parties soliciting their views, comments, and information about resources, study objectives, alternatives, and important features within the study area. The record was held open for a 90-day comment period. Over 70 written responses were received within the comment period, representing hundreds of issues. These issues were compiled and infused into the Restudy plan formulation process over the subsequent two and one-half years.

A sampling of issues resulting from the Scoping process included:

- Proper identification and selection of alternative evaluation tools/models;
- The need to restore more natural timing, volume, and flow patterns of water (i.e. hydroperiods and hydropatterns);
- Increasing spatial extent and restoration of landscape heterogeneity and biodiversity;
- The desire to employ adaptive management and flexibility in decision-making;
- Maintenance of flood protection and water supply functions of the C&SF Project;
- The need to ensure economic and environmental sustainability;
- A process directed at total ecosystem restoration, rather than strictly a species-specific approach to recovery;
- Concept of linkage and sequencing of separable restoration components;
- The importance of identifying clear restoration goals and objectives; and
- The Restudy interagency team process or approach, including the opinion that the study process is too long or too short.

A broad and all-encompassing array of specific issues and/or physiographic areas were discussed in written responses to the Scoping Letter. These included, among others:

- The need for close coordination between existing projects (e.g. the C-111 and Modified Water Deliveries to Everglades National Park Projects) with the Restudy;

- The need to improve hydropatterns in Shark River and Taylor Sloughs;
- The need to control exotic flora and fauna, particularly Melaleuca; protection and restoration of sea grass beds;
- Protection of tree island communities in the Everglades;
- Soil subsidence in the Everglades Agricultural Area;
- The need to capture water lost to tide and return it to the natural system through a series of Water Preserve Areas;
- And the desire to protect the natural resources of Lake Okeechobee, while still maintaining its water supply, flood control, and other functions.

11.3 OTHER REQUIRED COORDINATION

In addition to the Scoping required by the National Environmental Policy Act, coordination required by other Federal laws and regulations has been conducted with the following agencies:

11.3.1 U.S. Fish and Wildlife Service

Three Planning Aid Letters were received as part of the process for developing alternative plans and the information received was incorporated into the plan formulation process. A fourth Planning Aid Letter was received in response to coordination of the draft Implementation Plan. Draft and final *Fish and Wildlife Coordination Act Reports* were prepared and are included at *Annex A*. Conclusions and recommendations in the *draft Fish and Wildlife Coordination Act Report* were as follows:

- Alternative D-13R, if fully implemented, would do much toward restoring ecological function and structure in south Florida, particularly in the central and southern Everglades.
- Improvements to ecological performance need to be made in Northeast Shark River Slough, the Water Conservation Areas, Biscayne Bay, and St. Lucie Estuary. Further, water quality must be addressed throughout the entire system.
- The Department of Interior has every confidence that these issues can be satisfactorily addressed, resulting in a feasible conceptual strategy for

south Florida ecosystem restoration that the Department of Interior can fully endorse.

The Department of Interior recommends further refinement of Alternative D-13R prior to release of the *Final Integrated Feasibility Report and Programmatic Environmental Impact Statement* including:

- Northeast Shark River Slough: Total overland flow volumes to Florida Bay through Taylor Slough and Shark River Slough should be increased to better meet historic conditions as predicted by the Natural System Model.

- Water Conservation Areas 3B, 2B and Northeast 3A: Eliminate the potentially damaging high and low water events.

- Biscayne Bay: Restore more natural flows to the bay. The Department of Interior questions the feasibility of wastewater reuse and recommends that the Other Project Elements (refer to ***Section 7 - Formulation and Evaluation of Alternative Plans****)* be prioritized and other means of restoration be explored. The Department of Interior also recommended that the ongoing Biscayne Bay Feasibility Study include consideration of these other alternatives.

- St. Lucie Estuary: Although Alternative D-13R succeeds in eliminating Lake Okeechobee regulatory releases to the estuary, the runoff within St. Lucie Basin still exceeds the restoration target.

- Water Quality: The Department of Interior questions the adequacy of the water quality plan and the treatment of water returned to the natural system. Specifically, the Department of Interior recommends that specific pollutant loading targets be developed within each watershed. Further, the water quality problem is not limited to nutrients; other water quality parameters, such as pesticides and mercury, should be studied.

- Uncertainty: The Department of Interior is concerned about the reliance on unproven technologies such as regional-scale Aquifer Storage and Recovery, seepage barriers, and wastewater reuse.

Conclusions and recommendations in the ***final Fish and Wildlife Coordination Act Report*** were as follows:

- The final plan as implemented should include components from the D-13R_4 scenario that can provide for delivery of additional water to

Everglades National Park and Biscayne Bay by capturing additional runoff from urban areas.

- The Corps should give high priority to examining those groups of components related to movement of water from the central Everglades to the southern Everglades, including but not limited to, L-29 and L-67 A and C.
- The final Plan as implemented should be flexible enough to develop and substitute components during implementation.
- The Department of Interior recommends that the Corps not commit to the specific details of the L-67 levee component as conceived in either Alternative D-13R or the $D\text{-}13R_4$ scenario.
- The use of the currently designed S-140 as a means to restore hydropatterns in northern WCA 3A needs to be further evaluated during the Project Implementation Report process and in detailed design.
- Until the Comprehensive Plan is implemented, surface water flows for Biscayne National Park and the bay should meet or exceed the 1995 base condition.
- Waste water reuse as a means to supply additional flow to Biscayne National Park and Biscayne Bay should be considered as a last resort to other mechanisms that have more reasonably predictable environmental and economic consequences.
- Studies to verify restoration targets for Biscayne National Park and the bay should be funded and prioritized early during the implementation phase. The Biscayne Bay Feasibility Study, in particular, must be given a very high priority.
- Sufficient water treatment capacity needs to be built into the Comprehensive Plan to handle the increased water volumes needed to achieve the hydrologic characteristics as were observed in Biscayne Bay and Everglades National Park under $D\text{-}13R_4$.
- The Comprehensive Integrated Water Quality Plan needs to be given priority and specific funding identified for this purpose in WRDA 2000.
- The 2010 case study should be revisited to see if optimizing reservoir performance, reordering the implementation schedule, or phasing

components into increments, would improve performance of the comprehensive plan by the year 2010.

- High priority needs to be placed on further refinement of the Natural Systems Model early in the implementation of the Comprehensive Plan.

- The Corps and cooperating agencies should develop and test active management techniques that accelerate recovery of damaged soils in the Water Conservation Areas, including the development of peat/soil accretion/risk assessment models.

- The Corps should support an ongoing and in-depth scientific review throughout implementation.

11.3.2 Florida Game and Fresh Water Fish Commission

Two Planning Aid Letters from the Commission were received as part of the process for developing alternative plans and the information received was incorporated into the plan formulation process. A third Planning Aid Letter was received in response to coordination of the draft Implementation Plan. Three Fish and Wildlife *Coordination Act Reports* from the Commission were prepared and are included at ***Annex A***. Conclusions and recommendations in the first (Part I) ***Fish and Wildlife Coordination Act Report*** were as follows:

- Alternative D-13R makes substantial progress towards restoration of the south Florida ecosystem.

- Alternative D-13R shows the most promise for restoring the natural areas.

- A fundamental result of Alternative D-13R is that it restores an enormous amount of fresh water to a southward flow resulting in improvements in timing and reducing unnatural flows to the Caloosahatchee and St. Lucie Estuaries without undue reliance on Lake Okeechobee.

The Florida Game and Fresh Water Fish Commission supports Alternative D-13R as an alternative that merits further development during the detailed design phase. The following issues should be addressed during the subsequent phases of this project:

- Water Conservation Area 3B: The increase in water depths and duration appear to be at the acceptable limit and any additional increase in these hydrologic characteristics could be ecologically damaging.

- Overall hydrologic pattern: The alternative plans extend periods of inundation with fewer drying events than what we would expect to see in the pre-drainage ecosystem as predicted by the Natural System Model. This is a trade-off between decompartmentalizing the remaining natural areas of the Everglades and achieving pre-drainage hydrologic characteristics. This trade-off could have a potential long-term biologic effect.

- Eastern Water Conservation Area 3A: Alternative D-13R will affect wading bird nesting and foraging areas. Improvements in some areas, possible damage in others (sequencing and timing is key).

- Lost recreation opportunities: Alternative D-13R has the potential of reducing recreational opportunities by the removal of L-67A and L-29 Canals.

- Reliance on aquifer storage and recovery technology: Contingency plans should be developed in the event that aquifer storage and recovery is deemed not feasible.

- Water Conservation Area 2B: Alternatives should be considered to improve the "poor performance" of Water Conservation Area 2B.

The Florida Game and Fresh Water Fish Commission provided additional comments regarding:

- Uncertainty: Topography information in the natural areas, feasibility of Aquifer Storage and Recovery, and potential long-term ecological effects, such as, unintended shifts in community structure (cattail expansion).

- Implementation Plan: The staging of hydrologic changes is critical to avoid large environmental shocks that could induce ecological damage.

- Adaptive Management Strategy: The plan must include flexible water management actions including a well designed and comprehensive monitoring plan.

- Monitoring Plan: The results of the monitoring program must be acted upon expeditiously.

Conclusions and recommendations in the second (Part II) ***Fish and Wildlife Coordination Act Report*** were as follows:

- The performance of D-13R may provide insufficient flow volumes to Shark River Slough as predicted by the Natural System Model. Concerns in the Water Conservation Areas include: extended hydroperiods in much of WCA-3A, particularly south of I-75; deep water in eastern and northeastern WCA-3A and; extremely high and low water levels predicted in WCA-2B.

- The S-140 should be expanded to allow more water to be shunted to areas further south and a gradual rehydration of northern areas be implemented to allow areas time to acclimate to the new water regime. A water quality treatment facility is also recommended to be added upstream of the new structure.

- Accurate and up to date topographic information needs to be collected in order ensure future hydrologic restoration success.

- Most of the Other Project Elements need more information at a level of detail on which to base an assessment of their potential impacts on fish and wildlife.

- The removal of canals must be well justified in terms of hydrological and ecological benefits. The Florida Game and Fresh Water Fish Commission is further concerned with the potential loss of existing recreation access points, particularly off the Tamiami Trail.

- Portions of existing levees internal to the Water Conservation Areas should be retained and restored such that they provide a similar function as natural tree islands.

- The Corps should seek authorization, at least at the conceptual level, for the entire recommended Comprehensive Plan.

- Close coordination under the Fish and Wildlife Coordination Act will be necessary throughout the refinement and implementation of the comprehensive plan in order to ensure that the intended benefits to fish and wildlife are realized.

Conclusions and recommendations in the third (Part III) ***Fish and Wildlife Coordination Act Report*** were as follows:

- $D\text{-}13R_4$, while providing additional flow to Everglades National Park and Biscayne National Park, adversely impacts Water Conservation Area 2A and Water Conservation Area 3B, which would fare worse than they do under the 1995 or 2050 Base Cases.

- There are significant water quality issues to be resolved regarding the urban runoff component of $D\text{-}13R_4$ that may result in significant adverse impacts to native flora and fauna in the natural areas.

- There remains a lack of accurate topographic information that led to the conclusion that substantially more water than that provided by D-13R is needed in Shark River Slough. The Florida Game and Fresh Water Fish Commission suggests that a soil subsidence factor for south of Tamiami Trail should be factored into model assumptions for the Natural System Model.

- Improvements to one reggion of the natural systems should not be done at the expense of another region within the natural system.

11.3.3 Florida State Historic Officer

Coordination has been ongoing with the State Historic Preservation Officer in accordance with the procedure of the Advisory Council on Historic Preservation.

11.4 RECONNAISSANCE STUDY PUBLIC WORKSHOPS

In order to involve the public in the reconnaissance study, a strategy of three rounds of public participation was developed. The information developed through these rounds of workshops and meetings was used extensively in the reconnaissance study.

In December 1993, the Restudy Team conducted ten public workshops across south Florida. These workshops were the first of three scheduled rounds of workshops. The purpose of this first round was to provide information to the public about the study and gather input for the initial “problem definition” phase of the Restudy.

In June 1994, the Restudy Team conducted the second round of scheduled public workshops in south Florida. Four workshops were held. The purpose of the second round of workshops was to: 1) give the public feedback on the first round of workshops — that is laying out the problems and opportunities that were identified, and 2) presenting some of the preliminary ideas which had been developed to fix a problem or take advantage of an opportunity.

The third round of public meetings was held in October 1994 and consisted of five public meetings. The purpose of this round was to: 1) provide feedback on the results of the second round of workshops, and 2) present the preliminary plans, conclusions, and recommendations.

The three rounds of public workshops and meetings generated a large amount of correspondence from the public. During the 18 months of the reconnaissance study, thousands of letters concerning restoration and the Restudy were received from all over the country. The *Central and Southern Florida Project Comprehensive Review Study Reconnaissance Report* dated November 1994 contains a more detailed discussion of the public involvement activities conducted during the reconnaissance phase of the Restudy.

11.5 FOCUS GROUPS

As part of this feasibility study, the Restudy Team conducted two rounds of focus group meetings throughout south Florida. The first set of meetings, held from January to May 1997, were conducted to provide information to targeted area stakeholders and to get comments about the initial plan formulation effort. Twenty-one meetings were held in Palm Beach, Broward, Miami-Dade, Monroe, Lee, Hendry, and Okeechobee Counties, as well as meetings with tribal representatives and National Wildlife Refuge managers. ***Table 11-1*** gives the scheduling of the meetings.

During this first set of meetings, the Governor's Commission for a Sustainable South Florida's *Conceptual Plan for the Restudy*, which provides a guiding framework for the Restudy, and the *Water Resources Development Act of 1996* were reviewed, as was the Restudy schedule. It was also explained that the Comprehensive Plan for the Restudy must be submitted to Congress by July 1, 1999. The meetings proved a useful process by allowing the various constituencies to comment on whether the appropriate components to be evaluated had been identified and to note what may have been missed in the initial plan formulation phase. A summary of concerns from these meetings is found in ***Table 11-2***.

The second round of meetings, which took place from September through December 1997, informed the participants about the progress of the plan formulation process. Fifteen meetings took place in Palm Beach, Broward, Miami-Dade, Monroe, Lee, and Okeechobee Counties and Tallahassee. Approximately 150 community leaders attended, representing a cross-section of interests including agriculture, the environment, water supply, and urban residents. In addition to specific interest groups, the Restudy Team held sessions with Florida Department of Environmental Protection and other State managers, Florida Game and Fresh

Water Fish Commission, and U.S. Fish and Wildlife Service managers. ***Table 11-3*** shows the meeting schedule.

A portion of these second round of meetings showed how the comments and concerns provided at the first round of meetings had been incorporated and/or addressed. Participants were also able to see the hydrologic results of the "screening" phase of plan evaluation and preliminary information on ecological restoration targets and how these were going to be linked to hydrologic targets and socio-economic targets. Summarized comments from these meetings are found in ***Table 11-4***.

TABLE 11-1
RESTUDY FOCUS GROUP MEETING SCHEDULE
JANUARY – MAY 1997

January 28 Gulf Citrus Growers	**February 20** Palm Beach County and municipal utilities and county administrator
January 28 Caloosahatchee River Citizens Association	**February 21** Environmental Coalition of Broward County
February 10 Florida Keys environmental interests	**February 24** Broward County staff (DNRP, OES)
February 10 Florida Keys commercial fishing interests	**February 24** Broward County regulated / community interests
February 11 Various Florida Keys county and city commissioners	**March 19** Seminole Tribe of Florida
February 12 Friends of the Everglades / National Audubon Society / Tropical Audubon Society / Sierra Club	**March 20** Miccosukee Tribe of Indians of Florida
February 12 Miami-Dade County staff (DERM, WASA, Planning Department)	**April 15** Okeechobee County agricultural interests
February 13 Florida City / Homestead Chamber of Commerce	**April 15** Okeechobee County economic / recreational interests
February 18 Palm Beach County environmentalists	**April 15** Okeechobee and Highlands Counties governmental interests
February 18 Everglades Agricultural Area agricultural interests	**May 14** National Wildlife Refuge managers
February 20 Palm Beach County Water Control Districts	

TABLE 11-2
SUMMARY OF FIRST ROUND FOCUS GROUP MEETING CONCERNS

CONCERN*	FOCUS GROUP
Regional Aquifer Storage and Recovery: technical feasibility and permitability	Florida Keys environmental interests, National Audubon Society / Sierra Club, Palm Beach County utilities
8 1/2 square mile area: disposition of land and providing flood protection	Florida Keys environmental interests, Florida Keys commercial fishing interests, Various Florida Keys commissioners, Miami-Dade County staff
Curtain walls: technical feasibility and impacts to the aquifers and bays	Florida Keys environmental interests, Florida Keys commercial fishing interests, National Audubon Society / Sierra Club, Miami-Dade County staff, Broward County staff
On-site retention: as a method of regional water storage	Gulf Citrus Growers, Caloosahatchee River Citizens Association, Okeechobee County agricultural interests
Use of Lake Okeechobee and Water Conservation Areas for storage: retention of multi-purpose functions	Gulf Citrus Growers, Everglades Agricultural Area agricultural interests, Palm Beach County utilities, Okeechobee County agricultural interests, Okeechobee County economic / recreational interests
Water Preserve Areas: how the different areas will function	Gulf Citrus Growers, Various Florida Keys commissioners, National Audubon Society / Sierra Club, Homestead Florida City Chamber of Commerce, Palm Beach County environmentalists, Palm Beach County Water Control Districts, Palm Beach County utilities, Environmental Coalition of Broward County, Broward County staff, Broward County regulated / community interests, Seminole Tribe of Indians
Storage area seepage: will seepage be excessive?	Gulf Citrus Growers, Everglades Agricultural Area agricultural interests
Restoration goals and performance criteria: what will they be and how will they be generated?	National Audubon Society / Sierra Club, Everglades Agricultural Area agricultural interests, Palm Beach County utilities, Broward County staff, Miccosukee Tribe of Indians of Florida, Okeechobee County agricultural interests
South Miami-Dade modeling: lack of detailed information for the area	Homestead Florida City Chamber of Commerce
Peer review: how will this be handled for technical documents?	Everglades Agricultural Area agricultural interests, Broward County staff

*Note: concerns about water quality and the need for the study to be based on sound science were universal.

TABLE 11-3
RESTUDY FOCUS GROUP MEETING SCHEDULE
SEPTEMBER – DECEMBER 1997

September 15 Broward County / two meetings	**October 6** Okeechobee County
September 16 Miami-Dade County / two meetings	**October 7** FGFWFC & USFWS, West Palm Beach
September 17 Monroe County / two meetings	**October 16** FDEP / state resource managers, Tallahassee
September 18 Gulf Citrus Growers, Clewiston	**December 9** South Miami-Dade Agriculture, Homestead
September 19 Caloosahatchee River Basin Advisory Board, Ft. Myers	**December 4** Martin and St. Lucie counties
September 23 Palm Beach County / two meetings	

TABLE 11-4
FOCUS GROUP ISSUES AND CONCERNS

Level of detail of recommended Comprehensive Plan and timing of implementation (prioritization). Also, what will be the ‘interim’ operating plan?
The need for the Restudy to be based upon accurate technical data and science.
The Restudy’s coordination with other on-going efforts (e.g., Lower East Coast Regional Water Supply Plan, Southern Everglades Restoration Alliance).
Ensuring appropriate water quality for natural and urban systems.
Utilization of Lake Okeechobee and the Water Conservation Areas for water supply and the use of other publicly owned lands for water storage including the ability to backpump into these areas.
Operational flexibility needs to be incorporated into the system for the timing and distribution of water supplies and drainage.
Function, operation, and technical feasibility of reservoirs and seepage management measures.
Does the Internet web site take the place of traditional public involvement?
What are the environmental goals; concern about using the Natural System Model as a target?
Was cost effectiveness taken into consideration in the screening analysis and when will costs for construction and operations be determined?
Need to address the lack of adequate criteria (performance measures) for evaluating alternative plans for urban and agricultural areas.
Will the Comprehensive Plan provide for the 1 in 10 level of certainty for water supply (statutory requirement of HB 715) and flood protection?

11.6 STAKEHOLDER INVOLVEMENT AND OUTREACH

Subsequent to gathering input for the initial plan formulation process, a Restudy Strategic Communications and Public Outreach Plan was developed in January 1998. The Restudy Strategic Communications and Public Outreach Plan was comprised of four components: 1) stakeholder involvement, 2) media program, 3) a public information/awareness program, and 4) public meetings on the *Draft Integrated Feasibility Report and Integrated Programmatic Environmental Impact Statement*.

Further, the activities carried out through the Restudy Strategic Communications and Public Outreach Plan were divided into three phases:

- Near term – Through alternative plan analysis and leading up to the November 1998 public meetings;
- Intermediate – Through plan delivery to Congress on 1 July 1999 and its subsequent authorization; and
- Long-term – Multi-year information and outreach activities associated with plan implementation.

The following activities occurred within the near-term timeframe of Restudy Strategic Communications and Public Outreach Plan activities. ***Table 11-5*** summarizes these activities.

11.6.1 Stakeholder Involvement

There are specific stakeholder groups that are most affected by and interested in the Restudy. Environmental interests expect that restoration will be the highest priority of the feasibility study. Agricultural interests are seeking assurances that water supply and flood protection needs are met and that they will not bear more than their fair share of the Project costs. Finally, local governments and water utility representatives desire continued access to an inexpensive supply of potable water. A fundamental component of the Restudy Strategic Communications and Public Outreach Plan was to work closely with stakeholders during each stage of plan development to gather input and address concerns.

TABLE 11-5
STAKEHOLDER INVOLVEMENT ACTIVITIES
(Since September 1997)

DATE	LOCATION	PARTICIPATION
Stakeholder/Interest Group Meetings		
18 September 1997	Clewiston	Agricultural Interests
21 November 1997	Ft. Myers	AWRA Conference
4 December 1997	Miami	Greater Miami Chamber of Commerce
1 January 1998	Tamarac	Tamarac Garden Club
16 January 1998	Key Largo	Everglades Coalition
2 February 1998	West Palm Beach	Environmental Interests
17 February 1998	Ft. Lauderdale	Coastal Zone Management Committee
17 February 1998	Miami	South Miami-Dade County Agricultural Interests
25 February 1998	Clewiston	West Coast Agricultural Interests
4 March 1998	La Belle	Gulf Citrus League
18 March 1998	Okeechobee	Okeechobee County Commission; Utility Commission; other stakeholders
19 March 1998	Clewiston	EAA Interests
13 April 1998	Tamarac	Tamarac Garden Club
25 April 1998	Miami	NAACP Conference
17 May 1998	Miami	Friends of the Everglades
20 May 1998	West Palm Beach	Sustainable Agriculture Conference – various agricultural, business, and environmental groups
27 May 1998	Palm Beach Gardens	Loxahatchee River Coordinating Council
19 June 1998	West Palm Beach	Chamber of Commerce of Palm Beaches
1 July 1998	West Palm Beach	Palm Beach County Board of Realtors
15 July 1998	Cooper City	Everglades Coalition
23 July 1998	Miami	Miami Rotary Club
29 July 1998	Miami	Lake Belt land owners, Miami-Dade County, DERM, SFWMD
30 July 1998	Key West	AWRA Conference
3 August 1998	Delray Beach	Environmental Coalition of Palm Beach County
5 August 1998	Palm Beach Gardens	Northern Palm Beach County of Commerce
16 August 1998	Jupiter	Northern Palm Beach County of Commerce
27 August 1998	Tallahassee	State Legislature Lobbyists
28 August 1998	Miami	Hispanic Community Leaders
1 September 1998	Ft. Myers	Southwest Florida Environmental Advisory Committee
1 September 1998	Wilton Manors	Wilton Manors Sport Fisherman Club
3 September 1998	Hollywood	EAA Interests
4 September 1998	Hollywood	Agricultural Interests
15 September 1998	Okeechobee	Okeechobee County Stakeholders
15 September 1998	Okeechobee	Okeechobee County Agricultural and Economic Development Interests
17 September 1998	Naples	Conservancy of Southwest Florida Corporate Interests
17 September 1998	Bonita Springs	Lee County Building Industries Association
18 September 1998	Miami	Miami-Dade Environmental Task Force
23 September 1998	West Palm Beach	Palm Beach County Municipal League
1 October 1998	Miami	Latin Builders Association
7 October 1998	West Palm Beach	South Miami-Dade Agricultural Interests
16 October 1998	Stuart	Treasure Coast Restudy Celebration

DATE	LOCATION	PARTICIPATION
20 October 1998	Miami	Hispanic Community Leaders
21 October 1998	Delray Beach	League of Women Voters
21 October 1998	Miami	Hispanic Community
22 October 1998	Miami	Hispanic Community Leaders
22 October 1998	Overtown	African-American Community
23 October 1998	Naples	The Conservancy of Southwest Florida
24 October 1998	Tampa	Florida Farm Bureau Conference
29 October 1998	Jacksonville	Society of American Military Engineers
4 November 1998	Clewiston	Agricultural Interests
12 November 1998	Stuart	Stuart Rotary Club
13 November 1998	Stuart	Conservation Alliance
13 November 1998	Ft. Lauderdale	Broward County Technical Advisory Committee
20 November 1998	Miami	Chamber of Commerce; Beacon Council
30 November 1998	Miami	Chamber of Commerce; South
1 December 1998	La Belle	Agricultural Interests
4 December 1998	Tallahassee	State Legislature Lobbyists
8 December 1998	Washington, DC	Environmental Interests
8 December 1998	Washington, DC	Agricultural Interests
10 December 1998	Miami	Greater Miami Chamber of Commerce
10 December 1998	Boca Raton	Royal Palm Audubon
18 December 1998	Miami	Lake Belt Advisory Committee
21 December 1998	Naples	League of Women Voters
21 December 1998	Belle Glade	Florida Farm Bureau
1 January 1999	Tamarac	Tamarac Garden Club
12 January 1999	West Palm Beach	American Society of Civil Engineers
21-23 January 1999	Miami	Everglades Coalition
4 February 1999	West Palm Beach	EAA Interests
12 February 1999	Washington, DC	Environmental Interests
Advisory Committee Meetings		
25 September 1997	West Palm Beach	SFWMD Agricultural Advisory Committee
24 October 1997	Ft. Myers	Caloosahatchee Advisory Committee
27 October 1997	West Palm Beach	SFWMD Agricultural Advisory Committee
25 November 1997	West Palm Beach	SFWMD Agricultural Advisory Committee
12 January 1998	West Palm Beach	SFWMD Environmental Advisory Committee, National Park Service
23 January 1998	West Palm Beach	SFWMD Water Utility Advisory Committee
27 January 1998	West Palm Beach	SFWMD Agricultural Advisory Committee
17 February 1998	La Belle	Caloosahatchee Advisory Committee
20 March 1998	West Palm Beach	SFWMD Water Utility Advisory Committee
20 March 1998	West Palm Beach	SFWMD Agricultural Advisory Committee
23 March 1998	West Palm Beach	SFWMD Water Utility Advisory Committee
9 April 1998	Immokalee	Caloosahatchee Advisory Committee
22 May 1998	La Belle	Caloosahatchee Advisory Committee
28 May 1998	West Palm Beach	SFWMD Agricultural Advisory Committee
28 July 1998	West Palm Beach	SFWMD Agricultural Advisory Committee
20 August 1998	Sebring	Lake Istokpoga Interagency Team
16 September 1998	Fort Myers	Caloosahatchee Advisory Committee
25 September 1998	West Palm Beach	SFWMD Agricultural Advisory Committee
1 November 1998	Ft. Myers	Estero Bay ADM
5 November 1998	La Belle	Caloosahatchee Advisory Committee
21 January 1999	Ft. Myers	Caloosahatchee Advisory Committee
28 January 1999	West Palm Beach	SFWMD Agricultural Advisory Committee
3 February 1999	West Palm Beach	LEC Regional Water Supply Advisory Committee

DATE	LOCATION	PARTICIPATION
Technical Workshops		
3 November 1997	West Palm Beach	SFWMD Agriculture, Water Utility, Environmental Advisory Committees
18 December 1998	West Palm Beach	SFWMD Agriculture, Water Utility, Environmental Advisory Committees
2 February 1998	West Palm Beach	SFWMD Agriculture, Water Utility, Environmental Advisory Committees
20 March 1998	West Palm Beach	SFWMD Agriculture, Water Utility, Environmental Advisory Committees
29 July 1998	West Palm Beach	SFWMD Agriculture, Water Utility, Environmental Advisory Committees
29 July 1998	West Palm Beach	Implementation Plan Workshop
27 August 1998	West Palm Beach	Implementation Plan Workshop
23 November 1998	West Palm Beach	Implementation Plan Workshop
11 December 1998	West Palm Beach	Implementation Plan Workshop
1 February 1999	West Palm Beach	Implementation Plan Workshop
Federal/State Agency Meetings		
16 October 1997	Tallahassee	State Agencies
31 October 1997	Miami	Department of the Interior
19 February 1998	Dania	Office of Management and Budget
2 April 1998	Washington, DC	Department of the Interior

8 April 1998	West Palm Beach	
25 June 1998	Jensen Beach	
27 July 1998	Hollywood	
2 September 1998	Hollywood	
3 December 1998	Miami	
3 February 1999	Ft. Lauderdale	

A variety of meetings, workshops and briefings were held throughout the alternative plan and draft plan development processes:

- Stakeholder group meetings
- Small group meetings
- Technical workshops
- Legislative briefings
- Local government briefings
- Staff briefings

Each of these activities is described in more detail in the following sections.

11.6.1.1 Stakeholder Group Meetings

Numerous meetings were held with representatives of stakeholder groups including the Everglades Coalition; the Caloosahatchee Advisory Committee; the South Florida Water Management District Agricultural, Utility and Environmental

Advisory Committees; environmental, municipal, economic development, and agricultural interests.

11.6.1.2 Small Group Meetings

Throughout the alternative plan development processes, numerous informal meetings were held by request to maintain dialogue, clarify issues, and identify concerns. Meetings were held with representatives of the Department of Interior (e.g., U.S. Fish and Wildlife Service and National Park Service), local government resource and water utility agencies, and non-governmental organizations (e.g., environmental groups and agricultural interests).

11.6.1.3 Technical Workshops

Due to the high level of interest in the restoration of the south Florida ecosystem and the potential impacts resulting from implementation of the study, the Restudy Team gave numerous briefings and held workshops to inform interested parties about the more technical aspects of the study. This effort supported the Restudy philosophy that a more informed public can make more informed decisions.

The South Florida Water Management District's three standing advisory committees - Agricultural, Environmental, and Utility - were briefed separately and collectively on the Restudy's progress at several key points during the process. A series of four workshops were held with the committees to answer questions concerning the technical analyses of the study. The output of these workshops developed into a list of "Frequently Asked Questions," which in turn, were posted on the Restudy web site. Four technical workshops specific to the development of the Implementation Plan were held with stakeholders between July 1998 and February 1999.

11.6.1.4 Legislative Briefings

Presentations to members of Congress and Congressional aides were given periodically to provide an update on the plan development process and to ensure that key decision-makers were able to give timely input throughout the plan development process.

Presentations and briefings were also given to state legislators and their staffs. A briefing was made to the Governor and Cabinet in May 1998. The Florida Joint Legislative Committee on Everglades Oversight, whose purpose it is to oversee implementation of the Everglades Construction Project, expressed a keen interest in the Restudy and the South Florida Water Management District Governing Board's role and responsibilities as non-Federal sponsor of the project. A number of briefings were made to the Joint Legislative Committee on Everglades Oversight.

11.6.1.5 Local Government Briefings

Formal presentations to County Commissions were made periodically during the alternative evaluation and plan development processes. Presentations were made during both regularly scheduled commission meetings, as well as during "town hall" – type meetings. Presentations were also made to committees established by local governments (e.g., Broward County Water Advisory Board and Miami-Dade County Environmental Task Force). Local government officials were also briefed through the South Florida, Treasure Coast and Southwest Florida Regional Planning Councils.

11.6.1.6 Staff Briefings

Briefings of managers, technical and outreach staff of the South Florida Water Management District and the Corps were made throughout the process to provide updates on plan development activities and to discuss stakeholder concerns and possible remedies.

11.6.2 Public Information and Outreach

The Restudy public information and outreach effort was comprised of a media program, a public information/awareness program, minority outreach, and environmental education. Many of the activities conducted in 1998 are listed in ***Table 11-6.***

11.6.2.1 Media Program

A media program was also used to educate the public and stakeholder groups about the Restudy.

Specific media tools included press conferences (including three to announce the release of the draft plan), press releases, press kits, editorial board meetings, and discussing the Restudy individually with reporters. Numerous Restudy public events (such as monthly Governing Board and Governor's Commission meetings, and other conferences and events) provided opportunities for the media to remain apprised on the Restudy.

On a local level, efforts were made to inform small community newspapers about the Restudy. In particular, seven region-specific articles were written for placement in weekly newspapers. Guest editorials by the District Engineer and the Executive Director of the South Florida Water Management District were published in the larger papers. Editorial boards were arranged for a number of newspapers in advance of the November public meetings. Radio public service announcements also were produced and broadcast in advance of the November public meetings.

Efforts were made to reach minority groups. Team members communicated to African-American and Hispanic publications on the Restudy. A half-hour program on the Restudy was taped in Spanish and broadcast on a Spanish language television station. A Spanish language public service announcement was recorded and was also broadcast on a Spanish language radio station.

11.6.2.2 Public Information/Awareness Program

Besides the use of television and newspapers, a number of other means for informing the public were utilized. While a media program is the most effective method to reach the general public, equally important are more specialized efforts to reach people on a more personal level. These efforts include the following:

- Speaker’s Bureau: A speaker’s bureau was established. A Restudy-specific slide show was developed for use with lay audiences.

- Standing Displays: Five large standing displays were produced for the November public meetings. These explain the: 1) history of the C&SF Project, 2) problems associated with the project, 3) public participation for the Restudy planning effort, 4) the draft plan, and 5) benefits the Restudy will provide. The displays hold printed material to give to the public, as well. These displays continue to be used.

- Conferences: Restudy exhibits were organized for two conferences in 1998: the 72nd Annual Florida League of Cities in Miami Beach in August, and the 1998 Annual Conference on Water Management in Tampa in October. In January 1999, a Restudy exhibit was on display at the Everglades Coalition Conference held in Miami.

- Mailing List: A mailing list of approximately 2,300 people and groups who have an interest in the Restudy was developed. This includes groups such as drainage districts, the Florida Legislature, the Florida congressional delegation, environmentalists and others. It was essential to keep these key audiences apprised of Restudy activities, and provide them the most current information possible.

- Newsletter: A four-page newsletter, *C&SF Restudy Update*, was developed in 1998 to educate people on the Restudy’s progress. Issues were produced in June and October 1998, and in March 1999. It was mailed to the general mailing list, and was provided at the November public meetings, and other venues. The C&SF Restudy Update also was translated into Spanish.

- Restudy Focus: A series of information papers, *Restudy Focus*, were prepared on a number of topics and distributed to the public.

- Overview: A 30-page color overview on the draft report, designed for a lay audience, was prepared and released in October along with the draft report. A tri-fold summary document on the Restudy also was produced in conjunction with the draft report.

- Toll-Free Telephone Line: In October 1998, the South Florida Water Management District launched a toll-free telephone line (within Florida) for the Restudy. Produced in English and Spanish, the line has five options for listeners. Options initially included hearing about the November public meetings, receiving printed information, and learning how to comment on the draft plan. Listeners can also speak to a person, if they wish.

11.6.2.3 Minority Outreach

The Restudy Minority Outreach Program focused on the region's African-American and Hispanic communities. This program arose out of a need to increase participation by whole segments of the community who have been recognized as traditionally unaware, unengaged, or even disenfranchised from ongoing stakeholder and public outreach efforts. These two communities comprise a majority of Miami-Dade County's population and a significant portion of those of Broward and Palm Beach Counties. It is well recognized, however, that members of these communities have been largely absent from meetings, hearings, and other traditional venues for informing and gathering input on the plan.

Community leaders and organized interest groups were targeted as the primary contacts for these outreach efforts. The objective of the near-term minority outreach activities was to increase the knowledge and awareness of the African-American and Hispanic community leaders and activists with the goal of increasing minority engagement in the November public meetings. The ultimate goal of these activities was to increase the amount of meaningful and productive comment on the draft plan from the region's minority community.

A number of meetings were held with members of the minority communities. The objectives of these meetings were to inform participants, gather input, and cultivate other venues for increasing the broader minority communities' knowledge of and interest in the Restudy.

Specific minority outreach efforts included the following:

- Preparation of articles for distribution in local newspapers and other media outlets;
- Preparation of public service announcements for use on television and radio;
- Pocus groups involving community leaders and other key opinion leaders and decision makers;
- Briefings of key members and organizations of each minority community; and
- Preparation of Spanish language printed materials for distribution at the public meetings and through other appropriate outlets.

11.6.2.4 Environmental Education

In an effort to accomplish wide-ranging outreach to the community and to reach parents of school age children, an environmental education program was undertaken. The focus was on engaging high school students and teachers, as well as area elementary school children and teachers, in conjunction with the public review of the *Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement*. High school teachers were encouraged to produce a lesson plan related to south Florida's water resources, and bring participating students to the meetings. In some cases, students commented about the Restudy at the meetings. Elementary students created posters with their vision of the Everglades, which were subsequently judged and displayed at the meetings.

11.6.3 Governor's Commission for a Sustainable South Florida

On March 3, 1994, Governor Lawton Chiles created the Governor's Commission for a Sustainable South Florida through Executive Order 94-54. The Commission's charge was to make recommendations that will move south Florida toward a healthy ecosystem that can co-exist with, and be mutually supportive of, a sustainable south Florida economy and quality communities. This commission consists of business, agriculture, government, public interest, and environmental organization representatives. A number of Federal agencies are represented on the Commission as non-voting members.

The Commission's *Initial Report* (October 1, 1995) contained 110 recommendations with a central theme of sustainability – meeting the needs of the present without endangering the ability of future generations to meet their needs – revolving around the management of water. In that report, the south Florida ecosystem was defined as a community of organisms, including humans, interacting with one another and the environment in which they live. The Commission recognized that *"Our quality of life is inextricably linked to the health and viability of natural systems"* and *"that a healthy Everglades system is vital to natural plant, animal and human population alike."* The Commission also unanimously agreed that the south Florida ecosystem is not sustainable on its present course. A number of recommendations concerned water resources management and the Restudy. Specifically recommended was:

> *"...the Commission should provide the South Florida Water Management District and the Corps with specific recommendations describing its preferred alternatives in the Restudy." (Initial Report, 1995)*

Consequently, in October 1995, the Commission began to develop preferred alternatives for the Restudy and in August 1996 completed a *Conceptual Plan for the Restudy.* As described in the *Conceptual Plan*, the Commission envisioned the Restudy as an important component of sustainability and recognized it as the vehicle to address many of the regional water resources issues identified in its *Initial Report*. The Commission, in introducing its *Conceptual Plan*, also noted that it wished to ensure that the *Initial Report* objectives for sustainability and the interests of all south Florida were addressed by the Restudy.

In March of 1998, the Governor's Commission for a Sustainable South Florida began an intensive assessment of the Restudy process and products. This assessment was made for the expressed purpose of providing broad based recommendations and comments to Governor Lawton Chiles, the U.S. Army Corps of Engineers, the South Florida Water Management District Governing Board and the South Florida Ecosystem Restoration Task Force. Public input played a large role in the development of the Governor's Commission assessment. At the onset of this effort, the Commission spent many hours listening to the views and concerns of a variety of stakeholder groups (e.g., agriculture, water utility, rock mining, and environmental). Furthermore, each meeting of the Commission provided at least two opportunities for the public to express their views on the Restudy.

In July 1998, the Governor's Commission unanimously adopted its "*Interim Report on the C&SF Project Restudy*." The Interim Report both reiterated guidance originally included in the *Commission's Conceptual Plan for the Restudy*, and provided new recommendations for consideration during development of this *Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement.*

After release of the *Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement* in October 1998, the Commission convened panels of stakeholders in November and December 1998 to obtain input on stakeholder concerns about the draft report. Following that, the Commission prepared a document entitled "*Restudy Plan Report*" that was unanimously adopted by the Commission on January 20, 1999. The report provides recommendations on the Restudy on a number of issues including increasing water storage, Restudy scope expansion and coordination, improving water quality, and assurances to water users. The Commission's February and March 1999 meetings focussed primarily on the Implementation Plan and funding options and guidelines.

11.6.4 South Florida Ecosystem Task Force and Working Group

In an effort to ensure the coordination of Everglades restoration efforts at the Federal level, U.S. Interior Secretary Bruce Babbitt created in 1993, through an-interagency agreement, the South Florida Ecosystem Restoration Task Force. Establishment of the Task Force at the Cabinet level led in turn to the formation of a more local, Federal manager-level South Florida Ecosystem Restoration Working Group to help assist the Task Force in technical issues and actual implementation of restoration efforts. Subsequently, the Task Force and Working Group were expanded to include Tribal and state members and were formally established by Section 528 of the *Water Resources Development Act of 1996.* The Task Force now includes seven Federal members: the Miccosukee Tribe of Indians of Florida and the Seminole Tribe of Florida, two representatives of the state, the South Florida Water Management District, and two representatives of local governments in south Florida. The Working Group is larger and more broadly based, consisting of 14 local Federal members, the two tribes, five state agencies, the Governor's Office, the South Florida Water Management District and five representatives of local governments and regional planning councils.

In accordance with the provisions of the *Water Resources Development Act of 1996*, one of the duties of the Task Force includes consulting with, and providing recommendations to the Secretary of the Army during the development of the Comprehensive Plan. As part of its charter, the Working Group was charged with generally supporting and assisting the Task Force in undertaking its many duties, especially the development of the Comprehensive Plan.

Restudy Team members consistently briefed the Task Force and Working Group as work on the feasibility report progressed. While some of the Task Force meetings took place in Washington, Working Group meetings were held monthly throughout the south Florida region. All were open to the public. These meetings allowed for interagency discussion of the many complex technical and policy issues that arose during the course of the Restudy. In addition, there was opportunity for public comment at each meeting.

At the July 1998, meeting of the Task Force, the Initial Draft Plan was presented. In response to this presentation and as a result of many meetings during which complex technical and policy issues were considered by the Task Force and

Working Group, the Task Force adopted its initial recommendations on the Restudy and transmitted them to the Secretary of the Army in August 1998. The Task Force intends to transmit its final recommendations on the Restudy to the Secretary of the Army during the Washington Level review of the final feasibility report.

11.6.5 South Florida Water Management District Governing Board

As the non-Federal sponsor of the C&SF Project and as the state governmental body charged with water resource management in south Florida, the District's Governing Board provided policy guidance during the course of the study. Periodically after the feasibility phase began and monthly since October 1997, the Restudy Team briefed Governing Board members on the progress of the study. These meetings were open to the public and time was allotted for public comment. In April 1998, the Governing Board held a workshop with a panel of stakeholder representatives from their Environmental, Agriculture, and Urban Utilities Advisory Committees. The workshop provided the opportunity to the advisory committees to express their views on the Restudy to the Governing Board. The workshop also provided committee members and the Governing Board with the ability to engage in a question and answer dialogue with a panel of the interagency Restudy Team members. In January 1999, the Governing Board held a workshop with a panel of stakeholder representatives to discuss the issue of assurances to water users. At their February 1999, meeting, the Governing Board approved the letter of intent to be the non-Federal sponsor for implementation of the Restudy.

11.7 INTERNET WEB SITE

In order to facilitate communication between Restudy Team members and to provide the public with information about the Restudy and the formulation and evaluation of alternative plans, a web site for the Restudy was established (**http://www.restudy.org**). Information available on the web site includes: description of the planning objectives; assumptions for the with-and without-plan conditions; description of the alternative plans being evaluated; descriptions and applications of the hydrologic, ecologic, and water quality models being used to evaluate the alternative plans; summaries of technical workshops in the form of "Frequently Asked Questions"; hydrologic model output for each alternative in the form of performance measures; summaries of the evaluations of each of the alternatives; and Restudy documents such as this report.

11.8 REVIEW CONFERENCES

Four review conferences involving various agencies involved in the study were conducted during the feasibility study to review work and decide courses of action related to specific policy and technical issues. The conferences were:

- Special Resolution Conference (SRC): December 5-6, 1996 –Jacksonville, Florida. Representatives of the South Florida Water Management District, the Office of the Assistant Secretary of the Army for Civil Works, the U.S. Fish and Wildlife Service, Florida Department of Environmental Protection, the Natural Resources Conservation Service, the Environmental Protection Agency, and the Corps met to discuss procedural and policy issues related to implementing the provisions of Section 528 of the *Water Resources Development Act of 1996* that relate to the Restudy.

- In-Progress Review (IPR): December 17, 1997 – Jacksonville, Florida. Representatives of the Restudy Team and Corps higher authority met to discuss the on-going plan formulation and evaluation activities.

- Alternative Formulation Briefing (AFB): August 18-19, 1998 – West Palm Beach, Florida. Representatives of the South Florida Water Management District, Office of the Assistant Secretary of the Army for Civil Works, U.S. Fish and Wildlife Service, National Park Service, U.S. Environmental Protection Agency, Natural Resources Conservation Service, Florida Game and Fresh Water Fish Commission, Florida Department of Agriculture and Consumer Services, Florida Department of Environmental Protection, and the Corps met to discuss the development of the Initial Draft Plan and the preparation of the draft Integrated Feasibility report and Programmatic Environmental Impact Statement.

- In-Progress Review (IPR): January 12, 1999 – Atlanta, Georgia. Representatives of the Corps Jacksonville District, SFWMD, Corps higher authority, and the Office of the Assistant Secretary of the Army for Civil Works met to discuss remaining issues associated with completing the final Integrated Feasibility Report and Programmatic Environmental Impact Statement.

11.9 COORDINATION

11.9.1 Cooperating State and Federal Agencies

Regulations for implementing the *National Environmental Policy Act* state that, when requested by the lead agency, any other Federal agency which has jurisdiction by law shall be a cooperating agency. In addition, any other Federal agency which has special expertise with respect to any environmental issue which should be addressed in the statement, may be a cooperating agency upon request of the lead agency (40 CFR, Parts 1500-1508, § 1501.6). In November and December 1996, the Corps, through official correspondence, invited several state and Federal agencies to assist with preparation of a Programmatic Environmental Impact Statement for the Restudy. The geographic scope and range of issues involved in the Restudy and the desire to resolve, through consensus building, the many complex restoration issues under an interagency team format, made this cooperation desirable. The Corps, as the lead agency, organized cooperating agency meetings, assigned relevant tasks to the various cooperating agencies depending on agency authority and/or particular expertise, led and orchestrated preparation of the Programmatic Environmental Impact Statement, and coordinated issues, information and resources within and between the cooperating agency and the Corps.

The state and Federal agencies involved in the preparation of the Programmatic Environmental Impact Statement as cooperating agencies are the: National Park Service (Everglades National Park, Biscayne National Park, and Big Cypress National Preserve), Natural Resources Conservation Service, U.S. Environmental Protection Agency, U.S. Fish and Wildlife Service, Florida Game and Fresh Water Fish Commission, U.S. Geological Survey, and Florida Department of Environmental Protection. Cooperating agency responsibilities included, but were not limited to: conducting internal agency coordination and communication with the lead agency; preparation of existing baseline conditions within the ten physiographic regions comprising the study area; environmental impact assessment of the alternatives as developed during the plan formulation process; making available relevant information and technical resources for consideration in the Programmatic Environmental Impact Statement; assessment of benefits and environmental impacts of the Comprehensive Plan; and preparation of appropriate sections of the environmental effects section of the Programmatic Environmental Impact Statement.

11.10 REVIEW OF DRAFT INTEGRATED FEASIBILITY REPORT AND PROGRAMMATIC ENVIROMENTAL IMPACT STATEMENT

The draft *Integrated Feasibility Report and Programmatic Environmental Impact Statement* was sent to numerous local, state and Federal agencies and private interest groups for review and comment in accordance with the Council on Environmental Quality's *National Environmental Policy Act* regulations and related Corps guidance. Comments received during the review were considered in preparing the final study documents, and will be considered by subsequent reviewers and decision-makers in the Washington-level Federal review process.

11.10.1 Report and PEIS Recipients

Individuals

A list of individuals who received the *Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement* is on file in the Jacksonville District of the U.S. Army Corps of Engineers at the address shown on the cover page of this document.

11.10.2 Comments and Responses

The *Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement* was made available to the public on October 13, 1998. The draft PEIS was officially noticed in the Federal Register, Volume 63, Number 205 on October 23, 1998 and the public comment period ended on December 31, 1998. Review comments were received from approximately 200 state, Federal and local agencies, the native American Tribes, non-governmental organizations and concerned individuals. The comment letters received are on file in the Jacksonville

District of the U.S. Army Corps of Engineers at the address shown on the cover page of this document. A paraphrased list of the comments and the responses to them is contained in ***Appendix N: Comments and Responses***.

11.11 PUBLIC MEETINGS

A series of 12 public meetings were held in November and December 1998, to present the draft recommended plan to the public. Of these, 11 were held within the study area. The final public meeting was held in Washington D.C. ***Table 11-7*** shows the locations, dates, and approximate attendance for the public meetings.

All the south Florida meetings followed the same format. An informal "open house" was held from 5 p.m. to 7 p.m. for students, educators, local residents and other interested people to talk with Restudy Team members about the Restudy. Visitors were able to discuss issues with team members one-on-one and have specific questions answered. Five large, colorful standing exhibits were created explaining the C&SF Project and Restudy, from its past history to planned benefits. Displays featured public participation, problems with the C&SF Project, and the draft plan. Restudy Team members staffed each display.

The formal meeting to take public comment began at 7 p.m. A brief presentation on the Restudy, including introductory remarks from the District Engineer and the South Florida Water Management District Executive Director was presented. Then, public comment was taken throughout the evening.

TABLE 11-7
RESTUDY PUBLIC MEETINGS

Meeting	Date	Location	Approximate Attendance
1	November 2	Clewiston	165
2	November 4	Stuart	120
3	November 5	Okeechobee	160
4	November 9	Miami	75
5	November 10	Fort Lauderdale	150
6	November 12	West Palm Beach	190
7	November 16	Marathon	85
8	November 17	Homestead	85
9	November 18	Kendall	175
10	November 30	Naples	110
11	December 1	Fort Myers	100
12	December 8	Washington D.C	135

At almost every meeting, the public was able to view artwork from local elementary schools students. These students were participating in a poster contest. Participation was an optional part of the environmental education pilot program. The poster theme was “Our Florida, Our Everglades”. Students were asked to depict their vision of the Everglades when they grow up. Seven hundred and thirty-eight students from 21 schools participated in the contest.

Efforts were made to include south Florida minority groups as well. Meetings were advertised in minority community newspapers. Pre-meetings were held to brief African-American leaders on Restudy issues. The North Miami meeting was located in a community with a significant African-American population. The Kendall meeting was presented in English and Spanish, and publications were translated into Spanish.

A court reporter was present at each meeting and a transcript was made which serves as the official record of each meeting. Each of the meetings was also videotaped.

The following is a summary of the public meetings:

Clewiston

Primary concerns articulated by the Clewiston audience focused on the effect of proposed land acquisition and the effect it will have on land owners and on communities as a whole. Several speakers expressed concern that agricultural lands would be acquired for storage reservoirs and that the plan was designed to meet water supply needs of the lower east coast, further enabling population growth. Acquisition from willing sellers was stressed, as well as outright opposition to acquiring more lands in the Everglades Agricultural Area. Others asserted the plan was heavily weighted towards environmental restoration and asked for more information on measuring successful environmental restoration. Several speakers asked for water assurances to existing users and asked that state laws prevail in the implementation of the plan.

Concerns were raised about aquifer storage and recovery technology, water quality, seepage control for proposed reservoirs and whether the technology proposed will work. Some speakers questioned the process, specifically what Congress would authorize, the sequencing of projects and the implementation schedule. Concerns about funding were raised by several speakers.

Stuart

Many speakers expressed concern about the health of the St. Lucie Estuary, having experienced the negative effects of discharges made during the winter and spring of 1998. Several speakers recounted the negative economic impact caused by the discharge of fresh water and the resultant salinity changes, poor water quality and lesioned fish. Most speakers urged expedited implementation of Restudy projects that will stop these damaging discharges.

Several citizens reminded the group that Martin County had approved a one-cent sales tax increase to acquire land to be used for Restudy projects. Expedited land acquisition for Restudy projects was urged, especially north of the St. Lucie locks and in the Ten Mile Creek area. Concerns about the ooze in the St. Lucie River prompted some speakers to ask about the impact on human health of this and other possible water contaminants.

Okeechobee

Many speakers expressed concern about land acquisition, when lands would be needed, how much land would be required, and whether lands would be taken through eminent domain. Questions were raised about whether the benefits of the recommended Comprehensive Plan justified the negative impact on the rural lifestyle of the community and the loss of tax base such land acquisition would cause. Several speakers cited negative experiences with the Kissimmee River Restoration Project land acquisition process.

Several speakers expressed their concern that rural communities were being asked to bear the burden of supplying water to the growing East Coast and expressed a desire to see water storage areas constructed along the coast rather than in the Lake Okeechobee area. Others questioned proposed aquifer storage and recovery technology, seepage management and water reuse, water quality and how the plan will deal with uncertainties associated with technologies proposed for capturing and storing water.

Questions were raised about lake levels and whether the Restudy will improve fishing in Lake Okeechobee. Several speakers stated their objections to building a dike through the middle of the lake and were informed that that option had been modeled and rejected. Concerns were raised about the cost of the Restudy. Concerns about water assurance for existing users and flood protection were also voiced.

Miami (North)

The public expressed concern about the effect the Restudy will have on growth and urbanization. There were many concerns expressed about aquifer storage and recovery technology, seepage management and wastewater reuse, water quality and how the plan will deal with uncertainties associated with technologies proposed for capturing and storing water. Questions were raised about restoration of sheet flow, decompartmentalization, removal of canals or levees in the Water Conservation Areas and what goals would be accomplished through these strategies.

Questions were raised concerning land acquisition - specifically, how much land and through what process will these lands be acquired. The overall process for implementing the plan was of concern for many of the attendees. Several speakers raised concerns about funding, costs, and economic feasibility.

Several speakers mentioned water quality concerns associated with aquifer storage and recovery, wastewater reuse and backpumping. Questions were raised on whether the Restudy would improve water quality in local canals used for fishing. Additional concerns were raised concerning future water assurances for existing users and the percentage of African-American contractors to be used to construct the project. Several speakers objected to the engineering solutions proposed in the Restudy and urged more natural methods like flowways. Some citizens asked for an independent scientific peer review of the recommended Comprehensive Plan.

Plantation

Concerns were expressed about aquifer storage and recovery technology, seepage management and wastewater reuse, water quality and how the plan will deal with the uncertainties associated with technologies proposed for capturing and storing water. Several speakers asked that more “natural” methods be used to capture and store water and suggested that more land be acquired in the Everglades Agricultural Area and in the Water Preserve Areas for these purposes. Water assurance for existing users and the need for continued flood protection for the area were two issues raised by several long-time residents of the county.

Many speakers voiced their dissatisfaction with the plan’s impact on the ecological health of Water Conservation Area 2B and asked that modeling continue until the needs of this part of the Everglades are more fully met. Recreational users of the Water Conservation Areas expressed their concern about the removal of levees and canals and possible loss of access to favorite areas. Several citizens voiced their concern about the plan’s impact on the North New River, urban redevelopment on the coastal ridge, and the issues associated with that redevelopment like brownfields, gentrification and displacement of current residents. Concerns were raised that the plan will accelerate development in south Florida.

Some speakers questioned the wisdom of presenting a conceptual plan without a full implementation plan, detailed cost benefit analysis and a funding strategy. Others spoke to the need to proceed with haste as the area cannot afford more problems with water supply and contaminated wellfields. Several speakers asked for assurances that the plan place the greatest emphasis on restoring the environment, that enough water will be reserved for that purpose and short-hydroperiod wetlands not be lost in exchange for more water storage. Concerns were raised about the reliance on engineering solutions as opposed to more “natural” methods of water management.

West Palm Beach

Concerns were expressed about the effect the Restudy will have on growth and urbanization. There were many concerns expressed about aquifer storage and recovery technology, seepage management, wastewater reuse, water quality and how the plan will deal with uncertainties associated with these technologies. Several speakers mentioned the need for flood control and water assurances for existing users.

Land acquisition was an issue for many residents. Some citizens questioned the process, the impact on tax rolls, the amount of land to be acquired, and advocated fairness to property owners. Other speakers asked for more lands to be acquired in the Everglades Agricultural Area and the Water Preserve Areas in order to increase the spatial extent of wetlands and allow for more “natural” water management strategies as opposed to a reliance on engineering solutions. Several speakers from Martin County reminded the group that this county had serious concerns about the health of their estuary and expressed their desire to accelerate plan implementation in their area through passage of a sales tax to fund land acquisition.

Several speakers raised concerns about funding, costs and economic feasibility. Other citizens spoke to the need to expedite implementation of the plan for a sustainable south Florida, questioning whether we can afford the cost of doing nothing and asked that environmental restoration receive the highest priority. Local control of the system to be built and the lack of historic water management data were raised as issues.

Marathon

The majority of the speakers were concerned that the Restudy boundaries did not include the Florida Keys. They asserted that the Keys are part of the ecosystem and that there is a Federal interest in improving water quality as the Keys are home to a National Marine Sanctuary. Some recognized that the map boundary delineated the original C & SF Project canal system. One speaker expressed concern that including the near shore waters of the Keys in the plan would introduce too many variables for sound scientific analysis.

Many noted that poor quality waters from Everglades National Park negatively impacts Florida Bay and the reef. Several speakers asked for monetary and technical assistance in retrofitting the sewage treatment system for the Keys to protect the coral reef, Florida Bay, the Everglades and Biscayne National Park. Questions were raised about the adaptive management strategy outlined in the Restudy and how effectively on-going research on Florida Bay would be integrated into project design. The Corps was asked to include monitoring for salinity and toxins in the waters in the on-going analysis.

Some citizens stated their distrust of government, especially the Federal government. Some speakers expressed concerns about paying higher taxes for the project and asserted that the Restudy focused too much on environmental restoration to the detriment of water supply. Concerns were raised about aquifer storage and recovery technology and several speakers suggested more land acquisition in the Everglades Agricultural Area would allow more “natural” water management strategies instead of high tech solutions. Many expressed concern that the plan would facilitate more growth in south Florida.

Homestead

Concerns were expressed about decompartmentalization, specifically what levees and canals would be removed and what effect that would have on flood control in the area. Agricultural land owners asked for assurances that water levels in south Miami-Dade will not rise to levels that will saturate the root structures of their crops and orchards. Several speakers requested better modeling to understand the elevation of the agricultural lands in south Miami-Dade and the impact of altering groundwater levels. Other concerns pertained to water supply assurances for agriculture, an economic analysis of the impact of acquiring farmland in south Miami-Dade, and the lack of certainty about which lands may be taken out of production. Several speakers challenged the legality of the process, especially as it relates to land acquisition, and asked for more scientific information, a cost-benefit analysis and an economic impact study.

Some citizens from the Upper Keys asked to expand the boundaries of the Restudy to include the Keys and provide resources to improve water quality in Florida Bay and in the reef tract. There were questions raised about relying on engineering solutions like Aquifer Storage and Recovery, waste water reuse, water quality and seepage controls. Several speakers asserted that natural strategies like flow ways would be more cost effective. Concerns were raised about the cost of the project and the science behind the plan was questioned.

Integration of the C-111 project into the study was mentioned by several speakers. Some citizens questioned whether the plan was too weighted towards water supply for people and that not enough water was reserved for the environment. Issues were raised about population projections and the need to preserve agriculture in south Miami-Dade while providing water for the residents.

Kendall (South Miami)

Land acquisition was a great concern to many speakers, especially those with property in the Lake Belt Region and the 8 1/2 square-mile area. They expressed concerns about fair compensation, unfair targeting of small landowners, and questioned the constitutionality of the process. Several suggested that existing public lands be used for the components of the Restudy. Other citizens advocated more land acquisition, especially in the Everglades Agricultural Area.

The Miami-Dade Water and Sewer Department presented a list of concerns about water supply, water quality, water assurances, costs and future levels of flood control which were shared by the City of Medley. The Water and Sewer Department also expressed concerns about the cost of wastewater reuse and sought assurances that this technology would not affect existing wellfields and questioned whether reuse water was the best source for Biscayne Bay.

Several speakers expressed concern about more water for Biscayne Bay as well as the need for clean water for the most southern reach of the Everglades ecosystem. It was suggested that the Restudy consider another feasibility study on Biscayne Bay. Research was advocated for nitrogen as well as phosphorus limitations in the coastal waters. Some citizens voiced their concerns about the aquifer storage and recovery technology, the lack of a cost-benefit analysis and the reliance on engineering solutions as opposed to more “natural” strategies like flow ways and more above ground storage.

One speaker traveled from Martin County to remind this group of how tightly the whole system is woven together. Several speakers advocated proceeding with speed and expressed the view that the cost of not doing the Restudy far outweighs the costs of the plan.

Naples

Many speakers expressed concerns about how the Restudy will deal with southwest Florida issues and asked how the proposed Southwest Florida Feasibility Study will reflect recent citizen planning efforts. Several speakers asked for a better link between land use and water supply planning and asked for a carrying capacity study for the area that defines the water supplies available for future growth. Concerns were voiced that the Restudy will fuel growth and not protect natural resources.

Several attendees expressed their distrust of government, especially the Federal government. Some small landowners expressed their concerns about land acquisition and flood control. The cost of the project was of concern to some members of the public, as well as the lack of a full economic impact statement. Concerns were raised about aquifer storage and recovery technology and the uncertainties associated with that technology, with special concerns expressed about these wells in the Caloosahatchee basin. A few residents raised water quality and salinity issues.

Several speakers urged haste in implementing both the Restudy and the Southwest Florida feasibility study. Some residents suggested that the cost of inaction was unacceptable in terms of future generations and reminded the public that the Everglades is an important economic resource. Some speakers asserted that the costs could be reduced by using natural methods for water storage and management like reservoirs and flowways as opposed to engineering solutions.

Ft. Myers

Several speakers voiced their support for the Restudy and the feasibility study as an opportunity to develop water supply data for the region, steer growth to the right areas, and protect wetlands and other natural areas. Some asked for the feasibility study to become a carrying capacity study and spoke of their concerns that the Restudy will encourage more growth than the region's natural resources will sustain. Several members of the public had served on a local planning body that developed a vision for the area and asserted that the Alternatives Development Group's product should be incorporate into the Southwest Florida feasibility study.

Many citizens wanted assurances that the Caloosahatchee River Estuary would be protected from future freshwater releases and urged that more water be held in Lake Okeechobee and that the Everglades Agricultural Area hold more water on its own lands. Several speakers asked for more land acquisition to facilitate more natural methods of water management and storage like flowways and reservoirs as opposed to engineering solutions. Concerns were expressed about aquifer storage and recovery and the uncertainties associated with that technology.

Utilities and agricultural representatives sought water supply assurances and continued levels of flood control.

Many speakers expressed concern that the Restudy will accelerate growth and that the water needs of people would take precedence over the water needs of the natural system. Others feared that local government permitting decisions would undercut any benefit of the feasibility study.

The cost of the project was an issue for several citizens. Concerns were raised about seeking Congressional authorization for the Restudy without more information on costs, the proposed technologies and a detailed implementation plan. Some speakers expressed their distrust of government, especially the federal government, and were concerned that the Restudy would result in land condemnation. Several citizens asserted that the cost of the Restudy and the feasibility study are cheap compared to a water shortage in southwest Florida.

Washington, D.C

The overwhelming majority of the speakers supported the Restudy but did voice some concerns. The Corps was urged to use the principle of adaptive assessment as the plan moves forward and to be open to revisions as new information becomes available.

Members of the agricultural community expressed concerns about the reliance on aquifer storage and recovery, seepage control, and aboveground reservoirs. The lack of a funding proposal and questions about implementation and scheduling projects raised many concerns in this sector of the public. Questions were raised about the models used and issues were raised about the process used to formulate the conceptual plan. More detailed engineering and an economic feasibility study were requested. The agricultural community asked for a better integration of water quality standards into plan design and assurances that permitting built components would not become an issue in the future. Some questioned the model used to formulate the plan.

The industry sought assurances on water supply and flood control. Speakers asserted that Florida's Governor and Legislature must be formally involved in the implementation of the plan and that state laws govern all land acquisition and water supply requirements. The industry asserted that the conceptual plan had too many uncertainties to be authorized by Congress, but favored a limited authorization including pilot projects to test aquifer storage and recovery, seepage controls and a group of identified early action or critical projects that are technically and economically feasible. The industry asserted that all authorized projects undergo the traditional Corps analysis prior to implementation.

Land acquisition was a concern raised by every representative of the agricultural community. Speakers questioned the amount of land to be used for reservoirs and stormwater treatment areas. Representatives petitioned for a complete engineering and scientific justification for any land acquisition, asked that the Corps seek willing sellers, consider using public lands first and if condemnation is necessary, that the state condemnation process prevail. Concerns were raised about the economic impact on rural communities when lands are removed from the tax rolls and asked for fairness to landowners. Concerns were also raised about the devaluation of agricultural lands in a target area and the possible negative affect on crops on higher ground water levels.

The cost of the project was an issue with several speakers who raised concerns not only about the state's ability to cost share with the Federal government but also of the impact on individual citizens. Several speakers spoke of the link between the health of the ecosystem and a healthy economy and suggested that the price of inaction was unacceptable in terms of the continued sustainability of south Florida. Many speakers urged haste in implementing the plan and it was suggested that first priority be given to projects with a local cost share in place.

Several speakers from the environmental community voiced concerns that the Restudy will fuel continued growth in south Florida and that water will be diverted from the natural system to meet human needs. Several representatives asserted that the primary focus of the Restudy must be to improve the greater Everglades ecosystem and the secondary purpose was to meet human water supply and flood control needs. Speakers asked that a more concentrated modeling effort be undertaken to improve ecological performance in the Water Conservation Areas, Northeast Shark River Slough, Taylor Slough, Everglades National Park, the Model Lands, Biscayne and Florida Bays. It was suggested that the Restudy boundaries be expanded to include the Florida Keys.

Representatives of this segment of the public raised concerns about aquifer storage and recovery and other engineered solutions to water storage and management and suggested that more passive solutions like reservoirs and flowways would reduce the cost of the Restudy. This group sought more land acquisition for these purposes. Issues were raised about water quality with an emphasis on monitoring all toxins in the water column. Representatives for the southwest coast welcomed the proposed Southwest Florida Feasibility Study as an opportunity to protect their natural resources and provide for sustainable growth.

11.12 IMPLEMENTATION PLAN COORDINATION

The Implementation Plan presented in the *draft Integrated Feasibility Report and Programmatic Environmental Impact Statement* was very preliminary.

Additional work to refine and improve the Implementation Plan for this final report has been underway since the completion of the draft report. In addition to team meetings, five public workshops specific to the development of the Implementation Plan have been held with stakeholders. The first four workshops took place on July 29, 1998, August 27, 1998, November 23, 1998, and December 11, 1998. During these workshops and during the public comment period on the draft report, the public expressed a desire to have the opportunity to review and comment on the revised Implementation Plan prior to its inclusion in this final report. Accordingly, the revised draft Implementation Plan was released for public review on January 25, 1999. A public workshop on the Implementation Plan was held on February 1, 1999, to present the refined plan and solicit comment. Written comments on the draft Implementation Plan were received until February 5, 1999. The comments received from the public were used to finalize the Implementation Plan presented in ***Section 10*** of this report.

Comments on the Implementation Plan were received from agencies, stakeholders, and the public. Concerns were expressed about the level of restoration that will be achieved within the first ten years of implementation and the use of $400 million per year as an average for funding. The public was also concerned about accelerating land acquisition for the project. There were comments about integrating water quality improvements into the Implementation Plan. Some comments supported independent scientific peer review of the recommended Comprehensive Plan. Comments about the Project Implementation Report process and the list of projects recommended for initial authorization were also received.

SECTION 12
COMPLIANCE WITH ENVIRONMENTAL REQUIREMENTS

The alternative plans were considered in relation to compliance with Federal environmental review and consultation requirements.

12.1 NATIONAL ENVIRONMENTAL POLICY ACT OF 1969

Environmental information on the project has been compiled and a Draft Programmatic Environmental Impact Statement (PEIS), Central & Southern Florida Project Comprehensive Review study, was prepared on October 1998. A systematic interdisciplinary approach to planning has been utilized; alternatives have been studied, developed and described, and ecological information has been developed and utilized. A notice of availability for the Draft PEIS was published in the Federal Register, Volume 63, Number 205, on October 23, 1998. The Draft PEIS was coordinated with state, Federal and local agencies, native American Tribes, non-governmental agencies, and the public for seventy-one days until December 31, 1998. A Final PEIS has been prepared incorporating comments and recommendations provided by state, Federal and local agencies, native American Tribes, non-governmental agencies, and the public and including a compilation of reviewer comments and agency responses in ***Appendix N***. This Final PEIS is being circulated in accordance with the National Environmental Policy Act for a period not less than thirty days.

12.2 FISH AND WILDLIFE COORDINATION ACT OF 1958

In response to the requirements of this Act, the U.S. Army Corps of Engineers has and will continue to maintain continuous coordination with the U.S. Fish and Wildlife Service and the Florida Game and Freshwater Fish Commission during all stages of the planning and implementation of this project. Previous to completing the Draft PEIS, the Florida Game and Fresh Water Fish Commission submitted a Fish and Wildlife Coordination Act report on August 6, 1998. The U.S. Fish and Wildlife Service also submitted, under separate cover, a Draft Fish and Wildlife Coordination Act report dated August 7, 1998.. The comments provided as a part of these reports were reviewed by the Corps and served to provide a framework for future investigation of scenarios and modifications to the Initial Draft Plan. Following release and coordination of the Draft PEIS and prior to completion of the Final PEIS, the U.S. Fish and Wildlife Service, submitted a Final Fish and Wildlife Coordination Act Report (as a supplement to the draft) on March 1, 1999. The Florida Game and Fresh Water Fish Commission also submitted two additional Fish and Wildlife Coordination Act Reports (Part II and Part III) on

January 19, 1999 and February 19, 1999 respectively. These reports are included in their entirety in ***Annex A.***

The Fish and Wildlife Service and Florida Game and Fresh Water Fish Commission recognize that while implementation of the Comprehensive Plan should result in widespread restoration of natural systems in south Florida, the plan also continues to include some unresolved issues. These remaining issues are a source of concern among the resource agencies. Both of the Fish and Wildlife Coordination Act reports contain recommendations for addressing these concerns. An interagency effort was begun in September 1999, led by the Alternatives Evaluation Team, to better define, prioritize, and develop a strategy to resolve each of these concerns. Although resolution of these issues is on a fast track, the Alternatives Evaluation Team has shown that substantial new technical information, to be provided by additional research and modeling, will be required to address these efforts. The Restudy is committed to seeking resolutions to these concerns, in an interagency, consensus-building setting. Issue resolution will be an important function of the RECOVER process that will help guide the program through implementation. The following paragraphs contain recommendations as presented in the Fish and Wildlife Coordination Act Reports prepared by the U.S. Fish and Wildlife Service and Florida Game and Fresh Water Fish Commission and responses to the recommendations prepared by the Corps.

12.2.1 U.S. Fish and Wildlife Service draft Fish and Wildlife Coordination Act Report Recommendations

Comment #1 – The Department of Interior recommended that all progress toward achieving ecosystem restoration be continuously evaluated in a scientific forum. A peer-reviewed science-based adaptive management strategy, coupled with a sound monitoring program, is the recommended means for integrating all the past knowledge of the south Florida ecosystem with recent findings of the scientific community. Based on the monitoring information, the interagency adaptive management team will prepare annual reports and provide recommendations to decision-makers on how to proceed. This strategy will ensure that refinements to the Initial Draft Plan will be based on the best and most recent information. The annual reports will also be an avenue for keeping the general public fully informed.

Response – A specific strategy has been developed for conducting regular, science-based evaluations to determine how well the components of the Recommended Plan achieve the ecological targets set by the performance measures. A team of senior ecologists and hydrologists will compare actual ecological responses with predicted responses, as a basis for considering changes in plan components and for improving and redefining overall ecological measures of restoration success. The products of this internal review will be independently reviewed on a regular basis by the Science Advisory and Review Panel, appointed by the South Florida Ecosystem Restoration Task Force. The measures of ecological responses will be determined through a regional, integrated monitoring program. All evaluations and recommendations will be made widely available for review by means of annual reports.

Comment #2 – Proper sequencing of presently authorized projects and the components to be authorized in the C&SF Restudy must be determined and followed. Effective sequencing of actions proposed by the C&SF Restudy (relative to each other and to existing authorized projects) must be thoroughly analyzed and integrated in construction schedules.

Response – A multi-agency team, similar to the Alternative Development and Alternative Evaluation Teams, was formed to develop the implementation plan. The team has developed guidelines for the development of the implementation plan, an initial packaging of components, and initial sequencing of projects for the draft report. The implementation plan has been reviewed by the AET and other members of the Restudy team and has been considerably expanded in scope and detail in the final feasibility report.

Comment #3 – The Department of Interior strongly supported the completion of feasibility studies on the Water Preserve Areas, the Indian River Lagoon, and initiation of a feasibility studies on Southwest Florida, and Biscayne Bay.

Response – The Corps of Engineers completed a Reconnaissance Report for Biscayne Bay in 1995. The study proposed the development of a multi-phase modeling system to investigate the effects of Federal projects on water circulation, biological communities, and water quality in the bay. The first phase, which includes development of a hydrodynamic model with associated surface and groundwater models, is presently underway. The Biscayne Bay Feasibility Study is cost-shared with Miami-Dade County. The Indian River Lagoon and Water Preserve Areas Feasibility studies are currently ongoing and alternatives are being assessed by their respective inter-agency study teams. The NEPA process in support of regulatory actions for Southwest Florida has been ongoing for the past year and a draft Environmental Impact Statement will be coordinated in the near future with state, Federal and local agencies, native American Tribes, and the public.

Comment #4 – The Department of Interior recommended that Other Project Elements that provide the most significant ecological benefit receive the highest priority for future detailed planning and implementation.

Response – The Department of Interior participated in the evaluation of the Other Projects Elements. This evaluation is described in ***Appendix A5***. Based on this evaluation, and adjustments to the scope of the plan, nineteen Other Project Elements are recommended for inclusion in the Comprehensive Plan.

Comment #5 – Recreational opportunities in the natural areas of south Florida must be considered in detailed project design and in policy development as well as the perception that Federal lands are receiving restoration priority over state lands.

Response – Concur. Recreation is one of the C&SF Project purposes and future planning should attempt to minimize impacts which may affect existing recreation resources, while still restoring the natural functions and values inherent in a restored Everglades ecosystem. The Recommended Comprehensive Plan has been developed to benefit all natural areas of the ecosystem, not just Federal lands.

Comment #6 – Aquifer Storage and Recovery should be used in combination with surface storage reservoirs since the reservoirs would modulate peak flows to the wells. For water quality reasons, it would be preferable to recover the water from Aquifer Storage and Recovery wells into a buffer zone area designated for this purpose rather than directly into natural environments. Other water storage options should be investigated in the event Aquifer Storage and Recovery cannot be implemented on the scale proposed for the Restudy.

Response – A number of the construction features that involve surface storage include Aquifer Storage and Recovery features. Post-treatment of water withdrawn from Aquifer Storage and Recovery wells is included in the Comprehensive Plan but further planning and design, including pilot projects, will be needed to address the water quality effects of water recovered from these facilities.

Comment #7 – Opportunities for removal of structures that impede restoration should be a guiding principle; addition of structures must be clearly demonstrated to be unavoidable before being included in designs.

Response – The Restudy Team investigated a number of alternatives to remove barriers between natural areas in the Everglades. The Comprehensive Plan is a compromise between fully reconnecting the Everglades by removing the barriers that hinder continuous sheetflow and achieving ecologically based targets in the Everglades. Future refinements to the plan will reflect the importance of connectivity at a landscape scale and the desire of the team to reduce fragmentation along with the other problems artificial structures cause.

Comment #8 – Detailed design of all components should continually consider approaches that will promote passive systems over intensely active management.

Response – The Corps of Engineers prefers low cost and low energy consumption features to high cost features, as long as they produce the desired results. Preliminary studies have shown that passive management may work very well within Everglades National Park but less well in the bounded Water Conservation Areas, for example. Future studies will promote passive systems wherever they create and protect natural hydropatterns and the habitats that depend on them.

Comment #9 – Policies governing Clean Water Act authorization of wetland mitigation within the study area must be consistent with the goals of the C&SF Restudy. Enhancement of wetland function attributable to the C&SF Restudy should not be credited to other interests who are required to mitigate for wetland functional losses. As a policy, using lands inside the C&SF Restudy boundary to replace wetland functional losses occurring outside the C&SF Restudy boundary should be prohibited. To meet the stated goal of "increasing the spatial extent of wetlands" wetland mitigation should supplement, not supplant ecosystem restoration benefits attributable to the C&SF Restudy. Information on the location of features proposed in the C&SF Restudy must be made accessible to reviewers of permit applications, and all permit decisions must be compatible with the design and purposes of the C&SF Restudy.

Response **-** For unavoidable impacts to existing Regulatory mitigation sites, separable mitigation, on a case by case basis will be developed in subsequent phases of the project. This mitigation will be derived from sources other than the benefits identified in this report. The Corps of Engineers and the U.S. Fish and Wildlife Service are members of the interagency team developing the South Florida Comprehensive Conservation, Permitting and Mitigation Strategy. When completed, this strategy should provide consensus based guidance regarding the siting of mitigation sites, including banks, in relation to proposed features of the Comprehensive Plan. In addition, the Mitigation Bank Review Team should work closely with the Restudy Team and potential mitigation bankers regarding opportunities for environmentally compatible private mitigation banks in the project area that will supplement, not supplant, potential benefits of the Comprehensive Plan.

Comment #10 – Land acquisition funding should receive priority before restoration opportunities are lost. Although current activity is largely dependent on willing sellers, the Department of Interior finds that eminent domain procedures will likely be required to complete the plan.

Response – Lands, which can be identified as required for implementation of the plan, should be acquired as soon as possible from willing sellers to the extent possible. Normally, eminent domain may be used to acquire lands for authorized projects: (1) in the event the lands identified for the plan cannot be acquired from willing sellers; (2) only after the completion of necessary documents that identify what particular lands are required for the plan and approval of construction of the particular component by the State and Federal government; and (3) after execution of a Project Cooperation Agreement between the U.S. Army Corps of Engineers and the non-Federal Sponsor.

Comment #11 – The Water Preserve Areas of Palm Beach, Broward and Miami-Dade Counties are an essential feature of the C&SF Restudy that should proceed rapidly to detailed design, while preserving areas of existing high habitat value and providing fish and wildlife habitat enhancement features in others. The Department of Interior recommends that land acquisition in this critical area be accelerated and that the U.S. Army Corps of Engineers begin an expedited Feasibility Study of the area as soon as possible before restoration opportunities are supplanted by continued urban and agricultural development. Water storage and treatment in other portions of the C&SF Restudy area should also minimize impacts on fish and wildlife habitat.

Response – The Water Preserve Areas of Palm Beach, Broward and Miami-Dade Counties are essential features of the C&SF Restudy and are proceeding as part of the ongoing Water Preserve Areas Feasibility Study estimated for completion in September 2001. This study will take the features identified in the recommended plan in Palm Beach, Broward and Miami-Dade Counties and further formulate their concept in a Project Implementation Report that contains appropriate NEPA documentation.

Comment #12 – The Department of Interior recommended that an equivalent Task Team for invasive exotic animals be established, similar to the statewide strategic plan for managing and controlling exotic pest plants, being developed by the South Florida Ecosystem Restoration Task Force and Working Group Exotic Pest Plant Task Team.

Response – Concur. However, the issue of invasive exotic animals in south Florida reaches beyond the scope of the Restudy. The Department of Interior should present this recommendation to the South Florida Ecosystem Restoration Task Force so appropriate agencies can be tasked to develop a plan.

Comment #13 – The Department of Interior recommended that further refinement of the Initial Draft Plan be completed prior to release of the Final Integrated Feasibility Report and Programmatic Environmental Impact Statement. These refinements are described in Recommendations 13a - 13e, below.

Comment #13a – Total overland flow volumes to Florida Bay, through Shark River Slough, and Taylor Slough, should be increased to more fully reach Natural System Model targets, without adversely affecting the Water Conservation Areas, particularly eastern Water Conservation Area 3A, and 3B

Response - The Alternatives Evaluation Team has coordinated a process for creating a stronger technical consensus and a refined set of performance measures pertaining to the ecological implications of recovering various hydrological targets, including flow volumes, in the Shark Slough and Taylor Slough estuaries. The current range of technical opinion is that the combination of meeting or substantially improving a number of different hydrological targets, rather than a single parameter such as flow volume, is the best route to ecological restoration. The hydrological priorities suggested by the Conceptual Ecological Models, and in numerous documents of the Department of the Interior, indicate that hydroperiod duration and stages are the hydrological targets which can best be related to ecological needs. The southern Everglades sub-team of the Alternatives Evaluation Team developed multiple performance measures to gauge the effects of alternative plans on different needs of the system. The timing of flows, duration of hydroperiods, and stages were considered the higher priority restoration targets for the southern Everglades slough systems. The team chose to protect critical dry season flows even if wet season depths were somewhat reduced. Where an array of hydrological parameters are used to evaluate alternative plans, some weighting of the different values is necessary as a means of dealing with ecological priorities and modeling uncertainties. Because the U.S. Geological Survey (Bales et al. 1997) suggested that the Natural System Model could not be reliably used to simulate discharges (flows) in pre-drainage Florida, any targets based on predicted pre-drainage flows were weighted accordingly.

Comment #13b – The Corps should continue to seek opportunities that are not dependent on wastewater reuse in order to restore more natural flows to Biscayne Bay. Two Other Project Elements would benefit Biscayne Bay with or without the additional water that may be available through reuse facilities. These two Other Project Elements are entitled: South Dade Agriculture Rural Land Use and Water Management Plan and Biscayne Bay Coastal Wetlands. The Department of Interior believes that these projects and any others developed to improve ecological conditions in Biscayne Bay should be given priority. Under any future circumstances, total flow volumes to Biscayne Bay should be no less than those simulated in the 1995 Base.

Response – Concur. Additionally, investigations of less expensive forms of wastewater treatment will be explored that may substantially reduce the cost of that feature. As a point of clarification, the OPE Biscayne Bay Coastal Wetlands, is included as a part of the Comprehensive Plan. The South Dade Agricultural Rural Land Use and Water Management Plan is one of the Critical Projects nominated by the Working Group. This project is not included in the Comprehensive Plan as an OPE. Rather, it is considered to be a research/data collection activity that may be useful during the Project Implementation phase. In addition, this project (or a subset thereof) is being undertaken through the Biscayne Bay Feasibility Study.

Comment #13c – Restoration goals for minimum flows of fresh water to the St. Lucie Estuary and the elimination of regulatory releases to the estuary from Lake Okeechobee would be generally met in the Initial Draft Plan. However, runoff generated within the St. Lucie drainage basin is still significantly greater than the restoration target. The Department of Interior recommended further hydrologic modeling efforts be undertaken to restore the St. Lucie Estuary prior to release of the Final Programmatic Environmental Impact Statement. Moreover, this important restoration effort should be highlighted as a priority for future analysis and refinement under the authority of the U.S. Army Corps of Engineer's Indian River Feasibility Study.

Response – Hydrologic modeling of the St. Lucie Basin is ongoing although new information was not available for the Final Programmatic Environmental Impact. The Indian River Feasibility Study was initiated to ensure the modeling and analysis necessary to support the restoration effort continues beyond the completion of the Comprehensive Plan.

Comment #13d – The Department of Interior expressed concern that the C&SF Restudy does not include an adequate plan for treatment of water destined to be returned to the natural system. The Department of Interior recommended that specific pollutant loading targets be established and an implementation plan developed to reach defined targets within the watershed. Finally, planning should not be limited to nutrient loading; a variety of water quality parameters and pollutants also need to be addressed (e.g., pesticides and mercury contamination).

Response – The Comprehensive Plan includes stormwater treatment areas and other treatment facilities (e.g., aeration of Aquifer Storage and Recovery-recovered water) for treatment of water prior to return to the natural system. Except for total phosphorus (e.g., Taylor Creek/Nubbins Slough Stormwater Treatment Area [Component W2], L-28 Interceptor Modification Stormwater Treatment Areas [Component CCC6]), the stormwater treatment areas were not designed considering specific pollutant load and concentration targets. The State of Florida's Everglades Forever Act addresses specific phosphorus and non-phosphorus pollutant targets in the Everglades Protection Area; however, specific targets have not yet been developed for all pollutants in other impaired water bodies within the study area.

Under the Federal Clean Water Act, the State of Florida and Miccosukee and Seminole Tribes are required to identify impaired water bodies within their jurisdictions and develop specific pollution loading targets (Total Maximum Daily Loads). This requirement applies to all pollutants contributing to the impairment of the water body. While these actions are outside the scope of the Restudy, it is expected that development of Total Maximum Daily Loads will be integrated into the overall implementation of Restudy components. Specific targets, as they are developed, will be considered during future detailed design activities.

Comment #13e – The Department of Interior believes that water supply for all users (urban, agricultural, natural system) cannot be met in the year 2050, unless unconstrained water demands by urban and agricultural users is reevaluated. The Department of Interior recommended that a guaranteed water allocation to the natural system be developed and instituted as soon as possible.

Response - The Alternatives Evaluation Team has developed a process to better define the technical issues associated with any potential, future conflicts among water requirements for natural, agricultural and urban portions of the total system. In the future, as a part of the RECOVER program, an interagency task team would be assigned to determine the specific water supply issues that could result in conflicts and to make recommendations for prioritizing and preventing these conflicts. The Comprehensive Plan does include water conservation in both the future without plan condition and as a component of the recommended plan. A total reduction in urban water supply demands of 18 percent is estimated to occur as a result. All increases in water supply to agriculture are based on using high efficiency low volume irrigation now required as a part of the South Florida Water Management District's consumptive use permitting process. There are provisions in Florida law (Chapter 373) for the South Florida Water Management District to provide water for the natural system. These include establishing and implementing minimum flows and levels, implementing hydropattern restoration for the Everglades Protection Area and any other natural systems which are being restored, reserving water quantities necessary for the protection of fish and wildlife, and limiting consumptive use permit allocations to prevent harm to the water resources.

Comment #14 – The Department of Interior noted that the Restudy is proposing as many as 225 deep storage wells (Aquifer Storage and Recovery) as an option to improve water supply. In order to ensure the feasibility of regional Aquifer Storage and Recovery facilities, and the long term management of each site, the Department of Interior recommended the initiation of an Aquifer Storage and Recovery feasibility study including hydrologic modeling to evaluate technical uncertainty associated with regional scale Aquifer Storage and Recovery proposed in the Restudy. The feasibility study should investigate placing water removed from storage wells into "buffer zones", before being discharged into the natural environment, and other water storage options in the event that Aquifer Storage and Recovery cannot be implemented on the scale proposed for the Restudy.

Response – Aquifer Storage and Recovery is an important component in the Comprehensive Plan. It is recognized that there are technical and regulatory issues associated with the regional scale Aquifer Storage and Recovery components, therefore, pilot projects have been recommended prior to embarking upon full scale implementation of the technology. In addition, section 7 of the report includes a discussion of the potential alternatives to the Aquifer Storage and Recovery components.

Comment #15 – The Department of Interior recommended that improvements be made to hydrologic models that will be used in detailed planning for Restudy components to better account for water flows, including groundwater flow, identifying areas where more data are needed, securing better topographic data, particularly in critical areas, and addressing water quality concerns.

Response – Concur. The Corps and South Florida Water Management District have developed more detailed models that will be used for the Water Preserve Area Feasibility Study. It is anticipated that additional, more detailed models and data will need to be developed as the Restudy progresses into the detailed planning and design phase for other areas where modifications to the project will be made.

12.2.2 U.S. Fish and Wildlife Service final Fish and Wildlife Coordination Act Report Recommendations

Comment #1 – The final plan as implemented should include components from the $D13R_4$ scenario that can provide an improved capability for delivery of additional water to Everglades National Park and Biscayne Bay up to the amount in the $D13R_4$ scenario by capturing additional runoff from urban areas. The Implementation Plan should include a phased approach to provide for improvement and eventual full recovery of the WCAs, ENP, Biscayne Bay and those other natural areas that have been adversely affected to by the C&SF Project.

Response – The Corps has committed to implementing a final Comprehensive Plan that increases the capability for delivery of additional water to Everglades National Park and Biscayne Bay. Approximately 253,000 acre-feet of additional water, from urban canal basins, has been identified in the $D13R_4$ scenario that may provide this additional source of water. Implementation of this type of scenario necessitates resolving water quality issues prior to hydrologic restoration. Furthermore, the Corps is committed to protecting the environmental integrity of the Water Conservation Areas, such that incorporation of any elements of $D13R_4$, or future plan features which capture, store and convey additional water to ENP and BNP, will not adversely affect conditions in the Water Conservation Areas. Finally, the Implementation Plan includes a phased approach, as described in correspondence dated February 19, 1999 from the Corps to the U.S. Fish and Wildlife Service and Everglades National Park, providing clarification on the Comprehensive Plan.

Comment #2 - The Corps should give high priority to examining those groups of components related to movement of water from the central Everglades to the southern Everglades, including but not limited to, L-29 and L-67 A and C. The final Comprehensive Plan should be flexible enough to develop and substitute components during implementation that significantly reduce the operational and ecological trade-offs in balancing the restoration of flow patterns and volumes with the maintenance of appropriate water depths in the remnant Everglades, particularly in the WCA 3B/Pennsuco Wetlands/Northeast Shark Slough areas.

Response – The Comprehensive Plan has demonstrated flexibility in capturing, storing, and conveying water to various areas in the system to meet natural system and urban/agricultural demands. This was most recently illustrated during the scenario process that resulted in $D13R_4$ that was evaluated by the Alternative Evaluation Team. $D\text{-}13R_4$ was described in the Department of Interior Fish and Wildlife Coordination Act Report, dated March 1, 1999, as having "... demonstrated the flexibility in the conceptual plan for more closely approaching restoration targets for the southern Everglades and Biscayne Bay." The Corps is therefore confident that indeed, the Comprehensive Plan is sufficiently robust in its ability to meet restoration of flow volume, depths, duration and distribution of flows, while maintaining appropriate depths elsewhere in the system.

The components mentioned will be revisited during detailed design. The Corps, through an interagency process, has developed an Implementation Plan that will continue to consider ecological priorities (see ***Section 10***). Section 10.5.1.4 of the Implementation Plan describes a series of factors and rules to consider in developing the sequence of project implementation. These factors included: components that have physiographic and functional connectivity, provide immediate benefits, contribute to the overall system, components that may be implemented through ongoing projects, and components that need to be implemented to avoid lost opportunity potential.

Comment #3 - The Department of Interior recommends that the Corps not commit to the specific details of the L-67 levee component as conceived in either Alternative D13R or the $D13R_4$ scenario.

Response – All of the more than sixty components contained in the Comprehensive Plan were formulated and evaluated with a great deal of involvement from state, Federal and local agencies. This particular component was developed and evaluated through the Restudy interagency plan formulation process (AET/ADT), including U.S. Fish and Wildlife Service, and the National Park Service staff, and was done in response to a desire for more passive features over mechanical, engineered solutions. This component makes maximum use of passive features eg. earthen plugs and weirs, and is fundamental to the overall restoration of flows to the southern Everglades, while approaching appropriate depths in

Water Conservation Area 3B. However, as we progress into more detailed planning, we will be willing to consider more suitable methods to achieve the same goals.

Comment #4 - The use of the currently designed S-140 as a means to restore hydropatterns in northern WCA 3A needs to be further evaluated during the PIR process and in detailed design. The Department of Interior suggests a better balance between the use of the S-140 as a point of discharge and a series of inflow structures to spread out flow along the northern and western boundary of WCA 3A.

Response – Concur. This plan feature will be further evaluated during detailed planning, including preparation of appropriate NEPA documentation, to determine the precise implementation strategy for the S-140 in order to meet hydroperiod targets in northern WCA 3A without incurring unacceptable adverse impacts such as an expansion and proliferation of cattails.

Comment #5 - Until the Comprehensive Plan is implemented, surface water flows for Biscayne National Park and the bay should meet or exceed the 1995 base condition. Furthermore, there should be neither any annual or seasonal net loss in the total volume or any reduction in the spatial and temporal distribution of combined surface and groundwater flows.

Response – Concur in part. To the extent that the C&SF Project currently controls fresh water flows to Biscayne National Park, and the bay, operation of the Project will strive to meet or exceed 1995 base condition target flows. Only if there should arise a consensus conclusion, based on development of new performance measures for Biscayne Bay, that alternative flow patterns may be beneficial for restoration of the bay, would the Corps consider reducing flows below the 1995 base.

Comment #6 - Every effort should be made to find sources storage and means of distribution of water to Biscayne Bay that a) require minimal water treatment, b) are likely to receive adequate funding and have the greatest probability of success, and c) can achieve current and future restoration targets, with reasonably predictable environmental and economic consequences. Wastewater reuse should be considered as a last resort.

Response – Concur. The use of waste water reuse is already acknowledged to be a "last resort" feature in that the expense of building, operating and maintaining waste water reuse facilities is very high relative to other features. See component BBB; South Miami-Dade County Reuse, Section 9.1.8.24 of main report.

Comment #7 - Studies to verify restoration targets for Biscayne National Park and the bay should be funded and prioritized early during the implementation phase. The Biscayne Bay Feasibility Study, in particular, must be given a very high priority.

Response – The Biscayne Bay Feasibility Study is ongoing. Its first phase includes development of a hydrodynamic and circulation model for the bay. Later phases will investigate water quality and ecological baseline restoration needs. It will be vital for Department of Interior to play an active role in the development of this study as it progresses.

Comment #8 - The Department of Interior recommends that sufficient water treatment capacity be built into the Plan to handle the increased water volumes needed to achieve the hydrologic characteristics as were observed under $D13R_4$. Furthermore, the Department of Interior recommends that the Comprehensive Integrated Water Quality Plan be given priority and that specific funding be identified for this purpose in WRDA 2000.

Response – The Corps and its planning partners share these concerns and recognizes their significance in terms of creating potential significant adverse impacts to the natural area. The Corps is committed to full resolution and consensus based solutions to water quality issues prior to implementing hydrologic modifications throughout the south Florida ecosystem including the Everglades and Biscayne Bay. The Comprehensive Integrated Water Quality Plan will be initiated under the existing authorization for the Restudy, Section 309(l) of the Water Resources Development Act of 1992 (Public Law 102-580).

Comment #9 - The Department of Interior re-emphasizes its recommendation described in a February 18, 1999 Planning Aid Letter, that the 2010 case study be revisited to see if optimizing reservoir performance, reordering the implementation schedule, or phasing components into increments, would improve performance of the Comprehensive Plan by the year 2010.

Response – The 2010 case study was conducted to help to provide additional information relating to the sequencing of Comprehensive Plan components. Subsequently, the Comprehensive Plan schedule has been refined in an effort to expedite restoration efforts. The project implementation report process will also look for opportunities to enhance the performance of individual components through the detailed planning and design phases of implementation.

Comment #10 - High priority needs to be placed on further refinement of the Natural Systems Model early in the implementation of the Comprehensive Plan. Particular attention needs to be placed on the assumption that the ground elevation in the SFWMM is equivalent to the NSM model elevation south of Tamiami Trail, when evidence supports the fact that subsidence has occurred south of the Trail.

Response – Concur. Although further refinement of the NSM is an ongoing scientific information need and not a project feature of the Restudy Comprehensive Plan per se. The Corps and its sponsor agency, the SFWMD, actively support further development and refinement of the NSM in cooperation with the Department of Interior.

Comment #11 - The Comprehensive Plan should include support for development and verification of a peat accretion model, development of a risk analysis for chronic and acute loss of soil, and research on the effect of water depth on the expansion of cattails in the areas of greater soil subsidence in northern WCA 3A. The Corps and cooperating agencies should develop and test active management techniques that accelerate recovery of damaged soils in the WCAs.

Response – Concur. These are laudable and worthwhile research initiatives and the information derived from them will certainly help to improve performance of the Comprehensive Plan. Although the monitoring and adaptive assessment budget does not specify support for particular information needs, funds may be periodically programmed in support of these key information needs. The Corps looks forward to working cooperatively with the Department of Interior on these efforts.

Comment #12 - The Corps should support an ongoing and in-depth scientific review throughout implementation to help achieve the most appropriate balance in restoration of flows, patterns, volumes, and depths in maximizing overall ecosystem benefits.

Response – The Corps has supported, and will continue to support ongoing independent scientific peer review throughout the implementation of the Comprehensive Plan. Section 10.4.3 provides a more detailed review of past efforts and the plans for future peer review of the Comprehensive Plan including a discussion on the proposed Science Advisory and Review Panel to be appointed by the South Florida Ecosystem Restoration Task Force.

12.2.3 Florida Game and Fresh Water Fish Commission, Fish and Wildlife Coordination Act Report, Part I Recommendations

Comment #1 – Both Alternative D and D-13R perform very well for the lake; however, if regional Aquifer Storage and Recovery fails to perform adequately, we strongly recommend that the contingency plans avoid transferring the brunt of the storage lost to any part of the natural system.

Response – Concur. ***Section 7*** of the report includes a discussion of potential alternatives to Lake Okeechobee Aquifer Storage and Recovery.

Comment #2 – The Florida Game and Fresh Water Fish Commission recommended that the U.S. Army Corps of Engineers work closely with staff of the Florida Game and Fresh Water Fish Commission's Division of Fisheries to reduce or eliminate the potential for impingement and entrainment of fishes by new pumping facilities.

Response – Concur.

Comment #3 – In order to rectify hydrologic problems in Water Conservation Area 2B, every attempt must be made in the future to identify why the modeled alternatives, particularly Alternative D-13R, have failed to provide hydropatterns that would be conducive to an Everglades landscape. The Florida Game and Fresh Water Fish Commission suggested that the first area to be investigated is the operation of Water Conservation Area 2A and 2B.

Response – There is a clear understanding of the existing problem, but there is a lack of feasible solutions. The problem is related to the severed flow paths of the historic Everglades. When water is introduced to the northwestern side of Water Conservation Area 2A, at Natural System Model like values, water will pond along the southeastern side because the natural flow lines cannot be maintained in the remnant Everglades. Removal of the levee between Water Conservation Area 2A and 2B only exacerbates the problem. Because Water Conservation Area 2B has no natural outflow zone, water cannot flow through in a natural manner. Alternative D-13R, like other alternatives, provides an outflow at the southern rim of Water Conservation Area 2B, but it cannot remove water at the rate that water accumulates in Water Conservation Area 2B, even if there was an area in which to store the excess water. Complete flow through during a wet season would result in a larger dry season demand. At the time of alternative development, no solution existed. Clearly, more effort is needed to find appropriate targets and feasible solutions for these areas.

Comment #4 – Hydrologic performance in northeastern Water Conservation Area 3A should be improved during further modeling efforts. It is possible that changes in Stormwater Treatment Area 3/4 operational rules alone could lead to improved performance. Additional storage to the north, or the development of structures that would provide a more balanced distribution of inflows to the Water Conservation Areas during high rainfall periods, may also need to be included in the final plan.

Response – The operation rules for Stormwater Treatment Area 3/4 are based upon water quality and hydrologic characteristics of the treatment area and should not be changed. The problem again is related to the severed flow path of the historic Everglades. Water cannot flow from the area as it did under historical conditions. Water spread at the northeastern side of Water Conservation Area 3A for hydropattern improvement ultimately combines with water from Water Conservation Area 2A (unnaturally) and causes ponding since it can no longer flow in historical directions. Alternative D-13R removes a limited amount of the water that ponds in eastern Water Conservation Area 3A and passes it to Northeast Shark River Slough via the Central Lake Belt.

Comment #5 – The Florida Game and Fresh Water Fish Commission recommended that the U.S. Army Corps of Engineers and the South Florida Water Management District run a sensitivity analysis to determine whether the L-67A canal can be extended farther south and still capture the hydrologic benefits that the currently proposed design is anticipated to accomplish. In addition, it is the Florida Game and Fresh Water Fish Commission understanding that the removal of the L-29 levee automatically included removal of the L-29 canal, as well. In short, we would strongly support a design that clearly aids in restoring the overall hydrologic characteristics of the predrainage system; however, we would be opposed to removing canals that currently provide recreational fishing benefits when that removal provides little or no hydrologic restoration benefit. The Florida Game and Fresh Water Fish Commission recommended that the U.S. Army Corps of Engineers work in close cooperation with the their Division of Fisheries during the detailed design phase in order to determine the degree to which recreational amenities can be maintained and to fully mitigate for any losses (e.g., by designing the Water Preserve Areas so that they support recreational fishing).

Response – Concur in part. The Water Preserve Areas and the storage reservoirs proposed for the Caloosahatchee River Basin, north of Lake Okeechobee, St. Lucie Basin and the Everglades Agriculture Area may have recreation benefits, which could, in part, offset those lost due to filling canals within the Everglades. Those opportunities should be fully explored during the detailed design phase. Canals have been shown to function more than simply interrupting the natural hydrology of the Everglades, however. They also transport exotic plants and animals into relatively pristine areas, transport nutrients, and biocides from urban and agricultural areas into the natural system, and facilitate overdrainage of natural areas. For these reasons, it has been among the restoration objectives of the Restudy to address this previous negative impact of the C&SF Project.

Comment #6 – Because the long-term ecological effects of shifting to a hydroperiod longer than Natural System Model predictions in northern and central Water Conservation Area 3A are unknown, further modeling and design of the preferred alternative should include an effort to develop operational flexibility within the Everglades watershed. Operational and structural details should be explored that will allow hydroperiods within the remnant Everglades to be reduced in some regions without causing an overall loss of flow to more downstream parts of the system. The use of the S-140 structure and an associated spreader-canal system would be an example, as it might allow more water to be discharged into central Water Conservation Area 3A, if it became desirable to send less water into northern Water Conservation Area 3A as a means of discouraging cattail expansion.

Response – Concur. Further modeling, which will include structural and operational changes, will be explored during the detailed design phases of the project in an effort to improve the hydrologic performance of the recommended plan.

Comment #7 – The U.S. Army Corps of Engineers and local sponsor should work with the U.S. Geological Survey and others to expedite the collection of high-resolution topographic data in Rotenberger and Holey Land Wildlife Management Areas and throughout the Water Conservation Areas and Everglades National Park.

Response – Concur. High-resolution topographic data is needed for future modeling efforts for both South Florida Water Management Model and Across Trophic Levels System Simulation model, as well as future operational water management decisions. The Corps of Engineers is committed to working with the South Florida Water Management District and other agencies in achieving this goal.

Comment #8 – A concerted effort is needed to ensure that performance measures are developed that can more accurately predict the responses of peat soils, tree island vegetation communities, and wildlife (including wading birds) to hydrologic changes. Such measures should be scientifically supportable as best current estimates of ecological responses to changed hydrologic conditions, and they will need to be developed prior to detailed design of structures and operations that will alter hydrologic conditions within the Everglades watershed. Performance measures developed during the Restudy were acceptable for comparing between model runs, however existing measures are not yet sufficient to use as "real world" management goals.

Response – The Conceptual Ecological Models developed by teams of south Florida scientists will be used as a basis for further refining a set of ecological performance measures and targets. The conceptual models identify the hydrological stressors and ecological attributes (indicators) for each major landscape feature in south Florida. Workshops are planned for the purpose of reviewing the models, and for developing the specific measures and targets for the ecological attributes, which are shown by the models to be the best indicators of how these systems respond to the restoration efforts.

Comment #9 – In order to avoid unintended shifts in vegetative structure, the Comprehensive Plan should include two well-crafted sections: (1) an implementation plan that allows for careful staging of hydrologic changes so as to avoid large environmental "shocks" that could induce ecological damage to the marsh communities; and (2) an adaptive management strategy that ensures that monitoring is well designed and comprehensive over the total system. It will be crucial for monitoring results to be evaluated within an objective scientific framework, and to be acted upon expeditiously. Maintaining flexibility in water management actions in response to monitoring results will be critical during project implementation. Water management changes likely to be identified as part of an adaptive management process would generally take place on a time scale of months-to-years; hence, operational flexibility need not be incompatible with a system in which passive forms of water management play a dominant role.

Response – The draft Integrated Feasibility Report and Programmatic Environmental Impact Statement includes an implementation plan (***Section 10***). This implementation plan has been considerably expanded in scope and detail in the final Integrated Feasibility Report and Programmatic Environmental Impact Statement. It has also undergone independent review by agencies prior to incorporation into the final report. Recommendations in this plan for how plan components should be grouped, and for the sequencing of components during implementation, will be designed to maximize ecological benefits, and minimize or avoid ecological damage. The Conceptual Ecological Models should be used to link an adaptive assessment strategy with a well focused, regional monitoring program.

Comment #10 – The Florida Game and Fresh Water Fish Commission recommended that, if ecological restoration is to become a reality, a process be established to coordinate and balance the responsibilities and goals of the many resource and water management agencies responsible for different parts of the south Florida ecosystem.

Response – A multi-agency team, similar to the Alternative Development and Alternative Evaluation Teams, was formed to develop the implementation plan. The team has developed a set of guidelines for the implementation plan that includes continuing the multi-agency approach used throughout the Restudy process. The implementation plan also includes a RECOVER process that will provide continuing re-analysis of the Comprehensive Plan, refinement of performance measures and targets, implementation of the monitoring program, and the development and implementation of adaptive assessment protocols.

12.2.4 Florida Game and Fresh Water Fish Commission, Fish and Wildlife Coordination Act Report, Part II Recommendations

Comment #1 - The Florida Game and Fresh Water Fish Commission is concerned with the restoration of portions of the Water Conservation Areas, Shark River Slough in Everglades National Park, and the St. Lucie estuary. The performance of alternative D-13R may provide insufficient flow volumes to Shark River Slough as predicted by the NSM. Further concerns are with the performance of D-13R with respect to the Water Conservation Areas including: extended hydroperiods in much of WCA-3A, particularly south of I-75; deep water in eastern and northeastern WCA-3A and; extremely high and low water levels predicted in WCA-2B.

Response - The Corps shares the concerns of the Florida Game and Fresh Water Fish Commission with regard to possible further adverse environmental impacts to certain areas of the Water Conservation Areas identified with D13R and scenario $D13R_4$. The Corps, in its correspondence to the Florida Game and Fresh Water Fish Commission and U.S. Fish and Wildlife Service, dated February 19, 1999 stated its emphatic support for resolving the remaining operational problems of the Water Conservation Areas associated with implementation of the Comprehensive Plan and in not adversely impacting the Water Conservation Areas during development of scenarios designed to send more water to Everglades National Park and Biscayne National Park.

Comment #2 - The Florida Game and Fresh Water Fish Commission is concerned with the need to treat water discharged from the new S-140 structure. The Florida Game and Fresh Water Fish Commission recommends an expansion of the S-140 allowing more water to be shunted to areas further south and a gradual rehydration of northern areas be implemented to allow areas time to acclimate to the new water regime. A water quality treatment facility is also recommended to be added upstream of the new structure.

Response - Additional water quality treatment has been added to the Comprehensive Plan in the form of the Miccosukee Tribe Water Management Plan which includes a 900 acre facility which will treat water from tribal lands. Furthermore, additional water quality analyses will be conducted during the detailed design phase of implementing this component.

Comment #3 - Accurate and up to date topographic information needs to be collected in order to ensure future hydrologic restoration success.

Response - Concur. The Corps agrees that this is a key information need, necessary to resolve the uncertainty associated with several project features such as those designed to restore sheet flow. See response #7, Section 12.2.3, above.

Comment #4 - Most of the Other Project Elements do not contain sufficient information at a level of detail on which to base an assessment of their potential impacts on fish and wildlife. The Other Project Elements will have to be reviewed under the Fish and Wildlife Coordination Act individually as they are further developed.

Response - Concur. As stated in the report, the Other Project Elements will need to be further evaluated during detailed planning and design. Preparation of

Project Implementation Reports will include appropriate NEPA documentation and the Corps will continue to coordinate with the Florida Game and Fresh Water Fish Commission and the U.S. Fish and Wildlife Service under the Fish and Wildlife Coordination Act for each separable project element.

Comment #5 - The removal of canals, which are in some cases, important recreational amenities, must be well justified in terms of hydrological and ecological benefits. The Florida Game and Fresh Water Fish Commission is further concerned with the potential loss of existing recreation access points, particularly off the Tamiami Trail. The Florida Game and Fresh Water Fish Commission recommends providing suitable alternative access sites for those access sites removed under the Comprehensive Plan.

Response - Concur. At this time, modeling has shown that removal of certain levees and canals is necessary for the overall restoration of sheet flow and in attaining hydroperiod targets within the natural areas. One of the principal goals of the Restudy since the reconnaissance phase was the re-establishment of sheet flow and to reduce fragmentation (caused largely by canals and levees) of the ecosystem. The removal of levees and canals as specified in the Comprehensive Plan, is expected to advance these goals as well as to reduce the overdrainage of natural areas and slow the rapid conveyance of pollutants and exotic plants and animals that are often associated with canals. The loss of recreational access points eg. along the L-29, may ultimately be compensated for by establishing new recreational amenities on project features proposed under the Comprehensive Plan. The extent of removal of canals and levees to meet ecological objectives will be further evaluated in the detailed design phase of these project modifications. At this time the Florida Game and Fresh Water Fish Commission will be called upon to play an active role in plan formulation and evaluation.

Comment #6 - The Florida Game and Fresh Water Fish Commission recommends retaining portions of existing levees internal to the Water Conservation Areas and restore these remnant levee sections such that they provide a similar function as natural tree islands. This restoration initiative would be carried out only to the extent that the remnant levee sections, replanted with native trees and vegetation, would not inhibit the restoration of sheet flow.

Response - This is an interesting and innovative idea and one which should receive consideration during future detailed design. This idea fits well with the Restudy concept of adaptive assessment and monitoring in that the precise design (size, scale, location, and type) of project features will be further evaluated during future detailed studies, based on this programmatic document. The Corps looks forward to working with the Florida Game and Fresh Water Fish Commission to further evaluate this proposal during the detailed planning phase.

Comment #7 - The Florida Game and Fresh Water Fish Commission recommends that the Corps seek authorization, at least at the conceptual level, for the entire Restudy Comprehensive Plan.

Response - The Corps, as noted in Section 10.6.1, has proposed to seek Congressional approval of the Comprehensive Plan as a framework and guide for authorization. In addition, a series of pilot projects and specific components are proposed for initial authorization in the Water Resources Development Act of 2000.

Comment #8 – Close coordinated under Fish and Wildlife Coordination Act will be necessary throughout the refinement and implementation of the comprehensive plan in order to ensure that the intended benefits to fish and wildlife are realized.

Response – Concur. The Corps fully intends to continue coordination with the FGFWFC and USFWS under the Fish and Wildlife Coordination Act throughout the detailed planning and design phase. Furthermore, the Corps looks to expand the existing role of the FGFWFC under the Cooperating Agency Agreement currently in effect between all agencies (40 CFR, Part 1501.6(6)(3).

12.2.5 Florida Game and Fresh Water Fish Commission, Fish and Wildlife Coordination Act Report, Part III Recommendations

Comment #1 – The Florida Game and Fresh Water Fish Commission assessment of D-13R_4 is that while providing additional flow to Everglades National Park and Biscayne National Park, these benefits come at great cost to Water Conservation Area 2A and Water Conservation Area 3B, which would fare worse than they do under the 1995 or 2050 Base Cases.

Response – Concur. See response to comment #1, Section 12.2.4, above.

Comment #2 – The Florida Game and Fresh Water Fish Commission expressed concern with the feasibility of implementing D-13R_4 in terms of treating urban runoff to acceptable standards necessary for discharge into natural areas without significant adverse impacts to native flora and fauna.

Response – Concur. See response #8, Section 12.2.2, above

Comment #3 – The Florida Game and Fresh Water Fish Commission expressed concern over the lack of accurate topographic information that led to the conclusion that substantially more water than that provided by D-13R is needed in Shark River Slough, thus leading to the development of the D-13R_4 scenario and additional impacts to the Water Conservation Areas. The Florida Game and Fresh Water Fish Commission suggests that if soil subsidence south of Tamiami Trail were factored into model assumptions for the NSM then it is very possible that less water would be necessary to achieve desirable water depths in Shark River Slough.

Response - Concur. Sensitivity modeling has been done and the Corps is awaiting those results. See response #3, Section 12.2.4, and response #7, Section 12.2.3, above.

Comment #4 – Improvements to one region of the natural system should not be done at the expense of another region within the natural system.

Response – The Corps is fully committed to restoration of the natural system to the utmost extent possible. Development of the Comprehensive Plan has produced the best overall framework for restoring the natural system, given the level of information and evaluation tools currently available. In some instances, construction of the plan elements may result in localized adverse impacts to upland and wetland resources. Conceptually, these impacts have been determined to be justified in order to enhance the overall system hydrologically and ecologically. Siting of such facilities in subsequent phases of this project will endeavor to avoid or minimize adverse impacts to sensitive upland and wetland resources areas, and the Corps will coordinate with the U.S. Fish and Wildlife Service and Florida Game and Fresh Water Fish Commission, and other agencies as appropriate. In some instances, however, potentially adverse impacts, or plan underperformance relative to restoration targets, may result in certain areas of the system, in an attempt to improve performance in critically important areas. The study team will attempt to improve performance of the plan, while reducing ecological trade-offs to there areas of the natural system during the detailed planning phase which is already underway. The Implementation Plan for instance, includes a phased approach to provide for improvements and the maximum ecological benefits to the WCAs, Everglades National Park, Biscayne Bay, and those other areas that have been adversely affected by the C&SF Project. The Corps remains committed to resolving any outstanding operational problems and seeks full consensus on trade-offs wherever they may occur, with a view to implementing the best plan, which is acceptable and beneficial to all.

12.3 ENDANGERED SPECIES ACT OF 1973

Formal consultation was initiated on June 11, 1998, and a preliminary programmatic biological opinion was received from the U.S. Fish and Wildlife Service on August 7, 1998 (see ***Annex B***). The U.S. Fish and Wildlife Service has confirmed, by letter dated March 1,, 1999, the preliminary programmatic biological opinion as the final biological opinion (see Annex B). This project is in full compliance with the Act. The Corps will reopen consultation with the U.S. Fish and

Wildlife Service upon initiation of future tiered feasibility studies under this programmatic EIS.

12.4 NATIONAL HISTORIC PRESERVATION ACT OF 1966

The study is in partial compliance at this stage. Consultation with the Florida State Historic Preservation Officer has been initiated. Cultural resources investigations are ongoing to determine effects to historic properties. When completed, results will be coordinated with the State Historic Preservation Officer and the Advisory Council on Historic Preservation.

12.5 CLEAN WATER ACT OF 1972

The study is in partial compliance at this stage. Full compliance will be achieved with issuance of a Section 401 permit from the State of Florida. A Section 404(b) Evaluation is included in this report as ***Annex C***.

12.6 CLEAN AIR ACT OF 1972

Coordination with the U.S. Environmental Protection Agency and the Florida Department of Environmental Protection, Air Quality Division determined the proposed project is in partial compliance with the Clean Air Act. No permits will be required at this stage of planning. Full compliance will be achieved with receipt of comments on the Final Programmatic Environmental Impact Statement from the U.S. Environmental Protection Agency.

12.7 COASTAL ZONE MANAGEMENT ACT OF 1972

The study is in partial compliance at this time. Full compliance would be achieved with receipt of comments from the Florida State Clearinghouse. A Federal consistency determination in accordance with 15 CFR 930 Subpart C is included in this report as ***Annex D***.

12.8 FARMLAND PROTECTION POLICY ACT OF 1981

Coordination with the U.S. Department of Agriculture, Natural Resources Conservation Service in Gainesville, Florida to meet the requirements of the Farmland Protection Policy Act is ongoing. Almost all land in central and southern Florida used for agricultural production has been designated unique farmland. This land has a unique combination of soil quality, location, growing season, and moisture supply for producing high value food and fiber crops. The Initial Draft Plan includes several components that may require land in central and southern Florida to be removed from agricultural production. When detailed design information that locates each of the plan components becomes available, it can be determined how many acres of unique farmland will be affected. The Natural Resources Conservation Service will then be asked to complete the required Form AD 1006 to inventory the loss of acres of unique farmland from agricultural production.

12.9 WILD AND SCENIC RIVER ACT OF 1968

The Northwest Fork of the Loxahatchee River is designated a Wild and Scenic River. This resource is not expected to be negatively impacted, and in fact, should benefit from implementation of the proposed Comprehensive Plan. The study is in full compliance.

12.10 ESTUARY PROTECTION ACT OF 1968

The study is in full compliance. The Recommended Plan takes into account the restoration of all the estuaries in the project area. The Draft Fish and Wildlife Coordination Act report (***Annex A***) discuses the restoration components for each of the estuaries and the benefits to the estuaries.

12.11 FEDERAL WATER PROJECT RECREATION ACT OF 1965

The project is in full compliance at this stage. The effects of the proposed action on outdoor recreation have been considered. Continued recreation planning would be performed during detailed project engineering and design.

12.12 RESOURCE CONSERVATION AND RECOVERY ACT OF 1976

This law has been determined to be not applicable, as there are no items regulated under this act either being disposed of or affected by this project.

12.13 TOXIC SUBSTANCES CONTROL ACT OF 1976

This law has been determined to be not applicable, as there are no items regulated under this act either being disposed of or affected by this project.

12.14 MARINE PROTECTION, RESEARCH, AND SANCTUARIES ACT OF 1972

This Act is not applicable. Ocean disposal of dredged material is not proposed as a part of the C&SF Restudy.

12.15 RIVERS AND HARBORS APPROPRIATION ACT OF 1899

The study is in full compliance. The proposed work would not obstruct navigable waters of the United States.

12.16 COASTAL BARRIER RESOURCES ACT

This Act is not applicable. The study area is not in a designated Coastal Barrier Resources Act unit.

12.17 SECTION 904 OF THE 1986 WATER RESOURCES DEVELOPMENT ACT

Section 904 of the 1986 Water Resources Development Act requires that the plan formulation and evaluation process consider both quantifiable and unquantifiable benefits and costs of the quality of the total environment, and preservation of cultural and historical values. The study and report are in full compliance.

12.18 SECTION 307 OF THE 1990 WATER RESOURCES DEVELOPMENT ACT

Section 307 of the 1990 Water Resources Development Act establishes, as part of the water resources development program, an interim goal of no overall net loss of the Nation's remaining wetlands, and a long-term goal of increasing the quality and quantity of the Nation's wetlands. The recommended plan is in full compliance.

12.19 E.O. 11988, FLOODPLAIN MANAGEMENT

The study is in full compliance. The considered alternatives support avoidance of development in the flood plain, continue to reduce hazards and risks associated with floods and to minimize the impact of floods on human safety, health and welfare, and restores and preserves the natural and beneficial values of the base flood plain.

12.20 E.O. 11990, PROTECTION OF WETLANDS

The study is in full compliance. By nature of the project, it involves work in wetlands, and no practicable alternative to working in wetlands exists. Losses and degradation to the beneficial values of wetlands are minimized, and such values are preserved and enhanced. The public has been involved in early planning.

12.21 E.O. 12114, ENVIRONMENTAL EFFECTS ABROAD OF MAJOR FEDERAL ACTIONS

This executive order is not applicable to this study.

12.22 E.O. 12898, ENVIRONMENTAL JUSTICE

Executive Order 12898 requires the Federal government to achieve environmental justice by identifying and addressing disproportionately high adverse effects of its activities on minority and low-income populations. It also requires the analysis of information such as the race, national origin, and income level for areas expected to be impacted by environmental actions. Populations at risk have been profiled in Appendix E (Socio-Economics) in Section 2 (Population and Economy) and Section 12 (Other Social Effects). This profile data includes racial/ethnic population distribution, aged population, percentage of households below the poverty threshold, income, and unemployment, by county for the 16-county study area, as well as for the State and Nation for ranking comparison purposes. Section 12 (Appendix E) also discusses potential community impacts, acknowledging that some negative economic impacts may occur, particularly in rural areas where agricultural land may be converted to water storage facilities. On the one hand, it is acknowledged that the rural communities where reservoirs may be sited are characterized by low income and high unemployment populations, and therefore may be vulnerable to the effects of this part of project implementation. On the other hand, these are areas of low population, so that the affected populations are likely to be small. Further analysis of community impacts will be undertaken when more specific site information is obtained. During detailed implementation of the C&SF project modifications, facilities will be sited with care regarding low income, minority, and other at-risk populations, so as to minimize adverse effects, and if adverse effects cannot be avoided, affected parties will be engaged in dialogue to determine appropriate mitigation.

One of the largest anticipated economic impacts of project implementation (Appendix E, Section 11, Regional Economic Impacts) would be as a result of project spending on construction, land purchases, operation and maintenance. As with all Corps of Engineers projects, contracting action to implement the C&SF Comprehensive Plan will comply with The Small Business Act, as implemented by the Federal Acquisition Regulations and its supplements. Adhering to this policy helps to ensure that a certain percentage of contracting will be directed toward small and disadvantaged firms, which would have a significant positive economic effect on minorities.

Executive Order 12898 also requires Federal agencies to identify the need to ensure the protection of populations relying on subsistence consumption of fish and wildlife, through analysis of information on such consumption patterns, and communication to the public of associated risks. Potential patterns of subsistence consumption of fish and wildlife resources by Native American Tribal members and others, to the extent they exist, are likely to be positively enhanced by the outcome of the Comprehensive Plan. Implementation is expected to increase ecological values in the Everglades natural system, likely resulting in improved opportunities for those engaged in subsistence consumption.

SECTION 13
RECOMMENDATIONS

I am recommending a Comprehensive Plan that will restore, protect, and preserve a natural resource treasure – the south Florida ecosystem. Including the Everglades, this ecosystem is unique and nationally important. I believe that failing to act now will result in the irretrievable loss of an ecosystem, which exist no where else in the world. I am convinced that the Comprehensive Plan will allow us to reverse the course of the past fifty years and leave an Everglades legacy that future generations will be able to enjoy and benefit from.

I find that the south Florida ecosystem, which extends from the Kissimmee River - Lake Okeechobee region through the Everglades and Florida Keys and includes significant estuarine and near-shore communities, provides habitat for diverse species of fish and wildlife while providing important water supply, water quality, flood control, and recreation functions. The south Florida ecosystem, which has been reduced by almost 50 percent, is endangered as a result of adverse changes in the quantity and distribution of water, the timing of flows, and the degradation of water quality. Restoration of this ecosystem is vital to achieve environmental and economic sustainability in the region and to prevent an ecological disaster of unprecedented proportions. Modifications to the Central and Southern Florida Project are required to provide for the restoration, preservation, and protection of the Everglades and the south Florida ecosystem. Such modifications can be undertaken in a manner that allows us to continue to provide and enhance benefits necessary for the economic and social sustainability of the region.

Therefore, I recommend that the Comprehensive Plan, as described in the section of this report entitled “The Recommended Comprehensive Plan,” be approved as a framework and guide for modifications to the Central and Southern Florida Project. I further recommend that the pilot projects and the components for initial authorization, including monitoring, as described in the section of this report entitled “Implementation Plan,” be authorized for construction at 50 percent Federal cost sharing at a total estimated cost of $1,198,000,000 and an annual cost of $20,000,000 for operation and maintenance. The estimated Federal first cost is $599,000,000 with estimated annual operation and maintenance costs of $10,000,000; and the estimated non-Federal first cost is $599,000,000 with estimated annual operation and maintenance costs of $10,000,000. The Water Resources Development Act of 1996 provided authorization for Critical Restoration Projects in order to expedite implementation of the restoration effort. I also recommend approval of a similar programmatic authority to help expedite implementation of some components in the Comprehensive Plan and that the programmatic authority be limited to those components of the Comprehensive Plan that have a total project cost of $70,000,000 with a maximum Federal cost of $35,000,000. Authorization for the remaining components of the Comprehensive Plan will be sought after completion of more detailed planning and submission of Project Implementation Reports to Congress. Each Project Implementation Report will also contain an analysis of the Comprehensive Plan and any recommendations concerning modifications to the plan.

The above recommendations are made with the provision that prior to implementation of each project, the non-Federal sponsor shall enter into a binding agreement with the Secretary of the Army to perform the following items of local cooperation:

a. Provide 50 percent of the total project costs as further specified below:

(1) Enter into an agreement which provides, prior to construction, 25 percent of pre-construction engineering and design (PED) costs;

(2) Provide, during construction, any additional funds needed to cover the non-Federal share of pre-construction engineering and design costs;

(3) Provide all lands, easements, and rights-of-way, including suitable borrow and dredged or excavated material disposal areas, and perform or assure the performance of all relocations determined by the Government to be necessary for the construction, operation, and maintenance of the project;

(4) Provide or pay to the Government the cost of providing all retaining dikes, wasteweirs, bulkheads, and embankments, including all monitoring features and stilling basins, that may be required at any dredged or excavated material disposal areas required for the construction, operation, and maintenance of the project; and

(5) Provide, during construction, any additional costs as necessary to make its total contribution equal to 50 percent of total project costs.

b. Grant the Government a right to enter, at reasonable times and in a reasonable manner, upon land which the local sponsor owns or controls for access to the project for the purpose of inspection, and, if necessary, for the purpose of completing, operating, maintaining, repairing, replacing, or rehabilitating the project.

c. For so long as the project remains authorized assume responsibility for operating, maintaining, replacing, repairing, and rehabilitating (OMRR&R) the project or completed functional portions of the project, including mitigation features, with 50 percent of the funding provided by the Federal government, in a manner compatible with the project's authorized purposes and in accordance with applicable Federal and State laws and specific directions prescribed by the Government in the OMRR&R manual and any subsequent amendments thereto.

d. Comply with Section 221 of Public Law 91-611, Flood Control Act of 1970, as amended, and Section 103 of the Water Resources Development Act of 1986, Public Law 99-662, as amended, which provides that the Secretary of the Army shall not commence the construction of any water resources project or separable element thereof, until the non-Federal sponsor has entered into a written agreement to furnish its required cooperation for the project or separable element.

e. Hold and save the Government free from all damages arising for the construction, operation, maintenance, repair, replacement, and rehabilitation of the project and any project-related betterments, except for damages due to the fault or negligence of the Government or the Government's contractors.

f. Keep and maintain books, records, documents, and other evidence pertaining to costs and expenses incurred pursuant to the project to the extent and in such detail as will properly reflect total project costs.

g. Perform, or cause to be performed, any investigations for hazardous substances that are determined necessary to identify the existence and extent of any hazardous substances regulated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), 42 USC 9601-9675, that may exist in, on, or under lands, easements or rights-of-way necessary for the construction, operation, and maintenance of the project; except that the non-Federal sponsor shall not perform such investigations on lands, easements, or rights-of-way that the Government determines to be subject to the navigation servitude without prior specific written direction by the Government.

h. Assume complete financial responsibility for all necessary cleanup and response costs of any CERCLA regulated materials located in, on, or under lands, easements, or rights-of-way that the Government determines necessary for the construction, operation, or maintenance of the project.

i. To the maximum extent possible, operate, maintain, repair, replace, and rehabilitate the project in a manner that will not cause liability to arise under CERCLA.

j. Participate in and comply with applicable flood plain management and flood plain insurance programs in accordance with section 402 of Public Law 99-662, as amended.

k. Not less than once each year, inform affected interests of the limitations of the protection afforded by the project.

l. Publicize flood plain information in the area concerned and provide this information to zoning and other regulatory agencies for their use in preventing unwise future development in the flood plain, and in adopting regulations as may be necessary to prevent unwise future development and to ensure compatibility with protection levels provided by the project.

m. As between the Federal Government and the non-Federal sponsor, the non-Federal sponsor shall be considered the operator of the project for the purpose of CERCLA liability. To the maximum extent practicable, operate, maintain, repair, replace, and rehabilitate the project in a manner that will not cause liability to arise under CERCLA.

n. Prescribe and enforce regulations to prevent obstruction of or encroachment on the project that would reduce the level of protection it affords or that would hinder operation or maintenance of the project.

o. Comply with the applicable provisions of the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, Public law 91-646, as amended by title IV of the Surface Transportation and Uniform Relocation Assistance Act of 1987 (Public Law 100-17), and the Uniform Regulations contained in 49 CFR part 24, in acquiring lands, easements, and rights-of-way, and performing relocations for construction, operation, and maintenance of the project, and inform all affected persons of applicable benefits, policies, and procedures in connection with said act.

p. Comply with all applicable Federal and State laws and regulations, including Section 601 of the Civil Rights Act of 1964, Public Law 88-352, and Department of Defense Directive 5500.11 issued pursuant thereto, as well as Army Regulation 600-7, entitled “Nondiscrimination on the Basis of Handicap in Programs and Activities Assisted or Conducted by the Department of the Army.”

q. Provide 50 percent of that portion of total cultural resource preservation mitigation and data recovery costs attributable to the project that are in excess of one percent of the total amount authorized to be appropriated for the project.

r. Do not use Federal funds to meet the non-Federal sponsor’s share of total project costs unless the Federal granting agency verifies in writing that the expenditure of such funds is expressly authorized by statute.

The recommendations contained herein reflect the information available at this time and current Departmental policies governing formulation of individual projects. They do not reflect program and budgeting priorities inherent in the formulation of a national Civil Works construction program nor the perspective of higher review levels within the Executive Branch. Consequently, the recommendations may be modified before they are transmitted to the Congress as proposals for authorization and implementation funding. However, prior to transmittal to the Congress, the sponsor, the State, interested Federal agencies, and other parties will be advised of any modifications and will be afforded an opportunity to comment further.

Joe R. Miller
Colonel, Corps of Engineers
District Engineer

ACRONYMS AND ABBREVIATIONS,
AND CONVERSION TABLES

GLOSSARY OF TERMS

A

Acre-foot—The quantity of water required to cover 1 acre to a depth of 1 foot. Equal to 43,560 cubic feet (1,233.5 cubic meters).

Affected environment—Existing biological, physical, social, and economic conditions of an area subject to change, both directly and indirectly, as a result of a proposed human action.

Air quality—Measure of the health-related and visual characteristics of the air, often derived from quantitative measurements of the concentrations of specific injurious or contaminating substances.

Anthropogenic—Human-created.

Aquatic—Living or growing in or on the water.

Aquifer—An underground geologic formation in which water can be stored.

Authorization—An act by the Congress of the United States which authorizes use of public funds to carry out a prescribed action.

B

Back Pumping—The process of pumping water in a manner where the water is pumped from a site to a location of source. (e.g. from lake to contributory river).

Benthic—Bottom of rivers, lakes, or oceans; organisms that live on the bottom of water bodies.

Best Management Practice—(BMP) The best available technology or process that is practical and achieves the desired goal or objective.

Biodiversity—The number of different species inhabiting a specific area or region.

Biological opinion—Document issued under the authority of the Endangered Species Act stating the U.S. Fish and Wildlife Service and/or the National Marine Fisheries Service (NMFS) finding as to whether a Federal action is likely to jeopardize the continued existence of a threatened or endangered species or result in the destruction or adverse modification of critical habitat. This document may include:

> ***Critical habitat***—A description of the specific areas with physical or biological features essential to the conservation of a listed species and which may require special management considerations or protection. These areas have been legally designated via Federal Register notices.
>
> ***Jeopardy opinion***—The U.S. Fish and Wildlife Service or NMFS opinion that an action is likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat. The finding includes reasonable and prudent alternatives, if any.
>
> ***No jeopardy opinion***—U.S. Fish and Wildlife Service or NMFS finding that an action is not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat.

C

Candidate species—Plant or animal species not yet officially listed as threatened or endangered, but which is undergoing status review by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service.

Catch—At a recreational fishery, refers to the number of fish captured.

Channel—Natural or artificial watercourse, with a definite bed and banks to confine and conduct continuously or periodically flowing water.

Coastal Ridge—Area of land bordering the coast whose topography is elevated higher than land further inland.

Confined aquifer—An aquifer bounded above and below by impermeable or confining layers of distinctly lower permeability than the aquifer itself.

Conjunctive use—The planned use of groundwater in conjunction with surface water in overall management to optimize water resources.

Conveyance capacity—The rate at which water can be transported by a canal, aqueduct, or ditch. In this document, conveyance capacity is generally measured in cubic feet per second (cfs).

Cooperating agency—This is defined as an agency that meets the following criteria: (1) is included in 40 CFR Chapter V, Council on Environmental Quality (CEQ) Rules and Regulations, Appendix 1 - Federal and Federal-State agency National Environmental Policy Act (NEPA) contacts; and/or (2) has study area-wide jurisdiction by law or special expertise on environmental quality issues; (3) has been invited by the lead agency to participate as a cooperating agency; and (4) has made a commitment of resources (staff and/or funds), for regular attendance at meetings, participation in workgroups, in actual preparation of portions of the programmatic environmental impact statement (PEIS), and in providing review and comment on activities associated with the PEIS as it progresses. The role of the cooperating agency is documented in a formal memorandum of agreement with the lead agency.

Cubic feet per second—A measure of the volume rate of water movement. As a rate of streamflow, a cubic foot of water passing a reference section in 1 second of time. One cubic foot per second equals 0.0283 meter /second (7.48 gallons per minute). One cubic foot per second flowing for 24 hours produces approximately 2 acre-feet.

D

Density—The mass of a substance per unit of volume of that substance; i.e., the density of water changes with changes in temperature.

Dissolved oxygen (D.O.)—A commonly employed measure of water quality.

Dry Season—Hydrologically, for south Florida, two months associated with a lower incident of rainfall, December through April.

E

Ecosystem—A functional group of animal and plant species that operate in a unique setting that is mostly self-contained.

Endangered species—Any species or subspecies of bird, mammal, fish, amphibian, reptile, or plant which is in serious danger of becoming extinct throughout all, or a significant portion of its range. Federally endangered species are officially designated by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service and published in the Federal Register.

Enhancement—Measures which develop or improve the quality or quantity of existing conditions or resources beyond a condition or level that would have occurred without an action; i.e., beyond compensation.

Environmental consequences—The impacts to the Affected Environment that are expected from implementation of a given alternative.

Environmental Impact Statement (EIS)—An analysis required by the National Environmental Policy Act for all major federal actions, which evaluates the environmental risks of alternative actions.

Estuary—A water passage where the tide meets a river current; an arm of the sea at the lower end of a river.

Evaporation—The change of a substance from the solid or liquid phase to the gaseous (vapor) phase.

Evapotranspiration (ET)—Water evaporated from plant and soil surfaces or transpired by plant tissues.

Exotic species—Introduced species not native to the place where they are found.

Extirpated species—A species which has become extinct in a given area.

F

Fallowed land—Cultivated land that lies idle during a growing season.

Feasibility study—The second phase of a project. The purpose is to describe and evaluate alternative plans and fully describe recommended project.

Flow—The volume of water passing a given point per unit of time.

> ***Instream flow requirements***—Amount of water flowing through a stream course needed to sustain instream values.
>
> ***Minimum flow***—Lowest flow in a specified period of time.
>
> ***Peak flow***—Maximum instantaneous flow in a specified period of time.

G

Groundwater—Water stored underground in pore spaces between rocks and in other alluvial materials and in fractures of hard rock occurring in the saturated zone.

Groundwater level—Refers to the water level in a well, and is defined as a measure of the hydraulic head in the aquifer system.

Groundwater pumping—Quantity of water extracted from groundwater storage.

Groundwater seepage—Groundwater flow in response to a hydraulic gradient.

Groundwater table—The upper surface of the zone of saturation, except where the surface is formed by an impermeable body.

H

Habitat—Area where a plant or animal lives.

Heterogeneity—Unlike, dissimilar, not uniform

Hydrologic condition—The state of an area pertaining to the amount and form of water present. For example, saturated ground (water table at surface), lake stage, river flow rate.

Hydrologic response—An observed decrease or increase of water in a particular area.

Hydroperiod—For non-tidal wetlands, the average annual duration of flooding is called the *hydroperiod*, which is based only on the presence of surface water and not its depth.

Hydropattern—A less frequently used but nonetheless important term that refers to depth as well as hydroperiod is *hydropattern*. Hydropatterns are best understood by a graphic depiction of water level (above as well as below the ground) through annual cycles.

I

Indicator species—Organism, species, or community which indicates presence of certain environmental conditions.

Irrigation water—Water made available from the project which is used primarily in the production of agricultural crops or livestock, including domestic use incidental thereto, and the watering of livestock. Irrigation water also includes water used for domestic uses such as the watering of landscaping or pasture for animals (e.g., horses) which are kept for personal enjoyment.

J

Juvenile—Young fish older than 1 year but not having reached reproductive age.

L

Land classification—An economic classification of variations in land reflecting its ability to sustain long-term agricultural production.

Limnology—Scientific study of the physical characteristics and biology of lakes, streams, and ponds.

Littoral zone—The shore of land surrounding a water body that is characterized by periodic inundation or partial saturation by water level. Typically defined by species of vegetation found.

M

Marl—Soil comprised of clays, carbonates and shell remains.

Marsh—An area of low-lying wetland.

Mercury—Heavy metal that is toxic to most organisms when converted into a byproduct of inorganic-organic reaction. Distributed into the environment mostly as residual particles from industrial processes.

Mitigation—One or all of the following: (1) Avoiding an impact altogether by not taking a certain action or parts of an action; (2) minimizing impacts by limiting the degree or magnitude of an action and its implementation; (3) rectifying an impact by repairing, rehabilitating, or restoring the affected environment; (4) reducing or eliminating an impact over time by preservation and maintenance operations during the life of an action; and (5) compensating for an impact by replacing or providing substitute resources or environments.

Model—A tool used to mathematically represent a process which could be based upon empirical or mathematical functions. Models can be computer programs, spreadsheets, or statistical analyses.

Muck lands—Fertile soil containing putrid vegetative matter.

N

Nonconsumptive water use—Water uses including swimming, boating, waterskiing, fishing, maintenance of stream-related fish and wildlife habitat, hydropower generation, and other uses that do not substantially deplete water supplies.

O

Oxygen demand—The biological or chemical demand of dissolved oxygen in water. Required by biological processes for respiration.

P

Peat—Soil rich in humus or organic (exerts of oxygen demand) and is highly porous.

Percolation—In the context of this report, the downward movement of water through the soil or alluvium to the ground-water table.

Phosphorus—Element or nutrient required for energy production in living organisms. Distributed into the environment mostly as phosphates by agricultural runoff (fertilizer) and life cycles. Frequently the limiting factor for growth of microbes and plants.

Physiographic—The genesis and evolution of land forms.

Programmatic environmental impact statement—An environmental impact statement prepared prior to a Federal agency's decision regarding a major program, plan, or policy. It is usually broad in scope and followed by subsequent more narrowly focused National Environmental Policy Act compliance documents such as site-specific environmental assessments and environmental impact statements.

Proposed action—Plan that a Federal agency intends to implement or undertake and which is the subject of an environmental analysis. Usually, but not always, the proposed action is the agency's preferred alternative for a project. The proposed action and all reasonable alternatives are evaluated against the no action alternative.

Public involvement—Process of obtaining citizen input into each stage of the development of planning documents. Required as a major input into any EIS.

R

Recharge—The processes of water filling the voids in an aquifer, which causes the piezometric head or water table to rise in elevation.

Reconnaissance study—The first phase of a project. It has four phases (1) to define problem, (2) asses sponsor’s level of interest and support, (3) decide to progress to feasibility phase based on Federal interest, (4) estimate time and money to complete feasibility study.

Record of Decision—Concise, public, legal document which identifies and publicly and officially discloses the responsible official's decision on the alternative selected for implementation. It is prepared following completion of an Environmental Impact Statement.

Release—For this report, release is an intentional opening up of water control structures to allow stored water to flow out for 2 reasons. First, to lower water stage to acceptable levels. Second, to make available water for water supply demand (e.g., ecological, agricultural, or urban).

Release zone—Zone representing water level differentiation determining manner of release to be performed (e.g. gates wide-open, pulse release to simulate a storm).

Reservoir—Artificially impounded body of water.

Reservoir storage capacity—Reservoir capacity normally usable for storage and regulation of reservoir inflows to meet established reservoir operating requirements.

> ***Flood control storage capacity***—Reservoir capacity reserved for the purpose of regulating flood inflows to reduce flood damage downstream.

Riparian—Areas along or adjacent to a river or stream bank whose waters provide soil moisture significantly in excess of that otherwise available through local precipitation.

S

Scoping—The process of defining the scope of a study, primarily with respect to the issues, geographic area, and alternatives to be considered. The term is typically used in association with environmental documents prepared under the National Environmental Policy Act.

Seepage—Water that escapes control through levees, canals or other holding or conveyance systems.

Semi-confined Aquifer—A condition where the movement of groundwater is restricted sufficiently to cause differences in head between different depth zones of the aquifer during periods of heavy pumping, but during periods of minimal pumping the water levels recover to a level coincident with the water table.

Slough—A depression associated with swamps and marshlands as part of a bayou, inlet or backwater.

Spillway—Overflow structure of a dam.

Stream—Natural water course.

> ***Ephemeral stream***—Flows briefly only in direct response to precipitation.
>
> ***Intermittent or seasonal stream***—Stream on or in contact with the groundwater table that flows only at certain times of the year when the groundwater table is high.
>
> ***Perennial stream***—Flows continuously throughout the year.

Subsidence—A local mass movement that principally involves the gradual downward settling or sinking of the earth's surface with little or no horizontal motion. It may be due to natural geologic processes or mass activity such as removal of subsurface solids, liquids, or gases, ground water extraction, and wetting of some types of moisture-deficient loose or porous deposits.

Surficial aquifer—An aquifer that is closest to the surface and is unconfined. The water level of a surficial aquifer is typically associated with the groundwater table of an area.

T

Tailwater—Water immediately downstream of a water control structure.

Threatened species—Legal status afforded to plant or animals species that are likely to become endangered within the foreseeable future throughout all or a significant portion of their range, as determined by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service.

Tide—Water with relatively high salinity levels and is influenced by earth's diurnal tide cycle.

Tiering—Procedure which allows an agency to avoid duplication of paperwork through incorporation by reference of the general discussions and relevant specific discussions from an environmental impact statement (EIS) of broader scope into a subsequent EIS of narrower scope.

Total supply—Total water supply available to area (surface water plus groundwater).

Tributary—A stream feeding into a larger stream, canal or waterbody.

W

Wastewater reuse—Utilization of water whose source contains contaminants from man-made activities. For example, runoff from developed areas and sewage. Treatment levels are typically associated with deactivation of microbial activity and nutrient removal.

Water budget—An account of all water inflows, outflows and change in storage for a prespecified period of time.

Watershed—A region or area bounded peripherally by a water parting and draining ultimately to a particular watercourse or body of water.

Wetland—A zone periodically or continuously submerged or having high soil moisture, which has aquatic and/or riparian vegetation components, and is maintained by water supplies significantly in excess of those otherwise available through local precipitation.

Wet season—Hydrologically, for south Florida the months associated with a higher than average incident of rainfall, May through October.

Wildlife corridor—A relatively wide pathway used by animals to transverse from one habitat arena to another.

Wildlife habitat—An area that provides a water supply and vegetative habitat for wildlife.

Willing sellers—A term used to describe individuals who would be interested in selling real estate holdings.

GLOSSARY OF ABBREVIATIONS AND ACRONYMS

C	Canal
C&SF	Central and Southern Florida
Co.	County
Corps	U.S. Army Corps of Engineers
I-95	Interstate 95
L	Levee
mgd	Million gallons per day
mg/l	Milligrams per liter
NGVD	National Geodetic Vertical Datum
PEIS	Programmatic Environmental Impact Statement
ppb	Parts per billion
S	Structure
SFWMD	South Florida Water Management District
SR	State Route
USACE	U.S. Army Corps of Engineers
°F	degrees Fahrenheit

Attention: Planning Division

Re: Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement for the Central and Southern Florida Project Comprehensive Review Study (C&SF Restudy)

Dear Colonel Miller:

Thank you for your letter, dated February 19, 1999, clarifying the U.S. Army Corps of Engineers'(Corps) description of the Comprehensive Plan that will be presented in the Final Integrated Feasibility Report and Programmatic Environmental Impact Statement (PEIS) for the Central and Southern Florida Project Comprehensive Review Study (C&SF Restudy). The C&SF Restudy was authorized by section 309(I) of the Water Resources Development Act (WRDA) of 1992 (P.L. 102-580). The Department of the Interior (Department) has prepared the enclosed final Fish and Wildlife Coordination Act (FWCA) report. This fulfills the requirements of section 2(b) of the FWCA (48 Stat. 401, as amended; 16 U.S.C. 661 *et seq.*) and represents the Secretary of the Interior's report to Congress on the C&SF Restudy.

This report supplements the draft FWCA report we provided on August 7, 1998. The majority of our findings in the draft report remain in effect; the attached report serves as an update on the progress made in dealing with the most significant issues raised in the draft. We ask that the Corps include the draft report and this final report as the complete findings of the Secretary of the Interior in publishing the Final PEIS.

We also provided a preliminary programmatic biological opinion on August 7, 1998. Your February 19, 1999, letter requested that the Fish and Wildlife Service (FWS) confirm the preliminary biological opinion as the final biological opinion, based on the Corps' retention of Alternative D13R (addressed in the preliminary biological opinion) as the preferred alternative in the Final PEIS. We concur with your request. Therefore, this concludes consultation at the programmatic level in accordance with section 7 of the Endangered Species Act of 1973, as amended (16 U.S.C. 1531 *et seq.*). Please refer to the closing statement of our preliminary biological opinion regarding circumstances that would trigger the need to re-initiate consultation. We look forward to assisting the Corps in fulfilling its responsibilities under the Endangered Species Act as we proceed into detailed planning of the components of the Comprehensive Plan. The enclosed final FWCA report includes brief reviews of our findings relative to effects on federally listed threatened and endangered species for the 2010 Case Study and the D13R4 scenario, which have been analyzed since issuance of our preliminary biological opinion.

The Conceptual Plan you described in your February 19, 1999, letter creates the opportunity to provide enormous benefit to the South Florida Ecosystem. We commend your staff on their dedication and accomplishment. In particular, we wish to express gratitude to the technical staffs of the Corps and the South Florida Water Management District who worked tirelessly under extreme time constraints to address the most significant issues raised in the draft FWCA report. We are extremely encouraged by the progress made in addressing these issues, which is summarized in a table in the enclosed final FWCA report. Your February 19 letter included a number of commitments to approach future efforts in a manner consistent with the Department's recommendations in the enclosed report, and we express the Department's commitment to cooperate with you during detailed project design to translate those concepts to specific structural and operational features.

We believe that the multi-agency Restudy Team displayed a strong commitment to fully resolve the issues we raised in the draft FWCA report. Sustaining this level of commitment as we proceed with implementation will ensure that the Comprehensive Plan serves as the foundation for restoration of the natural values of the South Florida Ecosystem. We look forward to working with you on these next steps in implementation of the Comprehensive Plan.

Sincerely,

Stephen W. Forsythe
State Supervisor
U.S. Fish and Wildlife Service

Sincerely,

Richard G. Ring
Superintendent
Everglades National Park

Draft Fish and Wildlife Coordination Act Report

I. Introduction

This final Fish and Wildlife Coordination Act (FWCA) report supplements the August 7, 1998, draft FWCA report, providing an update of the progress in addressing the outstanding issues raised in the draft report. Both the draft and final FWCA reports should be included as attachments to the Corps of Engineers' (Corps) final Programmatic EIS, and the coupled FWCA reports, constitute the report of the Secretary of the Interior in accordance with section 2(b) of the FWCA. The Florida Game and Fresh Water Fish Commission (GFC) is providing a separate FWCA report, which will constitute the views and recommendations of the State wildlife agency.

Development of the Implementation Plan and the associated modeling of the 2010 Case Study are among the more significant accomplishments since delivery of the draft FWCA report. The Department of the Interior's (Department) comments on these efforts were addressed in a Planning Aid Letter (PAL), dated February 18, 1999, which is incorporated into this report as Appendix E. This final FWCA report supplements the discussion of the 2010 Case Study in the PAL with a discussion of its potential effects on federally listed threatened and endangered species. This report highlights selected recommendations provided in the PAL.

This report includes important analyses of recent modeling scenarios ($D13R_{1-4}$) and the preparation of issue papers on the most significant outstanding issues raised in the draft FWCA report.

The purpose, scope, and authority for the C&SF Restudy are described in the draft report. That report also provided brief summaries of the evolution of project designs and the evaluation methodology, which can be reviewed in more detail on the Restudy website: http://141.232.1.11/org/pld/restudy/hpm/index.html.

II. Progress Report on Key Issues Raised by the Department

The list of 14 issues in Table 1 was derived from the draft FWCA report (August 1998). This table is provided to summarize any progress in addressing these issues between September 1998 and January 1999. The Department understands that the issues raised in the draft FWCA will require long-term efforts to resolve. The additional modeling of the D13R1 through D13R4 scenarios was largely in response to the most prominent of the issues raised in the draft FWCA report.

Members of the Restudy Team held a series of multi-agency meetings, to deal with the highest priority issues, which were directly related to identified inadequacies in the performance of Alternative D13R. The participants decided that issue papers were needed for the first four items listed in Table 1. The intent was to circulate these issue papers for discussion and approval by the full membership of the Alternative Evaluation Team (AET). Issue papers on the St. Lucie Estuary, Biscayne Bay ecological restoration, and Biscayne Bay reuse followed that procedure. The original plan called for separate issue papers for the southern Everglades and Florida Bay, and for the northern and central Everglades. However, issues in these two areas were combined into a single issue paper for the Everglades, and this is attached as Appendix A. An issue paper has also been prepared on water quality, but it is being revised to include the proposed features of the D13R4 scenario, and it is not available to be included as an appendix to this report. The issue papers included as appendices to this report are the following:

Appendix A – Everglades Issue Paper
Appendix B – Issue Paper on Freshwater Flow to Biscayne Bay
Appendix C – Issue Paper on Flows to Biscayne National Park Utilizing Reuse
Appendix D – St. Lucie Estuary Issue Paper

Table 1. Summary of Progress on the Fourteen Issues in the Draft FWCA Report

ISSUE	PROGRESS
1) Increase total overland flow to Florida Bay, Northeast Shark River Slough (NESRS) and Taylor Slough to more fully reach NSM targets.	The D13R4 scenario was developed and evaluated by the AET. This demonstrated the flexibility in the conceptual plan for more closely approaching restoration targets for the southern Everglades and Biscayne Bay. D13R4 would substantially increase flows through Shark River Slough, improve hydroperiod in the Rocky Glades, and improve the salinity regime in the coastal basins adjacent to Florida Bay. An Everglades issue paper has been prepared discussing the performance of D13R4 and the trade-offs in meeting all restoration goals in the Everglades basin. **ACTIONS NEEDED:** Develop and implement a phased approach which resolves problems related to water delivery and water quality as increased volumes of water are captured.
2) Increase ecological performance in the WCAs by eliminating damaging high and low water conditions.	The D13R4 scenario was not entirely successful in producing desirable depth regimes in the WCAs while at the same time improving flows to NESRS. The Everglades issue paper discusses points of complete and partial agreement on restoration goals and recommends steps to better define and resolve the relative importance of hydrologic parameters in reaching short-term and long-term restoration goals. **ACTIONS NEEDED:** Resolve remaining operational problems affecting ecological performance in the WCAs, with emphasis on meeting all restoration goals.
3) Improve ecological conditions in Biscayne Bay by restoring more natural fresh water inflows, separate from the wastewater reuse proposed in D13R.	The D13R4 scenario demonstrated the potential to increase the average annual flow to Biscayne Bay by 77,000 acre-feet. This would significantly improve ecological conditions in the southern Bay, including Biscayne National Park, and the central Bay. Implementation of the D13R4, however, is contingent on resolving the water quality concerns and the effects on the WCAs. Two issue papers were prepared for Biscayne Bay, one dealing with the implications of the proposed water reuse component, the other with ecological implications of increased flow to the estuaries. **ACTIONS NEEDED:** Continue to emphasize the natural delivery of good quality fresh water flows to Biscayne Bay, in lieu of wastewater reuse.

ISSUE	PROGRESS
4) Restore target fresh water inflows and water quality in the St. Lucie Estuary.	A St. Lucie Estuary issue paper was prepared that summarizes views on the performance of Alternative D13R and recommends ways to enhance current planning activities through the Indian River Lagoon Feasibility Study. The C-44 basin storage is included in the proposed initial authorization (WRDA 2000). The St. Lucie Issue Team Interim Report (October 1998) recommended more immediate restoration actions to the Working Group. **ACTIONS NEEDED:** Ensure compatibility of Issue Team Interim Report recommendations with the Comprehensive Plan and proceed with Indian River Lagoon Feasibility Study.
5) Restore water quality throughout the Kissimmee-Okeechobee-Everglades watershed.	The Water Quality Subteam for the Restudy has met several times since September and has prepared an issue paper that includes discussion of the most significant aspects of the Restudy related to water quality. That issue paper is being updated to address the features included in the D13R4 scenario. The PEIS proposes to initiate a Comprehensive Integrated Water Quality Plan Feasibility Study. **ACTIONS NEEDED:** Expedite completion of the Water Quality Plan Feasibility Study to ensure that sufficient water quality components are included in the Comprehensive Plan.
6) Ensure adequate water volume is available to restore natural areas.	The Governor's Commission for a Sustainable South Florida report on the Restudy recommends that a "reservation" of water for natural areas can only be considered after urban and agricultural consumers have an assured water supply. This brings into question whether sufficient water volumes will ultimately be available to restore natural areas. **ACTIONS NEEDED:** Develop assurances that adequate water volumes remain available to restore the natural areas.
7) Establish an Exotic Animal Task Team.	The Working Group has established an interagency team led by NOAA. This will involve a long-term effort. **ACTIONS NEEDED:** Continue to work on this issue during project implementation, with the goal of developing an exotic animal plan in the next five years.
8) Current wetland mitigation permitting practices are shrinking the spatial extent of wetlands and supplanting ecological benefits attributable to the C&SF Restudy.	A threshold for determining when wetland restoration benefits attributable to the Comprehensive Plan are supplanted by regulatory permit actions, and a separable mitigation plan to compensate for losses of existing mitigation sites during implementation of the Comprehensive Plan, are immediate issues yet to be resolved. **ACTIONS NEEDED:** Expedite the development and implementation of the Comprehensive Wetland Permitting and Mitigation Strategy, ensuring coordination with the Restudy and State and Federal wetland regulatory programs.
9) The Water Preserve Areas are under continued and rapid threat of development.	The Project Implementation Report (PIR) for the Water Preserve Areas is a high priority in the Restudy's Implementation Plan. Detailed hydrologic modeling will commence this year. A multi-agency baseline field survey has been initiated, including an evaluation of existing wetland conditions in the Water Preserve Areas (WPAs) using the Wetlands Rapid Assessment Procedure. **ACTIONS NEEDED:** Ensure that the Water Preserve Area Feasibility Study is expedited, and that adequate land is purchased to ensure its full implementation.

ISSUE	PROGRESS
10) Improve identification of suitable lands to site water storage and treatment areas to minimize impacts on fish and wildlife resources.	Land acquisition is proceeding in the EAA; the Department is not concerned about the siting within the EAA. The Indian River Lagoon Study has made some progress in identifying storage sites in Martin and St. Lucie counties. The Department will assist the Corps in siting storage in the Caloosahatchee basin, north of Lake Okeechobee, Taylor Creek/Nubbin Slough, and other areas to minimize impacts on wildlife habitat. **ACTIONS NEEDED:** Integrate fish and wildlife conservation and enhancement measures during site selection for project land acquisition.
11) Develop a Scheduling, Sequencing and Priorities Strategy for implementing the Comprehensive Plan.	The Department has participated in meetings of the Restudy Implementation Team and has commented on the draft Implementation Plan (See Appendix E). **ACTIONS NEEDED:** Review and refine final Implementation Plan as necessary.
12) Expedite Feasibility Studies to further overall ecosystem restoration.	The PEIS and the Implementation Plan have included the intent to carry out the Southwest Florida, WPAs, Indian River Lagoon, Biscayne Bay, Florida Bay and Florida Keys, and Comprehensive Integrated Water Quality Feasibility Studies. **ACTIONS NEEDED:** Continue emphasis on expeditious completion of these feasibility studies.
13) Recreational opportunities must be maintained during implementation of the Comprehensive Plan.	This task must be carried out in development of the PIRs for each set of components. The GFC and DEP should be consulted regarding development of recreational plans on all State lands. **ACTIONS NEEDED:** Plan for and accommodate recreational needs during project implementation.
14) Develop a strategy to manage technological uncertainty and trade-off decision making.	The Implementation Plan has included six high priority pilot studies to test the feasibility of uncertain technologies presently included in the Comprehensive Plan. Several of the issue papers include recommendations to fill gaps in our scientific knowledge allowing better prediction of ecological responses. The proposed RECOVER team will play a role in interpreting empirical data obtained through the pilot projects and monitoring studies in natural areas and in independent scientific review. **ACTIONS NEEDED:** Emphasize coordinated and timely development of this strategy.

III. Review of the Performance of the D13R4 Scenario

A. Background

During the week of January 11-15, 1999, hydrologic modelers, engineers, and ecologists met to develop and evaluate a series of scenarios (referred to by some as the “New Water” scenarios) to explore the potential to capture additional volumes of fresh water, primarily intended to improve performance of Alternative D13R in the southern Everglades and Biscayne Bay. This intensive series of water model runs and evaluations was prompted mainly by comments in the Department’s draft FWCA report that stressed the need to address the most significant deficiencies of Alternative D13R prior to the Corps' completion of the final Programmatic EIS on the Restudy. This section focuses on the performance of the D13R4 scenario, which was the latest version of that week's series of model runs and was the center of discussion in the AET's review on January 20, 1999.

The D13R4 scenario captured urban and suburban runoff that had previously flowed to tide in the C-51 basin in Palm Beach County and the C-14/C-13 basins in Broward County. Modelers estimated the average annual volume of water captured from these sources at about 245,000 acre-feet. The majority of this water would be stored and treated either in the proposed Central Palm Beach County Storage Area or the proposed Site 1 Reservoir before being sent to WCA 2A. In addition to the more efficient capture of urban and suburban runoff, D13R4 included a change in distribution of flow from STA 3/4 and other operational changes within the WCAs, which would increase the total volume of "new water" potentially available for delivery to natural areas by an annual average of 271,000 acre-feet. The D13R4 scenario also altered the way water was released from the S-356 structures into northeast Shark River Slough. More details on the design of D13R4 are available on the Restudy website.

B. Evaluation of Results

No significant differences were noted relative to D13R for Lake Okeechobee, the St. Lucie River estuary, the Caloosahatchee River estuary, or the Big Cypress basin.

The reduction in freshwater flows to Lake Worth lagoon, as a result of the capture of flows that would otherwise be delivered through C-51, is considered to be a beneficial change relative to D13R. The target salinity envelope for Lake Worth Lagoon was established as between 23 ppt and 35 ppt, which is within the tolerance range of most commercially and recreationally important estuarine species. This target salinity range was correlated with freshwater inflows ranging from 0 cfs to 500 cfs. D13R4 resulted in a decrease from 96 to 22 occurrences in the simulation period of flow events greater than 500 cfs. This is expected to increase the growth of seagrass and other submerged aquatic vegetation that serves as feeding, sheltering, and breeding habitat for a variety of estuarine animals in Lake Worth Lagoon.

Significant benefits were observed under the D13R4 scenario in the areas where the intended improvements in performance were designed to occur – the southern Everglades and Biscayne Bay. Total overland flow volume into Everglades National Park would increase on an annual average by 267,000 acre-feet (from 1,159,000 acre-feet/yr. to 1,426,000 acre-feet/yr.) Average annual overland flow westward through a cross-section of Shark River Slough in Everglades National Park would increase from 1,097,000 acre-feet/yr. to 1,255,000 acre-feet/yr. The increased flows of fresh water through that cross-section are expected to enhance estuarine productivity in Whitewater Bay and the western portions of Florida Bay. Total southward flows to eastern Florida Bay via the Craighead Basin, Taylor Slough and the eastern panhandle of Everglades National Park would average 159,000 acre-feet/yr. with Alternative D13R and would rise to 175,000 under the D13R4 scenario. This added flow is expected to provide a more favorable salinity regime for coastal waters of eastern Everglades National Park and eastern Florida Bay.

The following performance measures, relating to water stages at Well P33 in central Shark River Slough, were used by the AET as an index to evaluate alternatives with respect to their effect on freshwater flows to estuaries. One measure is the number of months during the period of record when stages equal or exceed 6.3 feet msl at P33. Stages above 6.3 feet at P33 correspond to a reduced frequency of undesirable high salinity events in the coastal basins. A second measure is the number of months during the period of record when stages equal or exceed 7.3 feet msl at the P33 gage. Stages above 7.3 feet at P33 correspond to an increased frequency of desirable low salinity events in the coastal basins. Table 2 includes results for Alternative D13R, the D13R4 scenario, relative to NSM. D13R4 clearly comes closer to the NSM target for both performance measures.

Table 2. Number of months during 31-year simulation when stages exceed specified elevations at the P33 well in Shark River Slough

Performance measure	D13R	D13R4	NSM
Well P33 water level > 6.3 ft	228	235	258
Well P33 water level > 7.3 ft	18	23	30

The increased flows to the coastal basins adjacent to Florida Bay are expected to generally increase estuarine productivity. This would include an expected increase in foraging and successful nesting of wading birds in the mangroves and anticipated benefit for two federally listed endangered species – the American crocodile and the West Indian manatee.

The D13R4 scenario would increase freshwater flows to Biscayne Bay on an annual average basis by 77,000 acre-feet, to an average annual total of 851,000 acre-feet, compared to 774,000 acre-feet under D13R. Ecological benefits would be expected in wetlands and nearshore habitats in southern Biscayne Bay, including portions of Biscayne National Park. Central Biscayne Bay also would meet its recommended target of mean annual flow under the D13R4 scenario, whereas Alternative D13R fell short of the target. Overall, the performance of D13R4 in Biscayne Bay is excellent, except for flows through Snake Creek into northern Biscayne Bay, which would remain below the target under both D13R and D13R4.

The Department's draft FWCA report called for improved performance for the southern Everglades and Biscayne Bay as described above, while at the same time more closely approaching restoration targets for the WCAs. The draft FWCA cited potentially damaging high water and low water extremes in several regions of the WCAs in Alternative D13R that needed to be corrected. The following paragraphs discuss remaining difficulties in achieving restoration targets in the WCAs in the D13R4 simulation.

Simulation of the D13R4 scenario predicts mixed results for the WCAs. Loxahatchee NWR (WCA 1) would not be affected by the D13R4 scenario, relative to D13R. Some regions of WCAs 2 and 3 would not be significantly altered, others are slightly improved, and others are predicted to be adversely affected.

Increased flow through WCA 2B would improve hydroperiod and reduce the frequency of extreme low water conditions in the presently over-drained northern and eastern portions. Another example of improved performance is the predicted reduction in the frequency of extreme high water in Indicator Region 19 of WCA 3A, from 19 % in D13R to 15% in D13R4.

However, predicted performance of D13R4 in one region of WCA 2A and two regions of WCA 3B raises substantial concern about possible degradation of the current quality of fish and wildlife habitat. Performance worsened in the D13R4 scenario relative to D13R in terms of the frequency of extreme high water stages (>2.5 feet deep) in Indicator Region 24 (WCA 2A, south), Indicator Region 15 (WCA 3B, west) and Indicator Region 16 (WCA 3B, east). The percent of time during the simulation when the high water criterion was exceeded in Indicator Region 24 increased from 1% to 3%. It is not clear whether this slight increase would cause significant ecological damage, however, this is an increase in the frequency of adverse conditions relative to the performance of D13R, and is higher than the NSM, the 1995 Base, and the 2050 Base. The predictions for WCA 3B appear more likely to result in a significant increase in the period of extreme high water in the D13R4 scenario, relative to Alternative D13R. Alternative D13R4 would increase the percentage of extreme high water from 3% to 5% and from 5% to 11% in Indicator Regions 15 and 16, respectively. These percentages are equivalent to or higher than the 2050 Base, which is in turn higher than the NSM and the 1995 Base.

High water conditions would, therefore, be more frequent in the D13R4 scenario when compared to both alternative D13R and the future without project condition. This raises concern regarding balancing ecological trade-offs when restoring flow patterns and volumes versus maintaining appropriate water depths in the remnant Everglades, particularly in the WCA3B/Pennsuco Wetlands/Northeast Shark Slough areas.

Separate sections of this final FWCA report summarize the probable effects of the D13R4 scenario on federally listed threatened and endangered species and the Department's heightened concern about adequately addressing water quality in the Comprehensive Plan.

C. Summary

In summary, the D13R4 scenario was quite successful in demonstrating the ability to capture and re-route additional water to more fully achieve restoration targets for the southern Everglades and Biscayne Bay. However, D13R4 was not entirely successful in meeting those restoration targets while at the same time improving performance in the WCAs, which was one of the Department's recommendations for improvement included in the draft FWCA report. It has demonstrated the significant contribution in water volumes deliverable to natural areas through more efficient capture of urban and suburban runoff from Palm Beach and Broward counties. These features need to be explored in more detailed design of the components of the Comprehensive Plan. However, the final design of the components must ensure not only that adverse hydrologic conditions are avoided in the WCAs, but also that they more closely approach restoration targets.

D. Recommendations:

Central and Southern Everglades

1. The final plan as implemented should include the components from the D13R4 scenario that can provide an improved capability for delivery of additional water to Everglades National Park and Biscayne Bay up to the amount in the Dl3R4 scenario by capturing additional runoff from urban areas. The Implementation Plan should include a phased approach to provide for improvement and eventual full recovery of the WCAs, ENP, Biscayne Bay and those other natural areas that have been adversely affected by the C&SF Project. The ultimate amount of additional water recaptured and its distribution should be determined based on this phased approach and its ability to maximize ecological benefits in each of those areas.

2. The Corps should give high priority to examining those groups of components related to movement of water from the central Everglades to the southern Everglades, including but not limited to, L-29 and L-67 A and C. The final plan as implemented should be flexible enough to develop and substitute components during implementation that significantly reduce the operational and ecological trade-offs in balancing the restoration of flow patterns and volumes with the maintenance of appropriate water depths in the remnant Everglades, particularly in the WCA 3B/Pennsuco Wetlands/Northeast Shark Slough areas.

3. The Department recommends that the Corps not commit to the specific details of the L-67 levee component as conceived in either Alternative D13R or the D13R4 scenario. The long-term solution needs to maximize, to the extent possible, the joint restoration of both depth and flow patterns in the central/southern Everglades. For the Modified Water Deliveries/2010 Case Study time period, a set of passive features in L-67 having a combined flow capacity that does not exceed the current outlet capacity of the structures along L-29 should be designed and implemented. These initial features would avoid excessively deep water conditions in WCA 3B and would be more easily modified, depending on the final configuration of this component after removal of L-29 and the other features included in the Comprehensive Plan.

4. Both Alternative D13R and the D13R4 scenario presently use S-140 as a means to introduce water into northern WCA 3A. Although this approach has shown some positive results, detailed design through the PIR process is necessary for restoration of hydropatterns in northern WCA 3 A, which incorporates a better balance between the use of the S- 140 as a point of discharge and a series of inflow structures to spread out flow along the northern and western boundary of WCA 3A. This approach during the PIR process is intended to provide greater flexibility in distribution of inflows to the WCAs.

Biscayne Bay

1. The Comprehensive Plan is intended to provide surface water flows sufficient to meet restoration targets for Biscayne National Park and Biscayne Bay. In the meantime, surface water flows should meet or exceed the 1995 Base condition, and there should be neither any

annual or seasonal net loss in the total volume nor any reduction in the spatial and temporal distribution of combined surface and groundwater flows.

2. Every effort should be made to find sources, storage, and means of distribution of water to Biscayne Bay that (a) require minimal water treatment to reach ambient water quality in southern Biscayne Bay, (b) are likely to receive adequate funding, (c) have the greatest probability of success, (d) can achieve current and future restoration targets, and (e) for which the long-term environmental and economic consequences can be reasonably predicted (*e.g.* use reuse water as a last resort).

3. To avoid serious delay in the restoration of Biscayne Bay and Biscayne National Park, studies needed to verify restoration targets and assess the feasibility of restoration actions should be funded and conducted early in the implementation phase. The Biscayne Bay Feasibility Study, in particular, must be given a very high priority.

IV. Water Quality Concerns Raised By The D13R4 Scenario

Chapter VIII of the Department's draft FWCA Report (August 1998) discussed water quality concerns of the Interim Draft Plan, particularly the phosphorus removal capability of the proposed STAs, and the need to consider the effects of other environmental pollutants on fish and wildlife resources. The Restudy's Water Quality Team has drafted an issue paper addressing these and additional water quality issues. Among the principal areas of concern in the draft issue paper are: 1) remediation of nutrient loading in Lake Okeechobee, 2) water quality concerns in the St. Lucie Estuary, and 3) construction of an additional STA proposed by the Miccosukee Tribe of Florida to treat the anticipated increase in runoff volume that would be delivered to WCA 3A. That issue paper is being revised to include the additional water quality concerns associated with the D13R4 scenario.

The D13R4 scenario was devised and modeled mainly to increase flow volumes to Biscayne Bay and Everglades National Park (ENP). This scenario attempts to capture additional water from urban and suburban runoff and wet season flows from urbanized canals that was being lost to tide. This will improve water quality in Lake Worth Lagoon, which is the current receiving body of water for this flow. However, D13R4 represents a fundamental change in water routing relative to all previous Restudy model runs in that it sends water carrying higher pollutant loads to Biscayne Bay and Everglades National Park, which have an Outstanding Florida Waters designation. Sending this water to the Everglades increases the concern expressed in our draft FWCA report that the Comprehensive Plan does not include enough treatment capacity to handle the additional flows destined for the Everglades.

The D13R4 scenario presents a number of water quality concerns and a key factor for the re-routing is the need for additional sites to handle water treatment. The size and detention time of the proposed Site 1 STA to adequately treat nutrients and other pollutants is of particular concern. An analysis of the routing and detention times required for the additional treatment facilities will need to be completed during detailed planning. The proposed site for the buffer zone through which this water would be distributed into ENP has not yet been acquired.

Existing water quality monitoring data for the canals from which this additional water will be captured should be examined to determine the classes of pollutants and their concentrations. This may require a more advanced and detailed water quality monitoring program for these canals. Additional water quality modeling using these estimates of pollutant loads is planned to assess the implications of this new water. However, that analysis will not be finished in time to be reviewed in this FWCA report. A preliminary estimation of the flow-weighted mean concentration of phosphorus in water from the C-51, C-15, C-16, and Hillsboro basins is 166 ppb. Using this figure and the additional flow volumes needed to be treated in the Site 1 reservoir/STA in the D13R4 scenario, the South Florida Water Management District has made a preliminary determination that the Site 1 facility as described in D13R is too small. Improved evaluations of the appropriate size for this and the other proposed storage and treatment facilities must be conducted.

Recommendation:

Although the D13R4 scenario presents many challenges with respect to water quality, the Department recommends that sufficient water treatment capacity be built into the plan to handle the increased water volumes needed to achieve the hydrologic characteristics as were observed in Biscayne Bay and Everglades National Park under D13R4. Additionally, more thorough monitoring of a variety of pollutants will be required in the basins from which this water will be derived. These data will provide better estimates of the sizes of storage areas needed for initial treatment. Selection of appropriate technology for supplemental treatment (in addition to the STAs) must consider the potential ecological effects of all pollutants, not just phosphorus. The Draft Implementation Plan proposes development of a Comprehensive Integrated Water Quality Plan for the Restudy. The Department recommends that the water quality plan be given priority and that additional funding be specifically identified for this purpose in WRDA 2000 to ensure that adequate resources are expeditiously applied to this important effort.

V. Threatened and Endangered Species

A. Introduction

The August 7, 1998, preliminary programmatic biological opinion addressed Alternative D13R, which will remain the Corps'selected plan in the Final Programmatic EIS. The biological opinion determined that the Comprehensive Plan was not likely to jeopardize the continued existence of any federally listed species or adversely modify their critical habitats. Table 3 provides a summary in three categories of the determinations of likely effect.

Table 3. Summary of the Determinations in the Programmatic Biological Opinion

Species	Likely to Benefit	Likely to Benefit Overall, but Localized and/or Temporary Adverse Effects Also Likely	Likely to Adversely Affect, but not Likely to Jeopardize
West Indian manatee	ö		
American crocodile	ö		
Okeechobee gourd	ö		
Snail kite		ö	
Wood stork		ö	
Cape Sable seaside sparrow		ö	
Bald eagle			ö
Audubon's crested caracara			ö
Eastern indigo snake			ö
Florida scrub jay			ö

The preliminary biological opinion on the Restudy provided, as best can now be determined at this programmatic level, Reasonable and Prudent Measures to minimize incidental take of listed species. The opinion generally described several required actions: 1) designing and implementing a detailed monitoring and adaptive management program, 2) seeking advice from natural resource professionals to site water treatment and storage areas, 3) consulting with the FWS and other natural resource professionals during detailed planning and construction to minimize effects on listed species, and 4) sequencing the construction and operation of components in a way that will maximize benefits and minimize adverse effects on listed species.

Subsequently, we have reviewed model results for the 2010 Case Study and the D13R4 scenario. These additional model runs provide a sense of the range of flexibility in Alternative D13R. At the conceptual level of detail governing all of these simulations, we find that the findings of our preliminary biological opinion remain in effect. The following sections provide summaries of the possible implications of the additional simulations and recommendations to proceed into detailed design of components.

B. Brief Evaluation of the 2010 Case Study

Overall, the 2010 Case Study provides very little of the benefit to threatened and endangered species predicted for D13R. For the Cape Sable seaside sparrow, the 2010 Case Study provides some of the benefits expected from D13R and is a significant improvement over the 2050 Base. For the wood stork, the 2010 Case Study is not significantly different from the conditions in the 1995 Base, and does not provide any of the benefits predicted under D13R conditions. Snail kite index results show no significant difference between the 2010 Case

Study and 2050 Base foraging conditions under dry conditions. In average-to-wet years, the 2010 Case Study is a slight improvement over the 2050 Base. The 2010 Case Study does not show improvements in Shark Slough snail kite habitats that would provide additional suitable kite habitat compensating for the loss of habitat in WCA 3A during dry periods. The 2010 Case Study shows no change from the 2050 Base for the American crocodile or the West Indian manatee.

Recommendations: Our, February 18, 1999, PAL recommended that the 2010 Case Study be revisited to see if optimizing reservoir performance, reordering the implementation schedule, or phasing or breaking components down into increments might improve performance by 2010, more closely approaching the expected benefits of the final Comprehensive Plan. This approach would include consideration of the effects on threatened and endangered species summarized above. Effective monitoring of environmental responses (habitat changes, populations of listed species, and/or key life history requirements of listed species) in this phased approach will provide more useful information to assess the effects of interim actions and improve the performance by 2010 for listed species.

C. Brief Evaluation of the D13R4 Scenario

The likely effects of D13R4 on threatened and endangered species include two areas of concern and some beneficial effects. Cape Sable seaside sparrow population predictions from the ATLSS models (for the western subpopulation only) show a greater tendency for very low numbers under the D13R4 hydrologic conditions, when compared to D13R. The FWS believes that there is potential for significant adverse effects to the Cape Sable seaside sparrow within the range of flexibility demonstrated for Alternative D13R in running the D13R4 scenario. Although D13R4 appears to provide improved habitat conditions for the sparrow relative to the 2050 Base, according to the best scientific information now available, the 2050 Base would likely lead to extinction of the sparrow. For the snail kite, foraging conditions are good for both D13R4 and 2050 Base across many parts of the remaining Everglades. However, under D13R4, water levels are too high in portions of each of the WCAs to provide effective snail kite foraging. In addition, losses of snail kite nesting substrate in these areas, particularly in WCA-3B, would be expected due to the increased frequency of deep water conditions produced by D13R4. Significant improvements are expected for wood storks, American crocodiles and West Indian manatees under D13R4.

Recommendations: Our long-term recommendation is to continue the same approach recommended above for the 2010 Case Study. We are confident that with enlightened management, the various species that evolved to co-exist in south Florida can not only be saved from extinction, but also can be made more secure through recovery actions. This will require the proper balance in hydrologic conditions and other factors affecting habitat quantity and quality. We will only be able to determine and put into practice this proper balance through incremental steps in the implementation, testing, monitoring, and adjustment of the Comprehensive Plan. In addition to finding that balanced management, we must ensure that the transition from currently degraded habitat conditions to the preferred management condition involves the correct sequence of changes and a rate allowing populations of threatened and endangered species to adjust. Two of the most prominent examples (although certainly not the only ones) are:

1. Habitat for the Cape Sable seaside sparrow in northeast Shark River Slough must be enhanced and occupied prior to increasing the hydroperiod in the habitat for the subpopulation west of Shark River Slough. Hydrologic conditions expected to result from implementation of the Restudy are significantly different from hydrologic conditions under the current Experimental Water Deliveries program, which resulted in the FWS' February 19, 1999, jeopardy biological opinion. That opinion concluded that the current hydroperiod in the western habitat is contributing to jeopardy conditions for this subspecies. However, implementation of the Modified Water Deliveries project and the additional features of the Restudy would dramatically improve conditions in the sparrow's eastern habitats, providing additional flexibility for management of sparrow habitat, provided that conditions likely to result in extirpation of the western subpopulation continue to be avoided. In essence, the FWS' assessment of the short-term risk to the sparrow as expressed in the Experimental Water Deliveries biological opinion is heightened by the current scarcity of suitable habitat to the east and the limited flexibility available in the present water management system.

2. Habitat for the snail kite must be enhanced and expanded in Shark River Slough in Everglades National Park before the impounded areas of the WCAs currently used by snail kites are restored to a more hydrologically connected condition.

Careful monitoring and adjustment in management will ensure that these and other species will have adequate time to adjust and recover in the period of transition.

D. The Role of the Restudy in Implementation of the Multi-Species Recovery Plan

The FWS' February 24, 1988, letter to the Corps provided recommendations to help promote recovery of threatened and endangered species through implementation of the Restudy. This is in keeping with Federal Agencies' mandate under section 7(a)(1) of the ESA to do more than merely avoid the elimination of a protected species, but to "utilize their authorities in furtherance of the purposes of this chapter by carrying out programs for the conservation of endangered and threatened species…" 16 U.S.C. 1536(a)(1). Conservation is defined in the ESA as "the use of all methods and procedures which are necessary to bring any endangered species or threatened species to the point at which the measures provided pursuant to this chapter are no longer necessary." 16 U.S.C. 1532(3).
That letter provided a synopsis of the general habitat management practices and species-specific management actions (for those species the FWS considered relevant to the Restudy) contained in the FWS' draft Multi-Species Recovery Plan for the Threatened and Endangered Species of South Florida (MSRP).

The FWS has strived to ensure that the Comprehensive Plan is compatible with the MSRP and vice versa. Some of the key sections of the MSRP dealing with wetland-dependent threatened and endangered species were written by the same FWS employees involved in the Restudy. We are confident that the already substantial benefits to threatened and endangered species expected to arise from implementation of the Comprehensive Plan can further promote recovery of listed species, if this plan is coupled with the Corps' commitment to carry out the positive conservation intent expressed in section 7(a)(1). Please review our February 24, 1998, letter and work with us to focus the Comprehensive Plan towards carrying out any of the recovery actions included there.

VI. The Need for Further Multi-Agency Review of the Other Project Elements (OPEs)

The Department's comments on the draft PEIS (December 23, 1998, letter from James H. Lee to Russell Reed) pointed out that the evaluation and selection of OPEs was not performed by a multi-agency team. Further, there appears to be an inconsistency between the draft PEIS and the January 25, 1999, draft Implementation Plan in their discussion of: projects already authorized as Critical Projects under WRDA 1996; projects that might be authorized under a similar programmatic authority under WRDA 2000; and those OPEs that might be authorized in WRDAs past the year 2000.

Recommendation: We recommend that the multi-agency team reconvene so that participating agencies can better understand these projects and rank them according to a mutually agreeable set of criteria. We suggest participants should include roughly equal proportions of participants who have largely an ecological perspective and those who are more involved in water supply or urban planning.

VII. Science/Research/Peer Review

The draft FWCA report recommended that all progress toward achieving ecosystem restoration be continuously evaluated in a scientific forum. We were pleased with the Corps' discussion of the adaptive assessment strategy in the draft Programmatic EIS. The Department offers some additional recommendations below.

Recommendations:

1. The Department recommends that a high priority be placed on further refinement of the Natural Systems Model early in the implementation of the Comprehensive Plan. One of the main aspects of the NSM that needs review is the assumption that the ground elevation in the SFWMM is equivalent to the NSM ground elevation south of Tamiami Trail, when evidence supports the fact that subsidence has occurred south of the Trail. The NSM ground surface elevation should be raised the appropriate amount to account for this subsidence. His correction will have implications on the appropriate comparison of alternatives relative to the NSM in future detailed design of components in the Comprehensive Plan.

2. Determination of the hydrologic conditions most conducive to accretion of peat in the WCAs should be a high priority. The Comprehensive Plan should include support for research focused on two principal objectives: 1) development and verification of a peat accretion model, and 2) development of a risk analysis for both chronic and acute loss of soil.

The effect of water depth on the expansion of cattails in areas of greater soil subsidence in northern WCA 3A is also a management concern deserving priority as a research topic.

3. Simultaneously with the research recommended above to identify the hydrologic regime that best promotes accretion of peat, the Corps and cooperating agencies should try to develop and test active management techniques (in addition to or separate from long-term changes in water management) that would accelerate recovery of damaged soils in the WCAs.

4. The Corps should support an ongoing and in-depth scientific review throughout implementation (as appropriate in adaptive assessment) to help achieve the most appropriate balance in restoration of flow patterns, flow volumes, and depths in maximizing overall ecosystem benefits. This task should be assigned to the standing scientific review panel that the Science Coordination Team has recommended to the Working Group. Although that panel would be asked to review many aspects of the entire restoration effort, this specific issue needs immediate attention. This review will be concurrent with moving ahead through detailed planning and implementation of the Comprehensive Plan, rather than delaying progress in implementation until scientific review is completed. The review panel should include both scientists familiar with the Everglades ecosystem and others who have participated in other large-scale ecosystem restoration efforts.

VIII. Conclusion

The Conceptual Plan you described in your February 19, 1999, letter creates the opportunity to provide enormous benefit to the South Florida Ecosystem. During the early stages of implementation, the Department recommends further development of the structural and operational features of the D13R4 scenario, and perhaps other scenarios, which more fully achieve the ecological restoration targets in the Water Conservation Areas, the southern Everglades and Biscayne Bay. The Corps' February 19, 1999, letter included a commitment to implement the final plan in a manner that provides improvements to the operation of the WCAs as well as providing more water for Everglades National Park and Biscayne Bay. We are also pleased that the Corps' letter concluded that the ultimate amount of additional water recaptured from urban and suburban areas and its distribution will be determined based on a phased approach to obtain the maximum ecological benefits in each of these areas. Finally, that letter included a commitment to use passive hydrologic control features to the maximum extent practicable, limiting the use of active features, such as pumps and gates, to those situations where passive controls are not adequate. Those commitments are consistent with the Department's recommendations provided above, and we express the Department's commitment to cooperate with you during detailed project design to translate those concepts to specific structural and operational features.

The Department fully supports a science-based, independent peer review process. The peer review process, coupled with an adaptive assessment strategy, must be instituted early and must work effectively to guide the implementation of the Comprehensive Plan. The multi-agency, multi-disciplinary planning approach, which has worked well to date, must be sustained as we proceed to detailed project planning and design.

We must also ensure that the water quality aspects of the Comprehensive Plan are addressed fully and early in the implementation of the Comprehensive Plan. Adequate funding, design and technical review are essential in fulfilling these water quality goals.

Finally, the C&SF Restudy has been a successful and unprecedented endeavor on a National scale. The Corps has carefully managed a broad spectrum of stakeholders, far-reaching spatial and temporal scales, and complex policy and technical issues. The Department commends the Corps and the various planning partners for their diligent efforts, and looks forward to a continued close partnership during implementation of the Comprehensive Plan.

IX. Glossary of Abbreviations and Acronyms

(For the reader's quick reference, this list includes only those abbreviations and acronyms used in the final FWCA report. The draft FWCA report includes another list for the terms used there.)

AET	Alternative Evaluation Team
ATLSS	Across Trophic Levels System Simulation
C&SF	Central and Southern Florida Project
Corps	U.S. Army Corps of Engineers
Department	U.S. Department of the Interior
EAA	Everglades Agricultural Area
ENP	Everglades National Park
EPA	U.S. Environmental Protection Agency
ESA	Endangered Species Act
DEP	Florida Department of Environmental Protection
FWCA	Fish and Wildlife Coordination Act
FWS	U.S. Fish and Wildlife Service
GFC	Florida Game and Fresh Water Fish Commission
MSRP	Multi-Species Recovery Plan for Threatened and Endangered Species of South Florida
NESRS	Northeast Shark River Slough
NPS	National Park Service
NSM	Natural System Model
NWR	National Wildlife Refuge
OPE(s)	Other Project Element(s)
PEIS	Programmatic Environmental Impact Statement
PIR	Project Implementation Report
RECOVER	Restoration Coordination and Verification (a proposed system-wide review team)
SFWMM	South Florida Water Management Model
STA(s)	Stormwater Treatment Area(s)
WCA	Water Conservation Area
WPAs	Water Preserve Areas
WRDA	Water Resources Development Act

Appendix A -- Everglades Issue Paper

I. Introduction

This Issue Paper has been assembled from the disparate opinions of a number of authors. It does not represent the policy of any of the individual government agencies that participated (U.S. Fish and Wildlife Service, National Marine Fisheries Service, National Park Service, Florida Game and Fresh Water Fish Commission, South Florida Water Management District, Biological Resources Division of the U.S. Geological Survey). It also does not represent the views of the C&SF Restudy's Alternative Evaluation Team (AET), which reviewed and approved several other issue papers related to the Restudy. An earlier draft of this issue paper included detailed reviews of the performance of Alternative D13R and the D13R4 scenario in the central and southern Everglades and the southern estuaries adjacent to Florida Bay. However, due to a lack of time to adequately review those sections to ensure that they included an accurate and fully balanced treatment of the issues, the issue paper was shortened to provide only the background, conclusions, and recommendations.

The Department of Interior (DOI) identified fourteen outstanding issues in the draft Fish and Wildlife Coordination Act (FWCA) report (August 1998) on the C&SF Restudy. Two of these issues related to the Everglades basin:

> **1. Shark River Slough**
> *Total overland flow volumes to Florida Bay, through Shark River Slough, and Taylor Slough, should be increased to more fully reach Natural system Model targets.*
>
> **2.Water Conservation Areas**
> *While accomplishing the above, the hydrologic characteristics in the Water Conservation Areas (WCAs) (particularly northeastern WCA 3A, all of WCA 3B, and WCA 2B) should also more fully reach ecological targets. Alternative D13R was not able to eliminate potentially damaging high water and low water conditions in those areas. The DOI recommends that further modifications be pursued in order to achieve full restoration of hydrologic characteristics in Florida Bay, Shark River Slough and Taylor Slough without compromising full restoration of WCAs. A guiding principle should be that water flow is delivered as naturally as possible throughout all of the remaining Everglades.*

A related concern of the DOI was the deficiency in average water depth and hydroperiod in the Rocky Glades area of Everglades National Park expected with D13R. The AET evaluated the Rocky Glades as a distinct ecological landscape and determined that D13R would not improve the hydroperiod there sufficiently to restore aquatic communities characteristic of pre-drainage conditions. Although not explicitly mentioned in the draft FWCA report, hydrologic conditions in the Rocky Glades are linked to flows to Shark Slough and Taylor Slough, which were a major issue raised in the draft report.

Initial meetings to discuss resolution of these issues were held September-October, 1998. On November 30, 1998, writing teams were assigned to prepare six issue papers, including two separate issue papers for the southern Everglades and the northern/central Everglades. The present issue paper integrates concerns for both areas into a single treatment of the issues and incorporates results of the newly modeled modification to D13R, termed D13R4. Preparation of this combined paper has provided an opportunity to explore points of complete and incomplete agreement among the participants.

The authors reached broad agreement on what were the defining characteristics of the pre-drainage Everglades, but hold varying opinions on what combinations of these characteristics are necessary and sufficient for restoration of the Everglades. The relative importance of different hydrologic properties, including flow patterns, flow volumes, duration of continuous inundation, and water depths, in bringing about full restoration are at the heart of this issue. The Conceptual Model for the Everglades includes the major stressors on the system. The current version of the Conceptual Model emphasizes the importance of restoring the duration of continuous flooding in Shark River Slough, but it does not provide a formula for the relative importance of all hydrologic characteristics.

Hydrologic modeling conducted to date suggests that physical changes in the system hamper full restoration of all the defining characteristics of the Everglades described by the Science Subgroup (1993). These constraining physical changes include topographic changes due to soil loss, water supply and flood control obligations, shortage of water storage and treatment sites in key areas, and loss of the buffering capacity of upstream wetlands that are now part of the EAA. In particular, there are trade-offs between the restoration of flow patterns and volume and the restoration of water depths that have not yet been overcome. It has not yet been possible to restore natural flow lines through the Everglades and restore full flow volumes to the estuaries while at the same time eliminating or preventing unnaturally high water depths in eastern Water Conservation Area 3A and Water Conservation Area 3B.

Resolving these difficult problems will require detailed study and acquisition of new information, possibly leading to new paradigms for restoration of the Everglades ecosystem. It is therefore important that the COE and its planning partners proceed through the detailed design phase of this project with flexibility that will allow substitution of new design features that will maximize overall ecological benefits, providing balance between the restoration of flow patterns and volume and the restoration of appropriate water depths. One primary objective in design and implementation should be to advance toward long-term restoration goals (e.g., re-establishing pre-drainage flow patterns and volumes) without causing more immediate ecological harm.(e.g., increased frequency of extreme high and low water).

II. The Need for Continued Refinement of the Components

Throughout the development and evaluation of the C&SF Restudy, the COE has maintained that the Restudy would provide a flexible conceptual overview of the necessary components rather than a rigid plan. The authors of this issue paper strongly endorse the need to maintain flexibility in both the structural and operational assumptions modeled in Alternative D13R and the D13R4 scenario. Neither of those two model runs completely satisfies the requirements expressed above to increase flow to Shark River Slough while at the same time approaching more closely the restoration goals in the WCAs.

The COE and the SFWMD have recognized the need to refine the components of the conceptual plan through an adaptive assessment process, which will distinguish this effort from the original construction and operation of the present C&SF project. For example, we want to stress the need to be able to adjust the balance in the distribution of water to northern WCA 3A between the S-140 and a spreader canal along the northern edge of WCA 3A in response to observed environmental change. The construction and operation of STA 3/4 under the Everglades Construction Project (the future baseline condition for the Restudy) will provide opportunities to monitor the response of northern WCA 3A that should influence detailed design. The effect of deeper water in northern WCA 3A on the spread of cattails, the rate of peat deposition, and the susceptibility to loss of soil are among the responses that must be measured to assist in detailed design.

We believe that the general features of the D13R4 scenario allowing more efficient capture of urban and suburban runoff from Palm Beach and Broward counties should be incorporated in the conceptual plan. The structural and operational details will not be determined until detailed design, and although the detailed design will likely incorporate many of the concepts added between D13R and D13R4, changes in the specifics will most certainly be necessary.

III. Conclusions

1. The authors reached broad agreement on the **defining** characteristics of the pre-drainage Everglades, but hold varying opinions on the **necessary and sufficient** characteristics of a restored Everglades. Lack of full agreement on the relative importance of hydrologic characteristics, particularly flow patterns and water depths, in bringing about full restoration is at the heart of this issue.

2. Parker *et al*. (1955) found that the Everglades consisted of an eastern and western watershed (Figure 11 in that paper provides their interpretation of pre-drainage flow patterns.) The western watershed of the historic Everglades is still largely intact, providing a greater opportunity for full restoration than for the eastern watershed, where the outflow has been interrupted by development along the Atlantic Coastal Ridge. Some scientists now working on restoration may not be familiar with this and other early references on the pre-drainage condition of the Everglades. A modern synthesis of the previously published information is being prepared, and once this is peer reviewed and published, it may provide insights on restoration targets (particularly flow pattern) that were not fully appreciated in previous evaluations of the Restudy alternatives.

2. Even in the western watershed, soil subsidence is a physical constraint that will not allow full restoration of the flow patterns, water depths, and flow volumes of the pre-drainage Everglades. It may be physically possible to closely approach pre-drainage flow patterns and water depths, but not flow volumes. Flow patterns and flow volumes could also potentially be restored, but not without deviating from the pattern of water depths necessary for restoration.

3. Hydrologic modeling to date has not yet produced a simulation that restores natural flow lines through the Everglades, restores full flow volumes to the estuaries, and at the same time prevents unnaturally high water depths in eastern Water Conservation Area 3A and Water Conservation Area 3B.

4. Increasing accretion rates of peat and preventing conditions leading to chronic and acute loss of soils are keys to restoration, particularly in the northern portions of the present compartments of the remnant Everglades.

IV. Recommendations

1. The COE should not lock in to the specific details of the L-67 levee component as conceived in either Alternative D13R or the D13R4 scenario. The long-term solution needs to maximize, to the extent possible, the joint restoration of both depth and flow patterns. Interim solutions should concentrate on features that are more easily modified through an adaptive assessment process (such as earthen weirs), rather than permanent structures that might be constructed and later found to be less compatible with longer term solutions.

2. For the Modified Water Deliveries/Phase A time period, we recommend design and implementation of a set of passive features in L-67 having a combined flow capacity that does not exceed the current (and at any given stage of Phase A) outlet capacity of the structures along L-29. These initial features would avoid deep water conditions in WCA 3B and would be more easily modified, depending on the final configuration of this component after removal of L-29 and the other features included in the comprehensive plan.

3. The COE should give high priority to development of a Project Implementation Report (PIR) for those groups of components related to movement of water from the central Everglades to the southern Everglades, including but not limited to, L-29 and L-67 A and C. It may be possible to initiate this portion of the design of the comprehensive plan under the authorization of the Modified Water Deliveries Project.

4. Components presently included in either Alternative D13R or the D13R4 scenario should not take precedence over any substitute components that would reduce trade-off between simultaneously resolving the balance in restoration of flow patterns and restoration of appropriate water depths.

5. Both Alternative D13R and the D13R4 scenario presently use S-140 as a means to introduce water into northern WCA 3A. Although this approach has shown some positive results, we recommend that detailed design for restoration of hydropattern in northern WCA 3A incorporate a better balance between use of the S-140 as a point of discharge and a series of inflows to spread out flow along the northern and western boundary of WCA 3A. This approach is intended to provide greater flexibility in distribution of inflows.

6. Determination of the hydrologic conditions most conducive to accretion of peat in the WCAs should be a high priority. The comprehensive plan should include support for research focused on two principal objectives: 1) development and verification of a peat accretion model and 2) development of a risk analysis for both chronic and acute loss of soil. The effect of water depth on the expansion of cattails in areas of greater soil subsidence in northern WCA 3A is also a management concern deserving priority as a research topic.

7. Simultaneously with the research recommended above to identify the hydrologic regime that best promotes accretion of peat, we should also try to develop and test active management techniques (in addition to or separate from long-term changes in water management) that would accelerate recovery of damaged soils in the WCAs.

8. We support an ongoing and in-depth scientific review throughout implementation (as appropriate in adaptive assessment) to help achieve the most appropriate balance in restoration of flow patterns, flow volumes, and depths in maximizing overall ecosystem benefits. This task should be assigned to the standing scientific review panel that the Science Coordination Team has recommended to the Working Group. Although that panel would be asked to review many aspects of the entire restoration effort, this specific issue needs immediate attention. We emphasize that this review will be concurrent with moving ahead through detailed planning and implementation of the comprehensive plan, rather than delaying progress in implementation until scientific review is completed. The review panel should include both scientists familiar with the Everglades ecosystem and others who have participated in other large-scale ecosystem restoration efforts.

Appendix B -- Issue Paper on Freshwater Flows to Biscayne Bay

for the
Alternative Evaluation Team
February 5, 1999

Authors: Sarah Bellmund, National Park Service; Joan Browder, National Marine Fisheries Service; Sue Alspach, Miami-Dade County Department of Environmental Resources Management

I. Introduction

Under the Central and Southern Florida Project Comprehensive Review Study (Restudy), water flows under the recommended alternative reduced the quantity of water flowing from regional and local drainage into Biscayne Bay by 25 % in the dry season and 11% in the wet season. This water was replaced with a proposed wastewater reuse facility. The expense and uncertain nature of this technology have prompted concern over the quantity, quality, distribution, and timing of water delivered to Biscayne Bay and Biscayne National Park under the Restudy. Although the quantity, quality, distribution, and timing of water delivered to Biscayne Bay and Biscayne National Park have been severely altered from historic conditions, the need to restore the Bay to more estuarine conditions is an important issue. The South Florida Restoration Task Force Working Group, the U. S. Department of the Interior (DOI), the National Marine Fisheries Service (NMFS), Miami-Dade County, and the U. S. Environmental Protection Agency (EPA) have identified the lack of correct water flows to maintain nearshore estuarine conditions in Biscayne Bay as one of the top remaining issues to be resolved related to the performance of any chosen alternative under the Central and Southern Florida Project Comprehensive Review Study (Restudy). The U. S. Department of the Interior has identified this issue as follows:

"Improve ecological conditions in Biscayne Bay by restoring more natural fresh water inflows, separate from the wastewater reuse proposed in [Alternative] D13R." (U.S.F.W.S, 1998)

The Alternative Evaluation Team (AET) was tasked with further defining this problem and identifying a solution and a process to reach the proposed solution. The purpose of this paper is to present a synopsis of what is factually known about historic and current conditions in Biscayne Bay, identify concerns, and provide recommendations for addressing them. This paper outlines the historical hydrologic and biologic conditions related to the Bay, the current conditions in the Bay, and the problems and implications of altered water flow. A series of actions are proposed to formulate performance measures, define and acquire critical missing information, and determine alternative sources of water.

Background

Biscayne Bay is located along the southeastern coast of Florida and historically served as the eastern outlet of the Everglades (Davis, 1943; Parker *et al*., 1955). The central and southern portions of Biscayne Bay comprise much of Biscayne National Park. Biscayne Bay, its tributaries and Card Sound are designated by the state of Florida as aquatic preserves, while Card and Barnes sounds are part of the Florida Keys National Marine Sanctuary. Biscayne Bay was designated under the Surface Water Management and Improvement Act of 1987 as a priority water body by the Florida Legislature. The waters of Biscayne National Park, Biscayne Bay Aquatic Preserve and the two Sounds are classified as Outstanding Florida Waters (OFWs), and as such are subject to the most stringent regulations, including Florida antidegradation policies. Card and Barnes Sounds contain one third of all American crocodile nesting in the continental United States, and the east shore of Barnes Sound is within the Crocodile Lakes National Wildlife Refuge. Parts of this area are designated as critical habitat for the American crocodile and the West Indian manatee. In addition it provides important forage habitat for Roseate Spoonbills and White Crown pigeons (SFWMD,1995). Biscayne Bay is the largest estuary on the coast of southeast Florida and is contiguous with the southern Everglades and Florida Bay system. Historically, the Everglades, Biscayne Bay, and Florida Bay were part of a larger hydrologically connected natural system of coastal lagoons and wetlands. Although the connections have been altered by surrounding development and the Central and South Florida

Flood Control Project, Biscayne Bay today still supports a diverse natural system of seagrass, hardbottom and coastal mangrove communities.

Biscayne Bay is a historically shallow subtropical estuary with average natural depths of 3-9 ft that have been altered over time by extensive dredge and fill activities (Harlem, 1979; Kohout and Kolipinski, 1967). Under existing conditions, Biscayne Bay is a healthy estuarine lagoon whose salinity, circulation, and water quality depends primarily upon freshwater inflow, wind driven circulation and ocean exchange. Dominant circulation patterns vary based on the local effects within the four major hydrodynamic regions: 1) North Bay (from Dumfoundling Bay south to Rickenbacker Causeway); 2) Central Bay (from Rickenbacker Causeway south to Black Point); and 3) South Bay (from Black Point south to Jewfish Creek) (SFWMD, 1995). South Bay is usually subdivided into two sections: a) the South Bay Section, from Black Point to Mangrove Point, which encompasses the lower portion of Biscayne National Park, and b) the Extreme Southern Bay Section from Mangrove point to Jewfish creek, encompassing Card Sound and Barnes Sound, all of which are within the Florida Keys National Marine Sanctuary (SFWMD, 1995).

Historically, freshwater flowed overland to the Bay through natural sloughs and rivers, and as groundwater through the Biscayne Aquifer (Buchanan and Klein, 1976; Kohout and Kolipinski, 1967; Parker *et al*., 1955). This pattern has been altered by regional drainage, canal construction and operation, urban development, as well as construction of roads, levees, and other hydrologic barriers to surface flow. The Bay currently receives freshwater inflow as canal flow, minor overland flow, and groundwater (SFWMD, 1995; Kohout and Kolipinski, 1967; Buchanan and Klein, 1976). Freshwater flow to the Card Sound and Barnes Sound Section is composed of intermittent canal flow from the C-111 Canal and overland runoff from adjacent wetlands, which are extensive and composed of contiguous freshwater and coastal wetlands.

The coastal wetlands adjacent to Biscayne Bay in South Miami-Dade County extend from Matheson Hammock County Park southward to where Barnes Sound and Florida Bay intersect at US Highway One (US 1) and include the largest tract of undeveloped wetlands remaining in South Florida outside of Everglades National Park, the Big Cypress, and the Water Conservation Areas. This zone of coastal wetlands includes approximately 100,000 acres of brackish and freshwater wetlands, most of which is either in public ownership or designated for acquisition by the South Florida Water Management District and Miami-Dade County. The bulk of the wetlands in this region (approximately 80,000 acres) are located on both sides of US Highway 1 south of Florida City and are part of the South Dade Wetlands Management Area. Hydropatterns, landforms, water flow, and vegetation patterns in these wetlands have been altered due to regional drainage, subsequent salt intrusion, hurricane storm surges, mosquito ditching, farming practices and the construction and presence of US 1 (Egler, 1952, Environmental Protection Agency, 1994; Meeder *et al*., 1996). Much of the land has been disturbed at some time in the past century for agriculture or other uses, but at present most of these wetlands are not disturbed by farming or development. Farming in this region has been localized north of the South Dade Wetlands Management Area in one band west of US 1 and south of State Road 9336 and in another band east of US 1 between Card Sound Road and SW 137 Avenue. Florida Power and Light operates the Everglades Mitigation Bank east of US 1 in the management area, where exotic removal and enhancement of overland flow patterns are planned.

Historic Conditions

Prior to the alteration of system by human activities, the Bay received extensive freshwater input as both overland and groundwater flow. The Bay served as the eastern outlet for freshwater from the southern Everglades and provided estuarine and freshwater nursery habitat (Davis, 1943; Smith, 1898; Buchanan and Klein, 1976; Kohout and Kolipinski, 1967). Hydrologically, freshwater inflow to the Bay was controlled by water levels in and behind the coastal ridge and overflow through the coastal ridge from the Everglades (Parker *et al*., 1955; Kohout, 1960; Kohout and Kolipinski, 1967). Freshwater flow to Biscayne Bay decreased between 1953 and 1976 by twenty percent (Buchanan and Klein, 1976), wetland hydroperiods decreased, and the patterns of freshwater discharge changed from long, slow releases over a broad front to "pulse" releases from canals following rain events.

North Bay

North and South Biscayne Bay had very different characteristics historically, a condition that persists today in spite of, and sometimes because of substantial alterations to both systems. Prior to human intervention, north Biscayne Bay was a primarily fresh or brackish water system, due to large freshwater inflows and a lack of direct connections to the ocean (Harlem, 1979). Fresh surface water entered the northern bay from Miami River, Little River, Snake Creek, and Arch Creek, which served as outlets for the Everglades. Cypress trees bordered the larger rivers and streams that flowed into North Biscayne Bay (SFWMD, 1995). The opening of Bakers Haulover cut in 1925, the widening and deepening of Government Cut, extensive dredging and filling, bulkhead construction, and the channelization of overland and groundwater flow into canals, caused irrevocable changes to the salinity regime and ecological characteristics of North Biscayne Bay (Harlem, 1979; Buchanan and Klein, 1976). Haulover cut provided a direct connection with the ocean and changed the circulation patterns in north Biscayne Bay (Harlem, 1979). The widening and deepening of Government Cut further increased the influx of saltwater into the Bay. Dredging and filling activities altered circulation patterns and contributed to increased turbidity by changing the profile of the bay bottom and replacing the sloped shoreline that absorbed wave energy with vertical bulkheads that reflected it, stirring up bottom sediments (SFWMD, 1995). Both salinity patterns and water clarity were affected by such changes, and in turn affected submerged vegetation composition and distribution patterns.

Biscayne National Park and South Bay

Central and South Biscayne Bay were historically more brackish than North Biscayne Bay, although the region still contained areas of extensive overland and groundwater flow into the Bay. Dole (1914) reports that seasonally large quantities of freshwater moved into the Bay through springs in porous rocks and sediments as well as through streams along the western shore of the bay. Water moved into Central and South Bay through broad natural flow channels that are frequently referred to as transverse glades (Davis, 1943; Buchanan and Klein, 1976). Central Biscayne Bay received enough groundwater and overland surface water flow to maintain low salinity (mesohaline) conditions even though it has the largest natural direct connection with the ocean and receives extensive ocean circulation at the area known as the Safety Valve (Figure 1). Mesohaline conditions (i.e., 5-18 ppt salinities) existed in Manatee Bay in extreme South Biscayne Bay at the beginning of the 20th century (Ishman *et al*., 1998). The western shoreline of Biscayne Bay south of the Rickenbacker Causeway received sufficient freshwater to maintain extensive freshwater swamps and marshes with only a very narrow fringe of mangroves (Harlem, 1979; Reark, 1974; Thorhaug *et al*., 1976). These coastal freshwater marshes were drained and farmed during the first half of the 20th Century (Reark, 1974), until overdrainage, salt intrusion, hurricane storm surges and new opportunities to farm in the rocky uplands resulted in wholesale abandonment of coastal farmland (Environmental Protection Agency, 1994).

Alterations to Central and South Biscayne Bay included regional drainage activities that essentially eliminated inflow from subterranean springs by the 1940's (Reark, 1974) and channelized remaining overland and groundwater flow into canals, but Central and South Biscayne Bay did not experience physical alteration of the bay bottom and shoreline to the extent found in North Biscayne Bay. The most significant impact from alteration was the regional increase in salinity, which has resulted in the slow conversion of a productive brackish estuary into a more marine and occasionally hypersaline environment (SFWMD, 1995).

Salinities in Manatee Bay and nearby waterbodies have been substantially altered by changes in freshwater inflow. Faunal records in sedimentary cores indicate an overall increase in salinity over the past 150 yrs associated with sea level rise, a change from mesohaline (5-18 ppt) to euhaline (30-35 ppt) conditions in the early 1900s, possibly associated with the original drainage of the Everglades and construction of the Flagler railway, and recent extreme fluctuations between low salinities and hypersaline conditions, probably associated with completion of the South Dade Conveyance System, which includes the C-111 Canal, in about 1980. Miami-Dade County Department of Environmental Resources Management (unpublished, cited by Ishman *et al*., 1998) reports salinities from as high as 45 ppt to as low as 14 ppt in recent years. The coastal and freshwater wetlands adjacent to Biscayne Bay have also experienced dramatic changes as a result of these regional drainage activities and the construction of roads and other barriers to water flow.

Biological Setting

Biological information supports the description of Biscayne Bay as an estuarine or brackish water system. Smith (1898), in an assessment of aquaculture potential for the Bay, cites the overabundant and ubiquitous amount of freshwater just below the ground surface as a reason for not locating a sponge hatchery on the mainland. In addition, he described Red Drum as abundant and identified oyster bars within the main portion of the Bay. Red Drum is an estuarine species requiring mesohaline (5-25ppt salinity) habitat conditions (Serafy *et al*, 1997). The primary reason for the loss of this species from the Bay and the failure of reintroductions programs has been identified as the disruption of natural freshwater flows and loss of historic habitat structured by the resulting salinity regime (D. Serafy personal communication). Oyster bars require a salinity range of between 5-25 ppt for development due to the requirements of the oysters and the inability of oyster predators, (oyster drills and flatworms) to exist in this salinity range (Davis, 1958). Optimal development of oyster eggs and larvae is 22.5 ppt, and optimal growth of larvae is between 12.5 and 17.5 ppt salinity (Davis, 1958). Further changes to south Bay may extirpate such species as pink shrimp and spotted sea trout (Serafy pers. comm.).

Vegetation patterns in the South Dade Wetlands Management Area and the eastern panhandle of Everglades National Park reflects the effects of hydropattern changes. The inland border of a zone of sparse sawgrass and spike rush, interspersed with stunted mangroves, which Egler (1952) referred to as "the white zone" because of its appearance on aerial photographs, has migrated an average of 1.5 km and as much as 3.3 km since 1940 (Meeder *et al*., 1996). Such changes were already noticeable by the 1940's, when Egler (1952) studied the Southeast Saline Everglades, which encompassed the wetlands from approximately Black Point to the wetlands of the eastern panhandle of Everglades National Park. Egler observations on the inland boundary of the white zone led him to conclude that the road interfered with the natural west-to-east flow of water and changed the balance between fresh and salt water influence in the eastern wetlands. Meeder *et al.* (1996) have documented further shifts also noted that it was greater on the east side than on the west side of US 1. From this information they concluded that the trend toward decreasing influence of fresh water approaching the coastline had continued. Meeder *et al*. (1996) also found further evidence of increasing salt water influence in fossil mollusks in sediment cores.

Hydrologic Modifications

Biscayne Bay, along with its associated coastal and freshwater wetlands, has been affected by a reduction in overland flow and groundwater seepage, caused by the construction of roads and canals as well as by the general lowering of the water table on the east coast ridge 5-6 ft. by 1945, according to (Leach *et al.* 1972). The hydraulic gradient, defined near the coast as the difference between the water table and sea level, is a major factor determining the rate of groundwater movement.

The first major event to disrupt the connection of Biscayne Bay to its water sources, the coastal ridge and the Everglades, was the completion of the Miami Canal from Lake Okeechobee to the Bay and the concomitant destruction of the waterfalls in the Miami River, which served as a natural control on outflow of freshwater and inflow of saltwater (DuPuis, 1954; Parker *et al*., 1955). The opening of the primary canal system and its connection to the Bay allowed uncontrolled freshwater movement out of the Everglades, thus draining the coastal ridge and allowing saltwater inflow during dry periods (Kohout, 1960; Parker, 1952). Cypress trees were replaced by mangroves along the larger rivers and streams of North Biscayne Bay (SFWMD, 1995). Saltwater intrusion in coastal wellfields prompted the installation of saltwater control structures in the mouths of the coastal canals between the mid 1940s and the 1960's (Kohout and Kolipinski, 1967; Buchanan and Klein, 1976; SFWMD, 1995). Increased pumpage at coastal wellfields caused decreased freshwater head in the aquifer and led to landward migration of seawater in the aquifer (Kohout, 1960). Lowering the water table on the coastal ridge profoundly reduced groundwater flows to Biscayne Bay (Parker *et al*., 1955; Buchanan and Klein, 1976).

Current Conditions

General

Water quality has been an issue of substantial concern for Biscayne Bay. Water quality in Biscayne Bay is well inventoried through 1994 in the Surface Water Improvement and Management (SWIM) Plan for Biscayne Bay (SFWMD, 1995). Land use changes and human activities led to a decline in overall water quality for the Bay when compared to historical descriptions. A water quality monitoring program was established for the Bay in 1979, which has enabled regional managers to track progress in addressing water quality concerns. Improvements have been reported in many constituents, such as coliform bacteria (derived from sewage), but others have continued to be a problem (e.g turbidity). The SWIM Plan for Biscayne Bay (SFWMD, 1995) lists many of the water quality and biotic conditions of the Bay as currently improving or recovered. Although contaminant and some water quality parameters improved, canal operations continue to produce extreme freshwater pulses that create an irregular delivery of freshwater to the bay. This was recognized as a major structuring process as early as the 1960's by Kohout and Kolipinski (1967).

North Bay

North Biscayne Bay circulation and flow is highly restricted and directly affected by causeways, barrier islands, and artificially maintained ocean inlets (Wang and van de Kreeke, 1984; van de Kreeke and Wang, 1984; Metro Dade DERM, 1985). This area of Biscayne Bay is heavily influenced by canal flows from urban areas (SFWMD, 1995). Although phytoplankton may be the principal source of primary productivity in North Bay (SFWMD 1995), the area between the 79th Street and Julia Tuttle Causeways contains a large (approximately 3000 acres), healthy seagrass bed and supports a productive fishery (SFWMD, 1995). This productive and healthy seagrass bed supports high levels of biological diversity and appears to be flourishing in a highly urbanized area of the Bay (DERM unpublished data). Large portions of the area of North Bay, between Julia Tuttle and Venetian causeways, have not been dredged and contain a mixture of sparsely to moderately vegetated seagrass communities (SFWMD 1995). The submerged communities of this portion of North Bay and would likely benefit from improved water transparency, which would promote greater benthic coverage (SFWMD 1995). Near the mouth of the Miami River, seagrass communities are impacted by reduced water quality, reduced water transparency, and nutrient enrichment from the canal water, although the effect diminishes away from the mouth, as evidenced by the presence of extensive seagrass beds west of Virginia Key. Along the margins of rivers that fed North Bay freshwater cypress trees were replaced by mangroves due to increased salinity (Harlem, 1979). Most mangroves have been lost to urban development, and only a few stands of these mangrove forests, such as the extensive stands along the Oleta River and the mainland shore of the Oleta State Recreation Area, remain.

Central-South Bay

Central Biscayne Bay, which contains the extreme northern portion of Biscayne National Park, is characterized by freshwater canal inflow, groundwater seepage, and ocean exchange. This area is well flushed and is directly and primarily influenced by exchange with the ocean across the shallow channels and embankments known as the Safety Valve (Wang and Van de Kreeke, 1984; Van de Kreeke and Wang, 1984; Metro Dade DERM, 1985). The salinity patterns in this area are dynamic due to the alternating influence of large, pulsed canal discharges and direct ocean exchange. Seagrass communities in central Biscayne Bay range from poor to excellent (SFWMD, 1995). Dense seagrass communities still occur in shallow areas between Rickenbacker Causeway and Norris Cut (DERM unpublished data). Many of these grass beds have experienced propeller scouring due to heavy boat activity. In Central Bay, mangroves line the shore of Key Biscayne. They dominate the shoreline from Matheson Hammock County Park south along the entire shoreline of Biscayne National Park, Card and Barnes Sounds (Environmental Protection Agency, 1994; SFWMD, 1995).

The southern Biscayne Bay comprises the majority of Biscayne National Park. This portion of the Bay is characterized by restricted circulation, few connections with the ocean, a high rate of evaporation, and freshwater input from canals that drain the primarily agricultural region of south Miami-Dade county (SFWMD, 1995). These characteristics result in a much higher dependence on freshwater inflow to regulate salinity and periods of hypersalinity are not uncommon (SFWMD, 1995). Biscayne National Park serves as a nursery ground for offshore gamefish and commercial fisheries (Houde and Lovdal, 1985). Currently, fisheries conditions within the National Park are generally stable, with some exceptions, such as spotted sea trout catch per unit effort which has declined in Miami-Dade County over the past 10 years (Bartone and Wilzbach, 1997). Many gamefish species, such as red fish and sea trout, have not yet recovered to their previous healthy densities, and reintroduction attempts have not met expectations. Currently, the only area known to have active breeding of spotted sea trout is North Biscayne Bay, which has more favorable salinities. The southern portion of the Bay, primarily in Biscayne National Park, is typified by an area of extensive seagrass, hardbottom, and coral communities. Biologic productivity in southern Bay is primarily benthic. The relative health of these communities is documented in the Biscayne Bay SWIM Plan (SFWMD, 1995).

Coastal Sounds

The area from Mangrove Point south, which includes Card Sound, Barnes Sound, and Manatee Bay, is the most isolated portion of the southern bay due to natural separation from the rest of South Biscayne Bay by extensive banks, and separation from the Atlantic Ocean by the barrier islands. Wind and tide are the primary mixing forces in Biscayne Bay, and wind effects are roughly twice as strong as tide effects (Swakon and Wang, 1977; Lee, 1975). Both wind and tidal effects are muted in extreme South Bay. Mixing with the Atlantic Ocean is restricted by the barrier islands and by mud banks within the Bay, and turnover time is on the order of 2.3 months in Card Sound and 3.4 months for Barnes Sound (Lee, 1975).

The area of extreme south Biscayne Bay, retains most of its natural mangrove shoreline and is distinguished by shallow waters and broad mud banks. Brook (1975), describing his study site immediately south of Long Arsenicker Key, said that a narrow (5-m wide) band of Manatee Grass (*Halodule wrightii)* occurs near the shore and is replaced by turtle grass (*Thalassia testudinum)* further offshore, where water depth was 1.5 meters. His site was part of a larger seagrass area extending to the east and west and gradually thinning out to the south as depth increased. Observations in Manatee Bay indicate that the bottom habitat varies from dense *Thalassia* cover to seagrass with open patches of coarse sand (Ishman *et al*. 1998). Based on Brook's (1975) descriptions from Card Sound, this area has a resident fish community dominated by small forage species, including the hardhead silverside, silver jenny, goldspotted killfish, two species of pipefish, and yellowfin mojarra, supported by a food web he thought to be based largely on microalgae. Great barracuda frequent and spiny lobster utilize this area (Brook, 1975). Brook (1975) considered the biomass of small fish and their food organisms in the area to be low and proposed that the hypersaline conditions experienced by the area might be limiting secondary and tertiary production.

Currently, Card and Barnes Sounds receive the majority of their freshwater flow as direct rainfall and as groundwater, except for existing canal flows to Manatee Bay in Barnes Sound. The construction and operation of the C-111 Canal, which drains much of western and southern Miami-Dade County, introduced a new source of fresh water: canal discharge. Under the existing Modwaters/C-111 Project this canal flow is eliminated. Without replacement of freshwater overland or groundwater flow impacts to these downstream receiving waterbodies may result. Since Card and Barnes Sounds are the most poorly mixed parts of Biscayne Bay, requiring 2.3 and 3.4 months for complete exchange with seawater respectively, improving overland flows to this area is a serious restoration need.

The declining influence of overland freshwater flow and groundwater seepage in the area has been a major causal factor in the change in vegetation patterns within this century (Egler, 1952; Meeder *et al*., 1996). Fish biomass is positively affected by freshwater inflow to the coastal ecotone (Lorenz, 1997). Biomass, in combination with timing and rate of dry down, influence fish densities, which determine their availability to wading birds. Coastal wetlands are an important feeding area for wading birds, including Roseate Spoonbills, Wood Storks, and White Ibis, whose South Florida breeding populations have declined substantially in the past 60 years (Ogden, 1994).

II. Define Issues in Detail

Under the Restudy process, alternatives chosen for the restoration substantially decreased the amount of freshwater moving into Biscayne Bay. To make up for the amount of local and regional water removed from the Bay, waste water reuse was added to the chosen alternative as "make up" water to achieve the 'no harm' goals set for the Bay and perhaps improve conditions to achieve some of the proposed restoration targets within the Bay. Concern over the use of this expensive and uncertain technology prompted the inclusion of a new task to identify alternative sources of freshwater for the Bay. Attempting to "find water" from the local and regional system was identified as the first component of this process. A related component was defined as the identification of biologic performance targets for restoration, which are linked to freshwater inflow. This effort is in response to the conditions within the

Bay and the fact that marine and estuarine communities are structured by the volume, delivery and timing of freshwater flow as it is moved to the Bay.

Marine and estuarine communities are affected by event related salinity changes and long term salinity shifts. Salinity affects these communities by being both too high and too low. Biscayne Bay is a fragile ecosystem that relies on a balance of freshwater delivered in the proper amounts, with the proper timing, in the proper location. Currently, water is primarily conveyed into the Bay as point source discharge through canals and through groundwater inflows. The timing, volume and method of delivery of canal discharges can cause acute and long term chronic biologic effects, which are related to timing, volume and method of delivery. Currently, water is primarily conveyed into the Bay as point source discharge through canals and through groundwater inflows. The timing, volume and method of delivery of canal discharges can cause acute and long term chronic biologic effects, which are related to timing, volume and method of delivery.

Effects of Freshwater Pulses

Canal flows result in abnormal freshwater distribution and water movement. Water moving out through canals and into the Bay acts as a coherent and discrete stable water mass of low salinity that does not immediately mix with marine water due to the density difference between freshwater and saltwater (Chin-Fatt and Wang, 1987). The extreme and rapid shifts in salinity, which result as these water masses move into the Bay can severely impact or kill attached or rooted benthic organisms and plants as well as impacting fish communities (Serafy *et al*., 1997; Irlandi *et al*, 1997; Lorenz *et al*, 1997; Montegue and Ley, 1993; Brooke *et al*., 1982). Thorhaug (1976) observed that species diversity and numbers of fish, mollusks, crustaceans and algae decreased in the vicinity of a canal in Biscayne Bay. This effect can be eliminated by shifting point source canal flow to distributed overland flow (SFWMD, 1995). Salinity changes from the movement of distributed overland flow are gradual, and are less detrimental biologically to the Bay ecosystem (Serafy *et al*., 1997; Irlandi *et al*, in press; Lorenz *et al*, 1997; Montegue and Ley, 1993; Brooke *et al*., 1982).

Effects of Reduced Flow and Loss of Seasonal Low Salinity Areas

The reduction in total freshwater flow to Biscayne Bay, along with physical modifications in North Bay, have resulted in a regional increase in the average salinity experienced in any one portion of the Bay, and periodic hypersaline conditions (>40 ppt) in some areas. Channelized flow to the Bay through canals produce periods of abnormally high salinity (>40 ppt) alternating with extremely low salinities in inshore areas due to the pulsed nature of canal flows (SFWMD, 1995). The survival of many organisms depend upon the stable seasonal availability of low salinity environments (Serafy *et al*., 1997; Montegue and Ley, 1993; Brooke *et al*., 1982; Kohout and Kolipinski, 1967), and the reduction or loss of these environments has resulted in concomitant reduction or loss of species dependent on such conditions. In Biscayne National Park some of these organisms which are dependent upon low salinity conditions include penaeid shrimp, finfish, and crocodiles (SFWMD, 1995). In North Biscayne Bay sea trout spawning is believed to be linked to the presence of stable low salinity areas which are available seasonally (Serafy, pers. comm; Bartone and Wilzback, 1997; Berkley and Campos, 1984). Historical information on the distribution of the eastern oyster indicates that this area was once a more mesohaline (5-25 ppt salinity) environment. Red Drum were once abundant (Smith 1898), but this species, which requires mesohaline (5-25ppt salinity) habitat conditions (Serafy *et al*, 1997), has been lost from Biscayne Bay because of disruption of natural freshwater flows and loss of the appropriate salinity regime (J. Serafy personal communication).

Effects of Reduced Groundwater Flows

The reduction in groundwater flows to Biscayne Bay would have likely had a larger impact in Central and South Bay, where the area is more directly and primarily influenced by exchange with the ocean, than in North Bay. Springs and seeps distributed over the bay bottom would have mixed freshwater over a wide area, which would have resulted in an extensive region of lowered salinity, in spite of the high rate of tidal exchange in Central and South Biscayne Bay. Such springs essentially ceased flowing by the 1940"s (Reark, 1974), and current information indicates that groundwater flows to South Biscayne Bay are not detectable more than 400 meters from the coastline (USGS, personal communication). Within the zone currently influenced by groundwater flows, there is a slow, but constant inflow of freshwater to the nearshore environment. This constant flow may have a substantial effect on local salinity conditions, and may act to somewhat buffer the nearshore environment by keeping local salinities consistently lower. Any impact to groundwater flows could impact this nearshore region of lowered salinity and possibly disrupt nearshore communities.

Effects of Water Quality

Watershed land use changes have resulted in concurrent changes to the water quality of the surface and groundwater flows to Biscayne Bay. Although overall water quality in Biscayne Bay has improved in recent years (SFWMD 1995), water quality is still a substantial concern in the watershed. Water quality ranges from severely degraded in the Miami River to very good near the Featherbed Banks (SFWMD, 1995). The Biscayne Bay SWIM Plan reports the trend analysis for a wide variety of constituents.. The results of these analyses vary as to whether improvement in various parameters have occurred over time. Water quality issues are different for each of the drainage basins, and depend upon the specific land uses in the basin.

Downstream communities are directly impacted by water quality changes, although the spatial extent over which a specific water quality parameter exerts influence is a function of its solubility and biological activity. The inflow of nutrients can result in shifts in benthic productivity and species composition. Contaminants may enter the bay environment and cause different impacts, depending on whether the level of exposure is acute or chronic. Major cumulative impacts to the submerged communities of Biscayne Bay may result from chronic exposure to reduced water quality.

Effects of the Proposed Alternatives

Concurrently with development of this issue paper, a modification of Alternative D13R was prepared that provides additional water to central and southern parts of the Bay, including Biscayne National Park. This alternative is termed D13R4. For comparison, Table 1 provides flow estimates to each part of the Bay without inclusion of reuse water to Central and South Bay. These figures will differ from those presented on the web page as "Simulated Mean Annual Surface Flows Discharged into Biscayne Bay for the 1965-1995 Simulation Period" because reuse inputs to the Bay have been excluded in this table in order to better evaluate D13R and D13R4 flows to the Bay without this problematic component. No flow targets were established by the AET for North Bay and the Miami River, and these flows were generally unchanged by D13R4

Snake Creek:

Target flows to Snake Creek were not achieved in Alternative D13R. Specifically, dry season flows undershot the target by 67,000 acre feet and wet season flows overshot the target by 12000 acre feet. Snake Creek is reduced by 72% in the dry season (Snake Creek is not affected by the reuse proposal). Surface water flows to the Snake Creek region in Biscayne Bay in D13R are significantly lower than current conditions. Under Alternative D13R4 Snake Creek flows are reduced by 79% in the dry season compared to the target flows and by 61% compared to existing (1995 base) dry season flows. The existing Snake Creek watershed contains extensive mangrove forests in the Oleta River corridor. Under existing conditions this is a reasonably productive nursery area and restoration efforts are ongoing to preserve and enhance the region. Adequate freshwater flows are essential to minimize impacts to this coastal wetland corridor.

Miami River:

Surface water flows to Biscayne Bay at the Miami River were significantly reduced over existing conditions in Alternative D13R. Specifically, dry season flows were reduced by 42,000 acre feet and wet season flows were reduced by 89,000 acre feet with a total reduction of 131,000 acre feet. Flow in the Miami River is reduced by 67% in the wet season and 70% in the dry season from the 1995 base. Although it remains unclear as to what impacts will result in Biscayne Bay or what impacts to water quality in the Miami River may result from this reduction in surface water flow, it is likely that reducing flow so severely may potentially have negative biologic consequences.

Biscayne National Park

The following flows were estimated without the reuse component provided in both Alternative D13R and D13R4. D13R reduces flows to Central and South Bay by 12% and 14%, respectively, in the wet season and by 7% and 24% respectively, in the dry season when compared to target flows. D13R4 approximates or slightly exceeds target flows to both Central and South Bay. The area of most severe decrease under D13R is found in southern Biscayne Bay and represents a highly restricted portion of the Bay and the main body of Biscayne National Park. This area is also currently the healthiest portion of the Bay. Decreasing freshwater flow during the dry season by this magnitude can be expected to have negative biologic impacts within the National Park. The results of alternative D13R4 indicate that it is likely that additional water may be "found" within the regional system. It is additionally important to tie restoration flows for the Bay to the regulatory process so that this water will be reliably available to the Bay.

Table 1: Target and Model-Estimated Mean Annual Surface Flows (in thousands of acre feet)

	Wet season				Dry season			
Region	Target	95base	D13R*	D13R4*	Target	95base	D13R*	D13R4*
Snake Creek	67	121	79	78	93	51	26	20
North Bay		99	97	97		41	38	37
Miami River		132	43	49		60	18	17
Central Bay	161	161	142	170	83	64	78	104
South Bay	158	158	136	149	68	52	56	69

*Estimated without reuse water to Central and South Bay.

Southernmost Coastal Wetlands and Sounds:

There are two existing projects, the Modified Water Deliveries to Everglades National Park (Modwaters) and the C-111 Project as well as the proposed Alternative D13R under the Restudy, which will decrease the total quantity of water reaching the southeast coastal wetlands and Barnes and Card Sounds through the regional conveyance system. The Modwaters/C111 Project will eliminate point-source discharges to Manatee Bay in Barnes Sound from the C-111 Canal. A spreader system will be created north of the C-111 to introduce overland flow to the coastal wetlands west of US 1. Alternative D13R proposes to extend this spreader system east of US 1 and increase the pump capacity to 500 cfs to introduce overland flow to the midway down the coastal wetlands east of US 1. Replacement of ecologically damaging point source discharges to Manatee Bay with overland flow through coastal wetlands would be expected to be beneficial. There are several complicating factors however. These factors include that the volume of water delivered to this area may not be adequate to overcome evapotranspiration in the wetlands or evaporation in the Bays and may therefore be inadequate to maintain positive salinity gradients in this poorly mixed part of the Bay.

Based on hydropattern relationships to past and present vegetation patterns, the South Miami Dade Wetlands Alternative Evaluation Team concluded that D13R would not provide adequate freshwater to drive the hydropatterns required to restore natural vegetation patterns, build high fish biomass, and provide suitable conditions for wading bird foraging in the coastal wetlands on both sides of US 1. D13R4 appears to improve hydrologic conditions, but still may not provide sufficient water to this area.

Chosen Performance Measures

Performance measures used to evaluate the alternatives were based on the current state and health of Biscayne National Park and Biscayne Bay. Flora and fauna in Biscayne National Park and Biscayne Bay reflect improvement from the severely damaged conditions in the 1950's and 60's, however, this improvement is not indicative of the Bay's biotic diversity and abundance prior to channelization. Performance measures were developed for both surface water and groundwater inputs to Biscayne Bay, and for surface water levels in the wetlands adjacent to South Bay.

The ability to develop performance measures and performance targets for alternative evaluation was limited because physical and biological characteristics in Biscayne Bay and the associated wetlands are the result of a complex interaction between input parameters, circulation in the Bay, and biological activity involving one or more of the input parameters. Computer simulation modeling is a method for working with this type of complexity. A comprehensive hydrodynamic model covering all of Biscayne Bay and able to address both groundwater and surface water issues is under development through the Biscayne Bay Feasibility Study, but was not scheduled for completion in time to assist with the development or evaluation of performance measures. Additionally, this model would not be suitable for addressing wetland restoration issues in the watershed wetlands, so another means was needed to address wetland concerns.

Performance measures for surface water flows to the Bay were developed using either existing conditions as an interim measure, or other information, as available, to set more specific targets for specific regions of the Bay. This was done in the absence of a comprehensive hydrodynamic model, detailed organismal information, or community salinity relationships. For these reasons, targets were only developed for Snake Creek, Central Bay, and South Bay, and are needed for remaining areas.

Although no specific performance targets were set for groundwater, the performance goal was to maximize groundwater levels in each region (and thus maximize flows) without compromising flood protection to that region. This goal was based on the relationship between groundwater head and groundwater flows to the Bay. The groundwater models being developed under the Biscayne Bay Feasibility Study and the water preserve studies should eventually be able to quantify the relationship between groundwater head and groundwater flows to the Bay. This information was, however, not available to support performance measure development.

No performance measures were developed for water quality in Biscayne Bay due to the uncertainty of predicting future water quality conditions and associated loading rates. In addition, the absence of information concerning the fate of compounds entering the water bodies from the watershed limits model development or determination of specific impacts to biota. The Biscayne Bay Feasibility Study proposes to develop a water quality model in Phase 2 that will permit the development and evaluation of water quality performance measures, but completion of such a model is not expected for several years. This will require additional biological information and background studies to determine fate and effects of compounds moving from this watershed into different habitats within the Bay.

Performance measures were only developed for those wetlands in the Biscayne Bay watershed within the South Dade Wetlands Management Area. This was primarily due to the coarse grid size of the South Florida Water Management Model (SFWMM) and limitations associated with this model. Performance measures for the South Dade Wetlands Management Area were defined based upon wetland communities of this region, their hydric and hydrologic requirements, and the habitat-hydrologic requirements of the wildlife communities known to use this area. It was assumed that water levels that would support vegetation patterns similar to those observed in the 1940's would provide enhanced surface and groundwater flows to Card and Barnes Sound and Northeast Florida Bay. No relationship has been established, however, between upstream water stages and downstream salinity east of US Highway 1 in the two sounds to enable such an evaluation. A Modbranch model has been developed for the area east of US 1 and south of the C-103 (Mowry) Canal, but work is still ongoing to determine whether the water provided through any of the alternatives will produce any positive effects in the downstream sounds.

III. Identify and Define Missing Pieces of Information

There are substantial gaps in supporting information that must be addressed in order to maximize the restoration of Biscayne Bay and associated natural systems in the watershed. These include refining information on groundwater flow, especially in North and South Bay but also in Card and Barnes Sounds. The relationship between groundwater and the Bay is a critical missing piece of information for this process. Groundwater models and the relationship between groundwater and salinity in the Bay must be established as quickly as feasible. Other gaps of information include establishing relationships between salinity in various parts of the Bay and canal stages and/or ground/surface water levels in the watershed, and developing comprehensive information on loading rates and the fate of target water quality constituents. There is a specific need for more detailed data collection and modeling in the nearshore environments of Biscayne Bay, in the zone where groundwater flows have been measured, to determine the relative contribution of groundwater to salinity patterns in the nearshore environment. In addition, there is a strong need for more refined topographic information to support modeling. Watershed models with more refined grids that can provide more detailed information on water movement in the watershed are also necessary. There is also a need for the development of biologic Performance Targets, biologically based hydrologic relationships, and the models or other tools to evaluate these targets and relationships with a desired degree of accuracy. The definition of biologic Performance Targets should be based upon the historic environment within the Bay and a desired biologic goal that is based on preservation and enhancement of the existing system where full restoration is not feasible. Some of this information must still be compiled or determined.

IV. Identify Solutions

In order to adequately restore and/or enhance Biscayne Bay and the coastal wetlands, freshwater inflow and water quality targets must be developed and alternative sources of water should be identified for providing the freshwater needs of the Bay. This section describes the actions necessary to develop the targets and identify alternative sources of water.

1. Develop Freshwater Inflow Targets:
Freshwater requirements must be defined and quantified in terms of the quantity, quality, timing and distribution of flows necessary to provide and maintain sustainable biological communities in Biscayne Bay, Biscayne National Park, and the coastal wetlands. The following identifies the activities needed to develop the freshwater inflow targets:

Identify Organisms in the Bay with Direct and Indirect Salinity Relationships

This task has three components a) the need to identify missing but potentially useful salinity-organism relationships, b) the need to pick specific organisms or a suite of organisms to provide salinity requirements as targets for the Bay (these may potentially be different based on the geographic location within the Bay), c) and set freshwater inflow quantity distribution and quality based on the needs of target organisms.

Identify Historic Salinity-Organism Relationships and Historic Salinity Regime

While it is intuitively obvious that if the Bay is healthy relative to pre-1970's conditions, then the existing 1995 Base flows to the Bay are beneficial. The inshore areas of the Bay (out 400-500 meters) are the areas most severely in need of restoration. Restoration in this area is intrinsically connected to lower salinities which are determined by proper volume, timing, and distributed delivery of freshwater. However, due to a lack of information in this nearshore area, it is not possible to determine or quantify additional flows of freshwater beyond 1995 base flows, which may be necessary to restore lower salinities. Since there is little or no available salinity data for the early portions of the century prior to channelization of the Everglades, drainage of the coastal ridge, and the resulting disconnection of the coastal system from Everglades, it is necessary to utilize biologic surrogates of salinity to understand historic salinity conditions within the Bay.

There are several potential means to evaluate the historic conditions within the Bay using surrogates of salinity. It is possible to utilize historic data about the distribution of organisms historically found within the bay. It is possible to examine the paleo-environment of the Bay, utilizing any coring available for the Bay. It may also be possible to examine organism distribution within dredge spoils and dredge spoil islands that were created with known sources of spoil from within the early Bay to look for organisms with known salinity relationships. It is possible to look at isotopic relationships in corals or shell of known age. It is also possible to evaluate the hydrologic conditions necessary to create the documented large outflows of freshwater in the center of the Bay. Beginning with organismal relationships, there is more historic data available for organisms at the turn of the century than hydrologic or salinity data. Distribution of salinity intolerant organisms and specific fisheries with known salinity relationships make it possible to examine these and other comparable target organisms as salinity surrogates since various organisms integrate spatial and temporal components of salinity into habitat quality.

Identify Canal Inflow/Salinity Relationship

It is essential that the relationship between downstream (nearshore) salinities and upstream water management be defined. It is necessary to investigate various methods for defining this relationship and compare the results of the various methods investigated. The methods to be compared should include but not be limited to: the process to be utilized in the development of minimum flows and levels for Biscayne Bay by the South Florida Water Management District; performing a time series analysis (such as the Box-Jenkins transfer function model); and utilizing hydrodynamic and groundwater models (as available and applicable).

Develop Biologic Community Targets and Associated Salinity Regimes

In order to identify freshwater flow requirements, nearshore salinity targets must be developed. These targets may differ according to the geographic location within the Bay. It is necessary to develop these targets by identifying the desired biologic organisms for the various zones within the Bay. The salinity regime for the chosen biologic organism will then be the target salinity regime for that particular zone in the Bay.

Develop Inflow Freshwater Requirements

Once the relationship between downstream salinities and upstream water management activities are defined and the nearshore salinity targets are developed, the freshwater inflows needed to provide salinity targets can be developed. This analysis must include determining the freshwater delivery regimes and water quality requirements for the coastal wetlands (Biscayne Bay Coastal Wetlands and South Dade Wetlands Management Area) which will be affected by delivering the needed flows to the Bay.

2. Identify Sources of Water for Providing Target Flows:

Potential sources of water for providing target flows to the Bay should be identified and evaluated based on their ability to provide the quality, quantity, timing and distribution of target inflows. The potential sources include, but should not be limited to; operational modification of the existing or proposed system, "new water" identified by the Alternative Development Team, Floridan aquifer water, and wastewater reuse. Convene a technical team specific to this area to identify and investigate sources of freshwater for Biscayne Bay. This team would work on the output from future modeling of the regional system. It would also identify other potential sources of freshwater flow for the Bay as listed above. All "new water" scenarios must include water quality assurances to the National Park and other parts of the Bay.

3. Develop and Refine Tools:

A computer model is needed which is capable of simulating surface and groundwater flows to Biscayne Bay under various proposed modifications of the C&SF Project. The ability to simulate surface and groundwater flows to Biscayne Bay is a critical step in establishing targets, determining how much water Biscayne Bay needs from the regional system, providing boundary conditions for the Biscayne Bay hydrodynamic model.

Various water management modifications have the potential to shift the location of the fresh-salt water interface by changing groundwater levels. The effect of changes in groundwater levels may be magnified by the low land elevations of South Miami-Dade county coastal areas. The ability to simulate the location of the fresh-salt interface is needed to adequately evaluate the coastal effects of various alternatives of managing the C&SF system.

4. Develop Water Quality Criteria:

Biscayne Bay is classified as an Outstanding Florida Waterbody and, therefore, waters of Biscayne Bay Aquatic Preserve and Biscayne National Park are classified as Outstanding Florida Waters (OFWs), and as such are subject to the most stringent regulations, including Florida anti-degradation standards, which prohibit permitted discharges that will degrade ambient water quality. However, it is essential that numeric criteria and pollutant loading reduction goals be developed for several critical parameters so that treatment requirements can be determined and appropriate sources of water for the target flows can be identified.

V. Identify Impacts on Other Areas

The modeling under the Alternative D13R for "new water" shows the flexibility of the system to be managed for the water needs of the natural system. Providing water for the needs of all of the natural systems has been difficult however it is unacceptable to "trade off" the needs of the natural systems against each other. More detailed attention must be focused on providing for the water needs of the two National Parks and the natural systems of Miami Dade. This ecosystem of wetlands, uplands and saltwater bodies evolved as a whole and is interdependent. It is critical to avoid the temptation to sacrifice one of the National Parks for the other or to trade off the other natural areas that are not protected by this status. It is instead necessary to identify those components, which make it possible to provide restoration flows for the entire region and incorporation these as plan components or model elements.

The water needs of the natural systems of the South Dade Wetlands, Biscayne National Park and Biscayne Bay, as well as Everglades National Park and the extended Everglade system are not in conflict with management of water for urban areas. The management of water levels for natural systems maintains water levels to prevent saltwater intrusion, provide protection for existing wellfields from saltwater intrusion and provide flexibility in the management of the region. Potentially shortfalls in water for the Bay have been identified to possibly be made up by waste water re-use or other sources of water such Floridan Aquifer water. This water must be guaranteed to the Bay as 'restoration flows' if these sources are applied. The issues associated with Re-use water are investigated under the Water for Biscayne Bay Re-Use issue paper. Floridan aquifer water must be more thoroughly investigated for water quality issues with respect to such components as sulfur, mercury, and nutrients as well as others.

VI. Resolution Status

Much work has been done or is underway in addressing the biologic and hydrologic issues in Biscayne Bay. As a component of the water quality program, the 1995 Biscayne Bay SWIM Plan recommended "shall not exceed" values for certain water quality parameters in Biscayne Bay (SFWMD 1995). A multi-agency group has been formed (the Biscayne Bay Water Quality Group) to identify background water quality concentrations in Biscayne Bay and recommend non-degradation and restoration standards for the Bay. The South Florida Water Management District is in the early stages of developing minimum flows and levels for Biscayne Bay. An interagency group is in the process of evaluating current conditions and proposing restoration targets and developing a management plan for the Model Lands-South Dade Wetlands Wetlands Management area. Under the Biscayne Bay Feasibility Study, a hydrodynamic model is under development by the U.S. Army Corps of Engineers (ACOE) and the United States Geological Survey (USGS) to evaluate hydrodynamic and salinity effects in the Bay. Various groundwater and finer scale surface water models are being developed by the ACOE and the USGS to more realistically evaluate flow into the Bay.

In the Restudy's Draft Feasibility Report and Programmatic Environmental Impact Statement, the South Miami-Dade Reuse component has been included for the purpose of improving conditions in Biscayne Bay and for mitigating effects upon the Bay resulting from other components. This component was added to the Restudy as a means to restore water to the Bay that was removed by other components of the Restudy. It is critical that the purpose of this component is fulfilled and adequate water for restoration is delivered to Biscayne Bay, Biscayne National Park, and the Florida Keys National Marine Sanctuary (Card and Barnes Sounds). The South Miami-Dade Reuse component includes the identification of all potential sources of water for Biscayne Bay, and providing superior treatment wastewater reuse if it is determined to be the best source. Additional land must be identified as a component of reuse for treatment of this water. The purpose of the Biscayne Bay Coastal Wetlands-other project element component of the Draft PEIS is to rehydrate coastal wetlands, restore overland flow, redistribute and enhance freshwater delivery by sheetflowing canal discharges over the coastal wetlands bordering Biscayne National Park, and reconnect these wetlands to the Bay.

VI. Strategy for Resolving Remaining Items

The activities discussed in the Identify Solutions section are needed to resolve the outstanding biologic and hydrologic issues in Biscayne Bay. It is anticipated that those activities would proceed simultaneously. The following is also recommended:

1. Establish Technical Team:
Establish a team of scientists (biologists and hydrologists specific to Biscayne Bay) to pursue the activities discussed in the Identify Solutions section. The appropriate resource managers and members of the research community should be represented on the team. Additionally, the Technical Team should be established immediately in order to meet the proposed schedule. Sub-teams specific to individual subject areas would be created as necessary as a component of this team. Peer review would be organized for this process and its products by the team and in conjunction with the science coordination team.

2. Expedite Development of Hydrodynamic Model:
As discussed previously, a hydrodynamic model is under development by the U.S. Army Corps of Engineers (ACOE) and the United States Geological Survey (USGS) to evaluate hydrodynamic and salinity effects in the Bay. It is imperative that this work receive an adequate amount of funding and allocation of resources in order to complete the project in as timely a manner as possible. Delays, potentially up to one year, have already occurred in the groundwater portion of the project due to limited funding and resources.

VIII. Timetable (as defined under the Implementation Plan schedule)

Biscayne Bay performance targets and alternative source evaluation
July 1999 to June 2002.

Modeling for Alternative sources of water for the Restudy is ongoing
Current to May 1999.

Waste Water Re-use Feasibility
January 2000 to 2010

Appendix C -- Issue Paper on Flows to Biscayne National Park Utilizing Reuse
Alternative Evaluation Team
January 20, 1999

I. Introduction

The Restudy Team considered reuse in the alternative evaluation process as a means of "expanding the water pie." Wastewater reuse has the potential to provide a consistent source of fresh water which will assist in meeting the future needs of the South Florida region. Currently, wastewater is most often a loss to the water budget in that it is typically discharged to deep wells or to ocean outfalls. The Restudy Team recognized that the appropriate application of wastewater reuse can benefit natural, urban, and agricultural water supplies by adding to the water budget and reducing dependence on the regional system.

In the first several alternatives evaluated by the Restudy team, freshwater flows to central and southern Biscayne Bay fell significantly short of the target flows. The Restudy Team, therefore, developed the South Miami-Dade Reuse component which would provide superior treatment wastewater reuse to make up for the redirection of existing flows away from Biscayne Bay in previous alternatives. The Team anticipated that the reuse water would be treated to the level needed by the biologic communities in the Bay and by the wetlands over which the reuse water would discharge via overland flow. They also recognized the potential for reuse to supply a perpetual source of fresh water to the Bay that can be managed to optimally mimic target flow regimes even in the dry season.

Concerns have since been raised regarding Biscayne Bay's water quality needs, source water treatment requirements, and the timing of implementation and funding of the South Miami-Dade County Reuse component. The purpose of this paper is to identify the concerns and provide recommendations for addressing them.

II. Background

Biscayne Bay, the largest estuary on the coast of southeast Florida, is contiguous with and linked hydrologically to the southern Everglades and Florida Bay system. Historically, these three regions were part of a larger connected natural system of coastal lagoons and wetlands. Although the connections have been altered by surrounding development and the Central and Southern Florida Flood Control project, Biscayne Bay still supports a diverse natural system of seagrass, hardbottom and coastal mangrove communities.

Trend analysis on the Bay's water quality monitoring program indicates that, in many instances, efforts to restore and enhance Biscayne Bay have been successful (SFWMD 1995). The Biscayne Bay Surface Water Improvement and Management Plan (SWIM Plan) states that of 150 statistically significant trends in the data, 78% showed improvement. The parameters which showed the most improvement include turbidity, dissolved oxygen and total coliform bacteria. However, the parameters that showed the most declines in water quality were ammonia and nitrate/nitrogen. It is imperative that regional planning activities continue to bolster the ongoing water quality improvements in the Bay and, at a minimum, not exacerbate existing problem areas.

The C & SF Project Restudy provides an opportunity to protect and enhance Biscayne Bay hydrology and water quality by developing a water management strategy that more closely mimics the natural system. As mentioned previously, the South Miami-Dade Reuse component is included in the Draft Feasibility Report and Programmatic Environmental Impact Statement and proposes to investigate all potential sources of water to provide required freshwater flows to southern and central Biscayne Bay. If reuse is determined to be the best source, it would be implemented. Additionally, the Biscayne Bay Coastal Wetland component is included in order to rehydrate altered wetlands, redistribute and enhance freshwater delivery, and reduce point source impacts to the Bay by releasing canal discharges through the coastal wetlands bordering Biscayne National Park. Freshwater releases in this manner would contribute to reestablishing sheet flow of water to the Bay and provide for a broader mixing zone of fresh and salt water to buffer salinity changes.

III. Define Issues in Detail

The issue addressed in this paper is the importance of utilizing the best source of water for providing freshwater flows to southern and central Biscayne Bay due to the following concerns on Biscayne Bay's water quality needs, source water treatment requirements, and the timing of implementation and funding of the South Miami-Dade County Reuse component.

The primary Biscayne Bay issue under the C & SF Project Comprehensive Review Study is providing the quantity, quality, timing and delivery of freshwater to meet the requirements of the natural estuarine system. Because the wastewater reuse component is related to maintaining estuarine freshwater requirements, this issue is intrinsically coupled with the Issue Paper on Freshwater Flows to Biscayne Bay. The Issue Paper on Freshwater Flows to Biscayne Bay examines in more detail issues and processes necessary to more specifically define water quantity and water quality targets and alternative sources of freshwater for southeast Miami-Dade County. This paper focuses more specifically on the source of freshwater for the coastal and estuarine communities of Biscayne Bay and Biscayne National Park.

- **Water Quality and Biscayne Bay**

  As a consequence of strong tidal flushing and connection with offshore waters, open Biscayne Bay is oligotrophic and is characterized by extremely low concentrations of contaminants. Recognizing the significance of its natural values and the need to protect and restore them, almost all of Biscayne Bay and its tributaries have been designated for protection, either through inclusion within the boundaries of Biscayne National Park, within Florida aquatic preserves, or within the Florida Keys National

Marine Sanctuary. Biscayne Bay was designated a priority water body by the Florida Legislature pursuant to the Surface Water Management and Improvement Act of 1987. The area south of Biscayne National Park is included in the Florida Keys National Marine Sanctuary. Waters of Biscayne Bay Aquatic Preserve and Biscayne National Park are classified as Outstanding Florida Waters (OFWs), and as such are subject to the most stringent regulations, including Florida antidegradation standards, which prohibit permitted discharges that will degrade ambient water quality. Since the establishment of these protection measures, local, state and federal agencies have implemented monitoring, regulatory and management efforts at maintaining and enhancing biological, recreational, and aesthetic values of Biscayne Bay.

Due to the sensitivity of the Biscayne National Park ecosystem, special consideration must be given to water quality issues. An extensive long-term water quality monitoring database has been developed through cooperative efforts of local, state and federal agencies. The Biscayne Bay SWIM Plan recommended "shall not exceed" values for certain parameters based upon this database (SFWMD 1995). The database was further evaluated to define typical or background concentrations of inorganic nutrients for open waters of south Biscayne Bay by a multi-agency review group convened to develop recommendations on water quality criteria. Preliminary analysis indicates that inorganic nutrient concentrations are extremely low. Although specific performance measures and dynamic pollutant loading criteria have not yet been formally developed for Biscayne Bay, it has been suggested by the multi-agency review team that to sustain water clarity and seagrass/hardbottom benthic communities, the following nutrient concentrations must also be sustained: total ammonia, 20-50 ppb; nitrate-nitrite, 10 ppb; and total phosphorus, 5 ppb.

Since phosphorus is the limiting nutrient in Biscayne Bay, water clarity and ecological impacts are likely if nutrient levels are not adequate. Cumulative and combined (or multiple nutrients) effects are also a significant consideration, since there is evidence that ammonia and nitrate-nitrite levels are significantly elevated in the watersheds of southern and central Biscayne Bay. This is particularly a concern in the nearshore areas, which are most likely to be impacted by the quality of the source water. Low level, chronic releases of elevated nutrients in this region could fundamentally alter the type and quality of plant material available to support the food web.

In Biscayne Bay, concentrations of trace metals and organic chemicals are typically low or often below detection limits; however, such contaminants bind to particulate material and have accumulated in sediments of many canals and tributaries, particularly in more urban and industrial watersheds. Companion studies have documented that sediments in some canals and even relatively pristine areas of Biscayne National Park are toxic to aquatic organisms in standard bioassay testing (U.S. Department of Commerce NOAA 1998). Numerous past studies of occurrence and distribution of fish abnormalities in Biscayne Bay have suggested that these may be linked to contaminants in sediments. It is imperative that implementation of the Restudy Recommended Plan not increase loading of toxicants or biologically active compounds that could contribute to water and sediment quality problems. This is of critical concern in the intertidal coastal wetlands, which support a substantial food web that includes significant numbers of commercially important fish species.

- **Treatment of Water for Biscayne National Park**

Providing freshwater flows to Biscayne Bay without having to first treat the water would obviously be the most efficient and potentially most cost-effective method for meeting the water quality needs of the Bay. However, treatment may be necessary depending upon the source of water for the freshwater flows. It is important that the treatment method provided be adequate for treating the water to the appropriate levels and at the anticipated volumes without causing deleterious impacts to the coastal wetlands and Biscayne Bay.

The treatment train proposed for the South Miami-Dade reuse component assumed iron flocculation, filtration and reverse osmosis added on to advanced wastewater treatment technology. There has been limited use of this treatment combination, and therefore its effectiveness in removing contaminants to the appropriate level and at the assumed volume projected for the South Miami-Dade Reuse component must be determined. It has been assumed that this treatment train has the capability of reducing phosphorus levels to 10 ppb or less. Effectiveness for achieving acceptable concentrations of other nutrients and contaminants must also be evaluated.

Similar concerns exist for all other potential sources of water for Biscayne Bay and the coastal wetlands. Modeling and assessment of these issues is presently complicated by the lack of dynamic water quality information or pollutant loading measures. As a consequence, conservative treatment requirements must be assumed at this time based upon existing contaminant concentrations.

Additionally, the Biscayne Bay Coastal Wetland component, as it was originally designed, anticipated redirecting canal flows into the spreader system and, therefore, included treatment areas to a limited extent. A further examination of the extent of necessary treatment areas will have to be conducted in order to assess whether additional treatment areas will be needed to protect both Biscayne National Park and the healthy natural wetlands which currently comprise the Biscayne Bay Coastal Wetlands component.

- **Timing of Reuse Component Implementation**

The timeline proposed for the wastewater reuse study and pilot project is six years. It is proposed to take ten years to design and construct the treatment facility. Maintaining adequate freshwater flows to Biscayne Bay through the planning horizon for the recommended plan may conflict with achieving restoration or planning goals in surrounding systems. Therefore, this emphasizes the importance of pursuing other appropriate sources of water for Biscayne Bay which may be available sooner than the reuse component or can serve as interim sources until the reuse component is operational.

- **Reuse Alternatives and Cost**

  The wastewater reuse concept may provide another source of water, but it may be more appropriate and cost-effective to apply treated wastewater in areas where water quality requirements may not be as stringent as those for oligotrophic natural waters. For example, wastewater might be used to reduce demand for raw water from the shallow aquifer if used for irrigation in certain urban or agriculture applications elsewhere in the system. Similarly, treated wastewater might be distributed in conjunction with rehydration or hydrologic enhancement of disturbed wetlands in broader geographic buffers, rather than in limited wetlands adjoining Biscayne National Park. These alternate applications of wastewater reuse must be evaluated, along with identification of alternative sources of water for south Miami-Dade. This evaluation must include a cost-effectiveness analysis.

IV. Identify and Define Missing Information

Water quantity and quality targets or performance measures for Biscayne Bay need to be refined in order to more accurately evaluate freshwater requirements and alternative sources. While this need is discussed in detail in the Issue Paper on Freshwater Flows to Biscayne Bay, the following water quantity information is relevant to this issue paper also. In particular, adequate data on groundwater flow to Biscayne Bay, finer scale models with more accurate capabilities for assessing impacts upon Biscayne Bay, and accurate estimates on existing and simulated surface water discharge is needed.

Additionally, water quality targets and pollutant load reduction goals must be established so that sources can be evaluated and treatment requirements can be determined. There is extensive surface water quality and sediment chemistry data for Biscayne Bay, as well as descriptive information on distribution and productivity of benthic communities, but it needs to be linked to hydrologic models to assist in establishing dynamic targets. In order to expand the scope of hydrologic models to perform as comprehensive water quality models, additional data on atmospheric loading, groundwater quality, and sediment/water column dynamics will be required.

Additional characterization of toxicants and biologically active components of source water is required if it is to be discharged to Biscayne Bay surface waters or wetlands. The fate of these components under different treatment regimes and in receiving water bodies must be evaluated. Wildlife and habitat impacts should be examined to understand and address concerns about the potential for long-term water and sediment contamination. Biological effects data, such as toxicity or bioaccumulation testing may be required. Potential receptors depend upon treatment and conveyance methods selected. For example, if wetland treatment areas are used to reduce nutrient levels or otherwise enhance water quality, birds and other wildlife may be attracted to the area. Benefits, such as improved habitat may result, but risk associated with contaminant exposure will also have to be assessed.

Additional technical information is required to determine treatment requirements, where and how much water can be discharged, and size of wetland areas needed for water enhancement and conveyance. This will be necessary to protect both Biscayne Natural Park and existing wetlands. The south Miami-Dade reuse component is intended to replace the decrease in freshwater for the entire Bay occurring as a result of other components of the Restudy. Due to limitations imposed by the scale of the regional South Florida Water Management Model, the effluent generated by reuse was modeled as direct canal flows. Due to the projected nature and quality of this water, it is likely to require some type of wetland polishing treatment or detention. The intended purpose of the Biscayne Bay Coastal Wetland component as it was originally conceived is to rehydrate coastal wetlands, redistribute and enhance delivery, and reduce point source impacts by sheetflowing canal discharges over the coastal wetlands bordering Biscayne National Park. Although there are some treatment areas as components of the Biscayne Bay Coastal Wetlands, the size and design of these may have to be refined to accommodate the volume and level of treatment needed for wastewater.

V. Identify Solutions

1. As discussed in the Issue Paper on Freshwater Flows to Biscayne Bay, the refinement and finalization of the targets for the quantity, quality, timing and distribution of freshwater flows to the estuaries is the critical first step in resolving the source water issue. This will include, at a minimum, 1) the development of the analytical tools necessary to evaluate the effects of hydrologic modifications on Biscayne Bay (i.e. the hydrodynamic model currently under development, an associated water quality model, and hydrologic models capable of providing boundary conditions for the hydrodynamic model); 2) resolution on the Bay's water quality criteria and pollutant loading reduction requirements; and 3) collection of the data needed to support this process (i.e. surface and groundwater flow data, surface and groundwater quality data, biological effects from current water management operations, and delineation of the Bay's existing estuarine zone).

2. A thorough analysis of all potential sources of water to provide freshwater flows to Biscayne Bay must be conducted. This analysis should evaluate the capability of each source to provide the quality, quantity, timing and distribution of freshwater flows needed by Biscayne Bay. A parallel analysis should evaluate the potential for reusing or discharging treated wastewater elsewhere in the region. This analysis must consider the full geographic range of the C & SF Project.

3. A cost-effectiveness analysis should be conducted to compare the sources of water identified in the previous process.

4.   Adequate flexibility must be provided in the final Feasibility Report in order to implement alternative options which achieve similar purposes. For example, the Feasibility Report should allow for the provision of alternative sources of water, if identified, and redirecting wastewater reuse to meet other demands, if appropriate.

VI.   Identify Impacts on Other Areas

Potential benefits may result from identifying other sources of water for Biscayne Bay such as, overall Plan costs may be significantly reduced and/or wastewater reuse could alternatively be used to reduce or offset urban or agriculture water demands. One potential drawback is that reallocating freshwater to meet Biscayne Bay water quality and quantity requirements may reduce the availability of freshwater for other components of the system.

VII.   Resolution Status

Several of the solutions discussed above have been addressed in the Restudy Draft Feasibility Report. For instance, the current description of the South Miami-Dade County Reuse component provides for the identification of alternative sources of water for Biscayne Bay and that if other more appropriate sources are not identified, reuse water would be pursued for providing the Bay's freshwater needs. The Restudy Draft Feasibility Report also provides for conducting a pilot study to address the water quality issues associated with discharging reclaimed water into Biscayne National Park and to determine the level of superior treatment needed along with the appropriate methodologies for that treatment.

VIII.   Strategy for Resolving Remaining Issues

The refinement and finalization of Biscayne Bay estuary targets and the identification of alternative sources of water for Biscayne Bay should be identified as early action items in the final Feasibility Report. Science/technical committees should be used to establish the targets.

The process of identifying alternative sources of water for Biscayne Bay should be adequately characterized in the Restudy final Feasibility Report to fit into U.S. Army Corps of Engineers procedures.

The South Miami-Dade County Reuse component should be flexible enough to allow for redirecting costs for the design and implementation of a system for providing alternative sources of water for Biscayne Bay without having to pursue a reauthorization. The component should also be flexible to allow the redirecting of wastewater reuse to meet other demands.

Adequate costs should be allocated in the Final Restudy Feasibility Report for the refinement and finalization of Biscayne Bay estuary targets and for the alternative water source identification process.

IX. Timetable

The following timelines were taken from the draft sequencing schedule for the Feasibility Report's Implementation Plan.

Jan. 1999 to June 2002	Refine Biscayne Bay performance targets and identify and evaluate potential sources of water, including reuse, to provide needed freshwater flows
Jan. 2000 to Jan. 2014	Determine ecological effects of reuse, and design, construct and monitor the reuse pilot project

X. Conclusions

Providing the appropriate quantity, quality, timing and delivery of freshwater is critical for an ecologically viable Biscayne Bay. Concerns have been raised regarding Biscayne Bay's water quality needs, source water treatment requirements, and the timing of implementation and funding of the South Miami-Dade County Reuse component. Due to these concerns, all potential sources for providing fresh water to central and southern Biscayne Bay should be investigated. The decision on the appropriate source should be made in conjunction with the determination on the water quality, quantity, timing and duration of flows needed by the Bay.

Appendix D -- St. Lucie Estuary Issue Paper

Robert Pace, U.S. Fish and Wildlife Service
Steve Traxler, U.S. Army Corps of Engineers
16 December 1998

1. Background

The Department of the Interior (DOI) identified the incomplete attainment of the high flow restoration targets in the St. Lucie Estuary (SLE) as an issue needing resolution in an August 1998, Draft Fish and Wildlife Coordination Act (FWCA) report. The South Florida Ecosystem Restoration Task Force also recognized this as an issue needing more analysis in its review of the performance of the Initial Draft Plan (Beneke 1998). In this paper, we have used the word "issue" in reference to the concerns expressed above about whether or not the Initial Draft Plan presented in the C&SF Restudy is sufficiently close to the restoration targets. We have used the word "problem" in reference to the ecologically damaging conditions in the SLE that need to be corrected. This issue paper was written to briefly describe the fundamental ecological problems in SLE, the issue of certainty within the limits of error in the C&SF Restudy's analysis, and to outline a process to resolve this uncertainty.

The SLE is highly altered from its original condition. Around 1892, the St. Lucie Inlet was excavated to provide navigational access to the ocean, and a primarily freshwater system was converted to an estuary. The South Fork of the estuary was connected to Lake Okeechobee in 1924 through construction of the St. Lucie Canal (C-44). Much of the western portions of Martin County and St. Lucie County historically were covered with pine flatwoods containing scattered wetland depressions that could locally contain normal rainfall; extreme rainfall events most likely drained partially to the coast and partially to Lake Okeechobee or the northern Everglades. The SLE's watershed was greatly enlarged during the 1950s through connection of the C-23 and C-24 system of canals that now drain northern and western portions of St. Lucie County.

The restoration goals for the SLE recognize that it is impossible to return the system to its original freshwater condition. The goal is to allow the SLE to function as a productive estuarine system supporting a diverse assemblage of fish and wildlife. The Indian River Lagoon (IRL), a portion of which lies between the SLE and the Atlantic Ocean, is recognized as unique among estuaries in the United States in its mixture of temperate and subtropical flora and fauna. Swain et al. (1994) listed approximately 2,500 species of plants and animals directly associated with the Indian River Lagoon. Gilmore *et al.* (1981) documented over 800 species of fish in the IRL and associated waters. The IRL is among the most diverse estuaries in the United States (Indian River Lagoon National Estuary Program 1996).

The principal focus in setting restoration goals for the SLE in the Restudy has been establishment of a more favorable salinity regime. The target salinity gradient in the SLE was determined by a hydrodynamic model (Morris 1987), combined with estimates of the salinity requirements of two indicator species in the estuary, shoal grass (*Halodule wrightii*) and American oyster (*Crassostrea virginica*) (Haunert and Chamberlain 1994). We continue to support the selection of these as indicators of ecological conditions within the estuary. Although fish are economically important in the SLE, and although fish are clearly affected by adverse hydrologic events in the SLE, the mobility of many species of fish allows them to adjust their distribution in response to salinity changes. We believe that sessile organisms will provide a more responsive measure of the variation in salinity, turbidity, and nutrients at particular monitoring stations in the estuary. Because submerged aquatic vegetation and oyster reefs provide productive fish habitat in the estuary, we find that these are appropriate indicators of overall estuarine health.

Mere survival of remnant patches of shoal grass or oysters following an adverse hydrologic event (flood or drought) would not be considered to be successful restoration of the estuary. Sustainability of shoal grass and oysters as viable habitats is the goal. This helps explain why the predicted significant reduction in adverse events for Alternative D-13R relative to the 1995 Base and the 2050 Base is not be considered by some ecologists to be close enough to the restoration goals to provide adequate protection. The substantial reduction in the frequency of these adverse conditions may or may not prove adequate to sustain these indicator species across significant areas of the SLE. Only long-term monitoring of these resources will indicate how their area of coverage and density fluctuate relative to these stressors. Continued collection of baseline data must serve as reference for any gradual improvement of conditions in response to steps in implementing the features of the Restudy.

During the 1997-1998 winter-spring El Niño event, releases of fresh water from the S-80 structure on the St. Lucie Canal began in December, with peak discharges between March 1 and April 20 averaging 7000 cfs. The North Fork of the St. Lucie River, which normally averages 18 ppt salinity decreased to 0 ppt during peak flows. Portions of the SLE that normally average 24 ppt decreased to 5 ppt, and the IRL, which normally averages 30 ppt, decreased to approximately 20 ppt. The high volume fresh water discharges coincided with a high incidence of fish with lesions. Soon after this ecologically damaging event, the South Florida Ecosystem Working Group called for establishment of the St. Lucie Issue Team to immediately accelerate progress toward improving water and habitat quality in the SLE. Their Interim Report (October 1998) provides an excellent summary of the environmental problems affecting water and habitat quality in the SLE, provides details on the effects of the 1997-1998 El Niño rainfall events, and recommends short-term actions to alleviate the problem.

2. Define the Issues

Although the St. Lucie River Issue Team was formed immediately following a period of high volume discharges from Lake Okeechobee to both the SLE and the Caloosahatchee River, that team maintained proper perspective in not limiting discussion of ecologically damaging water management practices to regulatory discharges from Lake Okeechobee through C-44. We believe it is important to continue to educate the public that runoff generated within the drainage basins is as serious an ecological problem as regulatory releases from Lake Okeechobee. The St. Lucie River Issue Team properly described two ecological problems:

Problem 1 Excess fresh water entering the estuary from regulatory releases from Lake Okeechobee have direct and powerful adverse impacts on the water, sediment, and habitat quality of the estuary by not only reducing salinity but also carrying silts, sediments and other pollutants to the estuary.

Problem 2 Due to stormwater releases and water use from agricultural and urban development, even in the absence of Lake Okeechobee discharges, the desirable salinity envelope goal of the estuary is often violated by too much, or too little, fresh water entering the estuary from its own 827 square mile watershed.

The strategy to address these ecological problems throughout the iterative process of alternative development for the Restudy has centered on provision of storage areas distributed appropriately along the C-44, C-23, C-24, and C-25 drainage basins.

Haunert and Chamberlain (1994) originally devised the performance measures used in the Restudy. The performance measures for the SLE were not calculated directly by the South Florida Water Management Model (SFWMM). The calculations involved post-processing the output of the SFWMM for an alternative. This post-processing is performed through the estimation of basin runoff using the CREAMS-WT model, and the use of an optimization model (OPTI-2) intended to test operational rules for the storage reservoirs and to suggest optimum locations and sizes for the storage areas. The authors of this issue paper are not qualified to judge whether the additional step of linking these models to the SFWMM increases the level of uncertainty surrounding our predictions of ecological conditions, but we recommend that additional calibration and estimation of the confidence levels in these models should be included in the scope of the Indian River Lagoon Feasibility Study.

Alternative D-13R of the Restudy met the goals for providing low flows to the SLE. The performance measures called for no more 50 months in the 31-year simulation when mean monthly flow was less than 350 cfs. Alternative D-13R had only 50 months, as opposed to 163 months in the 2050 Base. However, the issue raised by the DOI's draft FWCA report and the Working Group is that D-13R did not fully reach the goal of eliminating the high flow violations in the SLE. The model predicted 15 months of mean monthly flow greater than 1600 cfs, as opposed to the target of no more than 9 months. The simulation also predicted 8 months of mean monthly flow greater than 2500 cfs, as opposed to the target of no more than 3 months.

The SFWMD performed a sensitivity analysis on the effects of varying the total amount of storage in the drainage basins of the SLE (Table 1). This analysis was performed in June 1998, and led to formulation of the components proposed in Alternative D-13R for the SLE.

Justification that the performance of Alt D-13R satisfies the performance targets of the Restudy (Konyha and Conboy 1998):
For low flows the critical period is spring (i.e. March, April, May). During these months the target data set had 28 months of low flows (<350 cfs) while D-13R had only 13 months. For

high flow months (>1,600 cfs), there is a good reason to count months of sequential exceedences as a single "event" rather than two months. Utilizing this method, the count drops to eight events greater than 1,600 cfs (vs. seven for the target) and five events greater than 2,500 cfs (vs. three for the target). In addition, three of the higher flow events (those > 2,500 cfs) exceed the target by less than 150 cfs (> 2,500 and < 2,650 cfs).

Table 1: Targets for the SLE and the number of months the simulations exceed the high and low flow criteria under various amounts of total storage volume. The targets are from the performance measures originally devised by Haunert and Chamberlain (1994).

Storage (Acre/feet)	Months <350cfs	Months >1,600cfs	Months >2,500cfs
Target	50	9	3
2050 base	163	71	36
1995 base	154	77	40
190,000 (Alt D)	56	24	9
232,000 (Alt D-13R)	50	15	8
285,500	46	12	5
380,000	46	10	6

Hydrologic and ecological modeling are tools with a number of assumptions built into them. When a model generates a number or "prediction", there is a certain confidence interval around that number within which the actual observation may (i.e. if the model output prediction is 9, the confidence limits around it could be 8 to 10 or 1-19 depending on how accurate are the model's assumptions and data). The same types of confidence intervals apply to the targets. Often these confidence values are difficult to determine. Some people misinterpret the targets and model predictions as if these were observed values with a high level of accuracy. One should remember is that these numbers are relative and should be used only for comparisons with other simulated alternatives. The model predictions will become more accurate as additional data are collected and incorporated into the models. The models do predict that Alt. D-13R is significantly better than Alt D and that both alternatives are greatly improved over the 1995 base and 2050 base conditions. For these reasons, the estuary subteam of the Alternative Evaluation Team colored the SLE as green (meaning that they thought restoration would be successful).

3. Define Additional Information Needed to Resolve Issues

During the Alternative formulation process for the Restudy, the best available ecological and modeling data was utilized. In conjunction with the Restudy, the IRL Feasibility Study was proceeding along. Whereas the Restudy is primarily a broad conceptual plan, the IRL Feasibility Study is focusing in on the actual project features for the components selected by the Restudy in D-13R.

The following tasks need to be performed to meet the restoration targets for the SLE and to complete the Indian River Lagoon Feasibility Study:

1. Continue optimization modeling **(underway)**.
2. Incorporate the HPSF runoff coefficients into the optimization model **(should be completed by December 1998**).
3. Further calibration and validation of the hydrologic model and the optimization model should be performed to reduce the uncertainty in each. Estimation of the remaining potential error in the models should be calculated and considered in detailed planning **(needs to be started in 1999 and reviewed periodically until completion of detailed design)**.
4. Continue a Land Suitability Analysis to identify more potential storage sites **(underway)**.
5. Use the recently completed St. Lucie Salinity model to determine regions where oysters and shoal grass potentially could recolonize.
6. Perform a screening analysis on the alternatives and on the various storage areas scenarios **(planned for spring 1999)**.
7. Continue analysis of the sensitivity of the indicator organisms (oysters and shoal grass) to salinity and other water quality stressors.
8. Develop a system wide monitoring plan to review the effects of the components on the ecosystem and guide the adaptive assessment **(underway, with oyster and shoal grass data being collected)**.
9. Develop a method to quantify ecological benefits to the estuary. The data from the salinity model and monitoring will be used in this process **(planned for February 1999)**.
10. Develop an operational plan for the storage sites **(planned for 1999)**.

4. Identify Potential Solutions

Currently, the Indian River Lagoon (IRL) Feasibility Study is conducting optimization and other types of modeling to determine the size and location of storage sites. Although increasing the total capacity for storage in the SLE's drainage basins above that used in Alternative D13R is a strategy that must be further analyzed, the sensitivity analysis cited above suggests that Alternative D13R may have reached a point of diminishing returns with respect to increased storage capacity. The ongoing IRL Feasibility Study utilizes the concepts outlined in the Restudy and further refines the plan formulation process initiated under the Restudy to seek solutions to the problems of the SLE. The practicality and feasibility of other components, such as ASR and back pumping to Lake Okeechobee, will be reviewed during the upcoming screening process. Additionally, operational alternatives, such as elevating normal water stage in C-44, will be modeled to determine if that feature produces any additional reduction of months of high flow.

5. Effects on Performance in Other Areas

Storage and release of runoff generated within the drainage basins of the SLE should not affect any other portions of the C&SF system. We recommend that planning and implementation of the IRL Feasibility Study proceed as quickly as possible to provide the needed storage facilities.

However, capturing regulatory releases from Lake Okeechobee in the C-44 basin has implications throughout the C&SF system. The linkage between ecological conditions in the littoral zone of Lake Okeechobee, the SLE, and the Caloosahatchee Estuary is recognized in the present C&SF system. The intent of the Restudy is to provide more capacity for storage in and around Lake Okeechobee to alleviate the constraints in the present water management system. The design and functioning of the additional components proposed by the Restudy will have an effect on the SLE, and conversely, the storage available in the C-44 basin to accept regulatory releases from Lake Okeechobee may affect the need for storage capacity elsewhere in the system. The most direct connections include:

1. Component GG4 – The ASR wells around Lake Okeechobee are needed to not only improve conditions within the lake's littoral zone, but also to reduce the need for regulatory releases to the SLE and the Caloosahatchee.

2. Component D4 – The C-43 Basin Storage Reservoir will provide some additional capacity to receive regulatory releases that might otherwise remain in the lake. Without this feature, high lake stages would be more frequent than those predicted under Alternative D-13R, and the remaining adverse effects would likely continue to be shared among the lake's littoral zone, the SLE and the Caloosahatchee.

3. Component A6 – The North of Lake Okeechobee Storage Reservoir is needed to reduce the impact of high rainfall events upstream of Lake Okeechobee and thereby, reduces the need for regulatory releases to the SLE and the Caloosahatchee.

If it is determined in detailed planning that any of these components cannot be built or that their efficiency is reduced, either the storage of regulatory releases along C-44 would have to be increased, or the performance predicted for Alternative D-13R would be degraded.

6. Strategy for Resolving Remaining Issues

The SLE has had a number of studies performed on it. Currently, the IRL Feasibility Study is working to integrate the data collected in these studies. The multi-agency team working to develop the feasibility study is screening the components to arrive at the best configuration to reach the targets for the SLE. These components will then need to be implemented in a method to yield the benefits as quickly as possible. A robust monitoring plan needs to be developed to determine how the system is responding to the project components and ultimately guide the adaptive assessment of the system. Development and implementation of the monitoring plan and the adaptive assessment strategy are high priority task for the participating agencies in following through with the Comprehensive Plan.

During the IRL Feasibility Study and the Restudy the NEPA process dictates public and agency input into both plans. From the projects beginnings (i.e. the first scoping letter) until the implementation of the project features, the public can make comments and influence the development of the plan. The Restudy team has just completed a series of public meetings and these comments will be incorporated into the Comprehensive Plan. Concurrently, public and agency comments are being solicited until the end of December 1998. Upon completion of the Draft IRL Feasibility Study, a similar public meeting and comment period will occur. Any remaining issues can be resolved during this process.

7. Timetable

Completion of the Restudy Final report:	July 1999
Completion of the Final IRL Feasibility Study	May 2001

The problems in the SLE have been developing over a number of years. Recently, with the unusually large amounts of rainfall, the damage to the estuary was very visible. Public support for restoration of this part of the C&SF system is extremely high. The conceptual plan D-13R of the C&SF Restudy has made progress toward meeting the SLE targets, especially when compared against the 1995 and 2050 base cases (Table 1).

The tasks outlined in section 3 of this paper will be included in the IRL Feasibility Study. That study will eliminate any uncertainty about the adequacy of the proposed facilities in solving the ecological problems of the SLE. Continued public support and involvement is critical throughout the whole restoration process.

Attention: Planning Division

RE: Draft Implementation Plan for the Central and Southern Florida Project Comprehensive Review Study

Dear Colonel Miller:

This is our response to the January 25, 1999, Draft Implementation Plan for the Central and Southern Florida Project Comprehensive Review Study (C&SF Restudy). We appreciate our recent discussions on the draft plan and your agreeing to allow the Department of the Interior (the Department) sufficient opportunity to have meaningful input into this significant effort.

The Department has prepared this Planning Aid Letter (PAL) for the Army Corps of Engineers: (the Corps) Draft Implementation Plan for the C&SF Restudy authorized by section 309(I) of the Water Resources Development Act (WRDA) of 1992 (P.L. 102-580). This PAL is intended to provide input for the Final Implementation Plan scheduled to be released on February 25, 1999. This PAL is provided in accordance with the Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C. 661 *et seq.*) and represents the views and recommendations of the Department.

The Corps and South Florida Water Management District (SFWMD) are to be commended for their collaborative and innovative approach to the project management for Restudy implementation. Considerable flexibility has been built into the plan (monitoring, feedback and adaptive assessment) that will allow the plan to move forward in a way that should maximize ecosystem restoration. We agree with the overall Guidelines and Sequencing Rules contained in the plan. Additionally, the plan recognizes that technical and cost uncertainties may greatly affect the restoration effort (e.g., ASR, seepage control). Contingency plans have been formulated to address the need to seek viable alternatives should these technologies be infeasible, or cost-ineffective. Pilot Projects are proposed for authorization in WRDA 2000 to test these technologies. This is a good strategy.

Following are the primary comments and recommendations the Department considers important to consider for inclusion in the Final Implementation Plan:

- o **ENVIRONMENTAL BENEFITS**: Based on our analysis of the 2010 Case Study, the Department believes the Draft Plan needs to provide greater environmental benefits during the first 10 years of implementation. We understand that the Corps has committed to making improvements to the Draft Plan to provide additional benefits, including assurances that fresh water flows will not be reduced to Biscayne Bay and that flows into the southern Everglades will be enhanced. These improvements are important in view of the examples in the Draft Plan showing SFWMD=s Minimum Flows and Levels are not met in many locations within Everglades National Park and that the 2010 Case Study does not perform as well as the 2050 base condition, during drier than average conditions, in much of the southern Everglades and its estuaries. Further, it is essential that the minimal ecological improvements shown in the Case Study for the WCAs and the southern Everglades be substantially improved.

  As the Corps proceeds with these improvements, a high priority should be given to examining those groups of components related to movement of water from the central Everglades to the southern Everglades, including but not limited to, L-29 and L-67 A and C. Particular consideration should be given to phasing or advancing elements of these components to improve benefits without causing harm to any part of the system. The Plan should commit to being flexible enough to develop and substitute components during implementation that significantly reduce the operational and ecological trade-offs in balancing the restoration of flow patterns and volumes with the maintenance of appropriate water depths in the remnant Everglades, particularly in the WCA 3B/Pennsuco Wetlands/Northeast Shark Slough areas.

  The Department recommends that over the next several months, the 2010 Case Study be revisited by the interdisciplinary team to revise and refine the project sequence. Special emphasis should be placed on not merely avoiding adverse effects on natural areas, but to produce conditions significantly better than today and approaching the benefits of the final Plan. The performance of the Implementation Plan could be improved by optimizing reservoir performance, reordering the implementation schedule, or phasing or breaking components down into increments. For example, water storage in the EAA was operated in the 2010 Case Study as it was in Alternative D13R (the 2050 condition). We suggest exploring interim operational plans for EAA storage that would maximize environmental benefits by 2010 (e.g., restoring the volume, timing and distributions of inflows to the WCAs and Shark River Slough).

- o **WRDA 2000 AUTHORIZATION**: The Department is pleased that several environmental restoration components such as AQQ@ (raising Tamiami Trail), AWW@ (C-111 spreader canal), and the OPE to protect wetlands adjacent to the Loxahatchee National Wildlife Refuge are included in the Initial Authorization Package. However, we recommend that a multi-agency team convene to review the list of projects already authorized as Critical Projects under WRDA 1996, projects that might be authorized under a similar programmatic authority under WRDA 2000, and those Other Project Elements that might be authorized in WRDAs past 2000 for the purpose of maximizing ecological restoration early in the implementation phase. The Department is committed to working with the Corps to rank these projects in this manner.

o **LAND ACQUISITION**: It is imperative that the necessary lands are purchased in order to realize our long-term restoration goals. With the rapid pace of development in south Florida, restoration opportunities will be lost if action is not taken quickly. This is particularly true for the Water Preserve Areas, where there is an eminent threat of development along the urbanized Atlantic Coastal Ridge. Routinely, it is a local, non-federal sponsor that must expeditiously act to acquire needed lands. In order to incur commitments necessary to acquire these lands, they must have assurances that lands acquired will be credited by the Corps as part of the federal project.

In light of the above, the Department requests the Corps implement the authorizing language in WRDA 1996, at section 528(d)(4) which provides for credit to non-federal interests for the Avalue of lands or interests in land acquired@ for activities which restore, preserve and protect the south Florida ecosystem.

o **WATER QUALITY**: The Draft Implementation Plan rightfully recognizes the need for an overall water quality strategy. Considerable work is needed to formulate the proposed Comprehensive Integrated Water Quality Plan. We recommend that the water quality plan be given priority and that additional funding be specifically identified now to ensure that adequate resources are expeditiously applied to this important effort. The Department recommends that those agencies responsible for water quality improvements necessary to implement the Comprehensive Plan be identified in WRDA 2000 and be held accountable for assuring that those water quality improvements are accomplished. We also recommend that these water quality features be scheduled to coincide with the construction schedule of the various project components to ensure that water deliveries are adequately treated before being released into the natural system.

o **ASSURANCES TO WATER USERS**: The discussion on assurances quotes from the Assurances Plan of the Governor=s Commission for a Sustainable South Florida. The Assurances Plan raises significant issues respecting the continued applicability of federal statutes and regulations to the C&SF Project operations and design, and to natural resource protection issues, generally. The Assurances Plan may also be construed to convert inadvertent project benefits, such as flood control benefits, into legal entitlements. Accordingly, the Department recommends a more general discussion of the assurances issue be included in the Final Implementation Plan instead of adoption of the Assurances Plan of the Governor=s Commission for a Sustainable South Florida, absent further review.

o **PROJECT IMPLEMENTATION REPORT (PIR) PROCESS**: As drafted, the roles and responsibilities of the Restoration, Coordination and Verification (RECOVER) team are not clearly defined. To avoid duplication of effort and confusion with agency statutory responsibilities, we recommend that the RECOVER strategy be clarified. The roles and responsibilities, scope of RECOVER review and involvement in the PIR process are the three primary areas needing clarification.

We envision a priority role for the RECOVER process to assist in the future planning to restore the remaining central and southern Everglades. There is a need for additional refinement of ecological performance measures, outside peer review, adaptive assessment, and a need for overall consistency. A multi-agency/interdisciplinary approach will be needed to accomplish these goals. This should be highlighted in the Final Plan.

To avoid serious delay in the ecosystem restoration of Biscayne Bay and Biscayne National Park, studies needed to verify restoration targets and assess the feasibility of restoration actions should be funded and conducted early in the implementation phase. Thus, the Department recommends that the Biscayne Bay Feasibility Study be accelerated and given a high priority. In the meantime, surface water flows to Biscayne Bay must meet or exceed the 95 Base condition, and there should be neither any annual or seasonal net loss in the total volume, nor any reduction in the spatial and temporal distribution of combined surface and groundwater flows to Biscayne Bay.

The Corps should also give high priority to examining those groups of components related to movement of water from the central Everglades to the southern Everglades, including but not limited to, L-29 and L-67 A and C. The final Comprehensive Plan should be flexible enough to develop and substitute components during implementation that significantly reduce the operational and ecological trade-offs in balancing the restoration of flow patterns and volumes with the maintenance of appropriate water depths in the remnant Everglades, particularly in the WCA 3B/Pennsuco Wetlands/Northeast Shark Slough areas.

Finally, both Alternative D13R and the D13R4 scenario presently use S-140 as a means to introduce Water into northern WCA 3A. Although this approach has shown some positive results, detailed design through the PIR process is necessary for restoration of hydropatterns in northern WCA 3A, which incorporates a better balance between the use of the S-140 as a point of discharge and a series of inflow structures to spread out flow along the northern and western boundary of WCA 3A. This approach during the PIR process is intended to provide greater flexibility in the distribution of inflows to the WCAs.

o **SCIENTIFIC PEER REVIEW**: The Department recommends that the Draft Implementation Plan include an independent scientific peer review process to provide continuing review throughout implementation of the Comprehensive Plan. This process should closely follow the implementation schedule and provide the assurance that the best science available is integrated into each step of project implementation. The Department looks forward to working with the Corps, Task Force members and others in establishing this peer review process.

o **<u>COORDINATION WITH THE SOUTHERN EVERGLADES RESOURCE ALLIANCE</u> (SERA)**: Specific consideration needs to be given to how RECOVER would coordinate with SERA. SERA is responsible for coordinating the Modified Water Deliveries Project and the C-111 Project. Both projects have Congressional authorization and are critical to restoration of the Southern Everglades. Recommendations made by SERA effect RECOVER and vice versa. For example, current implementation plans for the Modified Water Deliveries Project call for raising sections of Tamiami Trail several years earlier than proposed in the Draft Implementation Plan. Resolution of these conflicting schedules and timely implementation of these projects will be crucial to the Service=s= evaluation of endangered species impacts resulting from current operations.

The Corps has done a good job of bringing forward several of the Restudy components needed to support the Modified Water Deliveries and C-111 Projects (components O, QQ1/2, AA, V, FF, and WW); however, the DEPARTMENT requests that the scheduling of the following components also be moved forward. As currently drafted, the 2010 Case Study projects with delayed implementation include: WCA 3A/3B Levee Seepage Management (construction dates 2005-2009), Raising the East Portion of Tamiami Trail (2006-2011), WCA 3 Decompartmentalization (2018-2021), Additional S-345 Structures (2006- 2009), L-31N Levee Improvements and the S-356 Structures (2005-2010), and the C-111 Spreader Canal (2005-2008). In each case, the late dates for project design and construction would make it extremely difficult to link these components with the established project management plans for the Modified Water Deliveries and C-111 Projects. Accordingly, the Department recommends the SERA coordination process, including a discussion of potential scheduling conflicts, be discussed and clarified in the Final Implementation Plan.

The Department also recommends that the Corps not commit to the specific details of the L-67 component as conceived in either Alternative D13R or the D13R4 scenario. The long-term solution needs to maximize, to the extent possible, the joint restoration of both depth and flow patterns in the central/southern Everglades. For the Modified Water Deliveries/2010 Case Study time period, a set of passive features in L-67 (such as earthen weirs) having a combined flow capacity that does not exceed the current capacity of the structures along L-29 should be designed and implemented. These initial features would avoid deep water conditions in WCA 3B and would be more easily modified, depending on the final configuration of this component after removal of L-29 and other features included in the Comprehensive Plan.

o **<u>CRITICAL RESTORATION PROJECTS</u>**: Critical Restoration Projects (CP), previously authorized by WRDA 1996 (eg. C-4 East Coast Canal Structures, Southern Crew, Golden Gate Estates, etc.) appear on Table 5.3-1: AProgrammatic Authority@ in the

Draft Implementation Plan. We understand the dilemma faced by the Corps in regard to meeting rigid WRDA deadlines for CPs. The Department concurs that it is appropriate and in the best interest of Everglades restoration to place those CPs which did not meet Project Cooperation Agreement deadlines (September 30, 1999), in the Programmatic Restudy authority to assure that these projects are planned and built.

However, the Department also recognizes that these rigid CP deadlines have created a planning and interagency coordination environment which lacks the thoroughness of Congressionally authorized Civil Works studies which usually accompany efforts such as the proposed CPs. Specifically, CPs planned to date are conceptual in nature and typically would benefit from additional scientific data analysis necessary to improve both engineering and environmental design.

As the Corps and its partners move forward with the CPs, the Department recommends that the current list of CPs be thoroughly reviewed and re-prioritized, as necessary, to maximize both the environmental review and engineering analyzes necessary to ensure that ecological restoration goals are attained. The Department looks forward to working closely with the Corps in this regard.

We appreciate the opportunity to provide our comments on the Draft Restudy Implementation Plan. Please feel free to contact us if you would like to further discuss our comments and/or recommendations.

RE: Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement for the Central and Southern Florida Project Comprehensive Review Study (C&SF Restudy)

Dear Colonel Miller

The Department of the Interior (DOI) has prepared the enclosed Draft Fish and Wildlife Coordination Act (FWCA) report for the U.S. Army Corps of Engineers' (COE) Draft Integrated Feasibility Report and Programmatic Environmental Impact Statement for the Central and Southern Florida Project Comprehensive Review Study (C&SF Restudy) authorized by section 309(I) of the Water Resources Development Act (WRDA) of 1992 (P.L. 102-580). The Final FWCA report, anticipated for release in the spring of 1999, will fulfill the requirements of section 2(b) of the FWCA (48 Stat. 401, as amended; 16 U.S.C. 661*et seq.)* and will represent the Secretary of the Interior's report to Congress on the C&SF Restudy. This Draft FWCA report fulfills DOI's obligation pursuant to our 1997 Transfer Fund Agreement for the C&SF Restudy.

A summary of effects of the COE's Initial Draft Plan on federally threatened and endangered species is included in the Draft FWCA report. The Preliminary Programmatic Biological Opinion, dated August 7, 1998, for this conceptual plan is appended to this report. The Final Biological Opinion, also anticipated for release in the spring of 1999, will satisfy the consultation requirements of section 7 of the Endangered Species Act of 1973, as amended (ESA) (16 U.S.C. 1531 *et seq.)*.

The DO I commends the COE on efforts to date to develop a conceptual strategy to restore ecological function and structure in south Florida, particularly in the remaining central and southern Everglades. The Initial Draft Plan as represented in Alternative D13R, if fully implemented, would do much towards accomplishing this objective. Added modifications to improve ecological performance in Northeast Shark River Slough, the WCAs Biscayne Bay and the St. Lucie Estuary, as well as measures to protect water quality system-wide, are still needed. Further, the DO I looks forward to working with the COE to address other issues critical to the Initial Draft Plan, particularly those of plan implementation and technological uncertainty.

The DOI has every confidence that these issues can be satisfactorily addressed, resulting in a feasible conceptual strategy for south Florida ecosystem restoration that the DOI can fully endorse. The DOI commits to working with the COE to continue improvement and refinement of the ecological aspects of the Initial Draft Plan as the plan is finalized in the spring of 1999. Further, as the components of this conceptual plan proceed to more detailed design, the DOI looks forward to assisting the COE in further analysis under the National Environmental Policy Act. Additional coordination under the FWCA and consultation under the ESA will be conducted at the appropriate stages of detailed planning.

Finally, the DOI views the C&SF Restudy as a precedent-setting milestone in the Federal Government's and State of Florida's commitment to protect and restore the south Florida ecosystem.

Joe. we commend the efforts of both you and your staff in this extraordinary effort.

Sincerely,

Stephen W. Forsythe
State Supervisor

FOREWORD

The Central and Southern Florida Project Comprehensive Review Study (C&SF Restudy) is unprecedented in its scope and complexity. It has truly been a multi-agency and multi-disciplinary effort. Detailed documentation of the evaluation and alternative design process is available on the Worldwide Web, and the U.S. Army Corps of Engineers will also provide extensive documentation in the Draft Integrated Feasibility Report and the Programmatic Environmental Impact Statement for the C&SF Restudy. We find it unnecessary to repeat those details in this report.

Due to the DOI's direct involvement in the design and evaluation of the Initial Draft Plan, we have departed from previous formats for the Fish and Wildlife Coordination Act Report. We have organized this report largely as a series of issue papers providing the DOI's observations on the Restudy process and the challenges remaining to be fully resolved. We have provided, wherever the level of specificity in this conceptual plan allows, recommendations to assist the U.S. Army Corps of Engineers and the South Florida Water Management District in meeting these challenges.

Due to the large number of people who assisted in this endeavor, we elected to not individually list participants that merit acknowledgment. Therefore, rather than list individual acknowledgments, we express gratitude to all the participants from the Fish and Wildlife Service, the National Park Service, the Florida Game and Fresh Water Fish Commission, the Biological Resources Division and Water Resources Division of the U.S. Geological Survey, the National Marine Fisheries Service, the South Florida Water Management District, the U.S. Army Corps of Engineers, and several environmental organizations, especially the National Audubon Society, the World Wildlife Fund, and The Nature Conservancy.

EXECUTIVE SUMMARY

INTRODUCTION

Scope of Authorities

The Department of the Interior (DOI) has prepared this Draft Fish and Wildlife Coordination Act (FWCA) report for the U.S. Army Corps of Engineers' (COE) Draft Programmatic Environmental Impact Statement for the Central and Southern Florida Comprehensive Review Study (C&SF Restudy) authorized by section 309(I) of the Water Resources Development Act (WRDA) of 1992 (P.L. 102-580). The Final FWCA report, anticipated for release in the spring of 1999, will fulfill the requirements of section 2(b) of the FWCA (48 Stat. 401, as amended; 16 U.S.C. 661 *et seq.*) and will represent the Secretary of the Interior's report to Congress on the C&SF Restudy.

A summary of effects of the COE's Initial Draft Plan on federally threatened and endangered species is included in the Draft FWCA report. The Preliminary Programmatic Biological Opinion, dated August 7, 1998, for this conceptual plan is appended to this report. The Final Biological Opinion, also anticipated for release in the spring of 1999, will satisfy the consultation requirements of section 7 of the Endangered Species Act of 1973, as amended (ESA) (16 U.S.C. 1531 *et seq.*).

An analysis of the Critical Projects authorized under section 528 of the WRDA of 1996 and Other Project Elements identified as crucial to overall ecosystem restoration are discussed in this report, but will require future coordination under the FWCA and ESA as more detailed plans are developed.

Ecosystem Decline

Originally authorized by Congress in 1948, the C&SF Project has resulted in the channelization, compartmentalization and drainage of vast areas of the south Florida ecosystem for the stated purposes of meeting water supply and flood control needs. Considered to be the most complex waterworks in the United States, the project consists of more than 1,400 miles of canals and levees, more than 2,000 water control structures and pump stations, and approximately 256,000 acres of water conservation areas. The originally authorized C&SF Project has not been fully constructed to date.

The recently authorized C&SF Restudy is a subset of the larger C&SF Project. The C&SF Restudy includes approximately 18,000 square miles of south Florida extending from Orlando to Florida Bay. The entire Kissimmee/Lake Okeechobee/Everglades watershed was considered in this ecosystem planning effort.

Construction of the C&SF Project over the past 50 years has resulted in extensive urban and agricultural development which now shapes the south Florida landscape. It is fair to conclude that the south Florida landscape has been extensively altered and damaged and that ecosystem health and stability have declined as a consequence.

Today, it is recognized and documented that there will be a continued decline of the south Florida ecosystem if nothing is done to stabilize ecological integrity. The current condition of the ecosystem demonstrates the decline to date: wading bird populations in the southern Everglades have declined by 90 percent, 68 species have been listed as threatened or endangered, exotic invasive plant and animal species have infested large areas of the ecosystem, coastal estuaries continue to be damaged by discharges of large volumes of fresh water, and the overall spatial extent of the Everglades wetland ecosystem has declined by 50 percent and continues to decline at an alarming rate. At the same time, it is recognized that south Florida will experience accelerated development pressure due to a projected population increase in south Florida from five million people today to an anticipated 12 million people by the year 2050. Subsequent increases in water demand for urban and agricultural development will be felt system-wide.

Consistent with the Governor's Commission for a Sustainable South Florida, the DOI considers the implementation of ecosystem restoration an "investment" in the future of both the human and natural environments of south Florida. Thus, the DOI finds that the status quo is unacceptable, and that a comprehensive and scientifically sound ecosystem-based strategy to begin the process of ecosystem restoration is imperative and is the most prudent course of action. Ecosystem restoration is of particular concern and priority to the DOI as the major steward of federal lands (parks, wildlife refuges and preserves) and DOI trust resources (threatened and endangered species, migratory birds and wetland resources) in south Florida.

The Secretary of the Interior established the South Florida Ecosystem Restoration Task Force in 1992 to partner federal, state, tribal, academic, local and private resources to develop a long-term strategy to restore south Florida. Subsequently, the COE, South Florida Water Management District, and other interested agencies and parties developed a consensus-building process involving considerable multi-agency resources over the past five years through the C&SF Restudy Team. The Plan Formulation stage began in earnest in October 1997 with the establishment of the Alternative Development Team (ADT) and the Alternative Evaluation Team (AET). Both teams eventually included representatives of all interested agencies, local governments, agricultural interests, and Native American Tribes. Through an iterative process involving alternative plan development and evaluation based on hydrologic modeling and establishment of ecological restoration targets, the AET and ADT developed Alternative D13R. As a result of these extraordinary planning efforts, the COE now recommends Alternative D13R as the Initial Draft Plan.

In addition to preparing this Draft FWCA report, the DOI has participated in numerous planning meetings and workshops with the concerned planning partners and provided the COE with three Planning Aid Letters (PAL) identifying important issues to be addressed during the planning process. These PALs assisted the COE in developing a restoration plan which more fully meets the DOI's ecosystem restoration goals and objectives in south Florida.

ANALYSIS OF THE INITIAL DRAFT PLAN

Alternative D13R, if fully implemented, would make significant progress toward achieving ecological restoration throughout the C&SF Project, and the DOI endorses most of the elements contained in the Initial Draft Plan. However, Alternative D13R needs further improvements to more fully reach the restoration goals and targets established by the C&SF Restudy Team. Therefore, the DOI recommends further Initial Draft Plan modification prior to the development of the Final FWCA report and subsequent release of the Final PEIS in the spring of 1999.

The Draft FWCA report contains a detailed discussion of issues that the South Florida Ecosystem Restoration Task Force highlighted as most in need of continued analysis and development in the C&SF Restudy. The DOI concurs with the Task Force's issues, as well as others, and elaborates as follows:

Northeast Shark River Slough

Total overland flow volumes to Florida Bay, through Shark River Slough, and Taylor Slough, should be increased to more fully reach Natural System Model targets.

Water Conservation Areas

While accomplishing the above, the hydrologic characteristics in the Water Conservation Areas (WCAs) (particularly northeastern WCA 3A, all of WCA 3B, and WCA 2B) should also more fully reach ecological targets. Alternative D13R was not able to eliminate potentially damaging high water and low water conditions in those areas. The DOI recommends that further modifications be pursued in order to achieve full restoration of hydrologic characteristics in Florida Bay, Shark River Slough and Taylor Slough without compromising full restoration of WCAs. A guiding principle should be that water flow is delivered as naturally as possible throughout all of the remaining Everglades.

Biscayne Bay

Whether or not wastewater reuse on the scale proposed by the C&SF Restudy is feasible for Dade County, the COE should continue to seek opportunities that are not dependent on this technology in order to restore more natural flows to Biscayne Bay. Chapter VI of this report describes two Other Project Elements (OPEs) that would benefit Biscayne Bay with or without the additional water that may be available through reuse facilities. These two OPEs are entitled: South Dade Agriculture Rural Land Use and Water Management

Plan and Biscayne Bay Coastal Wetlands. The DOI believes that these projects and any others developed to improve ecological conditions in Biscayne Bay should be given priority. Under any future circumstances, total flow volumes to Biscayne Bay should be no less than those simulated in the 1995 Base.

St. Lucie Estuary

Restoration goals for minimum flows of fresh water to the St. Lucie Estuary and the elimination of regulatory releases to the estuary from Lake Okeechobee would be generally met in the Initial Draft Plan. However, the runoff generated within the St. Lucie drainage basin is still significantly greater than the restoration target. The DOI recommends that further hydrologic modeling efforts be undertaken to restore the St. Lucie Estuary prior to release of the Draft PEIS in the spring of 1999, and that this important restoration effort be highlighted as a priority for future analysis and refinement under the authority of the COE's Indian River Feasibility Study.

Water Quality

The DOI recognizes that the Water Resources Development Act of 1996 authorizes the protection of water quality as a project purpose of the C&SF Project. As such, water quality protection must be addressed throughout the entire Kissimmee/Okeechobee/Everglades watershed. The DOI remains concerned that the C&SF Restudy does not include an adequate plan for treatment of water destined to be returned to the natural system. The DOI recommends that specific pollutant loading targets be established and an implementation plan developed to reach defined targets within the watershed. Finally, planning should not be limited to nutrient loading; a variety of water quality parameters and pollutants also need to be addressed (e.g., pesticides and mercury contamination).

SUMMARY OF FWCA REPORT FINDINGS AND RECOMMENDATIONS

Detailed findings and recommendations can be found throughout various chapters of the FWCA report. The following is a summary of each chapter discussion:

Ecosystem Sustainability

The hydrologically restored wetland habitats of central and south Florida will not have the same distribution, abundance, and diversity of fish and wildlife as the pre-drainage Everglades. Provided the Initial Draft Plan is refined as described above, the DOI is reasonably certain that the restored wetland habitats of the remaining central and southern Florida Everglades ecosystem will have the necessary structure and function to be sustainable in the long-term.

Other Project Elements

The DOI has provided a review of the ecological benefits expected from implementation of the Other Project Elements (OPEs). These projects lie either outside of the South Florida Water Management Model assessment area, or at a scale not readily usable by the model, but are included in the report as important components of overall south Florida ecosystem restoration. Many of these projects provide ecosystem benefits on a regional scale. The DOI recommends that those OPEs which provide the most significant ecological benefit receive the highest priority for future detailed planning and implementation.

Water Supply

The DOI believes that water supply for all users (urban, agricultural, natural system) cannot be met in the year 2050, unless unconstrained water demands by urban and agricultural users is reevaluated. This is particularly important considering the projected human population increase in south Florida. For the natural system, on the other hand, an adequate water supply is a matter of ecosystem survival or collapse. The C&SF Restudy must maintain this perspective, otherwise, the ever-growing, highly specific demands of the urban and agricultural sectors are likely to take priority over the unchanging, less well-defined needs of the natural system. The DOI recommends that a guaranteed water allocation to the natural system be developed and instituted as soon as possible.

Exotic Plants and Animals

Control of non-indigenous species of plants and animals is an important aspect of ecosystem restoration in south Florida. Existing control measures should be accelerated, more effective techniques should be developed, and regulations should be revised and better enforced to prevent additional introductions of exotic species. The South Florida Ecosystem Restoration Task Force and Working Group Exotic Pest Plant Task Team are developing a statewide strategic plan for managing and controlling exotic pest plants. This effort should be vigorously supported and implemented. The DOI recommends that an equivalent Task Team for invasive exotic animals be established.

Wetland Mitigation

Policies governing Clean Water Act authorization of wetland mitigation within the study area must be consistent with the goals of the C&SF Restudy. Enhancement of wetland function attributable to the C&SF Restudy should not be credited to other interests who are required to mitigate for wetland functional losses. As a policy, using lands inside the C&SF Restudy boundary to replace *wetland functional losses occurring outside the C&SF Restudy boundary should be prohibited. To meet the stated goal of "increasing the spatial extent of wetlands" wetland mitigation should supplement, not supplant, ecosystem restoration benefits attributable to the C&SF Restudy. Information on the location of features proposed in the C&SF Restudy must be made accessible to reviewers of permit applications, and all permit decisions must be compatible with the design and purposes of the C&SF Restudy*

Land Acquisition

Land acquisition requirements, particularly for the Water Preserve Areas and other Water Storage Areas, are substantial in the Initial Draft Plan. The DOI has provided a review of our current understanding of these issues. Land acquisition funding should receive priority before restoration opportunities are lost. Although current activity is largely dependent on willing sellers, the DOI finds that eminent domain procedures will likely be required to complete the plan.

Water Preserve Areas

The Water Preserve Areas of Palm Beach, Broward and Dade counties are an essential feature of the C&SF Restudy that should proceed rapidly to detailed design, while preserving areas of existing high habitat value and providing fish and wildlife habitat enhancement features in others. The DOI recommends that land acquisition in this critical area be accelerated and that the COE begin an expedited Feasibility Study of the area as soon as possible before restoration opportunities are supplanted by continued urban and agricultural development.

Water Storage and Treatment Areas

Water storage and treatment in other portions of the C&SF Restudy area should also minimize impacts on a fish and wildlife habitat. The DOI has provided recommendations for the relocation of the currently proposed storage location in the Caloosahatchee River Basin and for siting of storage and treatment areas in the Taylor Creek/Nubbin Slough Basin.

Adaptive Management

The DOI recommends that all progress toward achieving ecosystem restoration be continuously evaluated in a scientific forum. A peer-reviewed science-based adaptive management strategy, coupled with a sound monitoring program, is the recommended means for integrating all the past knowledge of the south Florida ecosystem with recent findings of the scientific community. Based on the monitoring information, the interagency adaptive management team will prepare annual reports and provide *recommendations to decision-makers on how to proceed. This strategy will ensure that refinements to the Initial Draft Plan will be based on the best and most recent information. The annual reports will also be an avenue for keeping the general public fully informed.*

Scheduling, Sequencing and Priorities

Proper sequencing of presently authorized projects and the components to be authorized in the C&SF Restudy must be determined and followed. The DOI provides restoration planning priorities to integrate authorized projects in the Kissimmee River Basin (Headwater Lakes Revitalization and Kissimmee River Restoration Projects) and in the Southern Everglades (Modified Water Deliveries and C-111 Projects), as well as proposed project components (Water Preserve Areas, Water Conservation Areas, Indian River Lagoon Restoration, Lake Okeechobee Re-regulation, and others). Effective sequencing of actions proposed by the C&SF Restudy (relative to each other and to existing authorized projects) must be thoroughly analyzed and integrated in construction schedules.

Future Feasibility Studies

The DOI strongly supports the completion of the Water Preserve Areas, the Indian River Lagoon, and the Southwest Florida Feasibility Studies and recommends that a new feasibility study be initiated for Biscayne Bay.

Threatened and Endangered Species

The FWS concludes that the C&SF Restudy will promote recovery of several federally-listed threatened and endangered species. Other listed species will either not be affected, or will be adversely affected, but not jeopardized, by implementation of the Initial Draft Plan. Due to the conceptual nature of the Initial Draft Plan, the FWS anticipates an indeterminable amount of incidental take for several listed species as a result of the construction and hydrologic operation activities associated with the plan. Reasonable and Prudent Measures, coupled with required Terms and Conditions, are provided in the Preliminary Biological Opinion to minimize incidental take. In addition, affirmative conservation measures are provided to the COE to further overall listed species recovery in accordance with section 7(a)(1) of the ESA and the Memorandum of Understanding on Implementation of the ESA between the federal agencies.

Wildlife-Related Recreation

Recreational opportunities in the natural areas of south Florida must be considered in detailed project design and in policy development. Issues involved with access for hunting and fishing, management of fish and wildlife resources in *the Water Conservation Areas, and the perception that federal lands are receiving restoration priority over state lands are issues that must be addressed with the Florida Game and Fresh Water Fish Commission.*

Aquifer Storage and Hydrologic Models

The DOI provides technical recommendations regarding necessary studies on aquifer storage and recovery and on improvements to hydrologic models.

Decompartmentalization

Opportunities for removal of structures that impede restoration should be a guiding principle; addition of structures must be clearly demonstrated to be unavoidable before being included in designs.

Technological Uncertainty and Trade-Offs

As the COE proceeds to detailed planning of project components, there may be some components that are not feasible from a technical, regulatory, or a financial standpoint. Tradeoffs will become more prominent in decision-making and fall back positions will need to be devised to address ecological problems that would be compromised by these tradeoffs. Detailed design of all components should continually consider approaches that will promote passive systems over intensely active management.

CONCLUSION

The DOI commends the COE on efforts to date to develop a conceptual strategy to restore ecological function and structure in south Florida, particularly in the remaining central and southern Everglades. The Initial Draft Plan as represented in Alternative D13R, if fully implemented, would do much toward accomplishing this objective. Added modifications to improve ecological performance in Northeast Shark River Slough, the WCAs, Biscayne Bay and the St. Lucie Estuary, as well as measures to protect water quality system-wide, are still needed. Further, the DOI looks forward to working with the COE to address other issues critical to the Initial Draft Plan, particularly those of plan implementation and technological uncertainty. The DOI has every confidence that these issues can be satisfactorily addressed, resulting in a feasible conceptual strategy for south Florida ecosystem restoration that the DOI can fully endorse.

CHAPTER I -- IDENTIFICATION OF PURPOSE, SCOPE, AND AUTHORITY

Cheryl Buckingham and Robert Pace, FWS

A. Introduction

The Central and Southern Florida Project is a multi-purpose project, which was first authorized in 1948 to provide flood control, water control, and water supply to the area extending from Orlando to Florida Bay. While the project performed its intended purposes well, people soon noticed a number of unintended effects that pointed to a system-wide decline in environmental quality. Wading bird populations suffered steep declines, water quality problems emerged, and exotic and nuisance plants and animals rapidly expanded. By the mid-1980's, it became apparent that the alteration of flows through the Kissimmee River and the changes to depths, hydroperiods, and flow patterns in the Everglades were linked to the decline of commercial fisheries in Lake Okeechobee and Florida Bay. As ecological conditions worsened, the public realized that much of south Florida's economy is dependent on a healthy ecosystem and that this economy would decline with deteriorating environmental conditions. From an agency perspective, the thought process has shifted from a piecemeal approach to trying to fix the problems to the realization that a comprehensive ecosystem restoration strategy was needed. Public will and agency awareness resulted in the Central and Southern Florida Project Comprehensive Review Study (Restudy).

B. Purpose

The original Congressional authorization (WRDA 1992) described the purpose for the Restudy as follows: "to determine the feasibility of structural modifications to the project essential to the restoration of the Everglades and Florida Bay ecosystems, while providing for other water related needs" and "for improving the quality of the environment, improving protection of the aquifer, and improving the integrity, capability, and conservation of urban water supplies affected by the project or its operation." The DOI determined that the sequence of these purposes, as stated, implies that the primary intent of Congress was to provide a process for the restoration of south Florida's ecosystems.

In 1994, the COE's Reconnaissance Report acknowledged this Congressional intent by stating that, "the focus of this study is restoration of the ecosystem that was affected by construction of the Central and Southern Florida Project." (COE 1994)

In 1996, the COE's perspective on the purposes for the Restudy appeared to change as the COE started to compile a wide range of components or options (primarily developed from the C&SF Restudy Reconnaissance Report , the Governor's Commission for a Sustainable South Florida, and the South Florida Water Management District's Lower East Coast Regional Water Supply Plan) that could be included in the Restudy. These objectives and initial project components were reviewed by the Governor's Commission for a Sustainable South Florida, resulting in "A

Conceptual Plan for the C&SF Project Restudy" (Governor's Commission for a Sustainable South Florida 1996). As a result, a new set of "broader" Restudy goals and objectives emerged to "enhance ecological values and enhance economic values and social well being" (COE 1997). Minimizing the loss of existing services (water supply, flood protection, navigation) had been originally characterized as a constraint to achieving ecosystem restoration. Increased urban and agricultural water supply, enhanced flood protection, and improved opportunities for navigation now appear to be equivalent to ecosystem restoration as goals for the Restudy. WRDA 1996 reflected this shift in the emphasis of the purpose of the Restudy.

> "The Secretary shall develop, as expeditiously as practicable, a proposed comprehensive plan for the purpose of restoring, preserving, and protecting the South Florida ecosystem. The comprehensive plan shall provide for the protection of water quality in, and the reduction of the loss of fresh water from, the Everglades. The comprehensive plan shall include such features as are necessary to provide for the water-related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the Central and Southern Florida Project."

Although WRDA 1996 seemed to provide greater emphasis on "enhancement of water supplies" than WRDA 1992, its inclusion of authority for the COE to consider water quality issues was a significant step toward a comprehensive view of ecosystem restoration.

The South Florida Ecosystem now suffers the effects of over 100 years of human alterations and large portions of the ecosystem are showing signs of acute ecological stress. Because of the interdependence between the people of south Florida and the natural system, we believe the health and well-being of future generations depends on restoring the natural system and we must, within reason, remove the causes of that ecological stress. To achieve this outcome, we recommend a return to the original emphasis for purposes of the Restudy, as prescribed by Congress in the WRDA of 1992 and the COE in its 1994 Reconnaissance Report.

A Programmatic Environmental Impact Statement (PEIS) is being prepared for this Initial Draft Plan, which includes an adaptive, incremental process for implementing the plan, and identification of cost-effective increments. It serves as the basis for obtaining Congressional authorization for the Water Preserve Areas and other plan components determined to be feasible and cost effective. As subsequent feasibility studies are completed, the comprehensive plan will be reviewed and refined.

C. Scope

The study area encompasses approximately 18,000 square miles from Orlando to Florida Bay with at least 11 major physiographic provinces: Everglades, Big Cypress, Lake Okeechobee, Florida Bay, Biscayne Bay, Florida Reef Tract, nearshore coastal waters, Atlantic Coastal Ridge, Florida Keys, Immokalee Rise, and the Kissimmee River Valley. The Kissimmee River, Lake Okeechobee and the Everglades are the dominant watersheds that connect the remaining mosaic of wetlands, uplands, coastal areas, and marine areas.

The pre-drainage wetlands of southern Florida covered an area estimated at approximately 8.9 million acres. This region was a complex system of hydrologically interrelated landscapes, including expansive areas of sawgrass sloughs, wet prairies, cypress swamps, mangrove swamps, and coastal lagoons and bays. The pre-drainage wetland ecosystems of southern Florida had three essential characteristics:

- Large spatial scale
- Habitat heterogeneity
- A hydrologic regime that featured dynamic storage and sheetflow

As a result of land use and water management practices during the past 100 years in southern Florida, spatial scale has been reduced, habitat heterogeneity has been impacted, and the dynamic storage and sheetflow features have been greatly reduced. Understanding the role these characteristics played in the healthy ecosystem and the factors that impacted them has been the focus for setting restoration goals and priorities for the Restudy. While it is true that the pre-drainage wetlands cannot be fully restored, a successful restoration program will be one that recovers to the extent possible these defining characteristics of the former system. Achievement of this goal should result in the recovery of ecologically viable systems that functionally resemble the pre-drainage Everglades and its interrelated wetland systems.

The fundamental tenet of south Florida ecosystem restoration is that hydrologic restoration is a necessary starting point for ecological restoration. Water management changes have been the chief cause of the problems in this ecosystem and it is believed that restoration begins with the reinstatement of the natural distribution of water in space and time over a sufficiently large area. The water must also meet ecologically-based water quality standards, what is commonly referred to as “marsh-ready water.” It should be noted that the definition of these water quality requirements is constantly being modified as we learn more about the stressors on the system, and the definition will likely need to be tailored for the particular ecological structure and function of different parts of the remaining natural system.

The ecological goal for south Florida ecosystem restoration is to recreate, on a somewhat smaller scale, a healthy ecosystem large enough and diverse enough to survive the natural cycles of droughts, floods, and hurricanes and to support large and sustainable communities of native vegetation and animals. A successful restoration plan must encompass the whole regional system (the Kissimmee-Okeechobee-Everglades watershed), not smaller portions of the C&SF project in isolation.

D. Authority

The reconnaissance phase of the C&SF Restudy was authorized by Section 309(l) of the WRDA 1992 (P.L.102-580) and two resolutions of the Committee on Public Works and Transportation, United States House of Representatives, dated September 24, 1992. The Reconnaissance Report, completed in November 1994 by an interagency, interdisciplinary team, identified the hydrologic and ecological problems in southern Florida and opportunities that existed for solving them. Preliminary alternative plans were formulated that showed promise and the Corps of Engineers recommended the study move into the feasibility phase.

The feasibility phase was authorized by the WRDA of 1996 (P.L. 104-303) and is cost-shared between the federal government and the non-Federal sponsor, the South Florida Water Management District. The overall feasibility effort will be a series of feasibility studies, similar to the way the original 1948 C&SF Project plan led to a series of specific projects. The underpinning of the effort is the development of the Initial Draft Plan, which is intended to ensure that components work together as a comprehensive plan.

As required by WRDA, 1996, this Initial Draft Plan has been prepared in cooperation with the non-Federal project sponsor and the Interagency South Florida Ecosystem Restoration Task Force. It also has considered the conceptual framework presented in the report entitled "Conceptual Plan for the Central and Southern Florida Project Restudy", published by the Governor's Commission for a Sustainable South Florida in July, 1995, and approved by Governor Lawton Chiles.

E. Conclusion

Arthur R. Marshall's (1971) plea for restoration of the Everglades basin still rings true nearly 30 years later:

> The stresses of overloading the south Florida environment reflect on the general populace. For this reason the principal criteria for adjudging and instituting solutions must be in the public's interests.
>
> We must change direction. Our exploitive and technological orientation must be re-directed in favor of more considerate uses of natural systems. They have an efficiency of their own as well as finite limits which we can no longer disregard. We do not control nature. Our intrusions into natural systems merely bring into play other sets of natural laws -- some favorable to man, some not.
>
> The environmental problems of the Everglades are of such precipitous nature and so relevant to the broad public interest that no single agency of government has the perspective and authority to resolve them. If any is able to do so, that ability is not evident. Strong executive scrutiny, led by the Cabinet of Florida, is in order.

At the request of the COE, the DOI has been a full participant in the formulation and evaluation of alternative plans and in selection of the Initial Draft Plan (Alternative D13R). Throughout this process, the DOI has provided formal and informal assessments of the benefits and impacts of the Initial Draft Plan. Points of reference for the Initial Draft Plan in these assessments have included other analyzed alternatives (Alternatives A through D), an approximate simulation of the present condition (1995 Base), the future without project condition (2050 Base), and restoration targets (including, but not limited to, the Natural System Model). These analyses have generally been in keeping with the level of detail of the conceptual plans. A tiered approach is being used and more detailed analyses will be performed at the appropriate time.

This report constitutes the report of the Secretary of the Interior as required by Section 2(b) of the Fish and Wildlife Coordination Act at the conceptual level of detail. Additional 2(b) reports will be required for feasibility studies arising from this conceptual plan (e.g. the Indian River Lagoon, Water Preserve Area, and Southwest Florida feasibility studies) and the detailed design of all components in the Initial Draft Plan, including those identified as Critical Projects for immediate implementation.

CHAPTER II -- DEFINING EVERGLADES RESTORATION -- "THE FIELD OF DREAMS"

Robert Doren, ENP; Robert Pace, FWS

Everglades Restoration has been described and defined in several ways and in several plans. Each plan has a slightly different twist or nuance but all are essentially the same. Each recognizes that the original Everglades (ca. 1850) is the theoretical restoration target, and each recognizes that this target is no longer realistic. They recognize that the pre-existing Everglades can never be recovered given the dramatic changes that have occurred and continue to occur. However, each definition also recognizes that restoration today relates more to stopping further damage and "fixing" or reversing as many of the changes as possible.

Restoration definitions have therefore included the following concepts: 1) preventing additional deterioration, 2) undoing or reversing as many of the changes as possible, 3) allowing natural processes to reestablish, and 4) provide persistence and predictability to the "new" system in such a way that the reestablishment of natural processes take place within the ecological functioning of the ecosystem that is understood to be characteristic of the Everglades.

All ecosystems, especially at the landscape level, are self-regulating and self-organizing. This point is critical to understand in order to realize that, by returning a more natural hydrologic regime to the Everglades, there is sufficient expectation that the Everglades will then restore "itself." What this means is, that as the problems of water quantity, quality, timing and distribution, the impact of exotics, fire management, lack of connectivity, etc. are corrected or reversed, the natural system will respond in an ecologically positive manner. Resource managers can only reinstate those physical ecological parameters that they manage. The ecosystem is then allowed to respond. Since Everglades restoration is being attempted at the landscape level, restoration cannot pretend to restore form and must by necessity attempt to restore function and process with the assumption that form will follow function. However, even if everything possible is done to "put things right," the Everglades of the future will be a different Everglades than the past, or of today. With restoration, the Everglades of the future will exist in an alternative stable state relevant to the setting of the restoration goals inherent in maintaining an ecologically sustainable Everglades.

Although the literature on restoration ecology suggests that successful restoration of wetlands is largely dependent on establishing the desired hydrologic regime over suitable soils (Palmer *et al.* 1997), we should not assume that, if the future hydrologic regime approaches historic patterns, that the flora and fauna of the pre-drainage Everglades will entirely return to historic composition, distribution, and abundance. Too many potentially confounding variables have intervened in the system. We are aware of some of these -- existing species of exotic plants and animals and the threat of new introductions, soil loss and the resulting topographic changes, and the influence of soil-bound nutrients on the spread of cattails (even if surface waters contain target concentrations of nutrients). Presently unknown factors may also arise in unexpected ways to influence success in achieving restoration of fish and wildlife abundance and diversity. Although we have a reasonable expectation that the essence of what constitutes the Everglades can be recovered through re-establishment of improved hydrologic conditions, we must guard against carrying too far the "Field of Dreams hypothesis;" that is, "if you build it, they will come." (Palmer *et al.* 1997)

In the end, one cannot know *a priori* precisely what the restored Everglades will look like - whether all the species one expects in the Everglades will remain or return, or exist in the same numbers, distribution, or diversity. To quote Hobbs and Norton (1996), "...there is the potential for systems to follow alternative pathways depending on the precise combination of management, climatic, and biotic factors experienced. The stochastic nature of the environment means the outcome of a particular restoration measure may differ when carried out at different locations or different times." However, given the current unpredictable alterations consistently inflicted on the Everglades (flooding, draining, decompartmentalization into parcels by levees and canals, addition of fire out of season, addition of pollutants and exotics, etc.) and the responses the system has made regarding loss of species diversity and richness, community structure, and ecological function, further decline of the ecosystem is inevitable without intervention. Therefore, intervention by reversing the ills caused to the ecosystem - if reversed well enough so that the changes are persistent and within the natural patterns of variation that evolved with the ecosystem - will allow the ecosystem to reestablish sustainable functions characteristic of the Everglades.

As Don Boesch, Chair of the Florida Bay Science Oversight Panel, said; "...restoring the Everglades is not rocket science or brain surgery, it's much more complicated than that."

CHAPTER III -- BRIEF DESCRIPTION OF THE ALTERNATIVES

Robert Pace, FWS

The number of components and their design are too complex to easily summarize. The C&SF Restudy Web site (http://141.232.1.11/org/pld/restudy/hpm/index.html) contains both general and detailed descriptions of the alternatives. The detailed descriptions are lengthy documents, ranging from 85 pages for Alternative A to 95 pages for Alternative D. Alternative D contained the greatest number of components, totaling 60. The components range in complexity, in terms of the simulations and also as they might be designed and built in reality. For example, water supply provisions for the City of West Palm Beach were designed in detail, with corresponding detailed modifications to the South Florida Water Management Model (SFWMM). Other components, such as water storage and treatment in the Taylor Creek/Nubbin Slough basin, were simply added to the SFWMM as hypothetical storage for water from Lake Okeechobee, without definition of their location in the real world.

The revisions leading to formulation of Alternatives A through D from their precursors, Alternatives 3 through 6, resulted in less distinct differences among the alternatives because they shared many components.

The decompartmentalization of WCA 3 is one of the principal ways the alternatives differed. Alternative A retained most of the existing levees and structures around WCA 3, with dependence on large pumps along Tamiami Trail to deliver an increased volume of water to northeast Shark River Slough. This approach was not in keeping with the tenet of removing structures whenever possible from the remaining Everglades to achieve restoration. Alternative B involved removal of the Miami Canal, both the L-67A and L-67C and their associated canals, all of L-29 along Tamiami Trail and all of L-28. Alternative C also removed the Miami Canal, but left in place the western portion of L-29 and the L-28. A series of weirs were placed along the present location of the L-67A. Alternative D was similar in its approach to decompart-mentalization, except that it involved removal of the L-28 tieback, which was present in Alternative C. Alternative D13R involved complete removal of the L-29 and L-28, similar to Alternative B, but included refinement of the design of the weirs along the location of the L-67A. Alternative D13R also modified rules at selected water gage locations in the WCAs governing the importing and exporting of water. The northern two-thirds of the canal along L-67A would remain in place in Alterative D13R. Figure III-1 is a schematic representation of the components of D13R in the central Everglades, with notations as to how they differ from Alternative D

Other significant differences among the alternatives included the following:

1. Alternatives C and D extended the C-111 spreader canal east of Card Sound Road. The spreader canal extended only up to Card Sound Road in Alternative B and was absent in Alternative A.

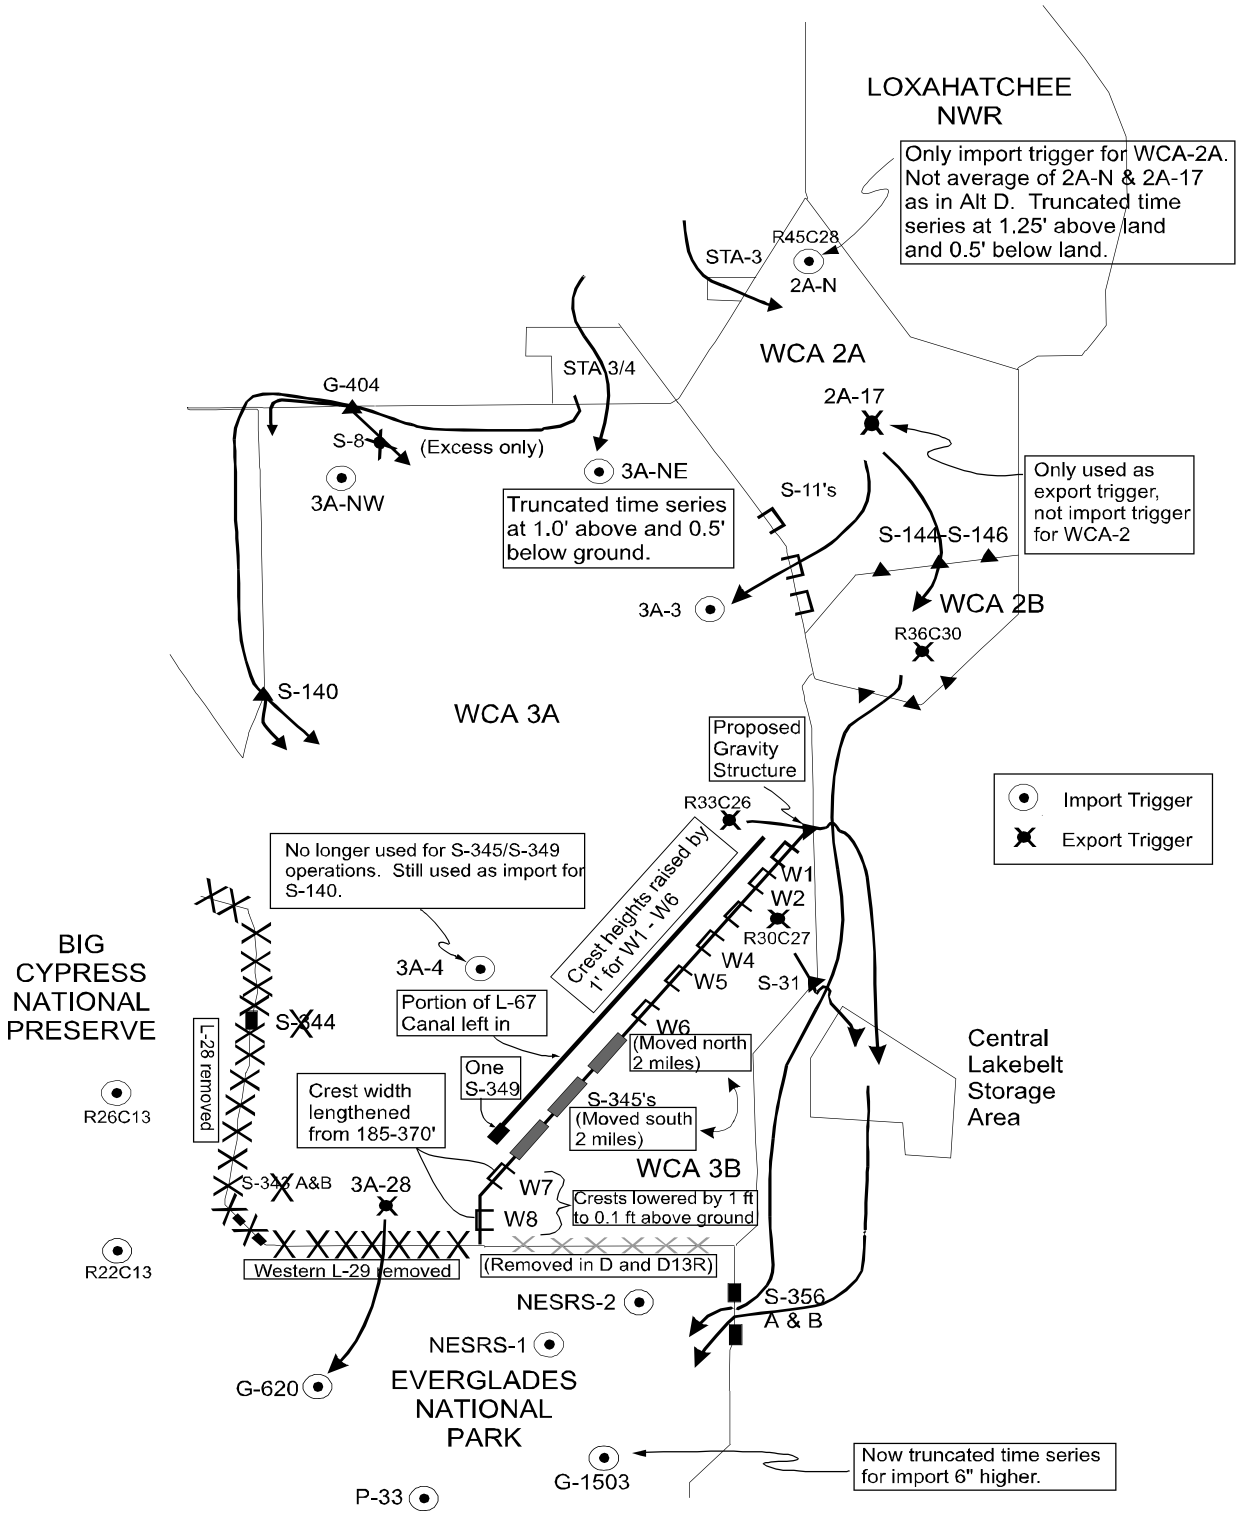
2. Alternatives C and D added South Dade County water reuse program.

3. Alternatives C and D modified the use of Central Lake Belt storage, relative to operation criteria for WCA 3 and South Dade County water reuse program.

4. Alternatives C and D modified the L-28 Interceptor.

5. Alternative D13R increased water storage in the Upper East Coast, including the C-23 and C-24 basins and the North Fork and South Fork of the St. Lucie River.

Figure III-1. Schematic representation of the conceptual design changes between Alternative D and Alternative D13R within the Water Conservation Areas.



CHAPTER IV -- EVALUATION METHODOLOGY

Cheryl Buckingham and Robert Pace, FWS

A. Plan Formulation and Evaluation

The plan formulation stage of the C&SF Comprehensive Review Study began in earnest in October, 1997 with the formulation of the Alternative Development Team (ADT) and the Alternative Evaluation Team (AET). Both teams included representatives of a number of interested agencies, local governments, agricultural interests, and Native American tribes. The ADT began the planning process by developing a set of components that were modeled using the South Florida Water Management Model (SFWMM). The results of the "Starting Point" model were posted on the C&SF Restudy Web site-http://141.232.1.11/org/pld/restudy/hpm/index.html-where members of both teams and the public could comment. The AET met, analyzed the comments, and suggested improvements to the ADT. The ADT met, incorporated the AET's suggestions into the next model run, Alternative 1. This iterative process between the AET and the ADT was repeated over the following nine months as Alternatives 1-5 were formulated. At the end of the nine month period, enough information had been gained on certain components that optimized versions of them were available. At about the same time, a number of underlying assumptions in the 2050 plan had been reevaluated and the final version of the Natural System Model (NSMv4.5 Final) had become available. The Restudy Team decided to re-visit the base conditions and re-evaluate the best performing of the alternative plans (Alternatives 3-5) to incorporate the new information. This ensured that both base conditions and the alternatives contained the latest, best information available. It also guaranteed that the earlier alternatives were not unduly handicapped simply because they contained preliminary, imperfect versions of components that had since been optimized. At this same time, the newest alternative was modeled. This plan would have been Alternative 6, but the "re-scaled" alternatives were renamed A through D to avoid confusing them with the earlier versions.

Extensive evaluations of the benefits and impacts of each alternative on the natural resources of the south Florida ecosystem were conducted by sub-region teams of the AET. The entire AET then met to review the sub-region team conclusions and to suggest improvements and priorities for the ADT to include in the formulation of the next alternative. Representatives from all of the resource agencies, including FWS, NPS, GFC, USGS, and NOAA/NMFS were fully integrated into the AET. Ample opportunity was made available to review, evaluate, comment upon, and to suggest improvements at each step in the plan formulation and plan selection process. For this reason, FWS determined that it was unnecessary to develop a separate evaluation of the alternatives to satisfy the requirements of the Fish and Wildlife Coordination Act Report. This evaluation, therefore, consists of a review of the tools used by the AET to analyze the alternatives (this chapter) and a summary of the AET's findings (Chapter V). The strengths and weaknesses of the selected alternative that FWS and the other agencies, particularly within the DOI, believe are important are included in Chapter V.

B. The Development of Evaluation Tools

A number of evaluation tools were used by the AET and ADT to communicate with each other and to evaluate the outputs of the SFWMM runs. These included the Natural System Model (NSMv4.5 Final), Conceptual Models, Performance Indicators, Performance Measures, River of Grass Evaluation Methodology (ROGEM), Across Trophic Level System Simulation (ATLSS), water quality tools, the Multi-Species Recovery Plan, scientific literature, and individual expertise. Each alternative was examined by the AET in light of the Existing Condition (1995 Base), and the Future Without Project condition (2050 Base) to ensure that progress was being made in the direction of restoration.

1. Natural System Model (NSMv4.5 Final). The NSMv4.5 Final simulates the hydrology of the Everglades under a more natural landscape. This model is based on the SFWMM with the man-made modifications to the landscape (including canals, structures, pumps, etc.) removed. All of the dominant hydrologic processes are included in this two-dimensional, integrated ground and surface water model. It covers many but not all of the areas of interest, the exceptions being the St. Lucie and Caloosahatchee basins, parts of western basin (west of State Road 29), Florida Bay, and Biscayne Bay. The NSMv4.5 Final runs on a daily time step using historical meteorological conditions for the period from 1965-1996 and illustrates the differences between the pre-drainage and the current, highly-managed systems. Greater spatial and temporal extent of surface water depths occurred under natural conditions and some of the deeper pools have relocated from the west side of the coastal ridge to the present-day Water Conservation Areas. Both ground and surface water flow volumes in all parts of the modeled area show significant differences in quantity and timing of flows throughout the Everglades basin. The NSM is useful as a conceptual goal, as a way to visualize the historic distribution patterns of flows, depths, and hydroperiods. Because the natural area is greatly reduced from historic conditions and has, in several ways, been irreparably altered, matching NSMv4.5 Final grid-for-grid in each location is neither practical nor advisable. Creating a system that mimics a scaled-down version of NSMv4.5 Final is also ill-advised because it is unlikely that a reduced version of the natural system would function the same way. During the formulation of alternatives 1-5, the provisional version of the NSMv4.5 was used in the SFWMM as the basis for the targets for many performance measures. When the final version of NSMv4.5 became available, Alternatives 3 through 6 and the two base conditions were rerun using NSMv4.5 Final and the alternatives were renamed Alternatives A through D.

2. Conceptual Models. Identifying targets for restoration for the south Florida ecosystem required many years of effort by a number of people associated with private organizations, government agencies and universities. In 1996, the Governor's Commission for a Sustainable South Florida completed a Conceptual Plan for the C&SF Project Restudy. This conceptual plan recognized the need for increased storage in the system, improved continuity in natural areas, adequate water quality, increased spatial extent, conservation of soils, protection and restoration of coastal estuarine and marine ecosystems, and control of invasive plants. In 1997, the Science Subgroup of the Working Group of the South Florida Ecosystem Restoration Task Force published a list of specific, measurable success criteria (Science Subgroup 1997). The group identified them to help design modeling and monitoring programs and to aid in the evaluation and reporting process. Some success indicators were considered to be “precursors” to restoration. These included hydropatterns, organic soil, nutrients, estuarine salinity patterns, and water clarity. The rest were considered “ecologic” indicators. These included landscape patterns and spatial extent (considered to be a precursor, as well), periphyton communities, coral reefs, contaminant body burdens, fish abnormalities, keystone and imperiled species, wading birds, fish populations and communities, and fish species.

Members of the Everglades Partnership conducted a Workshop on Ecological Sustainability Criteria for South Florida on April 25-26, 1996, at the University of Miami, with participation by natural and social scientists, representatives of public interest groups, and managers of government agencies. They reviewed the scientific basis for the selection of the Science Sub-Group’s indicators and broadened public and academic participation in the process. To implement the success criteria, they identified modeling, research, and monitoring needs and identified critical research issues that were impeding their evaluation. Although the Everglades partnership generally endorsed the Science Sub-Group’s selection of precursor and ecological indicators, the group recommended that clearer goals be established and that those goals eventually should form the basis for environmental “report cards,” which are considered the heart of annual reports of restoration success. They discussed the need for indicators to operate at different temporal and spatial scales to reflect the range of response times and levels of complexity within the C&SF Project. The group also addressed issues of societal preferences in the selection of important attributes of the system.

The group agreed on the need to form hypotheses around the system’s interactions that should be expressed in Conceptual Models to clarify the causal links between management options, precursor indices, and changes in ecosystem structure and function as expressed in ecological indices. Conceptual models, they believed, also would be an effective tool for describing and communicating these linkages to the public.

After the workshop, the group agreed to prepare a strategic plan to identify the roles of science in the planning, implementation, and evaluation phases of the restoration process. This strategic plan became the basis for the Adaptive Management strategy (Figure XIV-1)

Following the recommendations of the Sustainability Criteria Workshop, the Natural Systems Team (NST) subgroup of the Southern Everglades Restoration Alliance (SERA) and other *ad hoc* groups drafted a number of conceptual ecological models. A conceptual model as defined by the NST is a simple, non-quantitative model developed to build consensus on the most important ecological elements and linkages that characterize a stressed ecosystem. A conceptual model was drafted for most of the landscape types in the south Florida ecosystem, that defined the stressors, the effects of those stressors, and the attributes of the system that are important in illustrating the impacts of the stressors on the landscape. Conceptual models also identify performance criteria, also called performance indicators. For example, "low water levels (<11 ft)" are one of the stressors in the Lake Okeechobee conceptual model (Figure IV-1). The "effects" of low water levels include "exposure and drying of interior marsh, exposure and drying of shoreline vegetation, expansions of exotic and nuisance plants, loss of native plants and periphyton, and loss of desired invertebrates and forage fish. The "attributes" that exhibit the effects of low water levels are “fish and wildlife.”

Draft conceptual models were developed by the NST for Everglades Sloughs, Marl Prairies/Rocky Glades, Mangroves, and Florida Bay. Other *ad hoc* teams developed conceptual models for Lake Okeechobee, St. Lucie and Caloosahatchee Estuaries, Biscayne Bay, and the Big Cypress region. These conceptual models and their performance indicators were heavily relied upon by the AET team to develop performance measures to evaluate the set of base cases and alternative plans. Figures IV-1 and IV-2 illustrate the structure of two portions of the larger conceptual model for Lake Okeechobee-- those areas dealing with the extreme high water and extreme low water stressors, which were among the criteria for evaluation of the effects of the Restudy alternatives on Lake Okeechobee.

3. Performance indicators. Performance criteria and performance indicators, unlike performance measures described below, are usually recommendations for directional improvement and do not include quantitative targets. Performance indicators are means of measuring impacts of hydrologic conditions on different attributes of the system.

4. Performance measures. Performance measures were developed from performance indicators by identifying a specific target that defines the optimum condition. Hydrologic performance measures were based on the following: Outputs from the Natural Systems Model (NSMv4.5 Final) or other hydrologic modeling, information on optimizing the ecological attributes from the conceptual models, or best scientific evidence. Of the several hundred hydrologic performance indicators and measures developed to illustrate outputs of the SFWMM for each model run, a subset of performance measures was eventually selected that best represented the AET’s goals. Ecological performance measures were also developed for a number of species, guilds, and habitat types. Results of the AET’s analyses of these performance measures was posted on the Web site and formed the basis for: 1) the AET’s evaluation of alternatives in each iterative cycle of plan development, 2) the ultimate selection of the Initial Draft Plan (Alterative D13R), and 3) the DOI’s continual involvement in the process, leading to the findings of this report.

5. River of Grass Evaluation Methodology (ROGEM). ROGEM is a landscape-scale, habitat-based methodology, which yields outputs representing relative responses of wetland habitats to Restudy alternatives. ROGEM's methods and a preliminary set of equations were developed during the C&SF Reconnaissance Study and presented in the Reconnaissance Report (COE 1994). ROGEM uses a system-wide approach appropriate for a large, diverse study area. It focuses on hydrologic conditions within the study area and indicates relative habitat responses to changing hydrologic conditions resulting from project alternatives. ROGEM yields numeric output indicating relative habitat quality for each area and uses input from SFWMM and other models as available or appropriate (e.g. water quality). ROGEM, as used during the reconnaissance study, has been peer-reviewed through the SFWMD’s Expert Assistance Program. Because it operates at the landscape scale, ROGEM cannot be used to evaluate impacts at the species level (e.g. threatened and endangered species).

The classification of the different south Florida landscapes used in ROGEM was revised to be consistent with the Conceptual Models described above. A ROGEM analysis was prepared for each of the AET's sub-region teams. Each team developed hydrologic performance measures based on either their Conceptual Models, or, lacking them, on best professional judgement. Near the end of the iterative plan formulation process, sub-teams developed index variables based on the performance measures and combined them, weighting the elements they believed were most important or most indicative of restoration success. Most variables used spatial or temporal hydrologic data taken directly or post-processed from the South Florida Water Management Model (SFWMM). Equations also include some water quality and other appropriate variables. ROGEM outputs represent **quality** of fish and wildlife habitat on a 0 to 1 scale. The outputs are ordinal data with 1(one) representing optimum quality habitat and 0 representing worst quality habitat. Outputs show relative system-wide habitat responses to restoration plans. ROGEM was among the evaluation tools used by the AET to rank the relative performance of each alternative relative to the 2050 Base condition and to assess how closely each alternative approached its goals in each of the sub-regions.

ROGEM analyses were completed for Lake Okeechobee, freshwater marshes (Everglades), Big Cypress, Florida Bay, Southern Mangroves, Biscayne Bay, St. Lucie estuary, and the Caloosahatchee estuary.

The documentation for the ROGEM model used to evaluate effects of Restudy alternatives on Lake Okeechobee is provided at the end of this chapter.

6. Across Trophic Level System Simulation (ATLSS). Not every AET sub-region team represented a geographical landscape--the sub-teams for water quality and endangered/indicator species are examples. The endangered/indicator species subgroup reviewed the results of the Across Trophic Level System Simulation **(**ATLSS) model to gauge the effects of different restoration scenarios on biotic components of the south Florida ecosystem. ATLSS uses pseudo-topography to step down the 2-mile-by-2-mile grid scale of the SFWMM to 500 m or finer resolution. At this finer scale, a number of models are being developed at different trophic levels to capture the different scales that reactions to hydrologic changes can occur. Eventually, individual-based models and population-level models will be available for a wider, more representative set of animals. Currently, structured population-scale models exist for fish, macroinvertebrates, reptiles and amphibians. Individual-based, breeding potential or foraging potential models exist for the Cape Sable seaside sparrow, snail kite, wood stork, white-tailed deer and Florida panther. Model results for each alternative were compared to the results of the 1995 Base and to the 2050 Base to determine the effect of an alternative on a selected native species in south Florida. ATLSS has not been run using the NSMv4.5 Final due to the amount of uncertainty associated with defining pre-drainage vegetation patterns, but the results of such a model run would be welcomed by ecologists.

7. Water Quality Evaluation Tools. Other evaluations used the SFWMM output to assess potential effects of the Restudy alternatives on water quality. These include: 1) Lake Okeechobee Water Quality Model, 2) Everglades Water Quality Model, and 3) Dr. William W. Walker's water quality performance measures. Complete descriptions of these evaluation methods are available at the following Web sites:

Name of Evaluation Method	World Wide Web Address
Lake Okeechobee Water Quality Model	http://141.232.1.11/org/erd/osr/projects/lowqmweb/indexwq.html
Everglades Water Quality Model	http://141.232.1.11/org/erd/esr/projects/ewqm/restudy/java
Dr. William W. Walker's water quality performance measures	www2.shore.net/~wwwalker/restudy/index.htm

8. Multi-Species Recovery Plan for the Threatened and Endangered Species of South Florida. Recovery plans are prepared by the U.S. Fish and Wildlife Service. They delineate reasonable actions that are believed to be required to recover and/or protect listed species. The Multi-Species Recovery Plan for the Threatened and Endangered Species of South Florida (1998) identifies the recovery needs of 68 species that are listed as threatened or endangered pursuant to the Endangered Species Act of 1973, as amended (16 U.S. C. 1531 *et seq)*. Of these 68 species, 59 depend on the success of the South Florida Ecosystem Restoration Initiative. Each alternative plan was evaluated to determine not only its possible impacts to listed species, but its potential to recover them.

Editorial Note: The following pages provide examples of a ROGEM analysis using hydrology-based performance measures for Lake Okeechobee. The figures that follow illustrate those portions of the Conceptual Model for Lake Okeechobee that relate to the extreme high water and extreme low water stressors.

Priority Hydrologic Performance Measures for Lake Okeechobee
Authors: K. Havens (SFWMD), L. Manners (COE), R. Pace (FWS)

Five priority performance measures are calculated, weighted and summed using the River of Grass Evaluation Model (ROGEM) for Lake Okeechobee. The Lake Okeechobee ROGEM is comprised of metrics (Suitability Index Variables, or SIVs) that concern the fluctuation and timing of lake stages. These variables exert major controls over ecosystem structure and function. Fluctuation and timing of lake stages affect the distribution of native and exotic plant communities, and in turn the habitat quality (cover, nesting sites, foraging habitat) for fish, birds, and other wildlife (Aumen 1995). The ROGEM assumes that restoration of a more natural (within the constraints of the dike system) hydroperiod would result in positive biotic responses of the lake community.

Each SIV ranges from 0 (worst score) to 1.0 (best score). Relationships between hydrologic attributes and SIVs in this model are not linear, but reflect expert opinion that the degree of ecosystem stress is exacerbated by an increasing occurrence of undesirable events. This gives rise to a curvilinear relationship between hydrologic attributes and their SIVs. At a certain point (considered here to be 4 events or more per decade), the degree of stress is so severe that the ecosystem cannot recover its ecological and societal values.

An extreme low lake stage (<11 ft) performance measure ($\mathbf{SIV_{MINX}}$) indicates the frequency of events that result in a loss of over 95% of the littoral zone as habitat for aquatic biota, and promote expansion of exotic plants into pristine native-plant dominated regions of the lake. The goal is to have a minimal number of these events. The performance measure score is calculated as follows:

Lake stage never falls below 11 ft = 1.0
Lake stage falls below 11 ft on 1 occasion per 10 yrs = 0.9
Lake stage falls below 11 ft on 2 occasions per 10 yrs = 0.7
Lake stage falls below 11 ft on 3 occasions per 10 yrs = 0.4
Lake stage falls below 11 ft on 4 or more occasions per 10 yrs = 0

A moderate low lake stage (<12 ft) performance measure ($\mathbf{SIV_{MINM}}$) indicates the frequency of prolonged (>12 continuous month) events that substantially reduce the littoral area available as wildlife habitat, and promote exotic plant expansion. The goal is to have a minimal number of these events. The performance measure score is calculated as follows:

Lake stage never falls below the 12 ft / 12 month criterion = 1.0
Lake stage falls below the 12 ft / 12 month criterion on 1 occasion per 10 yrs = 0.9
Lake stage falls below the 12 ft / 12 month criterion on 2 occasions per 10 yrs = 0.7
Lake stage falls below the 12 ft / 12 month criterion on 3 occasions per 10 yrs = 0.4
Lake stage falls below the 12 ft / 12 month criterion on 4 or more occasions per 10 yrs =0

An extreme high lake stage (>17 ft) performance measure (**SIV$_{MAXX}$**) indicates the frequency of events that may cause wind and wave damage to the shoreline plant communities, and transport phosphorus-laden pelagic water into pristine interior regions of the littoral zone. The goal is to have a minimal number of these events. The performance measure score is calculated as follows:

Lake stage never exceeds 17 ft = 1.0
Lake stage exceeds 17 ft on 1 occasion per 10 yrs = 0.9
Lake stage exceeds 17 ft on 2 occasions per 10 yrs = 0.7
Lake stage exceeds 17 ft on 3 occasions per 10 yrs = 0.4
Lake stage exceeds 17 ft on 4 occasions per 10 yrs = 0

A moderate high lake stage (>15 ft) performance measure (**SIV$_{MAXM}$**) indicates the frequency of prolonged (>12 continuous months) events that may: limit light penetration to the lake bottom, resulting in a loss of the benthic plants and algae that stabilize sediments and provide habitat for invertebrates and fish; and promote greater circulation of phosphorus-rich turbid waters from mid-lake to less eutrophic near-littoral regions, where phosphorus inputs stimulate algal blooms. The goal is to have a minimal number of these events. The performance measure score is calculated as follows:

Lake stage never exceeds the 15 ft / 12 month criterion = 1.0
Lake stage exceeds the 15 ft / 12 month criterion on 1 occasion per 10 yrs = 0.9
Lake stage exceeds the 15 ft / 12 month criterion on 2 occasions per 10 yrs = 0.7
Lake stage exceeds the 15 ft / 12 month criterion on 3 occasions per 10 yrs = 0.4
Lake stage exceeds the 15 ft / 12 month criterion on 4 occasions per 10 yrs = 0

A spring recession performance measure (**SIV$_{VAR}$**) indicates the number of years during which January to May lake levels decline from near 15 ft to 12 ft, without any reversals greater than 0.5 ft. These conditions appear to be favorable to nesting birds and other wildlife in the marsh. They also may allow for re-invigoration of willow stands, and permit fires to burn away cattail thatch. The goal is to have a substantial number of events. The performance measure score is calculated as follows:

Stage recession between January and March from ~15 ft to ~12 ft NGVD, with no reversal greater than 0.5 ft NGVD, occurring every yr = 1.0
Stage recession occurring only in 9 out of 10 yrs = 0.9
Stage recession occurring only in 8 out of 10 yrs = 0.7
Stage recession occurring only in 7 out of 10 yrs = 0.4
Stage recession occurring only in 6 or fewer out of 10 yrs = 0

SIV Priority Weights

The five SIVs address important aspects of how water level and its seasonal variation affects the intrinsic ecological (e.g. habitat for wading birds and federally endangered species) and societal (e.g. recreational fisheries) values of Lake Okeechobee. However, the five SIVs are not considered of equal importance in regard to indicating an absolute level of stress (or benefit). A weighting scheme was developed, on the basis of best professional judgement, to reflect the relative importance of each SIV as an index of lake ecosystem health. For simplicity, a weighting scale of 1 to 5 (1 being least important, and 5 being most important) is used.

The SIVs associated with the >17 ft and >15 ft / 12 month criteria are given priority weights of 5. Extreme or prolonged high water levels have been documented to affect numerous ecosystem attributes, including: littoral plant and periphyton communities; benthic plants and periphyton; fisheries habitat; and water quality (including turbidity, phosphorus, and algal blooms). These effects are well documented by scientific research (Sheng and Lee 1991, Havens 1997, Steinman *et al.* 1997).

The SIVs associated with the <11 ft and <12 ft / 12 month criteria are given priority weights of 4. Extreme or prolonged low lake stages also may cause harm to the ecosystem, but the impacts are less documented and are not considered as serious on a lake-wide basis, that is, the effects primarily are restricted to the littoral zone proper, and negative impacts (e.g., loss of fisheries habitat) may in part be compensated for by enhanced growth of submerged plants in the southern near-shore pelagic region.

The SIV for spring lake level recession describes a seasonally-variable hydro-pattern that is considered by experts to benefit a variety of littoral zone values, including wading birds and certain native plant communities (Smith *et al.* 1995). It is the only SIV that relates to seasonal variation in lake levels and that variation is considered by experts (Havens and Rosen 1997) to be critical for a healthy ecosystem. However, there is a high degree of uncertainty in scoring the spring recession attribute. For example, do recession events that occur slightly earlier or later than the designated optimal (January-May) period have equal or lesser benefit to the community? Do recession events that occur over higher or lower ranges of water depth than the designated optimum (15 to 12 ft) have equal or lesser benefit to the community? There are no clear answers to these questions, and therefore, until further research results are available, the SIV associated with this attribute is given a weighting of 3.

Integrated Scoring

A Community Suitability Index (CSI) integrates the scores of five hydrologic SIVs and their respective weighting factors, and has an overall range of 0 to 1.0. The weighted CSI model is:

$$\mathbf{CSI} = (4*SIV_{MINX} + 4*SIV_{MINM} + 5*SIV_{MAXX} + 5*SIV_{MAXM} + 3*SIV_{VAR}) / 21$$

Table IV-1. Example of the results of the ROGEM analysis for Lake Okeechobee. Evaluation of Alternatives A through D, D13R, and the revised 1995 and 2050 base conditions.

Variables	95Base		50Base		ALT A		ALT B		ALT C		ALT D		ALT D13R		WEIGHT
	#	Value	#	Value	#	Value	#	Value	#	Value	#	Value	#	Value	
SIV min-x (Extreme Low Stage, <11')	3	0.4	4	0	2	0.7	2	0.7	1	0.9	1	0.9	1	0.9	4
SIV min-m (Prolonged Low,< 12' for 12 mo.)	1	0.9	1	0.9	1	0.9	1	0.9	1	0.9	0	1	0	1	4
SIV max-x (Extreme High Stage, > 17')	2	0.7	1	0.9	1	0.9	1	0.9	1	0.9	1	0.9	1	0.9	5
SIV max-m (Mod.Stage, > 15' for 12 mo.)	1	0.9	1	0.9	1	0.9	1	0.9	1	0.9	1	0.9	1	0.9	5
SIV var (Spring Lake Level Recession)	2	0	2	0	3	0.7	3	0.7	4	0.7	4	0.7	4	0.7	3
Weighted CSI	0.6		0.6		0.8		0.8		0.9		0.9		0.9		

CSI = ((SIV min-x * 4) + (SIV min-m * 4) + (SIV max-x * 5) + (SIV max-m * 5) + (SIV var * 3)) / 21

CHAPTER V -- ANALYSIS OF ALTERNATIVES

Summarized from the reports of the AET Sub-region Chairs

A. Threatened, Endangered, and Indicator Species (ATLSS Model Results)

Information on threatened and endangered species is presented in Chapter XVI of this report. Indicator species analyzed through the ATLSS modeling included a fish, white-tailed deer, and wading bird models. The following information summarizes impacts the C&SF Restudy will have on these indicator species.

1. Fish The ATLSS fish model results have consistently predicted higher overall fish abundances as flow volume and inundation duration have moved closer to NSM conditions. Based on these previous results, we can make some general predictions for Alternative D13R. Alternative D13R hydrologic conditions should produce average fish abundances higher than those expected for 2050 Base as expected hydroperiods increase consistent with NSM. In particular, increased hydroperiods in northeast Shark River Slough, Taylor Slough, WCA 3B, northeast WCA 3A, and Loxahatchee NWR should lead to greater fish abundance. This should also be true when only prey-sized fish at appropriate wading bird foraging depths are counted except for the deepest parts of Shark River Slough and WCA 3B.

2. White-tailed Deer Since ATLSS white-tailed deer results are not available for Alternative D13R, predicted effects on deer must be inferred from the ATLSS high resolution hydrology results and other sources. A review of performance measures for WCA 3A and 3B indicator regions shows that Alternative D13R reduces many of the excessive high water conditions and excessive inundation durations that had caused concern for eastern WCA 3A, southern WCA 3A and WCA 3B in several previous alternatives. These improvements should provide slightly better foraging conditions and reduced drowning losses for white-tailed deer in WCA 3 under Alternative D13R as compared to Alternative D. Overall, increased hydroperiods in most of the WCAs and northeastern Big Cypress under Alternative D13R as compared to the 2050 Base would likely slightly decrease habitat quality in these marginal deer habitats. Small areas of northeastern and southern WCA 3A and the Big Cypress-ENP border area are exceptions. Alternative D13R continues progress towards NSM-like conditions in most of ENP and would be expected to continue to produce reduced white-tailed deer habitat suitability in many already poor deer habitats for this region. For those few areas with high deer breeding potential (Long Pine Key and surrounding short hydroperiod marsh and northwest Big Cypress), there is little difference between Alternative D13R and the 2050 Base.

3. Wading Birds Since ATLSS wading bird results are not available for Alternative D13R, predicted effects to wading birds must be inferred from the ATLSS high resolution hydrology results and other sources. A review of performance measures for WCA 3A and 3B shows that Alternative D13R reduces many of the excessive high water conditions and excessive inundation durations that had caused concern for eastern WCA 3A, southern WCA 3A and WCA 3B in several previous alternatives. These improvements should provide relatively larger areas suitable for wading bird foraging and decreased flood-induced losses of wading bird nesting substrates in WCA 3 under Alternative D13R as compared to Alternative D. When compared to the 2050 Base, Alternative D13R provides mixed results for wading birds in WCA 3, with improvements in southern WCA 3A (due to reduced high water) and in northern WCA 3A (due to reduced drydowns), and losses in northeastern WCA 3A and WCA 3B (due to increased high water).

Hydrologic performance measures for the southern Everglades and for Florida Bay also indicate that Alternative D13R better matches natural conditions in these areas than other Alternatives. The improvement in the timing and duration of freshwater flows to Florida Bay estuaries and improved timing of fish-concentrating drydowns should lead to better wading bird foraging and breeding conditions in the southern Everglades under Alternative D13R relative to both base cases. Greater fish abundances expected under Alternative D13R, as compared to the 2050 Base, also suggest improved foraging conditions for wading birds.

B. Lake Okeechobee

Chapter IV provided the ROGEM equations for Lake Okeechobee as an example of an evaluation used by the AET.

The Initial Draft Plan appears to improvements conditions in Lake Okeechobee and its littoral zone. Both the 1995 Base and the 2050 Base had summary scores of 0.6 in the ROGEM analysis. These scores would be characterized as fair to poor in overall performance. All of the Restudy alternatives improved on these scores. Alternatives A and B had identical scores for all variables in the ROGEM equations; summary scores for these simulations improved to 0.8, through reduction in the number of extreme low water stages and an increase in the number of years when the water recession in spring is considered to be favorable to foraging by wading birds. Alternatives C, D, and D13R had identical scores for all of the ROGEM variables, with 3 of the 5 indices as high as those for Alternatives A and B, and with the remaining 2 indices higher. The two improved indices were those for avoidance of extreme low water and avoidance of moderately low water lasting more than 2 years. The summary ROGEM scores for Alternatives C, D, and D13R were 0.9, which we believe would achieve very favorable hydrologic conditions for fish and wildlife habitat in the lake's littoral zone. However, based on results from a model scenario in which the ASR component around Lake Okeechobee was removed, we believe that this level of success in reaching ecological targets is partially dependent on the feasibility of that feature. Should ASR at this scale prove to be infeasible, we expect that the ecological benefits would be significantly reduced. The COE has not completed sensitivity analyses on the Initial Draft Plan, which should include an evaluation of the effect of the inability to use large-scale ASR around Lake Okeechobee.

C. Estuaries - Caloosahatchee and St. Lucie Estuaries; Lake Worth Lagoon

The estuaries, bays, and lagoons of south Florida are the ultimate receiving waters for the flows retained and rerouted by the C&SF Project. Currently, groundwater and surface water flows to coastal waters are generally reduced with altered hydroperiods. To a large degree, surface water input is currently intercepted and delivered through regulated canals that are characterized by high amplitude and short duration storm flows during the wet season; and low base flow during the dry season. Abnormally high flows contribute to poor water quality with increased turbidity, color, and altered salinity levels that directly affect estuarine seagrasses by reducing light penetration necessary for photosynthesis and destroying wildlife, fish, and invertebrate habitat. Minimum levels of inflow and nutrients usually occur in April and May, at the end of the dry season, when juvenile fish depend on an abundant food supply of phytoplankton and zooplankton, which requires a minimum level of freshwater and nutrients.

1. Caloosahatchee Estuary The Restudy project alternatives were evaluated with performance measures based on flow needed to support optimum hydrologic conditions conducive to optimum quality habitat for fish, wildlife, and other aquatic resources in the Caloosahatchee estuary. The targets are based on model outputs of natural variation that would have occurred during the period 1965-1995 as well as on desirable salinity conditions for existing and potential aquatic resources within the estuary. A summary of the measures evaluated, the results, and recommendations are provided below.

Performance Measure- number of dry season months (November-May) that the mean monthly flow was less than 300 cfs from C-43 and Lake Okeechobee at S-79: The target number of months not to be exceeded, and considered better for estuarine aquatic biota, is 60 times for the 1965-1995 period. This should maintain sufficient minimum mean monthly flows from the lake in order to maintain favorable salinities and water quality within the estuary. Insufficient fresh water discharges contribute to poor estuarine water quality including inadequate fresh water to maintain desirable salinity envelopes. Allowing the estuary to become too saline has produced adverse effects on estuarine seagrasses, fish and invertebrates, including critical indicator species, e.g. *Vallisneria.*

Performance Measure- number of months of mean monthly flow greater than 2,800 cfs as measured at S-79. High volume discharges to the estuary contribute to poor estuarine water quality including increased turbidity, color and violation of favorable salinity envelopes. High flow events have direct effects on estuarine seagrasses by reducing light penetration necessary for photosynthesis, destroying fish and invertebrate habitat, and contributing to unfavorable salinities for aquatic vegetation, fish and invertebrates, including critical indicator species, e.g. the American oyster, turtle grass, and *Vallisneria*. The optimum scenario would have no more than 22 months of mean monthly flows of greater than 2,800 cfs during the simulation period. This should reduce high volume discharge events to the estuary and improve estuarine water quality to benefit estuarine vegetation, invertebrates, and fish communities.

Performance Measure- number of months mean monthly flows were greater than 4,500 cfs at S-79 for the 1965-1995 period. This is to reduce the occurrence of extreme discharge events and improve water quality in the lower estuary, including San Carlos Bay, in order to protect estuarine resources. Mean monthly flows above 4,500 cfs result in freshwater conditions throughout the estuary causing impacts to biota. This volume of flow also degrades water quality and adversely impact biota in San Carlos Bay. The total allowable number of monthly violations indicate that the optimum condition is to have no more than 6 months of mean monthly flows of greater than 4,500 cfs during the simulation period.

Performance Measure- number of days Lake Okeechobee Regulated Discharges from Zone A greater than 7,800 cfs. Zone A discharges have rapid and serious effects on estuarine seagrasses in the Caloosahatchee estuary and San Carlos Bay by reducing light penetration necessary for photosynthesis. Zone A discharges destroy fish and invertebrate habitat and contribute to unfavorable salinities for estuarine biota, including critical indicator species, e.g. the American oyster, *Vallisneria*, and other vegetation. The target is zero violations in order to reduce the occurrence of extreme discharge events from the lake to the estuary, improve estuarine water quality, and protect estuarine aquatic biota. Furthermore, the results of hydrologic modeling of the period 1965-1995 indicate that no daily flows greater than 7,800 cfs would have occurred.

An evaluation of the performance measures for each project alternative indicated that Alternatives A through D13R all score 1.0 on a scale of 0.0 to 1.0. Any of the alternatives would be considered very good for the Caloosahatchee Estuary. All the alternatives greatly exceed the target values set in the performance measures (except for regulatory releases which meets the target). Furthermore, Alternatives A through D13R show major improvements over the 1995, which scored 0.0, and the 2050 Base, which scored 0.1. One footnote is that D13 predicted better flows overall for the estuaries in southwest Florida than did D13R. The flow dynamics should be modeled to determine the cause of the apparent flow decrease.

2. St. Lucie Estuary The Restudy alternatives were assessed with performance measures based on the flow needed to provide optimum hydrologic conditions for optimum quality habitat for fish, wildlife, and other aquatic resources. Flow targets are based on natural variation that occurred during the period 1965-1995 as well as on desirable salinity conditions for existing and potential aquatic resources within the estuary. The St. Lucie estuary receives fresh water both through inter-basin transfer from Lake Okeechobee and from local watershed contributions. Inflow problems can be divided into two categories: 1) high inflow events, when large regulatory releases from the lake and/or the watershed cause poor estuarine water quality and 2) maintaining dry season base flows. Minimum levels of inflow and nutrients usually occur in April and May, at the end of the dry season, when juvenile fish depend on an abundant food supply of phytoplankton and zooplankton, which require a minimum level of fresh water and nutrients.

With regard to the first type of inflow problem, fish with tumors, lesions, and scale and other deformities have historically been present in the St. Lucie River and at least four fish disease events have been noted since 1979 that appear to correlate to high discharges from Lake Okeechobee. In early 1998, when the wet winter caused releases out the C-44 canal to reach a peak of 8,500 cfs, a disease event occurred with lesioned fish concentrated around the St. Lucie estuary. About 28 species of fish were reported with lesions, including mullet (*Mugil cephalus*), shark (subclass Elasmobranchii), bluegill (*Lepomis macrochirus*), gray snapper (*Lutjanus grisues*), bluefish (*Pomatomus saltatrix*), tuna (*Thunnus sp.*), snook (*Centropomus undecimalis*), red drum, spotted sea trout (*Cynoscion nebulosus*), and channel catfish (*Ictalurus punctatus*). No extensive fish kills were recorded, but rather a chronic disease situation appeared related to a toxic dinoflagellate, *Cryptoperidiniopsis.* The exact relationship between the dinoflagellate and discharges and water quality is not proven at this time. To address the second type of inflow problem, appropriate inflows to the estuary which produce a favorable salinity range were determined based on the requirements of submerged aquatic vegetation (SAV) and oysters. Surface water flows coming from the watershed and ground water should be in the range of 350 cfs to 1,600 cfs. Performance measures are described below.

Performance Measure- number of months with mean monthly flow less than 350 cfs for the 1965-1995 period. The objective is to maintain adequate mean monthly flows in order to maintain favorable conditions for estuarine organisms. This includes the importance of fresh water and nutrient input into the system in the appropriate quantity and timing to support primary and secondary productivity. Insufficient freshwater discharges during the dry season contribute to reduced estuarine productivity. For the estuary to act as a nursery for juvenile fish, plankton populations should be at a high enough density for fish to easily feed. The optimum scenario would have no more than 50 months of mean monthly flows of less than 350 cfs during the simulation period..

Performance Measure- number of months with mean monthly flows greater than 1,600 cfs as measured from the lake and the watershed for the 1965-1995 period of record. This is to reduce high volume discharge events to the estuary and improve estuarine water quality to protect and enhance estuarine habitat and biota. Recent analysis has determined that mean monthly flow should not frequently exceed 1,600 cfs. As flows exceed this limit, the salinity is reduced below desirable levels for some estuarine resources. These events have direct effects on SAV by reducing light penetration necessary for photosynthesis, degrading fish and invertebrate habitat, and contributing to unfavorable salinity concentrations for aquatic vegetation, fish and invertebrates. The optimum scenario would have no more than 9 months of mean monthly flows greater than 1,600 cfs.

Performance Measure- number of months with mean monthly flows greater than 2,500 cfs for the 1965-1995 period. The objective is to reduce the occurrence of extreme discharge events and improve water and sediment quality in the estuary to protect estuarine vegetation, invertebrates, and fish communities. Mean monthly flows above 2,500 cfs result in freshwater conditions throughout the estuary, producing severe impacts to estuarine biota. This volume of flow begins to impact the Indian River Lagoon to the north and south of the St. Lucie inlet. The optimum condition is to have no more than 3 months of mean monthly flows greater than 2,500 cfs.

Performance Measure- number of days with Lake Okeechobee Zone A discharges greater than 7,200 cfs per day at S-80 for the period 1965-1995. Zone A discharges transport large amounts of sediment and result in freshwater conditions within the entire estuary. These events can have rapid and serious effects on estuarine SAV by reducing light penetration necessary for photosynthesis, destroying fish and invertebrate habitat. They contribute to unfavorable salinity concentrations for most aquatic life, including the American oyster and SAV, as well as contributing to the occurrence and severity of fish diseases. These large volume discharges also cause adverse effects on large areas of the Indian River Lagoon surrounding the St. Lucie inlet and possibly influence nearshore ocean habitats adjacent to the inlet. Prolonged Zone A discharges result in even greater damage to the various ecosystems and more widespread adverse effects. Because of the magnitude of Zone A releases on the environment, this variable is the highest priority of the four performance measures. The objective is to eliminate extreme discharge events from the lake to the estuary, and improve estuarine water quality in order to protect existing and potential habitat for estuarine vegetation, invertebrates, and fish communities. No Zone A discharges of this magnitude are desirable. Furthermore, the results of hydrologic modeling of the period 1965-1995 indicate that no daily flows of greater than 7,200 cfs would have occurred during this period.

Alternatives A through D13R each scored 0.8 on a scale of 0.0 to 1.0. There is very little difference between Alternatives A through D13R for the St. Lucie estuary, although Alternative D13R performed slightly better due to the increased storage in the basin which will attenuate more flood flows. The basin runoff results in all alternatives are still about four times greater than their targets but regulatory release and low-flow targets were almost met.

3. Lake Worth Lagoon The performance measure used to evaluate Restudy project alternatives to Lake Worth Lagoon was wet/dry season average flows discharged through S-40, S-41, and S-155 for the 31 year simulation. The restoration target is to create estuarine conditions, to the extent possible, in the Lake Worth Lagoon. An estuarine salinity envelope of 23 ppt to 35 ppt was chosen as the target salinity range as it is a viable range for a number of organisms, many of which are commercially and important for recreation. To attain these salinities, a maximum flow of 500 cfs was predicted from hydrodynamic modeling to create a salinity of 23 ppt. To achieve a 35 ppt salinity, 0 cfs is the target because enough ground water enters the estuary to still allow these estuarine conditions.

Alternatives A, B, C, D were ranked with Alternative B best, followed by Alternative C, then Alternative D and Alternative A, with the 2050 Base coming in last. After closely examining the model output, the minimum flow performance criteria for Alternative D has a number of small releases that are above 0 cfs, but small enough so that they do not affect the salinity. So in actuality Alternative D is probably tied with Alternative C in the ranking. Alternative B was given a grade of "B", Alternatives C and D were graded a "C", Alternative A received a "D", and the 2050 and 1995 Bases were both graded "F." After reviewing the model output, it appears that Alternative D is probably very close to receiving a grade of "B". Alternative D13R has the same numbers as Alternative D and so would be ranked and graded the same.

D. Northern and Central Everglades Region

1. Evaluation Methods Model results for each alternative were evaluated at the level of individual indicator regions. Scores were then aggregated into spatially- and hydrologically-distinct groups. The final evaluation classified these indicator regions into ten sub-regions that correspond areas with distinct hydrologic performance. These are described in the AET's final report.

Initially, evaluations were based on five performance measures, with each measure containing one or two component variables. However, after inspection of initial scores, two of these were dropped resulting in the following performance measures and variables: 1) inundation pattern (variables - number and mean duration of inundation periods), 2) extreme high water (variables - number and mean duration of high water events), and 3) extreme low events (variables - number and mean duration of low water events).

Target variable values for the performance measures were those predicted by NSMv4.5 Final, with the following exceptions: 1) in Indicator Region 17, performance was evaluated by comparing values to the average of NSM values for Indicator Regions 14 and 18, 2) in Loxahatchee NWR, the targets were defined as the 1995 Base values, in keeping with the Refuge's current regulation schedule, 3) for high water extremes, the performance target was modified to be consistent with the number and duration of events less than or equal to NSM values, and 4) for low water extremes, the performance target was the minimization of the frequencies and duration of events.

Index values were developed for each performance measure and indicator region in order to simplify comparison of the alternatives. Indices were used as a basis for ranking Alternatives A through D relative to each other and the 2050 Base. For each performance measure and indicator region, indices were rounded to the nearest tenth and then ranked from 1 to 5, with ties given the mean of the tied ranks. These ranks were averaged across indicator regions (using spatial weights) and were also averaged across the three performance measures. Ranks for each alternative and the 2050 Base are presented in the AET's final report.

It was determined that the indices and ranks described above do not allow for a ecological interpretation of each alternative due to the largely arbitrary numeric scale. A separate evaluation was prepared for this purpose. Each performance measure for each indicator region was evaluated using best professional judgement of sub-team members as to the ecological consequences of the predicted performance. The sub-team then assigned each indicator region a color score of green, yellow, or red for each performance measure, with green assigned to a model performance if it predicted conditions expected to promote a sustainable Everglades marsh community. This color scheme is described in more detail in the AET's final report.

2. Sub-region Evaluations for Alternatives A through D13R

a) Loxahatchee NWR (Indicator Regions 26 & 27) (green). Loxahatchee performs well in Alternatives A through D13R, matching targets defined by the 1995 Base. The number and duration of extreme low water is reduced in each case, an improvement over the drier conditions predicted for the 2050 Base. The number and duration of high water events are also reduced compared to the 2050 Base, in fact, the alternatives meet performance targets for extreme high water. . There is some uncertainty about the effect of high water on tree islands in southern LOXAHATCHEE NWR, however, overall, the alternatives conform to current hydrologic management objectives for the refuge.

b) Holey Land and Rotenberger WMAs (Indicator Regions 28& 29) (green). These areas perform nearly identically in Alternatives A through D13R. The regulation schedule for Rotenberger WMA appears to eliminate high water extremes effectively while maintaining suitable inundation patterns. In Holey Land, extreme depths over 1.75 ft occur only rarely and the frequencies and durations of extreme low water are less than those predicted by NSM. There is uncertainty about the minimum conditions needed to protect peat soils but as long as the alternative provides dry season deliveries via the STAs, it should be possible to adjust operational details so as to avoid further soil loss in these areas.

It should be noted that in Holey Land WMA, differences in performance relative to the 1995 and 2050 Bases do not provide a realistic comparison with the alternatives because the bases assumed a 0-2' regulation schedule that is not currently in use, nor is it likely to be implemented in the future. Hence, the sub-team evaluation in this area was restricted to comparisons with target values.

c) WCA 2A (Indicator Regions 24 & 25) (yellow). In general, Alternatives A through D13R exhibit problematic performance in WCA 2A compared to the 2050 Base and it is uncertain whether these conditions would lead to a sustainable healthy marsh in the future. Generally, model results are poor in northern WCA 2A (Indicator Region 25) and mixed in southern WCA 2A (Indicator Region 24).

Inundation patterns in northern WCA 2A were much longer. NSMv4.5 Final predicts that northern WCA 2A dried out approximately every year, yet Alternatives B through D13R predicted dry-outs to occur less than once every three years on average. In southern WCA 2A they were similar to NSM in all four alternatives.

Both southern and northern WCA 2A failed to meet target values for extreme high water conditions. In all of the alternatives, high water conditions in the north were similar to the 2050 Base, but in the south, conditions were slightly worse. Although extreme high water events occurred only 1% of the time in the alternatives, the duration of those events was greater than NSMv.4.5 predictions. Alternatives A and D13R were less extreme than Alternatives B through D and the differences may or may not be significant, but they cannot be said to be an improvement over the 2050 Base.

Extreme low water events were also reduced in Alternatives A through D compared to the 1995 Base and the 2050 Base. Alternative D13R showed four additional low water events over the period of record in the southern part of WCA 2A, a situation that would not protect peat soils. Overall, northern WCA 2A has a very non-NSM-like hydropattern and southern WCA 2A has exaggerated extreme high water conditions and lengthy hydroperiods. Together, they create uncertainty about future marsh conditions in this area. It appears that there are trade-offs between the northern and southern parts of WCA 2A that may be solved by operations. In one interim scenario that preceded Alternative D13R, operations of WCA 2 were tailored to improve innundation patterns in the south. It worsened extreme high water conditions in the north. In another scenario, WCA 2A, was operated to improve conditions in the north. It worsened high water problems in the south. More detailed design is needed to determine if a balance can be achieved that promotes sustainable marsh conditions in both the north and the south.

d) WCA 2B (Indicator Region 23) (red). Although this area had good NSM-like innundation patterns as a result of the alternatives, problems with extreme high water, extreme low water, or both, caused it to fail to meet the targets. Alternatives B through D13R reduced high water extremes over both the 1995 and 2050 Bases but depths greater than 2.5 ft still occurred 10-11% of the time, far from the NSM value of 1%. The subteam concluded that although Alternatives B, C, D and D13R show significant improvement relative to both the 1995 and 2050 Bases, the frequent occurrence and long duration of extreme high and low water make it unlikely that this area would function in a sustainable manner as either a shorter- or longer-hydroperiod Everglades wetland. More attention needs to be given to this area during detailed design.

e) Northwestern WCA 3A (Indicator Regions 20 & 22) (green). Although Alternative C performed slightly better, Alternatives A through D13R performed better than the 2050 Base and much better than the 1995 Base on all performance measures. In Alternative D13R, inundation patterns match NSM planning targets, high water extremes are minimal and low water extreme events are much improved over the 95 and 2050 Bases. There remains some concern that the area represented by Indicator Region 20 may still be likely to experience more extreme low water than will be sufficient to protect peat soils. However, it may not be possible to further reduce low water events without causing trade-offs such as increased risk of cattail proliferation in ponded areas.

f) Northeastern WCA 3A (Indicator Region 21) (yellow). This area has a problem with a tendency toward both too much high and low water, a problem none of the alternatives completely solved. For inundation pattern, Alternatives B, C, D and D13R were close to NSM, with Alternative D13R most closely matching target values.

The frequency of high water events is greater in all alternatives, except for Alternative A, than in the 1995 and 2050 Bases. This increase raises concerns about potential negative effects on wading bird nesting habitat in this region. Changes in STA operations, additional storage, or re-routing of flood waters might alleviate or reverse this negative impact for some rookery sites.

Low water events are a problem whenever protection of peat soils is desired and the best target for this area is the one with the fewest extreme low water events. For extreme low water events, the 2050 Base has fewer events than NSM, although the duration of the events is same. While all alternatives were improvements over the 1995 Base, only Alternative A was better than both the NSM and 2050 Base. Alternative B was worse than both the 2050 Base and NSM. The rest of the alternatives, Alternatives C, D and D13R, were in between: they did better than NSM targets but had a few more events than the 2050 Base. While Alternatives A and D13R performed the best of the alternatives in reducing low water extremes relative to both base cases, the predicted frequency and duration of low water events still seems large and may not insure protection of peat soils.

g) Eastern WCA 3A (Indicator Region 19) (yellow). None of the alternatives approached NSM targets in this region. The area east of the Miami Canal and south of Alligator Alley is deeply ponded in both 1995 and 2050 Bases and remains so in all four alternatives. High water extremes are most notable in this area. All alternatives show substantial improvements over the 1995 Base but not necessarily over the 2050 Base. Alternative A predicts an improvement over the 2050 Base. Alternative B was similar to the 2050 Base and Alternatives C and D showed greater depths for longer periods than the 2050 Base. High water extremes, however, are dramatically reduced in Alternative D13R relative to Alternative D although the target is still far from matching the NSM target of 0% high water. This may be the result of changes in operations and retention of a portion of L-67A canal, which allows more rapid removal of water from this area. Overall, the eastern WCA 3A is far from reaching its target values. However, unlike the predictions for WCA 2B, extreme high water is not combined with an increased frequency of extreme low water events. Therefore the sub-team scored this area as yellow rather than red.

g) Central and Southern WCA 3A (Indicator Regions 14, 17, & 18) (green/yellow). In the southern and central WCA 3A, Alternatives A, B, and D13R performed reasonably well and Alternatives C and D performed poorly. Alternative A best matched target inundation patterns throughout this region, with performance very similar to the 2050 Base, however the frequency of high water events in Indicator Region 14 was slightly elevated. Alternatives B and D13R, by reducing the frequency of high water events, eliminated flooding of tree islands during high rainfall years. While Alternatives B and D13R show increased inundation durations, with fewer marsh dry-outs than NSM, especially within Indicator Regions 17 and 18, these plans meet the important target for tree island communities because of the greatly reduced frequency of extreme high water events.

h) WCA 3B (Indicator Regions 15 & 16) (yellow). In this area, only Alternative A approaches the inundation pattern predicted by NSMv4.5 Final. The other alternatives predict fewer drydowns and longer periods of inundation than the 2050 Base. The effect of very lengthy periods of inundation on WCA 3B is uncertain.

Alternative A met the targets for high water extremes and Alternative D13R significantly reduced the frequency of events enough to prevent damage to higher hammock tree islands; impacts on less-elevated tree islands still may occur in Alternative D13R. For extreme low water events, all the alternatives were better than 2050 Base, the best being Alternative D13R, but all had either a few more events or events of slightly longer duration than the NSM targets. Given the removal of the eastern L-29 levee in Alternatives C, D, and D13R, combined with the restoration of long hydroperiods and deeper water in northeast Shark River Slough, it appears inevitable that water depths and inundation durations in WCA 3B will increase.

i) Pennsuco Wetlands (Indicator Regions 52& 53) (green). Inundation durations are significantly increased relative to both the 95 and 2050 Bases although the overall inundation pattern in Alternative D13R differs from NSM predictions. High water extremes are also rare and occur much less frequently than under NSM. In general, Alternative D13R predicts "NSM-like" ridge and slough conditions with reduced drought frequencies. This would be expected to protect marsh soils and provide for a sustainable marsh for this area. Extreme low water occurs infrequently in Alternative D13R, which represents an improvement over Alternatives A through C and a dramatic improvement over both the 95 and 2050 Bases.

3. Summary of Evaluation

Alternative D13R appears to provide the best overall performance for the WCA system. While all the alternatives perform well with respect to alleviating excessive drought conditions that have damaged peat soils, Alternative D13R provides the best overall reduction in extreme high water conditions that would flood out tree island vegetation communities, especially in southern WCA 3A and WCA 3B. Thus, Alternative D13R appears to make substantial progress toward solving the two most significant problems that have resulted from the C&SF Project in this region of the Everglades.

Two notable areas of uncertainty remain, however. One of these is the effect on wading bird populations of changes in depth patterns in northeastern WCA 3A. Although overall restoration of the Everglades watershed is expected to improve wading bird nesting habitat regionally, the timing of development of suitable breeding sites to the south, relative to changes in current nesting sites, could have significant effects on regional wading bird populations. A more detailed analysis of anticipated effects of Alternative D13R on wading bird breeding and foraging habitat, combined with a plan for system-wide monitoring, will be important components in implementing the plan.

The second major area of uncertainty is the effect of a shift in the overall hydrologic pattern toward longer periods of inundation with fewer drying events than those predicted by NSM. The best overall match to NSM inundation patterns is Alternative A, where it appears that maintenance of the WCAs as compartments provides more control over water depths in different sections of the Everglades. With partial decompartmentalization such as that in Alternatives B and D13R, exact matches to local NSM predictions for the Indicator Regions in WCA 3 no longer appear to be possible, given the reduced overall extent of the Everglades watershed north of Tamiami Trail. Hence, the benefits of decompartmentalization in promoting sheetflow and reducing the frequency and duration of flooding appear to conflict with the ability of water management to match local NSM targets. In considering this apparent trade-off, the sub-team concluded that the long-term sustainability of the northern and central Everglades marshes probably depended more on the avoidance of extremes of drought and flood than on exact restoration of local pre-drainage hydroperiods. Only Alternatives B and D13R manage to avoid extreme high water in southern and central WCA 3A, and only Alternative D13R accomplishes this in WCA 3B as well.

In conclusion, Alternative D13R provides inundation patterns that are "NSM-like" and that seem likely to promote a sustainable Everglades ecosystem. There nonetheless remain many uncertainties about the biological response that will occur, and these uncertainties can only be overcome by a suitable plan for adaptive management that will allow timely and informed changes in water management as deemed necessary to promoting biological restoration goals.

E. Southern Everglades Region including Florida Bay Coastal Basins

1. Shark River Slough

The NSMv4.5 Final characterized Shark River Slough as a predominately aquatic system that was continually flooded and flowing during wet and dry seasons for wet years and in all but the most extreme dry years. The Everglades Slough Conceptual Model used the following performance measures for ecological restoration: 1) duration of uninterrupted flooding, 2) drought severity as measured by the duration of dry conditions, and 3) water depth during periods of flooding. Two additional performance measures that were also considered are the total annual flow volume and the seasonal distribution of that flow in Mid-Shark River Slough.

Alternatives A through D showed improvement compared to the over-drained base conditions in Shark River Slough, with Alternative D demonstrating a markedly higher level of achievement of performance measures. However, Alternative D fell short of the performance targets for the Slough when performance was averaged over the three indicator regions (northeast, middle, and southwest). The extended duration of dry conditions lowered the achievement index for that performance measure to 36% for the slough as a whole. As an example, the dry periods in northeast and middle Shark River Slough averaged three weeks longer in Alternative D than the three- to four-week duration indicated by NSMv4.5 Final. The overall achievement index for the performance measures for Shark River Slough under Alternative D was 64%. The AET determined that a 60% achievement of hydrologic performance measures does not provide adequate assurance that the ecological values identified would be restored under an alternative plan. This represents the case for Alternative D for Shark River Slough. In addition, Alternative D only partially restores hydrological and ecological conductivity of the Slough to its upstream reaches in WCA 3A due to the presence of western levee L-29.

Performance measures for the evaluation of Alternative D13R in the southern Everglades were the same as those used to evaluate Alternative D with one exception. The mean duration of dry conditions, which was used as a measure of drought severity in Shark River Slough, was replaced by the number of dry events during the period of record to compare Alternative D to Alternative D13R.

For Shark River Slough, Alternative D13R was successful in reducing the number of dry events during the period of record in order to closely approach the frequency indicated by NSMv4.5 Final. This reduction represented an 89% achievement of this restoration target for the Slough as a whole. However, the mean duration of uninterrupted flooding in Alternative D13R fell short of the NSMv4.5 Final values, resulting in an 76% achievement of this restoration target for the slough. This compares to a 25% achievement under the 1995 Base and 29% under the 2050 Base.

Alternative D13R also increased the mean water depth during periods of flooding in northeast, middle and southwest Shark River Slough, which allowed it to achieve 79% of the NSMv4.5 Final restoration target compared to 58% achievement under the 1995 Base and 67% under the 2050 Base.

The overall achievement index for the performance measures in Shark River Slough under Alternative D13R was 82% compared to 28% under the 1995 Base and 38% the 2050 Base. A 0.8 achievement of the hydrologic performance measures is considered to provide **reasonable assurance** that the ecological values identified in the Everglades Sloughs Conceptual Model would be restored under Alternative D13R in Shark River Slough. Additional confidence in Alternative D13R is gained for reaching these restoration goals due to the increased connectivity between the slough in Everglades National Park and its upper reaches in WCA 3 as a result of the removal of L-29.

2. Rockland Marl Marsh

NSMv4.5 Final characterized the Rockland Marl Marsh as a seasonally flooded system where water levels typically dropped below the ground surface during most years, except during prolonged high rainfall periods when the marsh remain flooded for multiple years. The Marl Prairie/Rocky Glades Conceptual Model identified three priority hydrologic performance measures for the ecological restoration of the Rockland Marl Marsh. These include: 1) duration of uninterrupted flooding, 2) drought severity as measured by the duration of dry conditions and depth below ground surface, and 3) the number of wet season water level reversals in which the depth drops to less than 0.2 feet during a period of flooding.

Alternatives A-D all showed improvement over the over-drained base conditions, with Alternative D more successful in achieving restoration targets. The average duration of uninterrupted flooding increased to 32 weeks, compared to 12 weeks under the 1995 Base and 23 weeks under the 2050 Base. The number of wet season water level reversals was reduced to three in 31 years. Dry conditions lasted an average of 24 weeks. These targets are very close to NSMv4.5 Final conditions. Overall achievement index for the performance measures in the Rockland Marl Marsh under Alternative D was 83% compared to 22% for the 1995 Base and 60% for the 2050 Base.

Alternative D13R prolonged the mean duration of uninterrupted flooding in the Rockland Marl Marsh to 30 weeks as compared to the NSMv4.5 Final duration of 44 weeks. This represented an achievement of 68% of the NSMv4.5 Final target. The number of wet season water level reversals was reduced to four under D13R. Dry conditions in the Marsh lasted an average of 21 weeks as compared to 26 weeks under NSMv4.5 Final.

The overall achievement index for the performance measures in the Rockland Marl Marsh was 76%. A 0.8 achievement of the hydrologic performance measures is considered to provide **reasonable assurance** that ecological values in the Marl Prairie/Rocky Glades Conceptual Model would be restored under Alternative D13R in the Rockland Marl Marsh.

3. Florida Bay Coastal Basins

The performance measures for recovery/enhancement of ecological conditions in Florida Bay are represented by the 5 coastal basins in or near Florida Bay as mentioned above. These performance measures use output from the SFWMD Model's predicted mean monthly salinity for the various basins in Florida Bay based on P-33 Stage/salinity relationships. The high and low salinity targets for these basins have been documented in the conceptual models. Two time periods were evaluated: the dry to wet transition period (March-June) and the wet season (August-October). The dry-wet transition is critical for the health of many organisms in Florida Bay including spotted seatrout, snook, red drum, tarpon and pink shrimp. Salinity changes/variation at this time of the year are considered much more important than salinity fluctuations during the wet season because salinities are at their highest and can change most rapidly as the wet season begins. Cumulative salinity differences were calculated for the Dry/Wet transition and wet season and compared to their departure from NSM and ranked. The method of calculating coastal salinities from P-33 stage needs to be integrated with rainfall in future, detailed analyses. Additional salinity transfer studies to address inland hydrology are planned during fall 1998.

NSMv4.5 Final characterized the Florida Bay coastal basins as estuarine environments that experience low to moderate salinity well below seawater concentrations the majority of the time. Four priority performance measures for the ecological restoration of the Florida Bay coastal basins are identified in the Florida Bay Mangrove Estuarine Transition Conceptual Model. All of these performance measures are based on relationships between mean monthly salinity in five coastal basins. The performance targets are to reduce cumulative salinity differences to values that do not exceed the cumulative differences produced by NSMv4.5 Final.

The 1995 Base indicated primarily high salinity conditions and very few low salinity events, which produced a shift in the estuarine environments of the coastal basins to more marine conditions. The 2050 Base revealed only a slight improvement over the 1995 Base. High salinity events were less frequent, but low salinity events were also less frequent under the 2050 Base.

Alternatives A through D all substantially improved salinity regimes in the Florida Bay coastal basins with each alternative nearly equal effective in overall performance. The performance of Alternative D approached restoration targets for the coastal basins for three of the four performance measures. The overall achievement index for the performance measures under

Alternative D was 78% compared to 20% for 1995 Base and 30% under the 2050 Base. However, a similar index, rounded off to 0.8 was also attained for Alternatives A through C.

Under Alternative D13R, the reduction in the number of high salinity events achieved 88% of the NSMv4.5 Final restoration target compared to 48% achievement under the 1995 Base and 69% under the 2050 Base. For low salinity events, Alternative D13R was successful during 18 months of the period of record (when P33 stages rose to 7.3 msl). Although this increase in the number of low salinity events resulted in a 60% achievement of the NSMv4.5 Final target under Alternative D13R, this is much improved as compared to 23% under the 1995 Base and only 7% under 2050 Base. The **cumulative** salinity difference from concentrations that marked high salinity events during March-June decreased to 660 under Alternative D13R as compared to the NSMv4.5 Final target of 440. However, the cumulative salinity differences from concentrations that marked low salinity events during August-October under Alternative D13R was 1025 as compared to the NSMv4.5 Final target of 525, representing a 60% achievement.

The overall achievement index for the performance measures in the Florida Bay coastal basins under Alternative D13R was 80% compared to 20% under the 1995 Base and 50% for the 2050 Base. A 0.8 achievement of the hydrology/salinity performance measures is consider to provide **reasonable assurance** that the ecological values identified in the Florida Bay Mangrove Estuarine Transition Conceptual Model would be restored under Alternative D13R in the Florida Bay coastal basins.

F. Big Cypress

1. Discussion

Given the poor topographic data in this region and the problems with the western part of the area being too near the boundary of the models, outputs of the NSMv4.5 Final and SFWMM, particularly depth estimates, should be viewed with caution. In order to best analyze the impacts of Restudy alternatives the Big Cypress subregion was divided into three major geographic areas which include North Big Cypress, South Big Cypress and Southeast Big Cypress. These three areas have distinct responses to the various Restudy alternatives.

All of the effects on the North Big Cypress occurred in Alternatives C and D, and were retained in D13 and D13R. The effects resulted from filling the L-28 Interceptor Canal and removing its western levee, creating openings for water to move south along the Western Feeder Canal, and replacing S-190 with a pump station to maintain upstream drainage. This scenario also required some sort of water treatment capability to assure that all water moving south and southwest from the upstream canal system would provide only clean water. These components converted an area about two cells wide for most of the length of the L-28 Interceptor along its western side to approximately NSMv4.5 Final conditions.

The most significant changes to South Big Cypress, occurred in Alternative D, with the removal of the L-28 Tieback Levee. With this structure removed, hydrologic conditions showed almost complete restoration to NSMv4.5 Final conditions, including restored hydroperiods and increased flows across the eastern portion of the Big Cypress. The model results for D13 and D13R were almost identical to one another, and both showed generally small but distinct increased deviations from NSMv4.5 Final. When looking at the hydrologic responses to these alternatives for individual performance measures and indicator regions, the geographic area where the deviations were greatest was in the vicinity and downstream of the Dade-Collier Transition and Training Airport (Jetport). We have not evaluated how the Jetport is modeled in the SFWMM, and it is possible that the fill associated with it may be extensive enough such that flows through this area are blocked under the hydrologic conditions that exist in Alternative D13.

In southeastern Big Cypress, along its border with the Everglades and below Tamiami Trail, the most significant changes occurred in Alternative B, when the L-28 and L-29 levees and canals were removed. According to the model, there were larger areas showing reduced hydroperiods and the reductions in hydroperiods and flows were greater than in Alternatives A, C, or D, all of which were close to NSMv4.5 Final condition. In Alternative C, the L-28 and only the western portion of L-29 were restored, which was sufficient to return conditions in this area close to NSMv4.5 Final. The removal of the L-28 Tieback in Alternative D did not seem to affect this portion of the Big Cypress. Alternatives D13 and D13R produced generally small and variable responses among the various performance measures.

2. Summary

The combination of components in Alternative D produced the greatest benefits in terms of restoring the largest amount of area in the Big Cypress to approximately NSMv4.5 Final conditions. It also seems that several of the most beneficial components could be implemented in any of the Alternatives, since they operate almost independently from the rest of the Everglades ecosystem. This would be the situation for the L-28 Interceptor and L-28 Tieback components. Changes to the L-28 South and L-29 have more extensive and complex interactions with other parts of the Everglades.

G. Biscayne Bay

1. Analysis of model outputs For the Restudy, Biscayne Bay is bounded by Snake Creek to the north (Oleta River State Park) and Biscayne National Park to the south. The influence of proposed water management alternatives on Card and Barnes sounds to the south of Biscayne Bay is considered as part of the Model Lands. Biscayne Bay has been classed as a shallow, tidal, bar-built estuary (Kohout and Kolipinski 1967). The salinity gradient that established estuarine habitat in Biscayne Bay is dependent on both surface and groundwater flows (Fatt and Wang 1987). Before 1910, freshwater input came through numerous coastal streams, sloughs, and springs and from wet season sheetflow to the tidal zone. Currently, groundwater and surface water flow to the bay is reduced and hydroperiods have been altered. Surface water input to the bay is now intercepted and delivered through 14 regulated canals that are characterized by high amplitude, short duration storm flows during the wet season and low base flow during the dry season when hypersalinity has been observed as a result of evaporation, retention of canal flow, and bay circulation (Lee 1975).

The effects of salinity changes have been documented for fish (e.g. Davenport & Vahl 1975, Provencher *et al.* 1993, Serafy *et al.* 1997) and for invertebrates (e.g. Brook 1982, Montague and Ley 1993, Irlandi *et al.* in press). The presence and operation of the canals and construction of permanent oceanic inlets has resulted in a loss of estuarine function and shifted Biscayne Bay to more of a lagoon system, adversely impacted from freshwater pulses and highly variable salinities. These conditions have been at least partly responsible for the loss of historically abundant estuarine species, such as red drum (*Sciaenops ocellata*), black drum (*Pogonias cromis*), and eastern oyster (*Crassostrea virginica*), the loss of juvenile fish habitat, and the significant increase in stress-tolerant fish species such as the gulf toadfish (*Opsanus beta*) (Serafy *et al.* 1997). In addition to loss of species, many fishes in the bay exhibit tumors and deformities which may result from water and/or sediment quality factors.

Biscayne Bay ecosystem restoration plans were initially considered by the South Florida Water Management District in a planning process that resulted in a water management plan, Surface Water Improvement and Management Plan for Biscayne Bay (SWIM Plan, Alleman 1995). This document clearly outlines the rational for: 1) reducing excessive canal discharges by flow management, 2) providing a stable brackish water habitat during the wet season, and 3) providing more water during dry periods to prevent hypersaline conditions from impacting important marginal wetlands and nearshore habitats. Based on this plan and the consensus of government resource managers and university researchers, performance measures that would promote restoration of the Biscayne Bay ecosystem were established to permit evaluation of Restudy water management alternatives.

Performance measures were developed based on the potential effect of water management alternatives on surface water reaching Biscayne Bay which was divided into five regions from north to south. The regions were Snake Creek, North Bay, Miami River, Central Bay, and South Bay. The flow targets consist primarily of the existing average annual inflow to Biscayne Bay as defined by the 1995 Base, with a 2% increase in total inflow budget to be applied in the dry season to the Central and South Bay regions. A separate target for Snake Creek was also developed based on canal discharge that would maintain salinities for oyster survival.

The ranking of alternatives in terms of supplying surface water to Biscayne Bay assumes all components, especially the use of ‘re-use’water in Alternatives C and D, are present. This refers to ‘re-used’water or tertiary-treated domestic wastewater to replace water that will be withdrawn from the existing water management plan. The assumption that is implicit is that ‘re-used’water will be available and appropriate for use in a valuable, pristine, marine environment that sustains Biscayne National Park. The subteam recommends that additional feasibility studies be pursued and completed before evaluating the proposed alternatives.

Biscayne Bay currently receives surface water in amounts that will, when properly distributed, permit partial restoration of the coastal ecosystem. Scores that are less than 1.0, as occurs in all the alternatives, indicate that performance measures are not meeting the targets established for Biscayne Bay. Alternative D13R performs the best in terms of available water, but in terms of total bay inflow, Alternative D13R does not improve conditions for restoration compared to 1995 Base conditions. As such, none alternatives as they are currently proposed appear to achieve restoration of Biscayne Bay.

H. Model Lands/C-111 Area

Alternative scenarios for the Model Lands were evaluated using six performance indices as follows.

High water index: The proportion of time that water levels are below the high water threshold when water levels are so high that they may stress the vegetation communities naturally characteristic of these areas.

Low water index: The proportion of time that water levels are above the specified low water threshold so that the period of time that water levels are below a specified low water level are minimized.

Extreme low water index: The proportion of time that water levels less than 1 ft below the specified low water threshold.

Relative dry period slope index: Relative measure of the steepness of the slope of the stage duration curve during dry periods.

Wet Season Inundation Pattern Index: Proportional measure of how many times during the 31-yr simulation that water levels drop below surface elevation during the July-October portion of the wet season.

Late Wet Season Inundation Index: Proportional measure of how many times during the 31-year simulation that autumn periods of inundation ended during the months of November and December. This index was applied only to Model Lands South, which includes habitat critical for roseate spoonbill (*Ajaia ajaja*) feeding. A good year for wading bird feeding would be characterized by water standing well into January. Premature drydowns in the early dry season in this region may severely reduce available food to support roseate spoonbill nesting.

Overall, alternatives that added water to this region yielded higher scores than alternatives that did not. Alternatives B, C, and D consistently scored higher than the base conditions or Alternative A. There were differences among the indicator regions, however, in which alternative produced the best results. Alternatives C and D were the configurations resulting in the greatest benefits to the region as a whole and are preferred to Alternative B for that region. A design that benefits the entire region is preferred to one that benefits only a part of it. Furthermore, should an additional source of high quality water be identified in the future, Alternatives C or D will provide the infrastructure necessary to distribute this water throughout the Model Lands area. Regional managers are already attempting to reduce artificial hydrological barriers between these indicator regions and manage the entire area as a connected system.

Although Alternatives C and D improved conditions in the region as a whole, these alternatives still did not reach stated targets. Water levels were below the low water thresholds more than half the time in all four indicator regions of the Model Lands.

The configuration and operation changes from Alternative D to D13 to D13R made no difference to hydrologic conditions in the Model Lands-C111 Area. There were no changes in any of the performance indices from D to D13 or D13R. According to the performance indices, the water needs of the Model Lands-C111 Area still are not met, although conditions will be improved if either Alternative D, D13, or D13R are implemented.

Many concerns should be addressed in the detailed design phase. Additional water is needed for the Model Lands-C111 Area. Furthermore, the quality and quantity of some of the water provided to the South Dade area in Alternative D13R must be confirmed. Some of the benefits in Indicator Regions 5 and 6 may have originated from the regional use of advanced treatment wastewater to maintain canal stages in South Dade, but this option may prove too costly or too impractical to implement.

The benefits of having higher water levels in the Model Lands-C111 Area are clear. Alternative sources of water should, therefore, be identified and investigated as part of the design process. The specific location and design for the water delivery system need to be carefully considered to minimize impacts to existing high quality wetlands and avoid disrupting the natural system with excessive infrastructure. To maximize benefits, an effort should be made to improve the design to ensure that the best configuration of components has been achieved.

I. Water Quality Team

The water quality team evaluated eight sub-regions in south Florida for its water quality ranking matrix contained within the AET's final report. Alternatives A, B, C, D, D13R along with the 1995 and 2050 Bases were evaluated from a water quality perspective. Due to a lack of model results (particularly the Everglades Landscape Model), alternative plans could not be ranked based upon an empirical evaluation of water quality impacts or benefits in Big Cypress National Preserve and the Holey Land and Rotenberger Wildlife Management Areas.

The limited availability of modeling tools, by default, restricts the number of pollutants that can be evaluated for water quality concerns. Performance measures for the sub-regions primarily included hydraulic/phosphorus loads and total flows. Chlorophyll *a* was also evaluated for Lake Okeechobee (median and maximum concentrations).

The water quality team determined that the base conditions and alternative plans should not be ranked using EPA's preliminary mercury model results since the model requires further development. It is believed that atmospheric deposition is the dominant contributor of mercury in the Everglades Protection Area and alternative plans are not expected to significantly affect mercury levels for this region.

The matrix presented in water quality team's report contains several important footnotes. For example, for many of the performance indicators evaluated for Lake Okeechobee, the **differences** between simulated conditions for the alternatives is within the uncertainty of the model and are

not statistically significant. However, the water quality team felt it was important to rank the alternative plans for Lake Okeechobee from a water quality perspective.

The cumulative score presented in the matrix indicates that Alternative D13R received the highest score and represents the preferred alternative plan from a water quality perspective. The changes made to Alternative D to create Alternative D13R provided significant improvements to the ENP and St. Lucie watershed sub-regions. The scores within the matrix indicate these improvements. The Water Conservation Areas (WCAs) received a higher ranking for the 2050 Base and in Alternative A due to the increases in flow volumes to the WCAs for the other alternative plans. This increase in flow will increase loads of any potential pollutants. However, the overall score for the WCAs was not statistically different between the alternatives for WCA 2A, WCA 2B, and WCA 3B. For WCA 2A, Alternatives B through D13R ranked equally and were improved over both the 2050 Base and Alternative A. For WCA 3A, structural loads of total phosphorus were reduced in Alternatives D and D13R, which produced a higher overall score for both of these alternatives.

Both the Lower East Coast sub-region and the Caloosahatchee watershed were ranked equally between Alternatives D and D13R, both of which are preferred over the other alternatives. Loxahatchee National Wildlife Refuge received equal scores for all of the alternative plans but all were preferred over both the 1995 and 2050 Bases.

J. Total System

There are three total system performance measures that look at large-scale attributes of the natural system. Because many of the barriers to flow were removed in Alternative D13R, performance in all three measures was improved significantly over the 2050 Base condition.

1. Continuity This performance measure addresses the differences in water surface elevations on either side of major artificial barriers in the remaining. Artificial barriers tend to create markedly different water regimes on their upstream and downstream sides. Water usually pools on the upstream side causing the area downstream to become drier. Water quality parameters also may differ widely. Smaller species that do manage to cross a barrier may find inhospitable conditions on the other side. Larger species such as wading birds that feed at particular depths for example, may have to travel much further to feed. The target condition is water elevation differences across each barrier similar to that predicted by the NSMv4.5 Final. Differences of more than one depth class from NSM predictions are considered poor.

Performance was improved in Alt D13R over the 2050 Base for two reasons: 1) upstream pooling effects disappeared when barriers like Miami Canal, Tamiami Trail and L-28 were removed and, 2) water flows more evenly throughout the system than it did in the 2050 Base.

2. Sheetflow Vast expanses of sheet flow characterized the pre-drainage system. The slow-moving water ensured water quality and stored water in the wet season for gradual during the dry season. In the managed system, both the directions of flow and the flow volumes were altered significantly. Gradual flows through WCAs were replaced by large areas of ponded water, often with increased depths. Other areas received less than their due, for example, flow volumes through major sloughs decreased. The direction of flow is known to given tree-islands in interior marshes their tear-drop shape. In some areas, the direction of flow in the managed system runs perpendicular to those islands.

The sheetflow performance measure looked at flow volumes across a number of transects situated throughout the remaining natural area. Both flow volumes and general directions of flow were improved in Alternative D13R over the 2050 Base. Flows volumes across Tamiami Trail increased 92% over 2050 Base. The proportion of flows crossing the Tamiami Trail line east of the L-67 vs. west of L-67 improved as well. In the NSMv4.5 Final, the proportion of flows east/west was 62%. The proportion improved from only 11% in 2050 Base to 55% in Alternative D13R. In addition, flows through southern WCA 3A increased from only 62% of NSMv4.5 Final volumes in the 2050 Base to 110% of NSMv4.5 Final in Alternative D13R **without** causing excessive high water events. Lastly, flows in western WCA 3A were spread more evenly into the dry season in Alternative D13R, preventing the premature dry season drydowns seen in the 2050 Base.

3. Fragmentation In its effort to control flood waters and provide water supply, the C&SF Project created miles of canals and levees that fragment the natural landscape. Canals and levees usually coexist; construction of a canal usually means a spoil levee exists alongside it just as a levee requires a borrow canal. Roadways usually involve combinations of levees and canals, sometimes with culverts to allow water to flow underneath. In some places, multiple canals, levees and water control structure form intricate patterns and prove formidable barriers to wildlife.

When levees block the flow of water, they also restrict the movement of aquatic and semi-aquatic life forms in the water. Land-based predators use the levees to invade the marsh interior, preying upon animals that attempt to cross the intrusive fingers of terrestrial habitat. Canals act as corridors particularly for non-native animals and plants that can extend their ranges rapidly from points of introduction and can move into wetlands where they can alter habitats and affect food webs (Loftus and Kushlan 1987, Loftus 1986). Artificial, deep-water habitats provide thermal and spatial refuge to large numbers of both non-native and native aquatic predators in the dry season, enhancing their survival and ultimate population sizes. During the dry season, these predators prey heavily on small marsh fishes and invertebrates moving in from the adjacent wetlands (Howard *et al.* 1995).

This performance measure compared the number of miles of canals and levees in the different plans to those in the base condition. In Alternative D13R, which represents a significant decompartmentalization scenario, the number of miles of canals was reduced by 40% and levees by 20% compared to the 2050 Base.

4. Summary Alternative D13R improves some important landscape-scale parameters of particular interest to ecologists. Improving hydrologic connectivity should create more natural interspersion of habitat types by equalizing the depth patterns in areas now characterized by high contrasts in depths. Improving sheetflow is expected to ensure high water quality and normalize the distribution of water and depth patterns throughout the system. Reducing fragmentation should reduce the ease with which exotic species invade the inner marshes and expand the ranges of a number of native species.

CHAPTER VI -- OTHER PROJECT ELEMENTS

Betty Grizzle, Steve Peacock, Robert Pace, and others, FWS

A. Introduction

Other Project Elements (OPEs) are defined by the following criteria: 1) the project must be a component or feature that cannot be evaluated using the SFWMD Model, 2) the project must support and be consistent with the C&SF Restudy objectives, 3) the project must have federal interest, and 4) the project should not be a stand-alone research or data collection project. The COE has also identified Critical Projects within this OPE list. Critical projects have been identified as those projects that are essential to the success of the Restudy. Once these projects are evaluated, they are authorized for approval and funding through COE Headquarters after which an abbreviated one-year feasibility study is conducted. A NEPA review and design study is then initiated. Once the NEPA process is completed, the project undergoes a detailed plan and specification phase, leading to contract award and construction.

This chapter presents a description of OPEs and evaluations for benefits to trust resources that have been proposed for the C&SF Restudy. The list of projects was provided by the COE and was compiled from three sources: the Governor's Commission for a Sustainable South Florida Conceptual Plan, the Critical Project nomination list, and the Restudy Team. The narratives are organized by regions of southern and southwest Florida as described in previous sections of this report. During this evaluation process, it was discovered that some projects on the original OPE list had no contact or reference information available. Therefore, it was determined that there was insufficient information to provide an evaluation of some projects. In addition, some originally proposed projects were found to be contained within either the 2050 Base or in all of the alternative plans under consideration for the Restudy (e.g. East Coast Canal Structures which is Restudy Component T6) and therefore will not be evaluated as OPEs.

Two documents that were frequently consulted for this evaluation, the Governor's Commission for a Sustainable South Florida conceptual plan for the C&SF Project Restudy (1996) and the Science Subgroup Report (1993) will be referenced in this introductory section rather that repeatedly throughout the narrative section.

Governor's Commission for a Sustainable South Florida. 1996. A conceptual plan for the C&SF Project Restudy. Governor's Commission; Coral Gables, Florida.

Science Sub-Group of The South Florida Management and Coordination Working Group. 1993. Federal objectives for the south Florida restoration.

An evaluation matrix, Table VI-1, was developed for the OPEs discussed in this section of the report and can be found at the end of the OPE discussion. Figure VI-1 represents a general location map for these OPEs. As stated previously, the FWS felt it was necessary for each of the OPEs to be assessed based on benefits to trust resources. The matrix represents a short-hand evaluation of the narrative discussion of each project. It should be noted that the original list of Critical Projects received from the COE was previously ranked during a South Florida Ecosystem Restoration Working Group meeting and does not necessarily reflect the assessment of the FWS.

The FWS has chosen to complete the matrix based upon the "best professional judgement" of each investigator. Benefits to habitat, hydrology, and improvements to water quality represent some of the parameters evaluated for each OPE. Each OPE was rated within these parameters by a low, moderate, or high score based upon a subjective determination as to the benefits of the projects components and/or design. The subjectivity of our evaluation was necessitated both by the short time given to compile this information and the great differences in the level of specificity of the proposals.

B. Discussion of Other Project Elements (OPEs)

KISSIMMEE RIVER WATERSHED

1. Increase Storage in the Kissimmee Chain of Lakes

Background, Scope, and Objectives

The Science Subgroup (1993) recommended modification of the regulation schedules for only the lower portion of the Chain of Lakes--Lake Kissimmee, Lake Hatchineha, and Cypress Lake to provide for seasonal lake stages up to 54 feet. Raising lake stages in this manner would re-flood an estimated 18,500 to 23,500 acres of wetlands. Subsequent project planning indicated that although the SFWMD has purchased lands around these lakes to the 54-foot contour, flood control concerns have limited the designed high pool stage to about 52.5 feet. The FWS (1994) estimated that the proposed new regulation schedule would restore approximately 7,200 acres of wetlands if three levees at specific locations along the lakes' shorelines were breached, and continued project planning is likely to include acquisition and restoration of all of these wetlands, including those beyond the three levees. The Science Subgroup report did not mention increased storage in the Chain of Lakes upstream of Cypress Lake. The Governor's Commission for a Sustainable South Florida (1996) stated the following:

> Additional storage within the Kissimmee River Basin could reduce the amount of runoff entering Lake Okeechobee during the wet season when the lake typically approaches high levels. This could shorten the duration of high water levels within the lake that damage its littoral zone and could reduce the frequency of high volume discharges to the east and west coast estuaries. The

> increase in water levels within the Upper Chain of Lakes could be restricted to avoid natural system impacts of high water levels and the need to maintain flood protection to lakeside residential development throughout the area. In support of the Commission's sociological and economic goals, this concept must be designed to balance the need for storage with the need to maintain flood protection to lakeside developments and should not result in the relocation of communities and agricultural areas.

We agree with the Governor's Commission regarding the potential benefits of this action if it could be accomplished without affecting flood control, but we do not believe this is possible. North of Cypress Lake in the Kissimmee Chain of Lakes, housing has encroached to levels around the shoreline that severely limit any attempts to store more water. The two largest lakes, Lake Tohopekaliga and East Lake Tohopekaliga, have two large population centers - Kissimmee and St. Cloud - close to their respective shorelines, and additional suburban housing is being constructed along the lakes' shorelines. Osceola County regulators require that new developments conform to floor elevation specifications, but this regulation was most likely based on the existing lake regulation schedule, and in any case, older homes not subject to regulation would likely be more vulnerable to flooding with a higher lake regulation schedule.

In addition to the potential downstream benefits of increased water storage in the lakes (benefits to Kissimmee River restoration and improved hydrologic conditions in Lake Okeechobee), greater fluctuation in lake stages would have an intrinsic benefit to the ecology of the Chain of Lakes. Flood control measures have reduced the historic high water levels, while water supply and navigation concerns attempt to minimize the severity of droughts. Short hydroperiod marshes which used to be inundated periodically by flood waters have been displaced by pasture grasses and invaded by shrubs. Deposition of a band of organic material around the lakes' shorelines is exacerbated by narrow restriction of lake levels. These conditions promote proliferation of dense tussocks of undesirable native species and exotic species of vegetation, which causes deterioration of habitat conditions for fish and wildlife. Due to the water supply and flood control constraints, natural year-to-year fluctuations in water levels is not feasible. Instead, extreme drawdowns of several months duration can be scheduled every seven to ten years to dry the built-up sediment load. Other management practices often included during the drydown are mechanical removal of the sediment and dense vegetation, discing, burning, and herbicide treatments.

Status of Project

Water managers have remained open to discussing changes to the regulation schedule for the upper end of the Kissimmee Chain of Lakes (above Lake Cypress). However, flood risk concerns have constrained opportunities. In fact, the 1997-1998 El Niño weather event prompted St. Cloud residents to call for consideration of lowering the maximum allowable pool stage in East Lake Tohopekaliga (J. Carnes, SFWMD, personal communication 1998). Such action would be contrary to the intent to remedy the adverse ecological effects of overly static water levels in the Kissimmee Chain of Lakes.

Recommendations

Lacking the ability to broadly fluctuate lake levels at both the high and low ends of the mean, extreme drawdowns must be planned and carried out on a seven- to ten-year cycle for all the lakes above Cypress Lake (Carnes 1997). The FWS (1994) recommended possible inclusion of an additional feature (not included in the authorization for the Kissimmee Headwater Lakes Revitalization Project) to further increase storage at Lake Cypress, where housing does not intrude around the lake's shoreline. Cypress Lake historically had a higher lake stage than Lake Hatchineha and Lake Kissimmee, but all three lakes are now held at roughly the same elevation. We recommend additional investigation of constructing a new water control structure at the northern end of C-36, allowing a higher maximum pool stage and greater water level fluctuation in Cypress Lake. It is uncertain whether the volume of boat traffic between Cypress Lake and Lake Hatchineha would require installation of a lock at this proposed water control structure.

Points of Contact

South Florida Water Management District (West Palm Beach and Kissimmee Field Station); Florida Game and Fresh Water Fish Commission (Kissimmee).

2. Additions to the Authorized Kissimmee River Restoration

Background, Scope, and Objectives

Restoration of the Kissimmee River represents the largest riverine restoration project ever conceived. Prior to channelization, the Kissimmee River meandered 103 miles within a one to two mile-wide floodplain. The C-38 channel cut a straight line through the bends in the natural riverbed, reducing the run of the river to 56 miles. The floodplain contained approximately 41,000 acres of wetlands (Pruitt and Gatewood 1976). Following channelization, water flow was restricted to the confines of the channel and regulated in a series of impounded "pools" (Koebel 1995). The floodplain remained inundated at the lower end of each pool, but the remaining wetlands were affected by elimination of water level fluctuations and altered flow. Approximately 30,000-35,0000 acres of wetlands were either drained, covered with spoil, or converted into canal (Toth 1993).

Historical records and aerial photographs indicate three dominant wetland habitats existed along the Kissimmee River floodplain. The most extensive community was broadleaf marsh, covering over 56% of the floodplains. Common plant species included pickerelweed (*Pontederia cordata*), arrowhead (*Sagittaria lancifolia*), cutgrass (*Leersia hexandra*), and maidencane (*Panicum hemitomon*). Willow (*Salix caroliniana*), buttonbush (*Cephalanthus occidentalis*), and other shrub communities were often interspersed within the broadleaf marshes or found along the river channels, and covered approximately 14% of the floodplain (predominately in the north-central section of the basin). Wet-prairie communities comprised about 26% of the wetlands present. Habitats, found on the floodplain periphery, experienced significant wet-dry cycling, and were dominated by maidencane (*Panicum hemitomon*) cutgrass (*Leersia hexandra*), and horned beakrush (*Rhynchospora inundata*). Lower elevation communities experienced short drawdown periods, and were comprised of a diverse group of forbs, grasses, and sedges, including water-hyssop (*Bacopa caroliniana*), watergrass (*Hydrochloa caroliniensis*), flatsedge (*Cyperus spp.*), netted nutrush (*Scleria reticularis*), and short-beak baldrush (*Psilocarya nitens*). Cypress swamps, and ash/oak forests were also somewhat common along abandoned tributaries and oxbows (Toth *et al.* 1995).

The currently authorized Kissimmee River Restoration, known as the Level II Backfilling Plan, extends from the middle of Pool B to the bottom of Pool D (Figure VI-2), and would restore approximately 24,000 acres of wetlands. The 1991 FWCA Report on the Kissimmee River Restoration, Level II Backfilling, included the upper end of Pool E, but this was deleted from the federally authorized project approved in 1992 (FWS 1991).

The 1991 FWCA Report predicted substantial benefits to fish and wildlife resources, particularly fisheries, waterfowl, and wading birds. The projected benefits to wading birds included greatly improved foraging conditions for the endangered wood stork (*Mycteria americana*). The bald eagle (*Haliaeetus leucocephalus*) also would find expanded opportunities for feeding in the restored ecosystem and would likely establish additional nesting territories. It was anticipated that the restoration project would likely have minor adverse impact on the threatened Audubon's crested caracara (*Polyborus plancus audubonii*). Impacts are not expected to jeopardize the species, and the FWS provided recommendations for maintaining suitable habitat conditions along the edge of the restored floodplain. Habitat management recommendations to protect the caracara include prescribed burning and continued sustainable levels of cattle grazing along the edge of the restored floodplain (FWS 1991). Appropriate management guidelines for cattle grazing on public lands along the Kissimmee River should be carefully considered, ensuring that the intensity of grazing pressure is compatible with restoration goals. Pruitt and Gatewood (1976) provide a historical perspective on cattle carrying capacity in the area.

The projects recommended below for further consideration as part of the Restudy are complementary additions to the Level II Backfilling Plan.

Status of Projects

a. Pool A

Pool A is the northern-most reach of the C-38 Canal, just south of the S-65 outlet structure at Lake Kissimmee (Figure V-1). This portion of the river was not included in the Level II Backfilling Plan due to concerns about the ability to effectively release flood waters from the upstream Kissimmee Chain of Lakes. One of the earlier restoration proposals for this reach of the river included shallowing of the C-38 canal. However, shallowing of the existing canal would provide limited restoration benefits to the floodplain. An existing 560-acre impoundment near Rattlesnake Hammock provides a model for additional impoundments in the upper portions of Pool A that would enhance, but not fully restore, the surrounding floodplain. Construction of the additional impoundments would involve removal of portions of the spoil banks of C-38, and this material would be used to enclose the adjacent floodplain, allowing enhanced hydroperiod in the floodplain. The majority of the area to be enhanced has already been acquired by the SFWMD and most of the floodplain could be enhanced, except for the River Ranch Resort. The downstream portion of Pool A would be enhanced by allowing greater pool stage fluctuation. The FWS' 1991 FWCA Report estimated that an additional 3,200 acres of wetlands could be restored in Pool A, but the exact area of wetlands to be restored depends on the detailed plans that will arise for impoundments and pool stage fluctuation in Pool A.

b. Pool E

The upper portion of Pool E was originally included in the Level II Backfilling Plan, but the Water Resources Development Act (WRDA) of 1992 removed it from the federally authorized plan. Pool E is considered a "locally preferred option" under WRDA 1992. The deletion of Pool E from the plan was based on concerns about flooding of homes along that stretch of the Kissimmee River. It was previously estimated that approximately 2,700 acres of floodplain was available for restoration by extending the Level II Backfilling Plan throughout Pool E (FWS 1991). How much of the floodplain will be enhanced by other proposals depends on their design and operation. The enhancement of conditions on the floodplain would be conceptually similar to the proposal for Pool A, except that additional land acquisition would most likely be required.

c. Paradise Run

Paradise Run is the southern-most segment of the Kissimmee River, and the highly convoluted natural river channel runs entirely west of the C-38 canal south of the confluence of C-41A and C-38. Allen *et al.* (1981) reviewed information then available for restoration of the isolated portions of the original river channel and the marshes that once were present in the floodplain. In addition to the loss of marsh habitat value, Allen *et al.* (1981) documented the absence of certain fish species, such as black crappie (*Pomoxis nigromaculatus*), largemouth bass (*Micropterus salmoides*), and channel catfish (*Ictalurus punctatus*) from Paradise Run, which normally would be expected to occur. The authors cited a combination of reduced flows, siltation, accumulation of organic matter, and nutrient enrichment from surrounding pastures as causing degradation in water quality, leading to restriction of the fish fauna to those species more tolerant to such conditions. Allen *et al.* (1991) proposed construction of an additional water control structure along C-41A downstream (east) of the existing S-84, with the intent of creating a water receiving area in the southern part of Pool E, which could then be delivered from C-41A through a culvert to the northern end of Paradise Run. The report also considered leaving the existing L-59 in place, in which case the Paradise Run restoration would be operated as a northern and southern compartment. The report mentions the accumulation of organic matter (seven to nine feet thick in some locations) in the natural river channel since construction of the C-38, and suggests that sediments may need to be dredged from the natural river channel before restoring flow. Flushing of sediments from the river channel through increased flow would be beneficial to the water quality and fisheries habitat in Paradise Run, but would add to the already high nutrient loading to Lake Okeechobee. Portions of Paradise Run have already been acquired by the SFWMD; these tracts are mainly located between the original river channel and C-38 (SFWMD 1998). To carry out restoration of Paradise Run, however, additional land must be acquired west of the original river channel. Although the remaining tracts west of the original river channel are presently included in acquisition plans for Save our Rivers (SFWMD 1998), the SFWMD may eliminate these from further consideration (F. Davis, SFWMD, personal communication 1998). This decision may be based on lessened recent attention by the GFC in promoting the habitat benefits to be gained and on the current lack of Federal involvement in the project. The Restudy provides an opportunity to increase State and Federal attention to restoring Paradise Run, which should increase the priority for acquisition of the remaining lands through the Save Our Rivers program.

Recommendations

i. Detailed planning of wetlands enhancement should proceed in those portions of the Kissimmee River not included in the Level II Backfilling Plan.

ii. Development and implementation of detailed plans should start with Pool A, where it appears enhancement can occur on lands already acquired by the SFWMD. Enhancement could then proceed to Paradise Run, where some land has been acquired, and finally include Pool E, where land acquisition needs must be determined in accordance with the design of an enhancement plan.

iii. We recommend that the remainder of the Save Our Rivers tracts identified for Paradise Run be acquired.

All of these projects are highly related both hydrologically and biologically. For example, consideration of storing water north of C-41A to drive restoration of Paradise Run must consider both the effects on current habitat conditions in Pool E and how this action may fit into future wetland enhancement goals for Pool E. Planning for all areas should consider the feasibility of dredging accumulated sediments from portions of the historic river channel prior to increasing flows, thereby reducing the threat of increased nutrient loading to Lake Okeechobee.

3. Lake Istokpoga Restoration

Background, Scope, and Objectives

Lake Istokpoga is located within the Kissimmee River Basin in Highlands County. Water levels in the lake were stabilized for flood control and water supply in the 1960s as part of the C&SF Project. This stabilization, in conjunction with development within the watershed and invasion of exotic plants, has led to degradation of fish and wildlife habitat. Tussock islands, composed primarily of water hyacinth (*Eichhornia crassipes*) and *Scirpus cubensis*, are estimated by GFC to occupy approximately 2,500 acres of the 27,692 acre lake. These dense, unnatural vegetation communities have increased dramatically over the last several years due to the stabilized water levels. The tussock islands displace natural habitat and create noxious conditions in the littoral zone for fish species. These islands also create navigational problems within the lake. Aquatic macrophytes, particularly cattails (*Typha* spp.), dominate much of the lake's historic sandy shoreline, inhibiting the continued survival of cypress swamps. Hydrilla (*Hydrilla verticillata*) also represents an important control issue for maintaining Lake Istokpoga's ecosystem. In addition, when hydrilla is not controlled, the lake serves as a continuous source for hydrilla throughout the downstream portions of the Kissimmee River Basin.

Restoration of natural water level fluctuations is essential to the long-term restoration of the lake. Creating a lake-level regulation schedule for Lake Istokpoga that more closely resembles a natural system rather than regulating the lake solely for water supply and flood control purposes would be an optimal goal. However, there is no storage available north or south of the lake and homes surrounding the lake eliminate any potential for increasing lake water levels.

The proposed restoration project would include the removal of tussock islands and shoreline cattails, and provide a control program for hydrilla. A partial drawdown of the lake would permit the removal of shoreline cattails and hydrilla and begin the recovery of historic cypress swamp habitat. In a broader sense, the project will design a management plan for Lake Istokpoga in order to provide a more natural water level regulation that will prevent the growth of tussock islands while promoting establishment of more desirable fish and wildlife habitat. The project will also provide more capacity for water storage as well as restore flood control capabilities for the lake. Lake Istokpoga water is used for agricultural irrigation and cattle operations.

Status of Project

The SFWMD, Lake Okeechobee Service Center, has been conducting interagency meetings to investigate the potential for establishing a more natural operation of the Lake Istokpoga system. The GFC, in cooperation with the SFWMD, has begun harvesting operations for the tussocks. The GFC has proposed two alternatives for the dredged material. Because it is extremely costly to transport this material out of the lake, one idea would be create 4-5 foot tall, "wildlife islands" within the lake and establish more compatible wildlife habitat on these islands. Another proposal would be to store the dredged material in upland, agricultural habitats along the northeast and western shoreline. The GFC is working with private landowners to locate areas that will allow for storage of this dredged material (K. Denson, GFC, personal communication 1998). The GFC, in conjunction with the SFWMD, is seeking funding sources for additional harvesting operations.

Recommendations

The restoration of Lake Istokpoga has been an ongoing issue for resource managers. This project is timely in the context of several other restoration projects either proposed or in-progress within the Kissimmee River watershed. The project also offers the opportunity to restore a portion of the water storage that has been lost within the Lake Okeechobee/Kissimmee River Basin in recent years. The DOI supports restoration efforts of natural systems, particularly those that are regional in scope. Because of the severe degradation of this lake, this project offers tremendous potential for enhancing fish and wildlife habitat and restoring an impacted fishery. The DOI would like to see a management plan that would provide a long-term solution to restoring a more natural lake regulation schedule, but we are uncertain how this can be accomplished without acquisition of properties that lie close to the present water elevation.

LAKE OKEECHOBEE

1. Restoration of Torry, Kreamer, and Ritta Islands, Lake Okeechobee

Background, Scope, and Objectives

The Science Subgroup Report (1993) did not provide specific guidance on restoration goals for this area, recommending only to “integrate the islands at the southern end of the Lake into an overall management plan for the Lake.” The Governor’s Commission report (1996) stated that “restoration of these islands would involve degrading selected levees to allow more natural water levels and transplanting native vegetation. These actions would not affect existing private properties. They could result in additional habitat for water birds, fish, and other wildlife. Contaminant studies need to be completed prior to restoration design.”

We find that although restoration of these islands may be valuable, and although several ideas have been considered, this project element currently lacks a clear vision of goals. Our investigation suggests that the generalized goal of filling agricultural drainage ditches and removing of abandoned levees should be part of a coordinated multi-purpose plan. These purposes would likely include: 1) provision of public access to wildlife observation trails and platforms, 2) waterbird management, and 3) planting of native trees and shrubs, which will promote recovery of the endangered Okeechobee gourd (*Cucurbita okeechobeensis* ssp. *okeechobeensis*).

Lake Okeechobee has a developing eco-tourism industry, primarily involving airboat tours. Although birding tour groups visit Lake Okeechobee, they have inadequate access to observation sites. Repair of the existing Torry Island Road, construction of parking, and an elevated wildlife observation deck would promote tourism and would foster public support for preservation and restoration of the wildlife values of the lake's littoral zone.

Soil samples from Torry and Kreamer islands in 1977 contained DDT, DDD, and DDE levels ranging from 2,200 to 110,000, 580 to 10,000, and 1,300 to 9,300 µg/kg, respectively (Pfeuffer 1985). A single sample was collected from southern Torry Island in 1985; this contained DDD and DDE residues at 4,900 and 300 µg/kg, respectively (Pfeuffer 1991). None of the parent compound, DDT, was found, suggesting that degradation or biotransformation of the pesticides may be occurring. Samples collected in 1992 from six sites on Ritta Island showed all analyzed pesticide compounds below the detection limit of 5 µg/kg (Pfeuffer, unpublished data 1998).

If contaminants are at acceptable levels, detailed planning of a waterbird management impoundment should proceed. A location should be selected where existing habitat values are minimal. The size and operation of this management area must be designed.

Status of Project

Although restoration of these islands has received some attention, the goals are still poorly defined. We recommend development of an integrated multiple-purpose design, as outlined above. Other than limited sampling of chlorinated hydrocarbons and some sporadic surveys for the Okeechobee gourd, little baseline information is available.

Future Needs for Information or Design

The resource inventories that will be required for effective planning include the following:

i. Vegetation map, topographic map, and analysis of a series of aerial photographs
ii. More extensive sampling of chlorinated hydrocarbons (DDT and DDE residues)
iii. Continued monitoring of the distribution of the Okeechobee gourd
iv. Inventory of breeding sites for wildlife, particularly any wading bird colonies or concentrations of alligator nests.

Recommendations

Other Project Elements (OPEs) must support and be consistent with C&SF Restudy objectives for achieving ecological restoration. The DOI would not support a plan that focused exclusively on waterfowl management. However, we could support use of a limited area for this purpose, provided that larger areas of the islands are opened to improved sheetflow through removal of remnant agricultural ditches and levees.

After the required resource inventories are completed, detailed planning should be initiated for improvement of access (limited to wildlife tours) along a portion of Torry Island Road and construction of boardwalks and an observation platform for viewing of wildlife. Results of the resource inventories would also be used to plan and carry out the control of *Melaleuca* and Brazilian pepper (*Schinus terebinthifolius*) and the planting of native trees and shrubs, such as pond apple (*Annona glabra*) and willow (*Salix caroliniana*). Because the endangered Okeechobee gourd now uses both exotic and native species to support its vines, planting of native trees and shrubs while exotic species are being removed would promote recovery of the Okeechobee gourd..

Because Ritta Island has extensive native wetland vegetation around its periphery, and because no road access is available for earth moving equipment, the ecological impact of reaching and working at this relatively remote site must be carefully weighed against the benefits of restoring drainage ditches and levees. Torry and Kreamer islands are more readily accessible, and the resource inventories might support a decision to restore drainage ditches and levees in all but the most environmentally sensitive areas.

All planning for these islands must consider present and probable future water regulation policies.

2. Lake Okeechobee Water Retention/Phosphorus Removal

Background, Scope, and Objectives

The proposed scope of this project includes four drainage basins, three of which are tributaries to the Kissimmee River (S-65D, S-65E, and S-154). The fourth basin is within the Taylor Creek/Nubbin Slough (S-191). These basins are known to contribute the greatest concentrations of phosphorus to Lake Okeechobee (SFWMD 1997). Initial projects are being tested at two parcels-the Palaez wetland in the S-154 basin and at Grassy Island Ranch, adjacent to Taylor Creek.

The Kissimmee prairie contains a highly complex mosaic of herbaceous and forested wetlands, many of which were historically in the form of small scattered depressions. These somewhat isolated wetlands historically trapped organic matter and dissolved nutrients. Conversion of native prairie to improved pasture, sod farms, or vegetable farms increased nutrient loading to the wetlands. Habitat conversion, when combined with ditching through the prairie and among previously isolated wetlands, transported nutrients via major drainage canals to Lake Okeechobee. In addition to the adverse impact of accelerated eutrophication of Lake Okeechobee, more direct and rapid drainage of these lands contributes to rapid inflows to Lake Okeechobee. Higher water levels in Lake Okeechobee also increase the suspension of nutrient-laden sediments in the lake (Havens 1997).

This project will include plugging the connections among remaining wetlands to drainage ditches and diversion of canal flows to wetlands. The enhanced retention of water in these scattered wetlands will promote natural retention of phosphorus and will reduce peak flows to Lake Okeechobee. In addition to reducing ecological damage to the lake, these actions are expected to extend hydroperiods in the prairie wetlands, which provide habitat for a variety of wildlife, including waterfowl such as the Florida duck (*Anas fulvigula fulvigula*), the Florida sandhill crane (*Grus canadensis pratensis*), and several species of wading birds.

Status of Project

Substantial planning efforts have been initiated for this project, including assessment of the two pilot projects and identification of additional sites in the basins. The project is consistent with the goals of the SWIM Plan for Lake Okeechobee and will supplement efforts to establish best management practices (BMPs) on dairy farms in the area. This proposal has received support from the SFWMD, NRCS, DEP, and the South Florida Ecosystem Restoration Working Group.

Recommendations

The DOI strongly supports implementation of this project. The pilot sites should be carefully monitored to provide information on how best to design facilities at other sites throughout the selected basins. Planting appropriate species of herbaceous and woody wetland plants would further enhance habitat values for fish and wildlife. Information on types of vegetation, availability of plants at native nurseries, and successful techniques should be provided to landowners cooperating in the program. The NRCS has expressed interest in providing technical assistance in this program, and because of their expertise, it is recommended that they assist in disseminating information on wildlife habitat enhancement.

3. Lake Okeechobee Tributary Sediment Dredging

Background, Scope, and Objectives

This project will remove sediment from eight sites that were identified within the study as containing the highest concentrations of phosphorus. It is estimated that 60 tons of phosphorus can be removed from the system by dredging these eight sites (B. Rosen, SFWMD, personal communication 1998). Two sites are located in the Taylor Slough/Nubbin Creek Basin on the L-

63N Canal where 45 tons of phosphorus will be removed. The other six sites are located in the S-65D, S-65E, and S-133 basins where a total of 15 tons of phosphorus will be removed (R. Sosnowski, SFWMD, personal communication 1998).

A two-year study conducted by Mack, Roos and Associates investigated phosphorus content and transport potential to northern Lake Okeechobee This study, completed in 1997, analyzed sediment from 84 sites within the tributaries for phosphorus content and determined that approximately 550 tons of phosphorus is contained in tributaries within an eight-basin area. (R. Sosnowski, SFWMD, personal communication 1998). The study also found the highest concentration of phosphorus occurs within the top twelve inches of sediment and that the phosphorus is bound to organic sediments.

Status of Project

A demonstration project has been proposed in a section of the L-63 canal, but its extent has not been determined. Permits from the COE and the DEP have not been filed as yet and it is anticipated that it will take seven months to obtain those permits. The demonstration project is scheduled to begin in the spring/summer of 1999. Success of the demonstration project will be evaluated in part by review of the phosphorus budgets for Lake Okeechobee which are currently in place (R. Sosnowski, SFWMD, personal communication 1998).

Recommendations

The DOI supports the removal of phosphorus from the tributaries to Lake Okeechobee. However, the project is in the preliminary stages and many questions need to be answered. A disposal site for the dredged material has not been determined or how it will be stabilized. The primary benefit of this project is to reduce phosphorus loading to Lake Okeechobee, which in turn will enhance water quality to all water users south of the lake, as well as the estuaries receiving water from the lake.

CALOOSAHATCHEE RIVER

1. Removal of the Sanibel Island Causeway

Background, Scope, and Objectives

In 1960, during review of the original permit for the Sanibel Island bridge, the FWS had recommended a completely elevated bridge, rather than the construction of the two islands forming the causeway. The FWS predicted that in addition to the direct effects of the project on seagrasses, the scallop fishery in San Carlos Bay would be adversely affected. The scallop fishery did collapse soon after, but it is uncertain to what degree this was caused by construction of the causeway since the Intracoastal Waterway channel and the Franklin Lock on the Caloosahatchee River were also completed in the mid-1960s.

In 1989, Lee County commissioned a hydrologic model of the Sanibel bridge and causeway. That study found that construction of the causeway affected velocities in Redfish and Captiva Passes by less than 1 percent, and that the construction resulted in a change in velocity over 1,620 acres immediately adjacent to the bridges and islands (Hydrosystems Associates, Inc. 1989). It was also found that removal of the eastern island would be more effective in increasing tidal circulation in nearby portions of San Carlos Bay than removal of the western island. Goodwin (1996), using a calibrated two-dimensional circulation and constituent-transport model, found that removal of the Sanibel Causeway did not significantly affect flushing of upper and lower Charlotte Harbor, but it had a slight effect on flushing of Pine Island Sound and San Carlos Bay.

We could find no specific reference to this project element in the Science Subgroup report (1993) or in the Governor's Commission report (1996). The FWS proposed consideration of this project element during the Restudy's focus group meeting with the FWS' refuge managers. The J.N. "Ding" Darling NWR has a strong interest in improving tidal flushing through the area. Productivity of seagrasses and other estuarine/marine habitats is directly related to fish and wildlife values on the Refuge.

Removal of the Sanibel Causeway islands is justified even if the positive effects are limited to southern Pine Island Sound and San Carlos Bay. Excessive freshwater pulses from the

Caloosahatchee River have been exacerbated by construction of bulkheads along the river, thereby eliminating the buffering capacity of wetlands and floodplains upstream of the estuaries. Coupled with measures to capture regulatory releases from Lake Okeechobee and to store excessive runoff from the Caloosahatchee drainage basin, removal of the Sanibel Causeway would promote restoration of Pine Island Sound and San Carlos Bay. In addition to the loss of the scallop fishery, portions of the former predominately marine ecosystems in these bays have been altered by depressed salinity, and loss of seagrasses (McNulty *et al.* 1972, Harris *et al.* 1983) and other benthic organisms, such as soft corals.

Status of Project

The Lee County Department of Transportation has proposed to replace the existing drawbridge with a high span, and their current plan includes removal of the easternmost causeway island. However, removal of the island has met some local opposition, because the island is used for recreation. Lee County DOT has considered dredging the eastern island and using the material to widen the remaining western island (B. McAuliffe, Lee County DOT, personal communication 1998) to replace area lost for recreational use.

Recommendations

The DOI strongly supports removal of at least the eastern of the two Sanibel Causeway islands. Although this project is currently proposed to be funded by a Lee County bond issue, Federal agencies should stress the regional benefits to be gained by this project to overcome opposition based on local concerns about the recreational use of the islands. We do not recommend disposal of dredged material to widen the remaining island, even if it can be demonstrated that this would not further impede tidal circulation. The direct impact of disposal of the material on productive bay bottom should be avoided. If only the eastern island is removed, we recommend that the suitable portions of the dredged material be used for beach renourishment. Any material determined unsuitable for disposal on beaches should be hauled away and deposited in an upland site; this could include adding to the elevation, but not the area, of the remaining island. We understand the current proposal by Lee County does not include funding for the additional expense to haul the dredged material away. If Lee County cannot fund this additional expense, supplementary Federal financial assistance should be provided.

2. Caloosahatchee River Remnant Oxbow Rehabilitation

Background, Scope, and Objectives

The Caloosahatchee River was first channelized in 1937 to improve navigation and provide flood control. During 1945, and again in the 1960s, the channel was widened and deepened to increase runoff within the basin and to provide greater discharge capacity from Lake Okeechobee. During that same period, two combination lock and dam structures were constructed, and the final lock and dam was added in the mid-1960s.

No fewer than 35 oxbows, remnants of the pre-channelized river, are present along the C-43 Canal between the city of LaBelle and the Franklin Locks (S-79) (FWS 1984). Oxbow lakes are shallow (maximum depth 1.5 to 3.0 m) and small (less than 1.0 acre to 11.6 acres). They range in length from 118 m (390 ft) to 720 m (2,370 ft). The majority are openly connected to the main channel, several are clogged by floating or emergent vegetation, and a few are blocked from the C-43 Canal by fill or sediment. The oxbow banks are generally steep. Drew and Schomer (1984) provided a list [adapted from Milleson (1980)] of vegetation found in the oxbows, and found that the abundance of floating mats of vegetation indicated lack of water current. They listed the presence of a number of exotic or nuisance species, but did not provide a measure of percent cover. Accumulation of organic sediments and nearly anoxic conditions were also noted in some of the oxbows. It is likely that additional degradation of habitat conditions has occurred since that report, including increased density of vegetation and abundance of exotic species, increased sediment loading, and a further decline in water quality.

The objective of the project is to improve flow through the oxbows and enhance habitat conditions. Habitat for fish and wildlife will be improved within the oxbows, and water quality improvements will likely be experienced in the adjacent portions of the canal and in the downstream estuary. Although some of the oxbows exhibit degraded habitat conditions, others are now in relatively good condition. Sport fishing along the Caloosahatchee River between LaBelle and the Franklin Locks occurs largely within the remaining oxbows; rehabilitation of the more degraded oxbows would promote recreational values in this stretch of the river. There are potential benefits to threatened and endangered species including the wood stork (*Mycteria americana*) and the West Indian manatee (*Trichechus manatus*), which occasionally migrates through the locks along the Caloosahatchee Waterway between the Gulf of Mexico and Lake Okeechobee.

Status of Project

This proposal has not entered the detailed design phase. Initial efforts, already underway, involve baseline studies in 10 of the 35 oxbows, which will contribute to the specific design of the rehabilitation projects and will provide a comparison for continued monitoring following rehabilitation (K.W. Cummins, SFWMD, personal communication 1998). A broad range of parameters are being evaluated in the baseline studies, including vegetation, fish, invertebrates, and a number of water quality measurements.

Recommendations

We recommend that this project proceed rapidly from the collection of ecological baseline data, to detailed design, and to implementation of the enhancement. Because the present ecological conditions in the oxbows and the problems and opportunities for enhancement vary among the oxbows, specific measures for rehabilitation should be determined on a case-by-case basis (K.W. Cummins, SFWMD, personal communication 1998). We are concerned about the potential short-term impacts on water quality if the remnant oxbows are opened to increased flow without stabilizing any remaining sediments in the oxbow. If rehabilitation includes dredging of sediments from the oxbows, proper stabilization of the dredged material must be ensured to prevent it from redepositing in the oxbows or the C-43.

In addition to exploring the potential for improved flow through the oxbows, we recommend that any drainage into the oxbows from adjacent properties be examined for opportunities to create filtration marshes. These marshes should reduce the loading of sediments into the oxbows and will buffer the inflow of runoff from the surrounding watershed. Land adjacent to the oxbows may need to be acquired to establish filtration marshes where local drainage enters the oxbows.

In addition to removing exotic vegetation and planting native emergent wetland plants, project planning should seek opportunities to re-establish growth of submerged aquatic vegetation. The submerged exotic *Hydrilla verticillata* is well established in the oxbows. This species provides productive habitat for fish and wildlife when it is present in moderate density, but high density beds become "topped out," and can cause choking of the waterway with poor water flow. We recommend establishment of native submerged species such as tapegrass (*Vallisneria americana*), and musk-grass (*Chara* spp.) wherever possible. Both of these species provide excellent habitat conditions for invertebrates that serve as food for fish, wading birds, and waterfowl. Water in this portion of the Caloosahatchee River is laden with tannin and suspended particulate matter, which limits light penetration in the water column. Because the banks of the oxbows are often relatively steep, suitable water depths with adequate light penetration to support *Chara* and *Vallisneria* are limited. We recommend that project planners investigate opportunities to create shallow shelves along suitable portions of the oxbows to allow planting of native species of submerged aquatic vegetation. Areas presently dominated by exotic species, such as *Melaleuca* or *Schinus*, are potential candidate sites for this type of enhancement.

Points of Contact

Kenneth W. Cummins, SFWMD, Tarpon Bay Environmental Laboratory, Sanibel, Florida.

UPPER EAST COAST

The upper east coast geographic area that encompasses the Indian River Lagoon and the Ten Mile Creek section of the St. Lucie River is considered hydrologically removed from the Everglades and Florida Bay ecosystems. Presently, the only connection is the C-44 or St. Lucie Canal that discharges water from Lake Okeechobee to the St. Lucie Estuary. However, the Restudy will evaluate alternative regulation schedules for Lake Okeechobee on a system-wide basis with consideration given to the environmental needs of the Indian River Lagoon and the St. Lucie Estuary.

Water Preserve Areas (also called Regional Attenuation Facilities) are designed to provide for the diversion of surplus rainfall runoff from drainage basins to storage areas where the water can be treated prior to discharge for environmental base flows and water supply purposes.

1. Ten Mile Creek Water Preserve Area

Background, Scope, and Objectives

Ten Mile Creek is the largest sub-basin delivering water to the North Fork of the St. Lucie River estuary, which discharges into the Indian River Lagoon. The St. Lucie River estuary and the Indian River Lagoon are each classified as Outstanding Florida Waters. The proposed project includes the acquisition of approximately 1,559 acres in the Ten Mile Creek basin and construction of an above ground water detention area. The proposed site is located southwest of Ft. Pierce in St. Lucie County, situated immediately west of the crossing of the Florida Turnpike and I-95, south of Highway 70 and north of Midway Road. The site is currently in two ownerships. Ten Mile Creek flows west to east across the north portion of the proposed site.

The project is designed to promote restoration of the North Fork of the St. Lucie River by reducing excessive stormwater flows into this section of the river. The Water Preserve Area proposed for this project will be used for seasonal or temporary storage of stormwater from the Ten Mile Creek basin. Storage of excess stormwater will allow for measured releases into Ten Mile Creek and allow for a more natural salinity regime within the estuary. Stored water can also be released during the dry season to augment insufficient flows. Sediment loads to the estuary should be reduced as a result of the settling of suspended solids in the storage reservoir. The project also proposes that the captured stormwater be passed through a polishing cell for additional water quality treatment before being released into the North Fork.

Ten Mile Creek is an important component of the St. Lucie River estuary and Indian River Lagoon Restoration Projects. The Indian River Lagoon Surface Water Improvement and Management Plan (SWIM Plan), Appendix B (SJRWMD and SFWMD 1989), provided a summary of the water quality conditions for the lagoon system. The water quality assessment for Ten Mile Creek was described as “fair” with relatively high levels of pesticides as a result of runoff from surrounding citrus groves. The SWIM Plan also noted that high rates of floodwater discharge from this drainage area appeared to transport excessive amounts of sediments into the North Fork of the St. Lucie River, which directly affects downstream estuarine environments. The proposed detention area would be important in reducing the amount of pesticide contamination and sediment load in Ten Mile Creek and would provide improved water quality in the North Fork.

The conceptual design proposed for the Ten Mile Creek Water Preserve Area includes the construction and operation of an above-ground reservoir with a pump station for filling the reservoir from Ten Mile Creek and a gated water level control structure for the release of water back to the creek. The "footprint" of the reservoir is estimated at approximately 550 acres with the remaining acreage to be used as a polishing cell and a natural preserve area. Based upon existing topography, stored water depths will average ten feet.

Status of Project

Preliminary siting studies have been conducted for this project with a preferred site and an alternative site selected. In cooperation with the COE, the SFWMD is the project sponsor; however, several agencies (e.g. DEP, FWS, and EPA) will be participating in the project design and environmental assessment.

Recommendations

The DOI supports restoration projects which would enhance Florida's estuarine environments such as seagrass beds and other important habitats that provide nursery grounds for juvenile fishes and invertebrates. Commercial and recreational fishing represent particularly important activities in this region and should be benefitted by improvements to the estuary. The Ten Mile Creek critical project described above represents a viable alternative to the present problems associated with undesirable discharges to the North Fork of the St. Lucie River. The primary concern for the DOI is the location of the Water Preserve Area. The site should be selected so that adverse impacts to the environment are reduced. Particular attention should be paid to avoid conversion or destruction of important upland habitat (e.g. scrub).

References

St. Johns River and South Florida Water Management District. 1989. Surface Water Improvement and Management (SWIM) Plan for Indian River Lagoon.

2. C-25 Basin Water Preserve Area

Background, Scope, and Objectives

The C-25 drainage basin consists of 134,500 acres located west of Ft. Pierce. Discharges from this basin occur via Taylor Creek into the Indian River Lagoon. To date, there have been no comprehensive studies of the basin's impact on the lagoon. Discharges from the basin are untreated and therefore water deliveries result in an unabated pollutant load directly into the lagoon system. The section currently impacted by C-25 basin discharges encompasses important segments of the lagoon including an area that contains the only open shellfish harvesting area (Big Starvation Cove) in the southern Indian River Lagoon. Based on information from water quality monitoring programs being conducted by the DEP and the SFWMD, the C-25 basin has been shown to transport significant sediment loads, nutrient loads, pesticides, polyaromatic hydrocarbons, and heavy metals into the estuary and offshore waters (G. Graves and D. Strom, DEP, written communication 1998). Twelve violations of state water quality standards have been documented between 1992 and 1997 for the pesticides malathion and ethion (MacDonald *et al*. 1996).

The proposed project would incorporate basin modifications to attenuate peak flows and provide storage to treat water prior to discharge, recharge ground water, provide storage for agricultural and urban demands during drought, and provide for dry weather minimum estuarine discharges. The C-25 basin design elements may also enhance the Ten Mile Creek sub-basin as discussed previously.

Status of Project

At the present time, this project is unfunded and has not proceeded beyond the nomination stage. The SFWMD currently provides limited monitoring of this basin and the canal as part of its region-wide water quality monitoring network.

Recommendations

Elements of the proposed project may assist in the restoration of reservoirs and wetland flow-ways, which can be beneficial to a variety of wildlife. Improvements in the timing and quality of water discharged by C-25 basin should improve water quality within the lagoon and may result in greater expanses of seagrass beds, less stress to resident fauna as a result of reduced levels of toxins, and enhanced protection of offshore reef systems. Benefits to both commercial and recreational fisheries would be expected as well. As with the Ten Mile Creek project, the DOI is supportive of estuarine enhancement projects but would like additional information concerning the site selection of the water preserve area in order to evaluate the impacts to existing wetland and adjacent upland habitats.

LOWER EAST COAST: PALM BEACH COUNTY

1. Pal-Mar/Corbett Land Acquisition Project

Background, Scope, and Objectives

Pal-Mar is a large pine flatwood/wet prairie/depression marsh complex located in Palm Beach and Martin Counties, northeast of the J.W. Corbett Wildlife Management Area (WMA). The project includes some of the highest quality pine flatwoods in southern Florida in an ecotone between pine flatwoods and the treeless Everglades (CARL 1997). The total proposed project area for Pal-Mar is 35,435 acres of which 2,552 acres have been acquired as of 1997 (SFWMD 1998). In addition to the Pal-Mar land acquisitions, the project may also include a privately owned parcel of land consisting of approximately 3,000 acres between Pal-Mar and J.W. Corbett WMA. If acquired, the project area would produce an unbroken 125,000-acre greenbelt extending from the DuPuis Reserve near Lake Okeechobee across the J.W. Corbett Wildlife Management Area and connecting with Jonathan Dickinson State Park (H. Trammall, SFWMD, personal communication 1998).

Status of Project

The acquisition of land at Pal-Mar is on-going. The acquisition of the parcel of land between Pal-Mar and Corbett (approximately 3,000 acres) is proposed.

Recommendations

The DOI supports the acquisition of the 3,000 acres which would provide a contiguous wildlife corridor from DuPuis Reserve to Jonathan Dickinson State Park. This would provide vital habitat connectivity for those species that require large unfragmented tracts of land for survival.

Points of Contact

GFC, West Palm Beach (Jim Schuette)

Trammell, H. Telephone communication, May 1, 1998.

2. Winsberg Farms Wetland Restoration

Background, Scope, and Objectives

The project involves the acquisition of approximately 175 acres of land that are currently farmed in row crops and a nursery. Following acquisition, the area would be converted into a wetland. The purpose of this project is to provide indirect use of treated wastewater and cost effective effluent disposal through irrigation of agricultural crops and recharge of local ground water. Secondary benefits that may result include reduced dependence on water from Lake Okeechobee, creation of wildlife habitat and open space, and providing a link to the county-wide greenway system. Acquisition of lands for the project will begin in 1998 and continue over a three-year period. The proposal is to purchase approximately 60 acres annually for the next three years, while allowing the current owner to farm the area until 2001 (H. Hadjimiry, Palm Beach County Water Utilities Department, personal communication 1998).

The Wakodahatchee wetland, a pilot project for this proposal, was constructed in 1996. This project involved the construction of wetland cells, planting native wetland vegetation to promote removal of nutrients and construction of a boardwalk throughout the wetland complex for environmental education/bird-watching. The Wakodahatchee wetland pilot project is well managed by Palm Beach County and 119 species of birds have been recorded in the area. Because the Wakodahatchee wetland has proven to be an extremely well-received project, it is anticipated that Winsberg Farms will also receive strong public support. The operation and management plans for the proposed project will be identical to the Wakodahatchee wetland. Pollutant removal performance by the Winsberg Wetland will be estimated through the application of empirical treatment models and by analysis of the Wakodahatchee wetland data.

When constructed, a research and monitoring plan will be developed and implemented to provide detailed descriptions of the water budget and water quality enhancement performance of the wetland. Wildlife utilization of the Winsberg wetlands will be quantitatively assessed through monitoring similar to surveys currently being conducted by Palm Beach Department of Environmental Resources Management for the Wakodahatchee wetlands.

Status of Project

Acquisition of the first parcel of 60 acres will be presented before the Palm Beach County Commission in June 1998. Some conceptual drawings and design work have been completed (R. Liberti, Palm Beach County Water Utilities Department, personal communication 1998).

Recommendations

The 175-acre wetland proposed for this project will increase the spatial extent of wetland habitat and provide a geographic link with other local natural systems. Intense development pressure in south Florida continues to fragment remaining natural areas. The DOI supports this acquisition and restoration project for the habitat it will provide to wading bird populations, snail kites, and other wildlife that currently utilized adjacent natural areas. The DOI is also supportive of projects that incorporate water conservation and reuse since it will reduce dependence on critical water supplies in the Everglades ecosystem.

3. Wetlands-Based Water Reclamation Project

Background, Scope, and Objectives

The City of West Palm Beach, Florida has developed a wetlands-based water reuse program to maximize water conservation, an innovative approach for the reuse of treated wastewater and augmentation of the drinking water supply.

The sources of drinking water for the City of West Palm Beach are Lake Mangonia and Clear Lake. These lakes are recharged with water from the city's 20-square-mile Wetland Catchment Area (WCA) via the M-Canal, which is augmented with water pumped from Lake Okeechobee via the L-8 Canal. To meet emergency drinking water needs, the city uses a standby wellfield which consists of ten wells. In order to reduce the amount of water needed to be pumped from Clear Lake and Lake Mangonia during peak usage, the city is developing an Aquifer Storage and Recovery (ASR) program. Wastewater is currently treated at the East Central Regional Wastewater Treatment Plant (ECRWWTP) and discharged via deep well injection to the Floridan aquifer which contains non-potable water in southeast Florida. The proposed approach is to tie these two systems together to meet the conservation goals of the city (Camp Dresser & McKee Inc. (CDM) , no date)

Treated wastewater will be sent from the ECRWWTP to existing wetlands adjacent to the treatment plant. These wetlands are in a state of decline as a result of alteration of the hydrologic regime in the area and the subsequent infestation of melaleuca (*Melaleuca quinquenervia*). The water will flow through the wetlands thereby maintaining a more natural hydroperiod (P. Gleason, CDM, personal communication 1998). Water from the wetlands will be piped to the aquifer near the standby wellfield where it will be recovered and pumped to the M-Canal and into Clear Lake and Lake Mangonia and from there to the city's water treatment plant.

The City of West Palm Beach has applied to the COE for use of this area as a mitigation bank. The proposal involves removal of melaleuca and the creation, restoration and enhancement of approximately 1,500 acres of wetlands in the project area. The bank would be established so that money from the sale of mitigation credits would fund the restoration and maintenance of the 1,500 acres of wetlands (E. Olson, City of West Palm Beach, personal communication 1998).

A threatened and endangered species survey was conducted by Ecosystem Research Corporation to determine which threatened and endangered species occur within the Wetland Reuse Site. Threatened or endangered species that were observed within the project site included the Florida snail kite (*Rostrhamus sociabilis*), American alligator (*Alligator mississippiensis*), wood stork (*Mycteria americana*), eastern indigo snake (*Drymarchon corais couperi*), limpkin (*Aramus* *guarauna*), little blue heron (*Egretta caerulea*), snowy egret (*Egretta thula*), tricolored heron (*Egretta tricolor*), and the gopher tortoise (*Gopherus polyphemus*). In addition, ten listed plant species occurred within the project site (City of West Palm Beach and Palm Beach County Utilities 1998).

Status of Project

A small-scale demonstration project has been completed through a cooperative cost-share agreement between the City of West Palm Beach and the South Florida Water Management District. This pilot project was used to evaluate chemical combinations and levels which optimize the process. An application will be submitted to the COE and the Florida Department of Environmental Quality in May 1998 to include the addition of the Advanced Water Treatment Facility, distribution lines, and the mitigation banking proposal.

Recommendations

The DOI supports the idea of water reuse since it will reduce dependence on critical water supplies to the Everglades ecosystem. This project will provide a more natural hydroperiod to the project area especially along the eastern perimeter where major hydrologic alteration has occurred. The increased hydroperiod will help reduce the spread of melaleuca, which has already invaded the area, and will enhance existing wetlands.

Any construction activity in the area will require initiation of consultation under the ESA. The request to the COE for creation of a wetland mitigation bank for removing melaleuca from the project site needs to be reviewed. The FWS concurs with the SFWMD's Environmental Advisory Committee (EAC) that "removing exotic plants from wetlands is essential for the health of those systems, however, removing exotic plants for mitigation credit is inappropriate because exotic removal alone does not replace lost wetland functions" (EAC 1997). However, the mitigation banking project appears to have elements of creation and restoration of wetlands as part of the proposal and not merely removal of melaleuca as the basis for the bank. Areas in the proposed bank which only involve removal of melaleuca would not be considered as appropriate mitigation.

4. Hillsboro Pilot Aquifer

Background, Scope, and Objectives

This project represents a regional Aquifer Storage and Recovery (ASR) demonstration project in the Hillsboro canal region to capture and store excess flows from local drainage and Loxahatchee NWR, that are currently being released to tide, for use during dry periods. The project involves construction of six, five-million-gallon-day (mgd) wells to the upper Floridan Aquifer. Four of the wells will be operated by the SFWMD and two of the wells will be on a cost-share and operational contractual agreement with Palm Beach County. The purpose of the demonstration project is to determine recovery rates and cycling necessary for a future larger project. Proposed cost for the project is approximately $15 million (L. Devillon, SFWMD, personal communication 1998).

Status of Project

A feasibility study for the project will begin in 1999. Filing for permits from the Florida Department of Environmental Protection will begin in 1999. The SFWMD is developing its contractual agreement with Palm Beach County for two of the wells.

Recommendations

The DOI supports the storage of water to prevent saltwater intrusion and to reduce direct dependence of utilities on surface water recharge from Lake Okeechobee or the Water Conservation Areas. If ASR is implemented, we recommend that all Federal and State rules and regulations pertaining to ASR be complied with. However, we recommend that other alternatives (back-pumping or water preserve areas) for water storage be reviewed, which may provide more benefit to fish and wildlife resources.

Points of Contact

South Florida Water Management District, West Palm Beach (Lou Devillon); Palm Beach County Water Utilities (Ray Liberti)

References

Devillon R. Telephone communication, April 20, 1998 and May 12, 1998.

5. L-8 Water Catchment Area-Loxahatchee Slough Infrastructure Improvement

Background, Scope, and Objectives

The land surrounding the L-8 Canal primarily consists of rural and suburban residential homes on acre-and-a-quarter lots. The canal and remnant wetlands provide foraging opportunities for snail kites and wading birds such as the tri-colored heron and wood stork that nest in the City of West Palm Beach's Water Catchment Area. The L-8 Canal delivers water from Lake Okeechobee to the M-Canal and on to the West Palm Beach Water Catchment Area. It also delivers water to the C-51 Canal, which discharges to tide in Lake Worth Lagoon. The southern L-8 sub-basin drains south through L-8 to C-51 or to the Loxahatchee NWR. Stormwater Treatment Areas under construction to help purify Loxahatchee NWR water are not designed to handle the L-8 water. In conjunction with this concern, there is an effort to treat and reduce C-51 discharges to the Lagoon. The objective is to divert runoff from the southern L-8 basin away from Loxahatchee NWR and the C-51 and into the West Palm Beach Water Catchment Area and perhaps the Loxahatchee Slough (Slough). Agricultural and urban runoff from the southern L-8 sub-basin can be treated and used as urban water supply for West Palm Beach, and might also be used to fill environmental water demands for the Water Catchment Area and Slough. However, it has yet to be determined that the Slough requires this extra water.

The current project plan as presented is to dredge the L-8 Canal and add pump capacity to take water from L-8 and route it to West Palm Beach into the Water Catchment Area. Several other pieces of an L-8 project have been considered including: extending the M-Canal two miles east and north; building a new water storage and treatment area near the west leg of the C-18 Canal; adding a pumping station at the north end of the M-Canal; placing a water control structure between the new reservoir and C-18; and constructing a new ten-mile-long canal to connect the Town of Jupiter's surface water recharge system with the North Palm Beach Water Control District.

Status of Project

This project is on hold until planning dollars become available.

Future Needs for Information or Design

The Loxahatchee Basin Hydrology model should be run to determine if and when the Slough might require excess L-8 flows. If it is determined that these flows are not required within the Slough, then the West Palm Beach Water Catchment Area may be considered for storage of this extra water, especially in wetter than normal years.

Other information needs include sampling of sediments and water for contaminants and locating an upland dredge spoil disposal site to handle potentially toxic material.

Recommendations

The DOI recommends that this project be further planned and constructed only if it is determined to be primarily positive for fish and wildlife resources of the L-8 area, Loxahatchee NWR, and the Loxahatchee Slough. We request that the COE certify that project hydrology will not worsen environmental conditions for the Loxahatchee NWR, or other conservation lands in the J.W. Corbett Wildlife Management Area, West Palm Beach Water Catchment Area, or Loxahatchee Slough.

The Department also recommends that best management practices be established and implemented for agriculture and for suburban residents of the L-8 Basin.

Earlier in the Restudy process, mention was made of constructing a 10-mile long Jupiter Seacoast Utility Water Supply Canal as part of the L-8 Loxahatchee Restoration Project. The DOI does not believe this concept appears consistent with the Restudy's focus on environmental enhancement and we suggest that other alternatives be considered.

Points of Contact

City of West Palm Beach (Erik Olson).

6. Loxahatchee Slough Restoration

Background, Scope, and Objectives

Since the construction of the C-18 Canal, the Loxahatchee Slough (Slough) has received less water. The C-18 redirects historic Slough flows into the Northwest Fork of the Loxahatchee River into the Southwest Fork (DEP 1997). The landscape can be described as a central, herbaceous freshwater slough with mesic pine flatwoods around the drier edges and dry prairie interspersed among the pines. The Slough is a swale system of herbaceous marsh and transverse ridges of cypress strands and some hammock tree islands (S. Farnsworth, Palm Beach County Environmental Resources Management, personal communication 1998). Palm Beach County Environmental Resources Management staff have recorded many Federal- and State-listed species including snail kite, wood stork, Florida sandhill crane, least tern, limpkin, little blue heron, tri-colored heron, alligator, gopher tortoise, eastern indigo snake, and Sherman's fox squirrel.

Plans to restore the Slough have been considered since the 1970's but have been constrained by land availability. In 1985, the Northwest Fork of the Loxahatchee River was under consideration for Federal Wild and Scenic Designation (which it achieved) and the environmental community requested the COE to initiate Slough restoration. The Fish and Wildlife Service prepared a Habitat Evaluation Procedure analysis in the mid-80's and proposed a target hydrograph to assist in this restoration process. The FWS proposed reflooding the slough predicated on 5,000 acres of land available for restoration in the mid-80's. In 1997, Palm Beach County purchased those 5,000 acres and 7,000 additional acres through their Environmentally Sensitive Lands Program. This Loxahatchee Slough Restoration critical project is designed to rehydrate the 11,000 acres while protecting existing urban areas. Overall project objectives are to restore the Slough and to ensure appropriate flows for the Northwest Fork of the Loxahatchee River.

Specific components of the project include placing a weir structure with a sliding concrete gate within the C-18 Canal to raise water levels from 14.8 feet to 17.5 feet and allow overbank flooding to rewater the County's land in the Slough. Also, because the Slough was historically contained within the West Palm Beach Water Catchment Area, the connection under the Beeline Highway will be enhanced with the new C-18 structure as water from the catchment area will rehydrate additional wetlands. Palm Beach County has committed to remove exotics from 1,600 acres of the Slough before it is reflooded.

As a side note, one problem within the Slough's general drainage basin area is the Indian Trails Development. This community has inadequate stormwater drainage and rights on the drainage canals are completely allocated. There has been concern about environmental effects of the development's flows. GKK mining approached the Water Management District for a 20-year permit for shellrock or limestone mining and offered to provide a storage reservoir for the Indian Trails Development. The proposed mining/reservoir area has already been rock-and-muck mined and GKK's reservoir could store water in the wet season and send it to the Slough during the dry season.

Status of Project

The Loxahatchee Slough Restoration project is currently under review by the COE. The SFWMD has provided a letter of intent to the COE who then drafted a letter report for the project. Details of project costs are being worked out.

Palm Beach County has provided a cost share for the exotic vegetation removal project component and intends to begin contracting as soon as possible. Exotic vegetation such as *Melaleuca*, *Lygodium*, and some Brazilian pepper will be removed over the course of three years.

The SFWMD and the City of West Palm Beach have developed a hydrologic model of the Loxahatchee basin and are testing possible hydrographs for the Slough against water users, rainfall, and baseflow required for the Northwest Fork of the Loxahatchee River (currently there is a 50 cfs minimum set).

Future Needs for Information or Design

The hydrologic model of the Slough should be run and calibrated to match actual events and then used to determine how much water can be used by the Slough and when and where and how likely the water is to be available. There is a need to determine the biologically appropriate flows and water levels and historic ranges within the Slough.

Recommendations

The restoration will lengthen the hydroperiod of the wetlands and stabilize the Slough. Fish and wildlife needs should received the highest priority of the restoration with irrigation and water supply withdrawals receiving secondary attention. The DOI recommends that water stored in the Slough should stay within the historic range of levels. We recommend setting wet-year flows/levels and dry-year flows/levels in such as way as to not over-inundate the Slough nor produce “draw-down” conditions. The Slough should not also become a stormwater dumping flow-way to the estuary. Neither the Slough nor the estuary will benefit from excessive or untimely discharges.

The Palm Beach Water Catchment Area and C-18 water are considered Class I waters. Other water sources are not. To prevent the degradation of Class I waters, we recommend the Slough waters be reclassified at least from its current Class III to Class II. Once the restoration project is complete, the area should be protected from point and non-point source runoff.

The freshwater marsh and other habitat components should be managed as a total system with a goal of increasing and maintaining heterogeneity (FWS 1998). The FWS recommends considering fire and drawdowns as management tools and managing for early successional stages to give more diverse habitat niches. Also, performing management measures on different areas at different times will sustain and improve habitat heterogeneity.

Points of Contact

7. Lake Worth Lagoon

Lake Worth Lagoon (Lagoon) is located along the coast of Palm Beach County. The Lagoon functioned as a freshwater system as recently as 100 years ago, but became a marine environment with the construction of permanent inlets to the Atlantic Ocean. The estuary provides spawning, nursery, and foraging habitat for many fish and invertebrate species, which sustain and mature into important inshore/offshore recreational and commercial resources. It is believed that fishery resources have declined within the past forty years as a result of loss of habitat and water quality degradation. Between 1940 and 1975, approximately 87% of mangrove habitat and emergent, aquatic vegetation along the Lagoon's shoreline disappeared (Harris *et al.* 1983). In addition to non-point source runoff from surrounding urban areas, excess fresh water and sediment loads from the C-16, C-17, and C-51 canals have contributed to the decline in the Lagoon ecosystem. These alterations and impacts to the Lagoon have seriously diminished its ability to function as a healthy estuarine ecosystem. Management of the Lagoon system is needed for the protection and enhancement of this coastal resource. A draft management plan for the Lagoon has been prepared by the Palm Beach County Department of Environmental Resources Management and the DEP and Palm Beach County has also developed a Draft Surface Water Improvement and Management (SWIM) Plan for the Lagoon.

a. Lake Worth Lagoon Water Quality Restoration - Sediment Removal

Background, Scope, and Objectives

The C-51 Canal extends from the north end of Loxahatchee NWR eastward into the Lagoon and represents one of three primary drainages entering the Lagoon. The Palm Beach County SWIM Plan (Palm Beach County 1997) identified this basin as the most critical area for reversing water quality and ecological degradation in the Lagoon.

Plans are being developed for diverting western C-51 basin waters to STA-1 East, providing treatment for this water, and routing the treated water to Loxahatcheee NWR. However, a solution for "de-mucking" eastern C-51 basin waters has also been identified. Because undeveloped land represents a scarce commodity in the eastern C-51 basin, no site is available for constructing a Stormwater Treatment Area (STA). Therefore, Palm Beach County has proposed to dredge existing sediments out of the C-51 Canal and to remove and dispose of sediments so that they do not flow through the S-156 structure into the Lagoon.

Status of Project

Palm Beach County has proposed this pilot project jointly with the SFWMD, who is assisting in identifying sources of revenue. Details of the project that have yet to be determined include the method and extent of the dredging. Planning will continue as funding sources are secured.

Future Needs for Information or Design

Information needs for effective planning include sampling of sediments and water for contaminants and developing disposal site vegetation and topographic maps using aerial photography.

Recommendations

The DOI supports this project if it can be demonstrated to be ecologically viable and not contribute additional contamination to the Lagoon or local ground water. A full assessment of contaminants in the sediments must be conducted for determining appropriate dredging methods and disposal of spoil. Spoil disposal must be located at suitable upland locations and remediation/mitigation may be required for habitat losses. Monitoring of the dredging and disposal operations and Lagoon turbidity trends should be included in the project.

After the removal of sediment from the C-51 Canal, aquatic vegetation should be re-established within the Lagoon in close proximity to the C-51 discharge point. Species should be selected according to salinity conditions (24 to 35 ppt for seagrass) and bottom contours (FWS 1998). Established vegetation can enhance water quality within the Lagoon and provide much needed nearshore habitat for estuarine organisms.

Points of Contact

Palm Beach County Department of Environmental Resource Management (Jim Barry); SFWMD (Tommy Stroud).

b. Lake Worth Lagoon Water Quality Improvements

Background, Scope, and Objectives

A draft management plan for the Lake Worth Lagoon prepared by Palm Beach County Department of Environmental Resource Management and DEP identified several basins as either critical, high, or medium priority for restoration efforts. The C-51 watershed and the middle and north Lake Worth Lagoon segments are critical for water quality and ecological degradation and for the environmental significance of the north Lagoon segment. The C-16 watershed, the south Lake Worth Lagoon segment, and Intracoastal Waterway watershed are considered high priority restoration areas due to the extent of water quality and ecological degradation and the environmental significance of the Intracoastal Waterway watershed. The C-17 watershed is identified as a medium priority area for restoration.

Project objectives include: 1) establish baseline information on general water quality, turbidity and salinity levels, 2) determine the optimum minimum and maximum flows of fresh water to the Lagoon, 3) manage excessive freshwater inflows from point and nonpoint sources, 4) decrease inputs of nutrients, toxic substances, and suspended materials, 5) identify anthropogenic loadings of fecal coliform bacteria in the Lagoon and reduce loads to below state standards or to natural background levels.

Status of Project

Some project needs for the restoration of water and sediment quality appeared in the draft management plan for the Lake Worth Lagoon prepared by Palm Beach County Department of Environmental Resource Management and the DEP (DEP 1998). The plan is expected to be approved and adopted by an interdisciplinary, multi-agency Lake Worth Lagoon Ecosystem Management Area Steering Committee. Funding for planning and implementing water and sediment quality restoration is needed.

Future Needs for Information or Design

The resource inventories and modeling efforts that will be required for effective planning include:

i. Baseline information on general water quality, turbidity, and salinity levels with protocols determined for sampling water quality parameters including, but not limited to, temperature, salinity, dissolved oxygen, nitrogen, phosphorous, suspended solids, chlorophyll, turbidity, fecal coliform, and color.

ii. Defining the relationship between light, water quality, and presence of seagrasses.

iii. Model and establish optimum minimum and maximum inflows of fresh water for the Lagoon.

iv. Develop predictive models that link light attenuation and water quality to nutrient loadings and epiphyte abundance.

Recommendations

The DOI recommends implementing management actions that will improve or maintain water quality conditions necessary for seagrass growth in the Lagoon. It is also recommended that mangrove communities and nearshore reef and hard-bottom habitat be protected from point and non-point source pollution. We recommend identifying sources and developing pollutant load reduction goals for sediments, nutrients, and toxic substances for the Lagoon using stormwater treatment, wastewater reuse, best management practices for uplands, etc.

Points of Contact

Palm Beach County Department of Environmental Resource Management (Jim Barry); SFWMD (Pat Walker).

References

Florida Department of Environmental Protection. 1998. Lake Worth Lagoon management plan (draft). West Palm Beach, Florida.

c. Lake Worth Lagoon Habitat Restoration

Background, Scope, and Objectives

Thirty-six project sites have been targeted within the Lagoon for this habitat restoration project. Components identified for this project are designed to: 1) restore, enhance, and create emergent mangrove and cordgrass wetlands, coastal hammock habitat, and protective upland buffer zones where feasible; 2) restore, preserve, and create seagrass beds, oyster bars, and other submerged benthic habitat; 3) construct artificial reef habitat, which will provide important intermediate and adult habitat required for estuarine- and marine-dependent fish and invertebrate species; 4) protect the Florida manatee, and other endangered, threatened and rare species, and species of special concern.

Status of Project

The DEP and the Palm Beach County Environmental Resources Management agency have drafted a restoration plan for the Lagoon (DEP 1998). The plan is anticipated to be approved and adopted by an interdisciplinary, multi-agency steering committee for the Lagoon. Funding is needed for planning and implementation components of the project.

Future Needs for Information or Design

The resource inventories that will be required for effective planning include the following:

i. Identify and map current extent of seagrass habitat in the Lagoon and assess status and condition, including species composition.

ii .Determine the relationship between light and water quality to growth of seagrasses in the Lagoon.

iii. Identify the extent of mangrove habitat in the Lagoon and identify areas that can be linked together.

Recommendations

The DOI strongly recommends funding all or part of this habitat restoration project. Specific habitat recommendations for the Lagoon include: 1) stabilize and increase seagrass habitat by preserving existing seagrass habitat and restoring additional seagrass where feasible, 2) stabilize and increase mangrove habitat, 3) where feasible, support mangrove restoration by restoring natural landscape contours and therefore restoring sheetflow hydrology, and 4) prevent burial and degradation of existing nearshore reefs and hard-bottom habitats in the Lagoon and re-establish impacted areas.

LOWER EAST COAST: BROWARD COUNTY

1. Restoration of the North Fork of the New River

Background, Scope, and Objectives

The North Fork of the New River, in the City of Fort Lauderdale, is the only remaining natural section of the New River. There is minimal tidal flow in this section of the river and large amounts of sediment and debris (tree trunks, tires, appliances, etc.) are distributed throughout the riverbed, creating unattractive areas and health hazards (K. Carter, Broward County Department of Natural Resource Protection, personal communication 1998). The existing riparian zones of the North Fork are actively eroding in some places and exotics have replaced native species in some areas.

North Fork water quality is characterized by high bacterial and nutrient concentrations and low dissolved oxygen levels. It is believed that contamination from nearby septic tanks and sewage lines has degraded water quality and concentrations of fecal bacteria are consistently high. Sediment samples collected and analyzed throughout the North Fork are virtually void of benthic macroinvertebrate communities. A portion of the sediment bed load consists of sludge previously deposited into the North Fork by a now decommissioned wastewater treatment plant (Broward County 1994a). The presence of heavy metals in sediment was measured at seven collection sites in the North Fork by Broward County Department of Natural Resources. Cadmium and lead levels were greater than the probable effect level (PEL) at six of the seven sites and mercury levels were above the PEL at one site (Broward County 1994b).

This project consists of: 1) spot dredging to improve water quality and water circulation; 2) removal of exotic plant species and revegetation with native plants; 3) implementation of a water quality monitoring program; 4) development of a master plan to promote revegetation and shoreline restoration, including shoreline re-contouring.

Status of Project

A grant agreement between the Florida Department of Environmental Protection and Broward County Commission to secure $50,000 in funding was executed on May 5, 1997. This grant was used to purchase equipment related to water quality testing and a pilot revegetation project, which has been completed. Approximately 80% of the dry season water quality sampling has been completed and the wet season sampling began in May 1998. A recent matching fund grant from the Florida Inland Navigation District and Broward County of $37,500 was implemented to conduct preliminary dredging tests.

Recommendations

The DOI supports the efforts to improve water quality and circulation in the New River. Spot dredging will increase circulation of water in the river, reducing occurrences of stagnation and improve water quality. However, proper disposal of spoil material represents a concern for this project. Disposal sites should be identified so that impacts to sensitive environments are avoided and sediments are not re-transported into the river.

The removal of exotic vegetation and restoration of aquatic and littoral vegetation in conjunction with planting of native species will enhance the biological diversity of the area. Native vegetation along the shoreline will protect against erosion and filter runoff entering the river. An increase in species abundance, richness, and diversity of migratory birds and other wildlife may occur.

Based on the location information provided in the critical letter report for this project, the FWS, Vero Beach office, conducted a GIS and Florida Natural Areas Inventory database check to determine potential species locations. This was done in conjunction with discussions with other Federal and State agency personnel in an effort to develop a sensitive species and critical habitats list for this project. Results of this search have determined that three instances of West Indian manatee (*Trichechus manatus latirostris*) mortality have occurred within approximately one mile of the project area. The West Indian manatee is both a Federal- and State-listed endangered species. One mortality was associated with a floodgate, another mortality was perinatal, and the cause of the third mortality was not determined. Should this project be funded, the FWS recommends initiating informal consultation under section 7 of the Endangered Species Act. Dredging in this area may result in direct or indirect impacts and may affect the Florida manatee.

Implementation of the Standard Manatee Protection Precautions will be required. These stipulations are essential to the protection of the manatee in this area and should be included as special conditions to any permit issued for the proposed project.

2. Western C-11 Basin Water Quality Improvement Project

Background, Scope, and Objectives

The western C-11 basin consists of 51,840 acres located in south-central Broward County, Florida. Stormwater runoff from this basin flows into the South New River Canal (C-11) where it is pumped into the Everglades Protection Area, Water Conservation Area (WCA) 3A, through the S-9 pump station.

In the past, untreated agricultural and urban runoff being pumped into WCA 3A through the S-9 pump station has created water quality concerns. The purpose of this project is to improve the timing and quality of the stormwater discharges from the western C-11 basin into the Everglades Protection Area.

The project involves changes to the pump operation schedule to reduce sump drawdown extremes; use of additional smaller electric pumps to pump seepage and reduce the frequency of high pumping rates that disturb bottom sediments; construction of a gated control structure in the western C-11 canal, west of US Hwy 27, to isolate seepage from stormwater runoff and maintain more consistent canal stages; changes in canal geometry; and rerouting of flows during peak storm events (COE 1998).

Status of Project

This critical restoration project was ranked fifth in importance by the South Florida Ecosystem Restoration Working Group. The project has been approved by Corps of Engineers Headquarters to proceed with the NEPA and preliminary design phase (M. Dollar, COE, personal communication 1998).

Recommendations

The DOI supports the idea of providing a cleaner water supply to the Everglades Protection Area.

Results from a Breeding Bird Survey conducted in 1985 identified an abandoned great blue heron colony adjacent to the project area (B. Stys, GFC, personal communication 1998). Although the components of this project are localized within the canal, the FWS recommends that impacts to wading birds resulting from construction operations be considered for this project if it is determined that sensitive species occur within the area.

Points of Contact

Southern Everglades Restoration Alliance (Louis Hornung).

LOWER EAST COAST: SOUTH DADE COUNTY

The Lower East Coast Urban Area (metropolitan and agricultural areas) as defined by the Science Subgroup Report (1993) contains a mosaic of developed and undeveloped lands. The remaining natural habitats are described as fragmented and are composed of tidal marsh/mangroves, freshwater wetlands, pine rocklands, and remnant coastal scrub. Those areas that adjoin the historical freshwater Everglades wetland habitat, east of the east coast protective levee system, are generally degraded as a result of over-drainage practices, the invasion of exotic plant species, and urban expansion.

Restoration efforts must achieve a balance of natural, urban, and agricultural landscapes. Hydrological restoration objectives identified by the Science Subgroup Report (1993) for this region include reducing the dependence of the urban metropolitan and agricultural areas on the Everglades/WCA water and managing the water budgets of the natural urban and agricultural areas for their mutual benefit. To this end, the COE has identified several critical projects (CPs) and other project elements (OPEs) for South Dade County in the Restudy.

1. WCA 3B Seepage Reduction

Background, Scope, and Objectives

This infrastructure project was proposed as an attempt to manage water seepage at the east coast protective levee on the east side of WCA 3B. This is an area where there are large documented seepage losses out of WCA 3B into the South Dade canal system. Due to the extremely high transmissivity of the aquifer at this site, water losses are high. The project is designed to reduce losses out of WCA 3B and improve water deliveries across L-29 to the eastern portion of the ENP. The project would install an underground seepage barrier, using grout technology, to a depth of 100 feet. The barrier would be located between two control structures, S-334 and S-335. An upstream collector canal connected to a downstream spreader canal by a pipe would allow water to pass through the system with the gate open and the barrier in place. The concept is to manage and control the seepage, not prevent it from occurring.

Status

The project was postponed indefinitely at a Governor's Commission Technical Advisory Committee meeting, at which time the proposal received much opposition. In addition, the rockminer's group in South Dade have withdrawn their support for this project.

Recommendations

If one of the primary restoration goals is to create more flow through the Everglades system, then the process of achieving a more natural flow by increasing water levels into the system will have the effect of increasing the groundwater gradient in some areas. This increase in the gradient will result in increased seepage losses in some locations. This project offers an approach to reduce these types of water losses, which can be very high for those aquifers with high transmissivities.

The design of the various alternative plans for the Restudy does not provide for the construction of extensive curtain walls. The alternative plans do address seepage at one location (L-31N) with a shallower 30-foot barrier and there are some provisions for backpumping to alleviate excess ponding. The WCA 3B project represents a type of “demonstration” project for seepage for those aquifers which have high transmissivity rates.

This project does pose the question as to whether hydrological mathematical models developed for the Restudy adequately address areas such as the east coast levee in an effort to better understand the hydrodynamics associated with levee construction and connections to the underlying aquifer. If more accurate models are developed that address seepage losses, then the impacts and/or benefits to trust resources as a result of these types of projects can be better be evaluated. Therefore, the DOI is unable to provide an evaluation of this project at this time.

Points of Contact

Larsen and Associates, Miami (Paul Larsen).

2. South Dade Agriculture: Rural Land Use and Water Management Plan

Background, Scope, and Objectives

The Governor’s Commission for a Sustainable South Florida (1996) addressed the issue of sustainable agriculture in its conceptual plan. This plan states that, for South Florida, the future of agriculture is dependent on several factors such as restoration measures, urban development, readjustment of water table levels, the long term availability of water, and, for many areas, the oxidation of organic peat soils.

The South Dade Agriculture and Rural Land Use and Water Management Plan is being developed by the Department of Planning, Development, and Regulation of Metropolitan Dade County to be included in the county’s Comprehensive Master Plan. This critical project actually consists of two separate projects, the first of which is entitled South Miami-Dade County Agricultural and Rural Area Retention Plan. The second plan will focus on lands within the watershed of South Biscayne Bay, including Biscayne National Park, and is identified as the South Biscayne Bay Watershed Management Plan. The intent and scope of this second project are still being defined at the present time.

The South Miami-Dade County Agricultural and Rural Area Retention Plan is described as an agriculture and rural character retention initiative for the South Miami-Dade County area and will identify the major components of agricultural production and agribusiness, primarily through the use of microeconomic and analytical techniques. Agriculture industry practices associated with each major crop (or commodity) within South Miami-Dade County will be inventoried and studied in conjunction with existing surface water and groundwater hydrologic data. Information will also be collected and analyzed to establish economic strategies and incentives that may be used to strengthen and retain the agricultural industry in this region. The results of this study will be used to determine operating conditions that would optimize water supply and flood protection to these agricultural areas while minimizing adverse impacts to water quality.

As it currently stands, the South Biscayne Bay Watershed Management Plan can be described as a study to develop a plan to direct the comprehensive management of the South Biscayne Bay watershed's land and water resources. Primary components of the study will include: the calculation of pollutant loading into receiving water bodies; analyzing and improving the quantity of distributors and timing of freshwater discharges into Biscayne Bay; identifying pollutant loading reduction levels and canal conveyance capacities, determining best management practices for existing land uses; and developing watershed management strategies. The results of the hydrological and pollutant models developed during the study will allow for the evaluation of various land-use scenarios in an effort to achieve a long-term land use and water management plan for South Miami-Dade County.

Recommendations

The South Miami-Dade County Agricultural and Rural Area Retention Plan, as currently defined, represents a land use-planning document for Dade County and as such is difficult to evaluate for effects on trust resources. The proposed South Biscayne Bay Watershed Management Plan, although still in draft form, may yield useful information concerning water quality issues for Biscayne Bay.

3. South Dade/C-111 Basin Hydrological/Water Quality and Sustainable Agricultural Program

Background, Scope, and Objectives

Proposed structural and operational changes to the C&SF Project are being evaluated to assess gross changes in regional hydrology. There are some concerns as to whether these models will adequately predict and assess changes in the water table and localized flooding in the South Dade agricultural area. For example, raising and lowering water levels in L-31N, C-111, and the rehydration of Taylor slough may effect agricultural land uses in South Dade. This project will evaluate and enhance the available regional hydrological and water quality data. It will also field calibrate, formulate, and develop a model that is capable of simulating the hydrology in the South Dade agricultural area. This will be accomplished by using a spatial and temporal scale that will allow prediction of localized impacts from proposed changes in the C&SF Project. The development and implementation of technologies guided by a localized model's predictions will be used to reduce not only the vulnerability of crops to the effects of extended high water tables, but also impacts to Everglades National Park (ENP), Biscayne Bay, and Florida Bay by minimizing ground and surface water pollution.

Status of Project

At the present time, this project is unfunded and has not proceeded beyond the nomination stage.

Recommendations

The finer resolution hydrological model produced from this project should provide a way to quantify fluctuations in water levels in the field and therefore improve the ability to assess the effects of various water management scenarios on agricultural activities in South Dade. The DOI would be supportive of this critical project if the model would also be used to assist in increasing water efficiency for this sub-region as well as reducing ground and surface water pollution that currently impacts ENP, Biscayne Bay, and Florida Bay.

4. Water Quality Treatment and/or Urban and Agricultural Best Management Practices (BMPs)

Background, Scope, and Objectives

The goal of the project is to ensure that agriculture in the South Dade County basin remains economically viable as well as a good and sustainable neighbor to both Everglades and Biscayne National Parks, both of which are adjacent to farmed lands. The project is designed to help increase water and fertilizer efficiency and reduce the amount of nutrients seeping into the Biscayne aquifer from these South Dade agricultural areas by developing best management practices (BMPs).

The University of Florida's Institute of Food and Agricultural Science (IFAS), Tropical Research and Education Center in Homestead is conducting this study in collaboration with South Dade farmers. Other project partners include the Florida Department of Agriculture and Consumer Services, the EPA, and the DEP.

The poor retention properties for both water and nutrients of the hard, porous oolitic limestone soil in the South Dade agricultural areas results in the tendency of farmers to use more fertilizer and water than necessary to promote new plantings and increase crop yields. Nutrients from leached fertilizers flow from the fields through the aquifer and into Biscayne Bay resulting in increased levels of nutrients to nearshore waters (B. Schaffer, IFAS, personal communication 1998). Research personnel from the Tropical Research and Education Center will be investigating systems to monitor soil moisture using a process called EnviroScan that can be used to determine the most efficient irrigation rates for the highest crop yields with the least amount of nutrients leaching into ground water. The study also includes the use of groundwater monitoring wells as well as monitoring of pesticides. The Tropical Research and Education Center staff will compare the use of EnviroScan technology with traditional methods of monitoring and scheduling irrigation to determine which method is most efficient, reliable, and cost effective. Once the three-year study is completed, the SFWMD may adapt the technology to other areas throughout South Florida.

Status of Project

This study is currently underway under the guidance of the Tropical Research and Education Center. Field demonstration tests for using Enviroscan technology have been initiated as well as tests to validate the fertilization rates developed by IFAS for South Dade soils and crop types.

Recommendations

This project provides an opportunity to improve water quality in south Florida agricultural areas by reducing non-point source pollution and excess water flows. The study is also designed as an educational/demonstration project to assist farmers in voluntarily implementing BMPs. These types of projects, while on a small scale, have the potential to provide valuable information that can be used to reduce adverse impacts from non-point source pollution, a water quality concern for many watersheds in south Florida. The DOI supports these studies for their inherent restoration effects to Biscayne Bay and nearshore waters.

Points of Contact

University of Florida, Institute of Food and Agricultural Science (IFAS), Tropical Research and Education Center, Homestead (Dr. Bruce Schaffer); SFWMD, West Palm Beach (Lisa Smith).

References

Schaffer, B. Telephone communication, May 13, 1998.

5. Restoration of Pineland and Tropical Hardwood Hammocks on previously Rock-plowed Land in C-111 Basin in Dade County

Background, Scope, and Objectives

Tropical hardwood hammocks are defined as evergreen, broad-leaved forests composed of shrub and tree species that are common to the Bahamas and Greater Antilles (Snyder *et al*. 1990). Along with rockland pine forests, these vegetative communities form the rockland ecosystems of south Florida. Rockland tropical hammocks occupy elevated, rarely inundated, and relatively fire-free areas in three major rockland areas of south Florida - the Miami rock ridge, the eastern Big Cypress Swamp, and the Florida Keys (Snyder *et al*. 1990). Rockland plant ecosystems can be considered as just one component of the diverse mosaic of plant communities that contribute to habitat heterogeneity and ultimately to the biological diversity of south Florida's natural environment.

This critical project is designed to demonstrate the techniques for re-establishing native conifer and hardwood forests on those lands that have previously been rock-plowed. The restoration project will consist of restoring native south Florida slash pine and hammock species within a 200-foot-wide strip on each side of two miles of State Road 9336 from the C-111 canal to the L-31W canal. Two one-acre hammock sites will be established in low lying areas on each side of the road. Native species initially proposed for the site include dahoon holly (*Ilex cassine*), gumbo limbo (*Bursera simaruba*), live oak (*Quercus virginiana*), sweet bay (*Magnolia virginiana*), paradise tree (*Simarouba glauca*) as well as a variety of shrub plants. Once the overstory has become established, the project will add additional shade species to provide an understory within the hammocks. Monitoring efforts will be included in the project design in order to demonstrate the progressive reduction in vulnerability to encroachment of exotics as the native plants mature.

Status of Project

At the present time, this project is unfunded and has not proceeded beyond the nomination stage.

Recommendations

Tropical hammocks that comprise the rockland plant ecosystems support the largest number (59 taxa) of rare and threatened plants (Gunderson 1994) and therefore represent important habitat for consideration in restoration efforts. This project is important if only for the valuable monitoring information it will provide relative to re-establishment of native species on rock-plowed lands. Other locations within the Everglades ecosystem that have been disturbed by past land use practices may also provide an opportunity to implement similar revegetation efforts and thus provide important habitat for sensitive plant and wildlife species. The DOI supports the implementation of this project.

6. L-31E Flow Redistribution Project

Background, Scope, and Objectives

This critical project consists of reworking and constructing a freshwater distribution system along a 3.5-mile length of L-31E levee and borrow canal from S-20G to S-21A. This work will include moving the levee toward the borrow canal on top of an existing road, creating a new ditch and berm along the east side of the canal, and constructing a series of culverts to convey water from the borrow canal along the west side of the levee to the new ditch along the east side.

The intent of the L-31E Flow Redistribution Project is to facilitate the restoration of the ecological integrity of Biscayne Bay by re-establishing the sheetflow of fresh water through coastal wetlands in Biscayne National Park. Historically, fresh water entered the southern Biscayne Bay estuary through a series of creeks and sloughs. This flow pattern was disrupted by the L-31E levee system constructed in the 1960s for flood control. Currently, freshwater flows discharge from a few control structures into the estuary resulting in frequent and wide swings in salinity at the canal discharges. Studies have documented disrupted benthic communities near the canal discharge zones as well as destruction of seagrass beds as a result of these pulses of freshwater.

Restoration benefits to the estuary are expected to include: (1) reduction in the frequency of damaging wide swings in salinity at water control structure locations, (2) delivery of fresh water to wetland communities and subsequent availability to the estuary, and (3) reduction in pollutant loading to Biscayne Bay by removal of contaminants. Freshwater flow will be restored into mangrove wetlands at appropriate locations. Point source discharges of freshwater, which may contain contaminants, into Biscayne Bay will be greatly restricted or eliminated. The project is expected to facilitate the restoration of essential fish and mangrove fringe habitat and thereby enhancing habitat for the endangered American crocodile (*Crocodylus acutus*).

Status of Project

Currently, the technical issues relative to the L-31E Flow Redistribution Project are being reviewed by the project's sponsor (SFWMD). The geographic scope of the project has been modified from the original proposal to one-half the area to reduce the cost. Measures of benefits will also be added to the project's scope.

Recommendations

Unrelated, but nearshore, ongoing projects sponsored by SFWMD are currently providing valuable monitoring information for the estuarine community in Biscayne Bay and should prove useful in redefining the scope of the L-31E Flow Redistribution Project. Because this critical project is still undergoing design change, at this time, it is difficult to provide a comprehensive evaluation or evaluation as to the benefits to fish and wildlife resources. This project may provide benefits to the natural resources described above for Biscayne Bay and the DOI is supportive of projects that assist in the restoration of the bay.

7. Biscayne Bay Coastal Wetlands

Background, Scope, and Objectives

Freshwater marshes, coastal wetlands, and nearshore estuarine ecosystems of western South Biscayne Bay have been seriously impacted by diversion of overland freshwater flow into canals and by a reduction in groundwater seepage along the shoreline due to the drawdown of the water table as a result of development along the east coast. This loss of groundwater seepage is believed to have seriously reduced the total flow of fresh water into Biscayne Bay during the dry season. This project is expected to create conditions that will be conducive to re-establishing oyster beds and other components of the oyster reef community. The diversion of the current canal discharges into coastal wetlands is expected to reestablish productive nursery habitat along the shoreline as well as reduce the severe freshwater discharges at the canal outlets that are physiologically stressful to fish and benthic invertebrates in the bay. The reduction or elimination of large pulses of fresh water to the estuary will also result in improved water quality for the nearshore environment.

The project is located in southeast Dade County, from the Deering Estate at C-100C, south to the Florida Power and Light Turkey Point Power Plant. This project has five sub-components that are designed to rehydrate the Biscayne Coastal Wetlands by creating sheetflow through the wetlands and reducing point source discharges to Biscayne Bay. These are described as follows (B.Perry, Biscayne National Park, personal communication 1998):

a) Deering Estate Flow-way - this sub-component will pump water from the SW 160th Street ditch (a tributary to C-100C) through property adjacent to the Deering Estate and into Cutler Drain, which runs through the Deering Estate. This feature is designed to rehydrate the coastal Deering Estate and reduce point source discharges to Biscayne Bay.

b) Cutler Wetlands - operation of this sub-component is designed to route water south from C-100A through a Stormwater Treatment Area (STA) (to be constructed adjacent to C-100B) to the Cutler Wetlands proposal area via a shallow distribution swale to C-100B. Water will be pumped from C-100B through the STA to the spreader swale and from C-100A south into the spreader swale to allow sheetflow to the east and Biscayne Bay. This will redistribute flow along the shoreline with a timing and volume schedule that will allow re-establishment of nearshore oyster bars, reduction of point source discharges into the bay, and restoration of coastal mangrove habitat.

c) L-31E Flow-way - A flow redistribution system will be designed west of L-31E, allowing for the restoration of existing wetlands in the area between L-31E and the western boundary of the redistribution system. A distributional swale, containing a western levee, will be constructed along this boundary. The wetland area west of L-31E is intended to be used for short-term, shallow ponding of water to maintain wetland habitat and distribute freshwater flow to Biscayne Bay, which will aid in re-establishing conditions for living oyster bars along the shoreline. This sub-component also includes design features that hydrologically isolate the Dade County landfill and backfill the Military Canal.

d) North Canal Flow-way - Two 200 cfs pumps will pump water from both the C-103 and the Florida City Canal to proposed STAs, when water is available, and reestablish sheetflow across freshwater and coastal wetlands to Biscayne Bay. This feature will distribute freshwater outflow to Biscayne Bay along the shoreline to help reestablish conditions for living oyster bars and to reduce point source discharges to the bay.

e) Barnes Sound Wetlands - Water, when available, will be pumped from Florida City Canal, to a shallower east-west spreader canal to be constructed south of a proposed 500-acre STA for spreading water to wetlands within Barnes Sound. The purpose of this sub-component is to restore coastal freshwater and mangrove wetland habitat and reduce point source discharges to Biscayne Bay.

Several general considerations for this project include: 1) the presence of existing ditches, which interfere with historic flow patterns, 2) the presence of exotic plants and animals, 3) water quality concerns, and 4) land ownership constraints. The project will therefore consider filling ditches and adopting an invasive exotic removal program. Most of the lands to be acquired are currently under acquisition efforts by the State and Dade County.

The proposed project will also include a variety of studies to verify and validate the effectiveness of the structures and operations of the project. Programs to be implemented include: 1) water quality monitoring (both surface and ground water), 2) estuarine habitat evaluation, and 3) benthic community and fish responses.

Status of Project

The Biscayne Bay Coastal Wetland Project is sponsored by the South Dade Wetlands group that is composed of representatives from Biscayne National Park, Everglades National Park, NOAA-NMFS, Miami-Dade Department of Environmental Resources Management, the SFWMD, and the COE.

Recommendations

The DOI strongly supports this project because of the potential to substantially improve the biological integrity and stability of this coastal ecosystem. Additional wetland and estuarine habitat will be restored for the bay and within Biscayne National Park as a result of restoring the natural hydrologic regime. A general increase in species diversity and abundance of estuarine fish and invertebrates is expected in response to implementation of this project as well as improvements to seagrass bed communities in nearshore waters.

WESTERN BASIN AND BIG CYPRESS

This subregion of southwest Florida presents an immensely varied landscape, dominated by seasonally flooded cypress savannahs and freshwater marshes, with interspersed hydric pine wetlands and pine-dominated uplands. The area also includes an extensive coastal fringe of mangroves, beaches, and numerous estuaries. Restoration of predrainage hydroperiods and water flow is an important goal for large areas of southwest Florida including Big Cypress National Preserve, the Fakahatchee Strand State Preserve, the Florida Panther NWR, Southern Golden Gate Estates, Corkscrew Swamp Sanctuary, the Ten Thousand Islands NWR, and the Rookery Bay National Estuarine Research Reserve (NERR). Some of these areas are linked hydrologically. Many changes are underway to watersheds in southwest Florida to accommodate both agricultural and rapidly growing urban land use. These changes may affect the neighboring and downstream natural areas listed above. As a result, several critical projects, some of which are extensive in size and scope, have been identified for this region and are described below.

Existing hydrological models used by the SFWMD, Big Cypress Basin, and others are inadequate in providing essential information regarding how changes in the hydrologic regime will effect the ecosystem. The Southwest Florida Project Coordination Team has proposed a Southwest Florida Water Management Model (SWFWMM) for those areas within southwest Florida that are not contained within the SFWMM. In addition, the COE, with sponsorship of the SFWMD, has proposed a separate feasibility study for southwest Florida as a part of the C&SF Restudy. In fiscal year 1999, a reconnaissance study will be initiated to identify water resource problems and opportunities, leading to the initiation of a full feasibility study in fiscal year 2000. Chapter XV provides an additional discussion of the Southwest Florida Feasibility Study and recommendations from the FWS.

1. Henderson Creek/Belle Meade Drainage Basin Restoration

Background, Scope, and Objectives

This critical restoration project is located in southwest Florida within Collier County, a region of Florida that is experiencing a tremendous increase in urban growth. Roads, canals, planned unit developments, commercial projects, and agriculture represent land uses within the Belle Meade watershed that pose adverse impacts to the coastal habitats and hydrology of Collier County. The impacts from these land use patterns and the subsequent channelization of natural systems has greatly modified the volume, timing, and quality of freshwater flows that drain into the Rookery Bay estuary and adjacent estuarine waters. These estuarine areas provide critical nursery habitat for commercially and recreationally important finfish and shellfish. In addition, the channelized flow in this watershed has severely restricted the ability of associated wetlands to filter pollutants.

The area known locally as Belle Meade Drainage Basin represents the primary drainage basin for the Rookery Bay NERR and is currently targeted for acquisition by the DEP, Division of State Lands, through the Conservation and Recreation Lands (CARL) Program. Historically, fresh water flowed across the land surface of the Belle Meade Drainage Basin, percolating through wetland flow-ways before entering Rookery Bay NERR. Acquisition and restoration of the remaining undeveloped lands surrounding Henderson Creek (which links the watershed basin with the estuary) is proposed with this project in an attempt to prevent further hydrologic and habitat degradation.

The project has five components: a) installation of culverts under State Road 951, b) construction of a filter marsh stormwater management system, c) Manatee Basin hydrologic restoration, d) construction of swale and spreader systems, and e) removal of the Road-to-Nowhere roadbed. Two of these components include land acquisition actions.

a. The installation of four additional culverts under SR 951 is proposed to help increase the surface water flow from the east side of the road to the west side. The four existing culverts recently constructed have improved flows but become overloaded during peak flow conditions.

b. The DEP Carl Program is pursuing the purchase of two parcels of land (approx. 25 acres) adjacent to the Henderson Creek canal. A proposed stormwater management system in the form of a filter marsh on these lands would allow water from the Henderson Creek canal to flow through this filter marsh, which would assist in removing pollutants from the water before it reaches the estuary. The water levels in the canal and the stormwater management system would be managed through the development of an operational plan for the Henderson Creek weir. In addition, invasive, exotic plants would be removed from this site, providing an enhancement benefit to the vegetation community.

c. The Manatee Basin hydrologic restoration consists of both acquisition and restoration activities. Four parcels (approx. 100 acres) of land that drain into the Manatee Basin have been targeted for acquisition by three different funding sources: the CARL Program, Collier County, and a combined FWS grant and Farm Bill funds. Restoration activities would involve: installation of additional culverts under US Route 41, filling of existing drainage ditches to the adjacent grade, returning a power line access road to an at-grade level and installation of GeoWeb materials to allow access for maintenance crews, removal of exotic plants, and creation of a berm along the southern boundary of these parcels to prevent downstream flooding of residential areas.

A public access point and interpretive boardwalk has been proposed, which would lead through the natural plant communities and provide a public viewing areas for manatees.

d. Two overflow swale and spreader systems are proposed from the US Route 41 canal to reintroduce freshwater into McIlvane Marsh and the Ten Thousand Islands NWR in place of the current canal and culvert system now in place under US Route 41. The two broad swale and spreader systems would direct freshwater overflows from the US Route 41 canal to the south. Residential and agricultural development south of US Route 41 currently limits the conveyance of freshwater sheetflow.

e. The Road-to-Nowhere was placed in the McIlvane marsh in the late 1960s as part of a development project. This area was then deeded to the state as part of a settlement agreement. Southern States Utilities currently has an outfall pipe for gray water that runs from its sewage treatment plant to the marsh system. Although not currently used, this pipe has been used for high-volume flows on an irregular basis. The goal of this aspect of the project is to remove the pipe and then the old roadbed. Recent surveys of the area have documented a nesting population of the endangered American crocodile. The removal of the road, or portions thereof, will be coordinated with the FWS and the GFC so that this listed species would not be adversely impacted.

Status of Project

Portions of the Henderson Creek/Belle Meade Restoration project are proceeding with grant monies received from the NMFS and the SFWMD. Work is currently underway by Collier County personnel to implement the swale/spreader system, primarily the acquisition of easements. Studies of nesting populations of the endangered American crocodile are being conducted by biologists associated with the University of Florida, Gainesville. Although eggs were laid in nests during 1997 and 1996, no hatchlings occurred in either year (Paul Moler, GFC, personal communication 1998). Researchers will be collecting eggs in 1998 and incubating them *ex situ* in an effort to determine egg viability and fertility. These biologists are also planning to conduct additional surveys of the southwest coast for populations of this endangered species.

Recommendations

This critical project as well as the Southern Golden Gate Estates Restoration Project and the Southern CREW Project Addition described below represent extensive habitat restoration projects for the Western Basin of south Florida. Some of the ecological improvements for the Henderson Creek/Belle Meade project include: 1) restoration of historic surface water flow patterns to estuarine and marsh habitats, 2) removal of invasive exotic plants, 3) improvement of water quality for flows to the estuary, and 4) improvements to habitat important for supporting sensitive species such as the American crocodile and the West Indian manatee. To the extent possible, historic overland flow-ways to Manatee Basin should be restored. The DOI strongly supports restoration in the Western Basin of southwest Florida, particulary those which can provide restoration of historic fish and wildlife habitats.

Moler. P. Telephone communication, May 18, 1998.

2. Southern Golden Gate Estates Hydrologic Restoration

Background, Scope, and Objectives

The Southern Golden Gate Estates (SGGE) study area encompasses approximately 94 square miles of important lands in southwestern Collier County, between the Fakahatchee Strand and Belle Meade watersheds. The Picayune Strand State Forest (previously the Golden Gate State Forest) encompasses the southern blocks of the Golden Gate Estates land area. The SGGE project area has been identified as an important surface storage and aquifer recharge area with unique plant communities and wildlife habitat. It also includes three major flow-ways that contribute fresh water to the Ten Thousand Islands estuary of the western Everglades watershed. Much of the area was logged for cypress in the 1940s and 1950s, after which the area was purchased for development of the Golden Gate Estates subdivision. Construction of road and drainage modifications in the 1960s and 1970s have resulted in reduction of aquifer storage, increased fresh water shock load discharges to the estuaries, invasion of upland vegetation, and increased frequency of forest fires. A study was commissioned in 1975 to study the feasibility of restoring the area south of Interstate 75. Since then, numerous studies have been conducted to develop methods of restoring the area to its former condition. In 1985, SGGE was included in the "Save Our Everglades" portion of the Conservation and Recreational Lands (CARL) program. The primary objective of this critical project is to restore the environment of the area to its natural state by re-establishing the historic flow-ways and reducing the shock load of fresh water discharges to the estuary.

Status of Project

An Interagency Technical Committee, with representatives from SFWMD, COE, Florida Department of Forestry, NRCS, GFC, Big Cypress Basin, DEP, and the FWS, has been meeting on a regular basis in an effort to evaluate the SGGE Hydrologic Restoration Project. Active acquisition of private lands is still ongoing through a willing seller program (CARL) administered by the DEP. The implementation of this project is entirely contingent upon acquisition of lands. Of the 55,200 acres of land proposed for acquisition, 37,312 acres have yet to be acquired, of which approximately 7,500 acres are controlled by nearly 4,200 land owners. The Federal Farm Bill grant has allocated monies in non-matching funds to assist in the acquisition of the project site. Active land acquisition is presently ongoing for the adjacent Fakahatchee Strand State Preserve on the east and the Belle Meade CARL project located on the western side of the project site.

Recommendations

The Picayune Strand State Forest Resource Management Plan (1996) presents a list of fish, wildlife, and plant resources for the area; however, a comprehensive plant and animal survey has not been conducted for the forest due to lack of funding. The proposed area is located almost entirely within the Florida Panther Preservation Area and within Florida panther (*Felis concolor coryi*) telemetry locations and therefore is considered to be within potential Florida panther habitat. Because the panther prefers upland habitats, the project planning process must include protection of upland areas that may be impacted by increase flows to the preservation area as well as evaluation of extended hydroperiods for these areas. Biologists from the Florida Panther NWR (which is located immediately adjacent to SGGE) have suggested that wildlife inventories be conducted for this area to include monitoring of movements for both the endangered Florida panther and Florida black bear (*Ursus americanus floridanus*), which is a candidate for Federal listing. Additionally, to the immediate southwest of this study area, there are nesting locations for the federally-endangered red-cockaded woodpecker (*Picoides borealis*) and one bald eagle (*Haliaeetus leucocephalus*) (a federally-threatened species) nest within the study region. Other species of concern that have been identified as occurring within the project region include the endangered wood stork (*Mycteria americana*) and the threatened eastern indigo snake *(Drymarchon corais couperi*). State-listed species that are known to inhabit this area include the Big Cypress(=mangrove) fox squirrel (*Sciurus niger avicennia*) and the southeastern American kestrel (*Falco sparverius paulus*). The status of each of the above described species should be determined and the potential impacts resulting from re-establishment of historic flow-ways in this region assessed.

Since the proposed project will most likely change freshwater discharges to the Ten Thousand Islands NWR, which contains habitat for the endangered West Indian manatee and endangered American crocodile, impacts to these listed species should be considered in the planning process. West Indian manatee critical habitat has been designated for all connected bays and estuaries for this portion of Collier County. The FWS would be interested in any proposed alteration of flows of fresh water to Faka Union Canal as a result of this project, since this canal is known to be an aggregation site for the manatee and has contributed to boat-related manatee mortality. Increasing sheetflow as opposed to canal flow may reduce the risk of manatee mortality.

Coordination with the COE, the SFWMD, GFC, and the SGGE Interagency Technical Committee is essential to this project. The Big Cypress Basin (Basin) office of the SFWMD has been tasked with developing a Watershed Management Plan for the Basin, which includes the SGGE area. The SFWMD requested watershed planning assistance from the NRCS. The scope of work in developing a Basin Watershed Management Plan has been reviewed by the Interagency Technical Committee. The NRCS will acquire and analyze topographic, soil, and vegetation data and perform hydrologic modeling analyzes for the SGGE area to be used in developing the plan. This information will be important for guiding the hydrologic restoration critical project for SGGE. The Basin office has earmarked $40,000 in additional funds to extend the Watershed Management Plan project to September 1999. This will ensure that the work is funded until fiscal year 2000 WRDA monies can be allocated to continue the biological and hydrological monitoring in the SGGE area.

The DOI believes that the SGGE Hydrologic Restoration project represents an important critical project for southwest Florida. The biological surveys and hydrological information gathered for the SGGE area for developing the Watershed Management Plan for the Basin will be essential for the design and implementation of this project.

Florida Department of Agriculture and Consumer Services, Division of Forestry. 1996. Forest resource management plan for the Picayune Strand State Forest, Collier County, Florida.

3. Southern Corkscrew Regional Ecosystem Watershed (CREW) Project Addition/Imperial River Flow-way

Background, Scope, and Objectives

This project will involve acquisition of 4,670 acres of land in the southern Flint Pen Strand region of Lee County and the historical Imperial River flow-way to Estero Bay. After restoration of historical flows, this land area will be added to the Corkscrew Regional Ecosystem Watershed which lies on the eastern border of the proposed project. The project area has been significantly altered by construction of roads, house pads, agricultural berms, and ditches. This has resulted in restriction of historical sheetflow, unnatural water impoundments and flooding, increased pollutant loading to the Imperial River and Estero River, and disruption of natural wetland functions. The lands proposed for acquisition have been divided into five and ten acre tracts that are being developed into single family home sites. This critical project will include purchase of lands in the impacted region before additional homes are constructed. The area has a history of flooding problems that have required the evacuation of residents. If the land continues to be developed for housing, additional roads, house pads, septic tanks, and drain fields will increase the blockage of the surface water flow and contribute to the degradation of water quality in adjacent environmentally sensitive areas.

Hydrologic restoration will include the following activities: removal of existing road beds, removal of single family homes, removal of debris, filling of ditches, and removal of agricultural berms and canals. Other project components include modifications of the Kehl Canal weir and replacement of the Imperial Bonita Estates (IBE) bridge. The Kehl Canal weir will be raised in order to provide more storage capacity and gates will be added to allow better water management and control of the canal which flows through the land proposed for acquisition. The IBE bridge located over the Imperial River downstream from the Kehl Canal weir will be replaced so that it will allow a more direct flow path and eliminate a constriction that currently exists within the natural stream channel as a result of the current bridge design. The project sponsor will be responsible for acquiring any authorizations under Section 10 of the River and Harbors Act and Section 404 of the Clean Water Act, as required.

This acquisition project will not only mitigate future impacts, but also should provide long-term benefits to a watershed of over 300 square miles. The removal of structures and filled areas in the project site will restore the historical flow-way of the Imperial River and reduce the depth and duration of stormwater impacting natural areas. Additionally, the re-establishment of historical flows across the project site will reduce the potential that currently exists for forcing water eastward through the CREW Project and the Corkscrew Swamp Sanctuary, causing harm to natural wetlands by increasing the depth and duration of hydroperiods in these areas. The Kehl Canal weir modifications are designed to reduce the dry season flows (overdrainage) to the Imperial River by acting as a natural storage area. As stated earlier, the project will eventually be added to the CREW with perpetual management to maintain natural system qualities.

Status of Project

In a combined effort, Lee County and the SFWMD have already purchased 2,000 of the total project's 4,760 acres of land. The urgency of this proposed acquisition is high due to the ongoing residential development in the area and the potential impacts of this development to the water quality of the Imperial River as well as to the environmentally sensitive lands of the CREW and Corkscrew Swamp Sanctuary.

Recommendations

The above described critical project represents one piece of an important watershed in southwestern Florida, a region of Florida that is currently experiencing tremendous urban growth pressures. The project land acreage is contained within the identified Florida Panther Preservation Area and within panther telemetry locations. Specifically, the lands within this project that are located east of Bonita Grand Road and north of Bonita Beach Road are classified as Priority 2 panther habitat based upon the less frequent use of this area by the endangered panther (Logan, *et al*. 1994). These lands are composed primarily of wetland habitat adjacent to agricultural lands and have been impacted to some extent by housing development. The acquisition, restoration, and management of this land acreage would provide benefits to the panther by: 1) providing a buffer area from urban use, 2) providing habitat on the periphery of the range that is suitable for dispersing subadult populations, and 3) to a lesser extent, providing habitat for a panther with an established home range (such as one female that currently utilizes Corkscrew Swamp (A. Eller, FWS, personal communication 1998). Two additional federally- listed species that are expected to occur within the Southern CREW project addition are the threatened eastern indigo snake and endangered wood stork. Biological surveys to document population distribution and abundance should be conducted for these species.

The proposed Southwest Florida Water Management Model and an expanded NSM model would be beneficial in understanding the altered hydrologic system for this region. Model outputs would provide important design information for this restoration project and others proposed for southwest Florida.

4. Seminole Tribe Big Cypress Water Conservation Plan

Background, Scope, and Objectives

The Big Cypress Seminole Reservation (Reservation) is the largest of the federal reservations held in trust by the United States government for use by the Seminole Tribe of Florida (Tribe) and is located in Hendry and Broward Counties, Florida. The Reservation has a hydrologic connection to the C-139 Basin, the EAA, the L-28 Basin, WCA 3A, Feeder Canal Basin, L-28 Tie Back Basin, the Miccosukee Reservation, Big Cypress National Preserve, and, ultimately, to Everglades National Park (ENP).

The C&SF Project, primarily the construction of major canals, levees, and control structures, continues to have a major impact on central and southern Florida natural systems, including those within the Big Cypress Reservation. Continued deterioration of the wetland habitats on the Reservation, increase in spatial extent of exotic species, and continued decline in water quality can be expected without changes to the current hydrological system.

A Conceptual Water Conservation System Design (Conceptual System Design) prepared by AMS Engineering and Environmental (1995) has been presented by the Tribe in an effort to: 1) utilize available, native wetland resources to reduce the total phosphorus concentration in accumulated surface water runoff prior to discharge, 2) store surface water for irrigation, 3) attenuate peak storm runoff discharges, and 4) provide the opportunity to rehydrate a portion of the Big Cypress National Preserve Addition. The Tribe has proposed that it will integrate the use of field applied best management practices, “on-line” surface water storage cells, and existing swamp and marsh wetlands as effective treatment areas within the proposed Water Resource Areas (WRAs) to reduce total phosphorus concentrations in surface waters leaving the Reservation.

The Big Cypress Water Conservation Plan (Plan) is a water conservation project that would implement the Conceptual System Design proposed by the Tribe. The Plan is designed to improve the quality, quantity, timing, and distribution of water on the Reservation. The western portion of the project consists of 2,092 acres and is being considered as a critical project for the Restudy with work being performed by the COE. The eastern portion of the project consists of 5,043 acres and is being proposed under programs to be funded in part by the NRCS.

The proposed critical project will provide for the design and construction of water control, management, and treatment facilities in Basins 1, 2, 3, and 4 and the major conveyance systems necessary to bring the Tribe’s water entitlement into these four basins. The project is designed to improve the water quality and runoff from phosphorus generating agricultural sources within the Reservation. The phosphorus goal has been set at 50 ppb. However, the project will be designed to allow for additional treatment technology to meet stricter phosphorus levels, if required.

Status of Project

The Tribe has filed for a Section 404 permit with the COE for the **eastern** portion of the water conservation project. The FWS evaluated the public notice and provided recommendations to the COE requesting the following information: 1) provide any available wildlife survey information for the Reservation, 2) provide a description of the vegetative communities that will be affected by the project, and 3) conduct a wetland assessment to quantify lost wetland functions and values as well as the benefits of wetland creation, enhancement, and preservation that may mitigate lost functions and values. An interagency Wetland Rapid Assessment Procedure (WRAP) has been recommended for this task.

Although the critical project addresses the **western** portion of the Conceptual System Design, the FWS believes that the above concerns should be addressed for the critical project as well. The FWS requested that the COE combine both projects into one NEPA review to facilitate an analysis of total project effects.

Recommendations

The DOI is supportive of restoration projects within the western basin of southwest Florida. The Tribe's proposed Water Conservation Plan (**which includes all seven basins within the Reservation**) presents a conceptual design to address such issues as flood attenuation, water quality, water supply, and environmental enhancement goals on the Reservation. However, there are a number of unresolved concerns related to this project that must be addressed before the project can proceed. These include: 1) determining the extent of wetland impacts, 2) mitigation measures to be taken for wetland impacts, 3) preservation of adjacent wetland habitat, 4) establishing a monitoring program for the project, 5) the redirection of water to Big Cypress National Preserve (e.g. water quantity), 6) details on how the irrigation cells will function, especially during storm events, 7) operational design of the WRAs, 8) treatment of other pollutants other than phosphorus, and 9) objections expressed by the Miccosukee Tribe relative to the 50 ppb phosphorus target for the project. The need for wildlife surveys must be addressed for the project area. It is anticipated that the COE, the FWS, the EPA, and SFWMD will work with the Tribe to resolve these and other issues.

AMS Engineering and Environmental. 1995. Conceptual water conservation system design for Big Cypress Reservation. Prepared for Seminole Tribe of Florida.

5. Town of Fort Myers Beach

Background, Scope, and Objectives

The Town of Fort Myers Beach in southwest Florida (Lee County) has identified the need for the protection of adjacent Estero Bay and local beaches from pollutants transported via stormwater runoff from the island on which the town is located. Most of the town is urbanized and has an inadequate stormwater management system. Components identified for this critical project include: inventory of stormwater systems, sediment sampling, screening of illicit connections, and implementation of an urban retrofit project. The project is designed to enhance Estero Bay and has received full support of local government and residents of the community. Apparently, the town has no other alternative for stormwater treatment, such as creating a filter marsh, due to lack of space. The town has already begun to identify stormwater "hot spots" through inventory and sampling procedures and has converted 48,000 square feet of asphalt to pervious paving materials. Pores in the asphalt of these materials allow runoff from parking lots to flow through the pavement into an underground reservoir of small stones, and then gradually filter into the surrounding soil. Other options for controlling urban runoff that are under consideration include installation of "water quality inlets," which are baffled concrete tanks for solids and oil separation, as well as numerous other best management practices (e.g. encouraging the use of slow-release fertilizers, etc.) The project is expected to provide immediate water quality and ecological benefits to the Estero Bay Aquatic Preserve by reducing pollutant loading to receiving waters.

Status of Project

At the present time, the town is seeking revenue sources to implement components of this project. A private consultant planning group, is presently working with local land owners to initiate volunteer efforts to repave their parking lots with pervious paving materials. The Town of Fort Myers Beach is developing a comprehensive plan that will include a stormwater management element.

Recommendations

This critical project does have the potential for improving the water quality of Estero Bay and nearshore waters by reducing the effects of stormwater runoff and subsequent pollutant transport. However, the DOI would expect this very localized project to be resolved by the city with monies from grants or through a levy on local utility bills. We are uncertain as to whether this project is of adequate scope to generate Federal interests. The project may be significant for providing a model stormwater management program for other coastal communities throughout Florida.

6. Lake Trafford Restoration

Background, Scope, and Objectives

Lake Trafford, located approximately three miles west of the city of Immokalee (Collier County), is the largest lake south of Lake Okeechobee with a surface area of 1,494 acres. The lake represents the headwaters of the Corkscrew Swamp Sanctuary to the southwest, the Corkscrew Regional Ecosystem Watershed (CREW) to the west, and the Fakahatchee Strand system to the south. Lake Trafford is an integral contributor to the sheetflow that traverses the CREW and Southern Golden Gate Estates. As the only major lake in southwest Florida, Lake Trafford represents an important resource for wildlife, including migratory birds.

Approximately 8.5 million cubic yards of unconsolidated muck (loose, flocculent organic material) has accumulated on the bottom of the lake as a result of deposition of organic matter over time and herbicidal treatments of the lake in the 1970s for hydrilla (*Hydrilla verticillata*). Hydrilla is a particularly troublesome exotic weed that outcompetes both native and other exotic plant species. During storm events, bottom sediments are disturbed resulting in an increase in suspended solids, dissolved nutrients, and an increase in biological oxygen demand. The decrease in water clarity and low dissolved oxygen levels has resulted in a severely depressed fishery for the lake.

The objective of this critical project is to restore water quality and habitat functions for the lake. A multi-agency task force evaluated the muck removal aspect of the restoration project and determined that a one-time dredge event would provide lake restoration. Sediment analysis of the muck determined that the spoil material was suitable for disposal on farmland. The material will be pumped to an upland disposal site on existing farmland less than one mile from the lake. The disposal area consists of a 449-acre, diked, agricultural facility, which will be divided into three cells. Recurrence of the muck layer is not anticipated due, in part, to improved aquatic plant control methods. Surrounding agricultural lands, which are expected to receive enhanced productivity benefits from the muck disposal, are expected to commit to using best management practices to reduce pollutant loading into the lake. In summary, the long-range goal for this restoration project is to 1) restore native aquatic plant communities and fish spawning habitat for the enhancement of fish and wildlife populations, 2) provide enhancement of the quantity and diversity of benthic organisms, 3) control nonpoint source pollution through BMPs, and 4) develop a long-term management plan for the lake.

Status of Project

This critical project is currently under review by the COE Jacksonville District Office. Request for funding is expected by the end of this fiscal year. The project sponsors (DEP, GFC, and SFWMD) will provide all lands, easements, rights-of-way, relocations, and disposal area requirements.

Recommendations

The DOI strongly supports ecological restoration projects that are designed to improve lake habitat, particularly those which contain components that address muck removal and disposal. The dredging activity would need to be coordinated with the FWS in order to address potential impacts to threatened or endangered species that may be present at this site. The timing of these activities may need to be adjusted so as to avoid the nesting/breeding seasons for avian species. Benefits to the Lake Trafford fishery will occur as a result of implementation of this project. It would be useful to include monitoring components within the scope of this project in order to document changes in the abundance and distribution of fish species as well as other aquatic species (e.g. invertebrates, periphyton, macrophytes). The importance of containment of the deposited material on farm lands cannot be underestimated for this type of project. The proposed BMPs to control erosion on the receiving farms must be agreed upon in advance and closely monitored.

7. Tamiami Trail Culverts

Background, Scope, and Objectives

U.S. Highway 41, also known as Tamiami Trail, is a two-lane highway in south Florida that connects Miami to Naples. The project area is located within Big Cypress National Preserve, Collier County, between State Route 92 (Collier Seminole State Park) to the west and 50-Mile Bend to the east. Modified Water Deliveries to Everglades National Park project will address the hydrological impacts of the highway east of the 40-Mile Bend. The elevated roadbed of the Tamiami Trail currently acts as a barrier to the north-south sheetflow to Ten Thousand Islands NWR, Southern Golden Gate Estates, Fakahatchee Strand State Preserve, southeast Big Cypress National Preserve, and Everglades National Park. This sheetflow is important for the support of these regional wetland ecosystems. A borrow canal immediately north of the Tamiami Trail intercepts the south-southwest flow and transfers it to an east-west direction until it is intercepted by bridges or water control structures at which point it exits to the south. Due to this channelization of flow-ways, seasonal hydropattern characteristics (distribution, timing, and water quality) of this surface water flow are disrupted and some wetland habitats receive too much freshwater, while other areas receive too little.

The project is designed to help restore a more natural hydropattern to both the Big Cypress Basin and coastal areas. Initial design features involve placing 87 additional culverts under Tamiami Trail at 30 separate sites along with construction of 29 blocking plugs within the existing borrow canal. The exact locations for these sites would be determined after field inspection to determine the best location in the natural drainage swales to isolate the culvert structures. This would help to block the east-west flow of the borrow canal. The project will be completed in three phases: Phase I - conduct a comprehensive assessment of the hydrological impacts from the Tamiami Trail (currently being initiated by USGS and Florida Department of Transportation); Phase II - identification of locations for additional water conveyance structures (i.e. bridges, culverts); and Phase III - installation of additional water conveyance structures and, if necessary, upgrade of existing structures. All lands required for this project are owned by the local sponsor(s). This project is associated with several other south Florida restoration projects including the Southern Golden Gate Estates Restoration critical project.

Status of Project

This critical project was ranked second by the South Florida Working Group and is proceeding as scheduled according to the project's implementation schedule. The project is now within the design phase and a proposed plan is expected to be completed by September 1998. Initiation of NEPA coordination with the FWS is expected at that time.

Recommendations

The implementation of this proposed flow enhancement project is likely to provide improvements to the water quality of the coastal estuaries by converting the freshwater point discharge to sheetflow along an approximately 34-mile wide front. The reintroduction of this overland flow through coastal marshes would serve to increase marsh and mangrove habitat productivity, moderate salinity fluctuations, and provide a more desirable mix of fresh and saline water conditions that will produce a more favorable environment for the survival and protection of juvenile fishes and shellfish beds. Recreational and commercial fisheries would also be expected to improve by the re-establishment of this overland flow. However, it would be important to monitor (i.e. sample) this re-routed water flow into the coastal estuaries to evaluate the potential for pollutant transport. Culverts should be placed, to the extent possible, at the ground surface so as to not promote pooling of water on either side of the road.

Restoration of flows into certain portions of marsh habitat located south of the highway that will be affected by this project may need to be evaluated for impacts to historic breeding habitat of the endangered Cape Sable seaside sparrow (*Ammodramus maritima mirabilis*). Although this particular section of south Florida is not designated critical habitat for the sparrow, the potential exists for birds to recolonize marl prairie communities that support hydroperiods conducive to breeding. Therefore, identification and protection of potential habitat in this region should be evaluated. In addition, consultation with the FWS and GFC will need to be initiated for this project, in part, for listed species, such as the State-listed (threatened) Everglades mink (*Mustela vison evergladensis*) that have been documented in this area.

8. Spring Creek Connection and Rehydration Project

Background, Scope, and Objectives

In the early 1960's, a 40-foot wide canal was dug that cut off approximately 2,200 linear feet of Spring Creek which flows into Estero Bay in Lee County, Florida. In 1990, the canal was designated an Outstanding Florida Water (OFW). The project, located in Lee County, Florida, will restore approximately 2,200 linear feet of the original Spring Creek floodplain through three major construction components: 1) re-establishment of the headwaters of Spring Creek by construction of a weir to redirect flow into the floodplain flow-way, 2) removal of approximately 1,015 cubic yards of spoil that currently segments the floodplain into three segments in order to restore the creek channel and floodplain, and 3) revegetation in areas where spoil has been removed. Construction of the weir and storage for stormwater runoff is required by the SFWMD for the permit. The project would allow land to be configured for the 75 lots approved by zoning for low-cost housing (G. Beardsley, Tropical Environmental Consultants, personal communication 1998).

Status of Project

Some preliminary design work has been completed for this project, including a wetland delineation within the proposed development. There is no partnership funding for this project which is why Partnership in Housing submitted the proposal. Partnership in Housing is the local sponsor for this OPE and is requesting funding support.

Recommendations

The project will enhance approximately 11 acres of wetlands adjacent to the original Spring Creek channel. The project is directly connected to the Private (Pueblo Bonito) Partnership in Housing, Inc. for development of 75 lots. Partnership for Housing stated SFWMD was a sponsor for the project which is incorrect. SFWMD has no involvement with the housing project except to permit the storage requirements. In addition, SFWMD has plans underway to restore hydrology to many of the old creek channels east of I-75 which will provide more ecological benefits than the proposed project. (C. Merriam, SFWMD, personal communication 1998).

The DOI recommends that this project be removed from consideration since there is no project sponsor and more ecological benefit would be provided from other SFWMD projects.

9. Lakes Park Restoration Project

Background, Scope, and Objectives

Lakes Park is located east of Cape Coral in Lee County, just west of Highway 41. The park consists of an old rock mine with a series of borrow pit "lakes." The entire area drains south into Hendry Creek, an Outstanding Florida Water, which flows for a few miles before entering Estero Bay. Lee County has developed the area as a regional park with a bathing area along the shoreline of the lakes. Adjacent to the developed area, the remaining natural habitat contains pine flatwoods with some cypress heads. Gopher tortoises have been documented within this upland habitat.

The pits capture runoff from the surrounding developed area (commercial, industrial, and residential). County monitoring has indicated a decline in water quality in the lakes. The lakes are infested with hydrilla and adjacent uplands and islands are covered with exotic plant species such as Australian pine and Brazilian pepper.

The project proposes to restore the 10-foot deep rock mine/borrow pit area to 40 acres of meandering flow-way lined with littoral marsh. Fill will be placed between islands to direct flow into a meandering channel. The vegetated littoral zones and trees in the uplands will provide habitat and a nutrient sink for incoming flows. The littoral zone will be harvested periodically to remove excess nutrients from the system. Exotic vegetation will be removed and replaced with native vegetation on 11 upland acres.

Status of Project

Lee County has committed to funding 50% of the project. Planning actions are on hold pending additional funding.

Future Needs for Information or Design

Natural resource needs for effective planning include a freshwater marsh and water quality management plan.

Recommendations

The DOI supports improvement of water quality and habitat conditions by creation of a marsh/flow-way in the mine site at Lakes Park. Should funds become available for planning, we recommend that the mine site, wetlands/flow-way, and Hendry Creek be combined into one comprehensive management effort. Fire and drawdowns may need to be considered for the management of early wetland plant successional stages with more diverse habitat niches. Management actions should be evaluated for different areas at different times in order to sustain and improve habitat heterogeneity (FWS 1998).

Provisions need to be made to sustain the gopher tortoise and potential eastern indigo snake populations on site. Biologists should inspect the area prior to exotic vegetation removal and be on site during vegetation removal procedures to ensure heavy machinery does not coincidently cave in tortoise burrows or run over the animals.

Best management practices need to be evaluated and implemented for adjacent areas in the drainage, especially golf courses. An upland buffer should also be maintained on either side of the wetlands/flow-way and linked with any other existing or planned greenways in the region.

Points of Contact

DEP (John Outland); Lee County (Rick Joyce or George Parker)

10. Reversing Overdrainage from the Barron and Turner River Canal Basins

Background, Scope, and Objectives

This conceptual project is intended to provide hydrologic restoration to approximately 500 square miles of impacted wetlands in the Big Cypress National Preserve (BICY), a unique 729,000 water-dependent ecosystem. The Barron River Canal and the Turner River Canal, which lie within the western portion of BICY, currently act to channelize overdrainage from the BICY watershed. These canals directly connect freshwater uplands of the BICY with the saline estuaries within ENP causing rapid drainage of these areas. The reduced hydraulic head enhances salt water penetration into the freshwater environment of the BICY. This rapid drainage also reduces the productivity of cypress forests and wet prairie ecosystems.

The restoration of historic flow-ways is expected to reintroduce the historic natural environment and help to eliminate nuisance exotic species. This project should also provide water quality improvements to the Ten Thousand Islands NWR and ENP by converting freshwater, point source discharges to traditional overland sheetflow.

The project proposes the use of the SFWMD Natural System Model to evaluate the impacts of overdrainage by simulating pre- and post-channelization conditions in the BICY. Water management strategies may include the installation of canal blocks and operation/design changes of water control structures.

Status of Project

This project is unfunded and has not proceeded beyond the nomination stage.

Recommendations

The conceptual nature of this project does not allow for a complete evaluation of the hydrologic restoration components of this project. The reintroduction of overland sheetflow would enhance marsh and mangrove productivity, moderate salinity fluctuations, and provide overall enhancement of the recreational and commercial fishery resources of the estuaries currently impacted by point source discharges of fresh water. However, there are potential constraints to the installation of water control structures that may be considered for the project. Two major highways are located adjacent to the canals - Highway 29 to the west of the Barron Canal and Highway 41 to the south of the Turner River Canal. The restoration of sheetflow may cause flooding in these areas. In addition, the potential for transport of pollutants, such as pesticides from nearby agricultural areas (i.e. Immokalee), will need to evaluated in the project design.

EVERGLADES NATIONAL PARK

1. Nutrient Removal/Dosing Studies at ENP

Background, Scope, and Objectives

One of the major problems facing the Everglades wetlands is the quality of water being delivered into these areas directly from the Everglades Agricultural Area (EAA) and surrounding urban areas. Changes in the vegetation community have occurred as a result of phosphorus enrichment has been documented in Everglades National Park (ENP) (Davis 1994). The Everglades ecosystem apparently developed under conditions of relatively low nutrient inputs with phosphorus being the limiting macronutrient. Historically, the marshes are considered to be nutrient-starved and the overlying water highly oligotrophic. Because of this nutrient limitation and extreme dependence on internal recycling of elements, Everglades wetlands are highly susceptible to excessive inputs of allochthonous nutrients. Walker (1991) reported significant increases (4-21%) in total phosphorus at eight of nine inflow sites to the ENP. The problem posed for researchers and managers is to determine how much phosphorus is excessive.

This project is part of an ongoing Phosphorus Threshold Dosing research study being conducted in the ENP by Dr. Ron Jones of Florida International University. Research efforts will be designed to provide critical baseline information needed to establish Class III water quality standards for the Everglades Protection Area. Included in this research project are the construction of three, four-channel flows or flumes in pristine *Eleocharis* spp. wet prairie marshes to investigate the effects of low-level phosphorus addition on Everglades wetland communities. Each flume will have a control channel and three experimental channels representing a range of phosphorus concentrations that bracket current proposed water quality standards.

An understanding of the interaction of ecosystem changes is essential to predicting the effects of the addition of phosphorus on Everglades wetlands. This study will examine ecosystem responses at several hierarchal levels and the project will quantify all major processes associated with macronutrient cycling and generate biogeochemical budgets for each. The structural and functional dynamics of the various plant and animal communities will also be measured along with the quantification of food web structure and energy flow.

Status of Project

This ongoing project is currently funded via a contract with SFWMD and the ENP, with a three year extension beyond 1998 at $250,000 per year, pending budget approval by SFWMD. The three flumes have been constructed and are fully operational. Phosphorus dosing was scheduled to begin at the onset of the 1998 wet season, or approximately June 1. Dosing will continue for three full years when there is adequate flow.

Recommendations

This critical project represents an important short-term study concerning nutrient loading in Everglades wetland habitat. The DOI supports these projects, while recognizing that they are just one step in providing a solution to this problem.

FLORIDA BAY AND FLORIDA KEYS

1. Florida Keys Tidal Creek Restoration

Background, Scope, and Objectives

The objective of this proposed critical project for the Florida Keys area is to restore flows to tidal creeks by installing culverts under U.S. Highway 1 at three locations in Monroe County (between mile markers 54 and 57). These projects are similar to a culvert project at Key Colony Beach completed in 1991, which was very successful in improving the near-shore water quality The individual projects can be described as follows: 1) restore Tarpon Creek just south of mile marker 54 on Fat Deer Key, 2) restore an unnamed creek between Fat Deer Key and Long Point Key south of mile marker 56, and 3) restore tidal connection between Florida Bay and the Atlantic Ocean at mile marker 57. Restoration benefits expected by installation of these culverts include enhanced circulation and flushing, improved water quality, and restoration of marine habitats. The accumulation of organic material in these creeks has resulted in a degradation of water quality and sea grass habitat. Impacts originally occurred as a result of the construction of the Flagler Railroad bed (currently U.S. Highway 1) which blocked tidal flow and circulation in near-shore waters.

Status of the Project

At the present time, this project is unfunded and has not proceeded beyond the nomination stage.

Recommendations

The culvert project known as the Key Colony Beach restoration provided evidence that tidal creeks of the type described above can be restored with significant improvement to water quality and thus to the entire marine ecosystem. Additional restoration projects of this type will provide further benefits to improving surface water circulation and the DOI supports this project.

BASIN-WIDE PROJECTS

1. Exotic Plant Eradication Project

Background, Scope, and Objectives

Melaleuca trees and other invasive exotic species are rapidly invading the natural Everglades habitat. The exotic tree *Melaleuca quinquenervia* was introduced in the 1900's, rapidly spread in the 1940s and now infests approximately 500,000-1,500,000 acres of south Florida's fragile wetlands. The potential range of melaleuca includes the entire peninsula of Florida south of Lake Okeechobee, excluding the saline zone (Bodle, M.J. *et al*. 1994). Lake Okeechobee, Everglades National Park, Big Cypress National Preserve and the Water Conservation Areas are all at risk. Growth has become so dense in some areas that native habitats have been replaced resulting in a dramatic decrease in native flora and fauna. Melaleuca also represents a navigation and fire hazard. Experts agree that we are unlikely to control this pest without the aid of biological agents.

Research in its native Australia indicates that biological control agents offer immense potential to reduce the projected billion dollar impact to the south Florida ecosystem. One melaleuca insect, *Oxyops vitiosa*, has been through the quarantine process and was released in April 1997. Initial field reports indicate that this insect is very effective in controlling melaleuca.

Quarantine studies and release of approved candidates are being delayed due to limited quarantine facilities. Conventional chemical and mechanical melaleuca control continues, but incorporation of biological control agents into the management strategy is essential. A consortium of Federal, State and local agencies have funded overseas research to identify candidate biological control insects for melaleuca. Approximately ten candidates have been identified.

This is a three part project consisting of: 1) construction of a Melaleuca Quarantine and Research Facility to enable the testing of organisms brought into the United States from Australia for biological control of Melaleuca at Fort Pierce Florida, 2) upgrading existing quarantine facilities at Gainesville, Florida and 3) implementation of biological controls. These facilities would accelerate the integration of biological control technology into melaleuca management efforts.

Status of Project

Construction of the new quarantine facility was initially to be located at Davie, Florida and the pre-final design of the facility was completed by the Jacksonville District in 1997. However, since the project is now proposed to be located in Ft. Pierce, Florida, some modification of the design will be required. The project will be located on University of Florida property adjacent to the U.S. Department of Agriculture/Agricultural Research Service Facilities Division. Surveys and rights of entry have not been conducted and an Environmental Assessment has not been prepared.

Recommendations

The DOI strongly supports the construction of a Melaleuca Quarantine and Research Facility, upgrading the existing quarantine facilities and implementation of biological control agents. The invasive nature of *Melaleuca quinquenervia* requires immediate attention to prevent further spreading of this exotic species. The proposed actions would significantly accelerate the quarantine process and are highly recommended.

CHAPTER VII --WATER SUPPLY ISSUES

Compiled by Cheryl Buckingham, FWS

A. Introduction

This issue paper does not attempt to resolve all of the varying opinions presented below, only to summarize some of them. Most of these ideas have been raised at one time or another, but never expressed clearly in writing. It is hoped that initiating discussions with representatives who have different viewpoints and attempting to clarify each position will elicit further constructive comments. Once the arguments on all sides are understood, perhaps more common ground can be found.

B. The Issues

1. Issue: "Is there enough water to restore the Everglades or are urban and agriculture water supply demands too high? Are the Lower East Coast (LEC) and the environment in direct competition for water?"

There is no evidence that the climate in south Florida has changed sufficiently to alter the dry and wet season rainfall patterns since the first attempts to drain the Everglades. Many people believe, therefore, that restoration is possible, even with the water supply requirements of the urban and agricultural community, given that the sharply-reduced size of the Everglades will reduce its demand for water.

One of the primary functions of the C&SF Project is to provide a highly-efficient flood control system designed to keep urban and agricultural areas dry in the wet season by discharging excess water to tide or into the WCAs and ENP. Rapid wet season flood releases, coupled with the lack of retention in Lake Okeechobee, the northern historical sawgrass plains, and the eastern peripheral wetlands and sloughs, have severely reduced storage within the system causing excessive dry season demands on the regional system. The sawgrass plains, for example, once stored and slowly passed on much of the water that overflowed from the Lake. Today, a large portion of the sawgrass plains habitat that was converted to agriculture within the Everglades Agricultural Area (EAA), quickly passes excess runoff to the WCAs and the coast during the wet season. Releases of Lake Okeechobee water are then necessary to meet dry season demands. The lack of storage, not the lack of water, is the problem.

Minimum levels for LEC canals are set by Florida Legislation principally to provide the volume of water needed to protect the Biscayne aquifer from saltwater intrusion, a major threat to this water resource. The head created in the canals raises groundwater levels, recharging the aquifer and the urban wellfields. During the wet season, wellfields are recharged by local rainfall and by the regional system which provides ongoing seepage from the WCAs and the canals. During the dry season, they are more dependent on the regional system. Unfortunately, during the wet season, "excess" storm water is passed through the canals and out to tide when it should be stored and used during the dry season. Without sufficient storage, it has been difficult to have water available during the dry season without causing flooding during the wet season.

Water users within the urban areas argue that the LEC is largely self-sufficient and efficient because the ground water seeping through the LEC would eventually reach coastal waters were it not withdrawn by the utilities. The SFWMM illustrates how this works. As demands increase, the volume of water that reaches coastal waters decreases. In the SFWMM, at Snake Creek, north of Miami, 121,000 ac-ft of water was lost through groundwater seepage during the wet season in the 1995 Base. That amount *decreased* to 114,000 ac-ft in the 2050 Base as urban water supply demand *increased*. In the Miami River, in the 1995 Base, over 192,000 ac-ft was unrecoverable (wet and dry season total). In the 2050 Base, only 121,000 ac-ft was unrecoverable.

Others argue that the urban area is far from self-sufficient. While the pattern described above occurs during wet seasons and during normal rainfall years, during extremely dry years, no water reaches the coast and the urban wellfields depend heavily on the WCAs, (including the ongoing seepage from these areas), the canals, and Lake Okeechobee for water supplies. Even during normal dry seasons when flood releases are minimal, some believe that the high demands on the system from urban water supply withdraw water from the natural environment that should be kept in the system for late winter and spring biological rejuvenation. In addition, during drought years, the urban and agricultural areas create additional demands as the need for irrigation increases. Those needs, they expect, will be given priority status well above the environmental demands, increasing the harm to the natural system.

In a related issue, one concern is that, at present, the flow of water along the eastern protective levee is from the wetlands to the coast. Some argue that keeping the water levels high west of the Atlantic coastal ridge and levels low to the east of it results in large groundwater losses from the remnant Everglades throughout the year. This situation, they say, is what has severely reduced the coastal groundwater flows into estuaries like Biscayne Bay and has made it necessary to import regional water to the LEC to maintain adequate coastal groundwater levels to prevent saltwater intrusion.

The amount of water needed to recharge urban wellfields is small compared to the tremendous volumes needed to prevent saltwater intrusion. Preventing saltwater intrusion is important for several reasons. For example, if significant saltwater intrusion occurred even once, the easternmost wellfields would be contaminated indefinitely and would be replaced with wells further west. This situation has already occurred in Metro-Dade County.

Although significant, the amount of water needed to prevent saltwater intrusion is much less than the wet season coastal releases. Some people maintain that those flows alone, if captured and stored, would be more than sufficient to maintain the dry season salinity barriers without the need to take water from the natural system. Also, retaining coastal outflows near the coast and maintaining higher groundwater levels along the coastal ridge would allow large quantities of regional water to be used for dry-season environmental benefits.

There are also ecological benefits within the Lower East Coast to maintaining groundwater levels. Lower groundwater levels can and have had serious negative effects on estuaries. Biscayne Bay for example, has suffered the consequences of both ground and surface water losses, including increased salinity, lower visibility, and lower water quality. Alternative 3 simulated cutting off groundwater seepage from the WCAs which reduced flows to Biscayne Bay from 20% to 55%. In south Dade County, lowered groundwater levels have caused wetland desiccation and produced shifts in vegetation types.

Sensitivity analyses were performed using the SFWMM for Alternative 5 in which urban water supply demand (as measured by the demand from urban wellfields) was reduced to zero in one scenario and doubled in another. The results showed only minor stage improvement in the natural areas by reducing water supply to zero. These results appeared at first glance to back the view that water supply represents a relatively small volume of water. Others note that the reduction in pumping in the "zero demand" scenarios was roughly equal to the total amount of LEC ASR yield in the alternatives.

When the Alternative 5 scenario was run that *doubled* water supply, however, two issues arose. First, Shark River Slough was significantly drier in dry years. Although the stage differences appear small, in such a shallow system, even slight reductions in stage in drought years can vastly extend the spatial extent and duration of dryouts. Small stage differences also translate to large flow differences and a reduction in flows would affect the deliveries to Florida Bay. Therefore, in very dry years when demands are high everywhere in the system, the LEC, under the double-demand scenario, would rely heavily on the regional system to the detriment of the natural system. This implies that if urban water supply demand continues to expand *beyond the 2050 projection*, eventually the natural system will receive an inadequate water supply unless alternative, non-traditional supply sources like reverse osmosis are used.

Second, a significant percentage of the per capita use of water goes towards landscape maintenance, primarily watering lawns from shallow wells. Unfortunately, this element was not modeled in a way that allowed it to be "turned off" in the zero–demand sensitivity analysis. In that scenario, the regional system is still recharging the aquifer and watering lawns, even under the "zero-water-supply" scenario. Consequently, the total urban water demand as such was underestimated and the more general benefits of maintaining ground water were overestimated.

2. Issue: "Are canals without salinity barriers wasting water?"

For locations without salinity barriers, much more water is required to maintain ground water due to the large losses through the canals. Appropriate canals need to fitted with salinity control structures.

3. Issue: "Were the wrong projections used for future water supply demand?" Depending on the source, these projections are viewed as either too conservative or not conservative enough.

Two different methods of extrapolating the future demands were used. The Bureau of Economic and Business Research (BEBR), University of Florida, Gainesville, developed a method that projects only to the year 2020. The other method used the Department of Commerce Bureau of Economic Analysis (BEA) rates of growth. The BEBR model indicated a higher growth curve than BEA. According to the U.S. Army Corps of Engineers (COE), they used the BEBR figures up to the year 2020, then extrapolated to 2050 using the BEA rate. Once the projections were in place, the IWR-MAIN Water Use Forecasting System was used to estimate water consumption as a function of population, employment, demographics, income, and variables such as rainfall and temperature. Dade County asserted that its population growth projection is even higher than the BEBR estimates because of immigration, so for Dade County, the COE used the County's projections up to the year 2020 instead of the BEBR values and extrapolated to 2050 at the BEA rate. Dade County is still concerned that the estimate may be low. The COE believes they have struck a balance.

4. Issue: "Is the level of conservation in Alternative D13R too high to be realistic?"

One of the most effective components for avoiding water supply shortages in the system, as modeled in the alternatives, is to implement water conservation in the urban areas. In the 1995 Base, 173,000 ac-ft/year was pulled from the WCAs; in the 2050 Base, urban water supply demand increased to 252,000 ac-ft/yr. Yet, due to the addition of water conservation in the 2050 Base, all Phase 2, 3, and 4 water restrictions were eliminated in the North Palm Beach area. In Alternative D13R, demand from WCAs was reduced to 133,000 ac-ft/year, 47% below the 2050 Base, because of the additional conservation component.

There were three different conservation scenarios identified in the alternatives:

- Use the conservation measures now in place, already approved and adopted, assuming the very modest 2-3% of water saved for 1990 remains the same through 2050. This is the high demand scenario.
- Use aggressive conservation measures, apply the already approved measures, retrofit existing structures, enforce requirements, and require that all new structures meet requirements. This is the low demand scenario. This scenario reduces demand about 18%
- Use a program that lies in between these two options. Following St. Lucie County's example, this model assumes less rigorous enforcement and no requirement to retrofit existing structures, only implementation of existing measures. This model reduces demand about 12%.

The high demand scenario was used during the formulation of Alternatives 1-5. A team was formed at the time the "re-scaling" of alternatives took place to determine whether conservation projections needed to be revised. Some team members were worried that the high-demand scenario gave the LEC counties too little credit for the conservation strategies they have adopted. They preferred the aggressive scenario because they preferred to assume that by the year 2050, approved conservation measures would be in place and technological problems would be worked out. Even the “aggressive” approach, they noted, included only already-approved measures and assumed these would be fully implemented and enforced. Other county representatives believed the aggressive conservation scenario would require additional measures on their part, stricter regulations, and more enforcement. They cited the uncertainty associated with some of the technical conservation problems, like low-volume toilets that must be flushed a number of times. They also are aware that conservation will result in loss of revenue unless rates are raised. The team decided in the end to use the more conservative 12% reduction from the high demand scenario for the 2050 Base and the 18% reduction, low demand scenario for Alternatives C and D.

In a similar issue, some team members would have preferred that all the alternatives assume maximum buildout, with maximum per capita consumption figures. Utilities prefer maximizing demand to ensure the greatest amount of recharge from the regional system, thereby diminishing the need for local water development projects. Resource agency representatives believe that planning for the worst-case scenario would allow a system to be built that would last far beyond 2050, rejecting the assumption that consumption will tend to level off. The resource agency concern is that future escalating water supply demands could cause future political forces to tap into the Everglades again. (This concern also added fuel to the desire for decompartmentalization of the Everglades. That is, water management structures that will not exist cannot be used in the future to fulfill urban water supply demands.)

5. Issue: “Why don’t you monitor the urban water supply demand to make sure they do not exceed their projections?”

Water supply demand projections should be included in the adaptive management program. Hypotheses need to be developed based on the projections, targets need to be defined, a thorough monitoring program should be developed, modeling should continue and be refined, and an annual analysis should be conducted as a part of the ongoing annual assessments producing report cards with recommendations every year. If urban water supply demands exceed projections, resource agencies tend to believe the burden should be on the urban areas to supplement their water supply with reverse osmosis or some other source, rather than request additional water from the C&SF system.

6. Issue: “What is a ‘1-in-10 level of certainty’ and does having it as a goal for the LEC conflict with Everglades restoration efforts?”

Chapter 375.0361(2)(a)1 of the Florida Statutes requires that the South Florida Water Management District plan for a 1-in-10 level of certainty. The AET accepted a performance measure proposed by the water supply subgroup that set a target of no more than three water supply cutbacks of any severity that last for more than seven months for the 31-year period of record for the LEC Service Area.

The 1-in-10 level of certainty for water supply represents an ideal goal, but like many of the targets of the Restudy, the target cannot be completely met. In addition, model results must be viewed with a certain degree of uncertainty because it is unlikely that the SFWMM model can predict a 1-in-10 scenario with a high level of accuracy. Regardless, the 1-in-10 water supply planning goal is designed to encourage planners to minimize the frequency of restrictions. In Alternative D13R, North Palm Beach and Service Area 1 meet this goal while Areas 2 and 3 fail to meet the goal by only 1 and 3 months of restrictions, respectively. The situation in Alternative D13R is far better than the 1995 Base and is a significant improvement over conditions in the 2050 Base.

7. Issue: "Isn't the purpose of a regional water supply system to meet all local water demands."

.

Those who work with urban water supply issues on a daily basis understand that urban water supply demands cannot always be met all of the time. Urban demands have been and will always be "unquenchable." The purpose of planning targets has been to build a system that requires extreme measures only during extremely low water years which may occur in Florida every 10 years or so. Water supply planners believe the performance measures and projections developed for the Restudy allow them to evaluate what to expect in the future and will help garner support for or generate opposition to projects.
