Others strongly believe it is not appropriate to insist that all urban and agricultural water supply demands must be met as a priority over the natural system because restoration of the Everglades is the primary goal of the Restudy. They believe that the comprehensive review study was initiated as an attempt to halt and even reverse the decline of the natural system. Uncontrolled demands for flood control and water supply have been the primary causes for placing the natural system in such poor condition. To continue to demand the same or increased anthropogenic demands on the natural resources will undoubtedly set the restoration effort up for failure. Many environmentally conscious people are of the opinion that current urban and agricultural demands are already beyond the level that will support a sustainable natural system and that future increases as proposed by the Restudy will accelerate the decline of the south Florida ecosystem.

Some parties have expressed concern that the performance measures used to evaluate success in the LEC are overly restrictive, and are, in fact, much stricter than those used to define success in the natural areas. Water restrictions are imposed at certain points and the effects on the urban landscape are immediate, noticeable, and easy to quantify (even if the measure is number of consumer complaints or acres of lawn degraded). On the other hand, in the natural system, a certain number of dryouts are healthy, even in the wettest parts of the system. Dryouts can "pulse" the system by releasing nutrients bound in the soils. Unfortunately, it is difficult to define the point at which drought conditions begin to cause excessive damage to the ecology, damage that may take years to repair. Some say the natural system is being penalized because not enough is known about the system to define the stricter ecological performance measures they believe will be necessary. In addition, while the amount of water available to the project and the amount of water needed for the natural system remain steady over time, the LEC demand increases from 925 mgd in the 1995 Base to 1278 mgd in the 2050 Base. Yet, the definitions of success for both the steady-state natural system and the ever-increasing LEC demand remain the same. Looking beyond 2050, the situation does not appear to be sustainable. At some point, it seems the ever-growing, highly specific demands from the urban sector may take priority over the unchanging, less well-defined needs of the natural system unless alternative water supply sources are developed or demand is kept in check.

8. Issue: "Isn't the placement of urban water supply wells more of a problem than the absolute number of wells or the volume of water pumped from them?"

Local wells need to be placed where they can be recharged more easily, for example, near the influence of canals. Unfortunately, municipalities located at greater distances from canals or the WCAs have little flexibility while larger municipalities have the advantage of distributing wells over a larger area. When wells cannot be recharged easily, they either suffer saltwater intrusion or draw down the groundwater table. As a result, they usually place an undue demand on the regional system. Unfortunately, political entities are reluctant to relocate wellfields independent of political boundaries.

9. Issue: "Some of the technologies proposed for the Restudy, such as ASR, have a great deal of risk and uncertainty associated with them. What happens if they do not work as well as expected?"

Will they be able to get permits to implement them? Will water quality be acceptable? Will they work at a regional scale? Some alternatives proposed that a large proportion of Palm Beach County's water supply rely on ASR, for example. If these technologies do not work as expected, there is a risk of not meeting water supply demands. While inter-aquifer transfer seems to work well, storing large volumes of surface water in ASR wells remains much more uncertain as a water management technique. If water quality treatment is required, it will increase the cost of the project.

The COE is performing risk and uncertainty analyses to determine how dependent the alternatives will be on uncertain technologies. If dependency and uncertainty remain high, it would be wise for a task team to draft alternative components.

10. Issue: "Is the Restudy attempting to wean urban water supply from the regional system, the WCAs and Lake Okeechobee? If urban areas are expected to rely on either expensive alternatives or water supply cutbacks in the future, rather than on the regional system as they do now, why should they support the plan?

All of the alternative plans do, in fact, reduce the dependence of users on the regional system. In Alternative D13R, there is less water delivered from the regional system through the structures to the LEC than in the 1995 Base case and almost 23% less than in the 2050 Base case. The future for urban water supply looks very bleak in the 2050 Base without a C&SF Restudy, even if the health of the environment were not a consideration. The urban areas will benefit from a sustainable system that supports their *future* water supply demands *and* restores the Everglades ecosystem. In addition, as expensive as these projects are, they are likely to be even more expensive if delayed farther into the future.

11. Issue: “Are large, complex, regional reuse facilities to costly to ever be built?

Treating the water to the level necessary to discharge into the natural system makes them even more expensive.

Because of time constraints and the relatively coarse 2-by-2-mile scale of the SFWMM, only large-scale projects could be evaluated. There may well be better, smaller-scale ways to include “reuse” water that are worth investigating as planning continues. For example, reuse facilities could be designed to reduce demands on the natural system. Reuse facilities could store water and release it back to agricultural areas during the dry season without the requirement for nutrient removal if other water quality requirements were met. Nutrients could be useful in irrigation water. Depending on the location, a reuse facility could reduce the demand on Lake Okeechobee, freeing up water for other uses. Reuse water could also be used to maintain canal levels, preventing saltwater intrusion and recharging urban wellfields, while reducing the demand on the natural system. Water is currently being discharged to deep wells or out to tide that could be available for reuse. In the S-4 basin, water with high phosphorous concentrations flows into Lake Okeechobee when lake stage drops below 15.5 feet. This water could be captured in reservoirs in Hendry and Glades Counties and used for irrigation, or if an STA were added to remove nutrients, the water could be made available to the Big Cypress basin or the Caloosahatchee River. These possibilities and others should be addressed in the detailed planning phase. At this time, however, counties and resource agencies are wary of reuse water being used for these purposes, primarily because of high cost and water quality concerns. Reuse water systems are feasible only if the water does not contain pesticides, heavy metals, or pathogens.

12. Issue: “If Congress mandated the C&SF Restudy project to be truly multi-objective and to meet all water supply needs, why have water supply and flood control concerns not received adequate attention in the plan formulation process?”

Some local governments did not believe they were sufficiently represented in the planning process. Local governments believe they have much to offer. They believe that the COE has a more balanced approach, but others, particularly DOI, need to take a more holistic view. As the Restudy gets closer to defining its goals, all the participants need to work together. This group believes that DOI should recognize where real improvements will be made and not take the approach that NSM goals must be met. The Restudy should identify *all* goals and objectives for South Florida.

The impetus of the Restudy has been to restore the Everglades. Congress has directed the COE to pursue this objective while enhancing water supply and not compromising flood control and other original purposes of the project. While there has been resistance to the idea of enhancing water supply as part of a restoration project, the definition of water supply includes water supply to the natural areas, not just urban and agricultural water supply. Indeed, much of the planning process was aimed at increasing water supply throughout the system.

Many components in the alternatives were designed to enhance urban water supply. Many believe that planning for the expected growth of the LEC and its unavoidable increase in urban water supply demand will better protect the water supply earmarked for natural areas. Refusing to give water to a rapidly growing urban area is unlikely to slow or stop the influx of new residents, as urban planners in the western states have discovered. Instead, as happened out west, as the urgency of the situation increases, political pressure mounts to take the water from natural areas regardless of ecological consequences. Not recognizing urban growth would put the Everglades at risk again in the future.

The original AET was asked to set hydrologic goals for the natural system and the ADT was tasked with meeting those goals within the confines of water supply and flood control systems. Performance measures allowed both teams to see how well each alternative functioned. Fortunately, both the AET and the ADT refused to stay in their defined "boxes." For example, the AET began recommending structures as well as targets. The give-and-take that occurred with each AET/ADT round resulted in the hydrologic targets being refined and redefined until a single set of targets was agreed upon and understood. The process was an organic one that grew from putting together a group of highly motivated, often polarized agency representatives and interested stakeholders. While team members still do not represent a united front, in the nine months since the process began, a number of misconceptions have been brought to light concerning urban and environmental water supply. This learning process will continue as the project progresses into detailed planning and design. The team has learned that it is highly important to bring important stakeholders, including local governments, together with people from the diverse fields of planning, ecology, hydrologic modeling, and hydrologic engineering. As detailed planning continues, representation of all groups will continue to be a high priority.

CHAPTER VIII -- WATER QUALITY ISSUES

Susan Jewell, Betty Grizzle, and Kofi Fynn-Aikins, FWS; Mike Zimmerman, ENP

A. Overview

The completion of the C&SF Project's water control facilities provided a primary flood control system to south Florida. With the mitigation of floods and droughts produced by this water management program, urban and agricultural development proceeded rapidly. However, because this water control system was not designed for water quality concerns, degradation of the Everglades ecosystem and many coastal estuaries has occurred.

The natural Everglades system evolved under oligotrophic conditions and is therefore very sensitive to eutrophication produced by elevated nutrient levels. Drainage from the Everglades Agricultural Area (EAA) has severely impacted Everglades marsh surface waters, with phosphorus identified as the primary pollutant. Coastal estuarine environments, particularly Florida Bay, Biscayne Bay, and the St. Lucie estuary, have been damaged by both poor water quality conditions and unnaturally high volumes of water discharged by the C&SF Project canals. Stormwater runoff and point source discharges from extensive urban developments have also contributed to the degradation of water quality in coastal ecosystems and within local watershed basins.

The natural Everglades system evolved under sheet flow conditions. There were no levees, canals and pumps. The construction of internal canals and levees has caused drying and oxidation of soils in some areas of the Everglades and ponding in other areas. The canal system has allowed various pollutants to be transported deeper into pristine areas of the Everglades. Bechtel *et al.* (1996) found that pumping at S-7 pump station caused negative impacts to water quality, specifically dissolved oxygen. Point source discharges as opposed to surface water sheet flows or groundwater flows, have also caused water quality degradation to the Everglades Protection Area and the estuaries. For these reasons, decompartmentalization that includes the removal of pumps and levees and filling of canals, will be an important ingredient in the total strategy to restore water quality in central and south Florida.

Although the Restudy attempts to reduce seepage from the remaining Everglades to urban areas, the present amount of seepage has a positive effect on water quality through dilution of the agricultural and urban pollutants present in the canals adjacent to the Everglades. Walker (1997) discovered a negative correlation between phosphorus concentration and head differential between marshes in ENP and adjacent canals in the C-111 Basin. Increasing water elevations to NSM values is not only desirable to restore the intrinsic ecology of the Everglades, but also in maintaining a higher head differential between the Everglades and surrounding areas. Localized rainfall in urban areas at the edge of the Everglades can temporarily reverse the normal head differential and threaten to carry pollutants into the Everglades via seepage. The closer water levels are to NSM targets in the Everglades, the lower the likelihood of this reversal in head differential.

The Governor's Commission for a Sustainable South Florida conceptual plan for the C&SF Project Restudy (1996) stated that the natural system, including the Everglades and coastal estuaries, can only be restored through the supply of clean rainwater and surface water from upstream marshes, rivers and sloughs, and Lake Okeechobee. The Restudy alternatives proposes water storage in wetlands, reservoirs, and aquifer storage and recovery (ASR) facilities. This water will be delivered from a variety of sources including ground water, surface water, and agricultural and urban runoff. Water released from these storage areas will be used for maintenance of groundwater levels, wellfield recharge, Everglades water supply, and estuarine water supply. Water-management alternatives being considered under the Restudy can influence water loads, nutrient loads, and depth regimes in reservoirs and stormwater treatment areas (STAs). These changes can effect performance, as measured by outflow phosphorus concentrations or load reductions (Walker 1998).

B. Stormwater Treatment Areas (STAs)

STAs have been designed under the Everglades Construction Project (ECP) to reduce phosphorus concentrations in agricultural runoff and releases from Lake Okeechobee prior to discharge into the Everglades Water Conservation Areas. STAs are defined as constructed wetlands (also known as filtration marshes) that provide enhanced filtration and nutrient removal based on water flow operations and maintenance of specific plant species. Agricultural best management practices (BMPs) and STAs will be used to meet interim treatment requirements established in the State/Federal Settlement Agreement (1991) and Everglades Forever Act (EFA) (1994). BMPs have been fully implemented in the EAA since about 1995. The Everglades Nutrient Removal Project (a 3700-acre pilot-scale STA) has been in operation since August 1994. The first full-scale STA (STA-6) began operation in December 1997, while the last STA (STA-3/4) is scheduled to be fully operational by October 2003 (Walker 1998).

Although STAs represent an important water treatment technology for Everglades restoration efforts, there are operational issues to consider. For example, STAs have not, to date, been proven to remove phosphorus to the low levels required in state standards (10 ppb). Also, some pollutants may not be removed by STAs. Determining the best operational schedule will be essential for meeting the target goals defined by the STA design.

Requirements of the EFA and the Settlement Agreement are included in the base conditions for the Restudy and are assumed to be met in the alternatives. The EFA does not specify treatment strategies for other areas which discharge to the Everglades. Those areas are covered by the non-ECP permit issued to the SFWMD by DEP, which requires evaluation of, among other things, the construction and operation of water treatment facilities.

Additional technologies, other than STAs, are also available for the treatment of surface runoff. Drawbacks of these alternatives include: 1) the addition of potentially harmful chemicals to the water source, 2) removal of beneficial organisms and elements with filters, 3) treatment of a single pollutant, 4) production of contaminated sludge, 5) large land requirements, 6) high operation and maintenance costs, and 7) the construction of artificial complexes surrounding the Everglades environment (PEER Consultants 1996).

C. Environmental Pollutants

At present, very few water quality pollutants can be modeled within the Restudy alternatives. Phosphorus has been the focus for Lake Okeechobee, the WCAs, and Everglades National Park. Lack of model results (particularly the Everglades Landscape Model) for much of southwest Florida, including Big Cypress National Preserve, and Holey Land/Rotenberger Wildlife Management Areas make it difficult to determine water quality impacts of Restudy alternatives. A preliminary mercury model being developed by the Environmental Protection Agency (EPA) will provide some answers relative to atmospheric depositional loads in the natural Everglades system.

Environmental pollutants are ubiquitous and an ever increasing problem in south Florida. Human activities have degraded water quality in large areas of south Florida during the last century. Water in urban and agricultural canals commonly has high concentrations of nutrients and toxic compounds compared to water in marshes that are remote from canals. Drainage of nutrient and pollutants from urban and agricultural lands has degraded lakes, streams, canals, estuaries, and bays of the region (McPherson and Halley 1997). In addition, discharge of nutrient-laden sewage and storm water runoff into canals also carries bacteria, viruses, oil and grease, toxic metals, and pesticides. The urban canal water discharges into coastal waters or enters the groundwater system and the public water supply (Klein *et al.* 1975).

Federal and State agencies and environmental organizations have agreed that the south Florida environment, and especially the Everglades, should be protected and restored, to the extent possible, to its pre-drainage conditions. Contaminants play a role in the decline of species, keeping numbers at suppressed levels and preventing species from recovering. Therefore, the restoration goals can be successfully accomplished only if serious consideration is given to the negative effects of contaminant loading from agricultural, industrial, and urban sources on our trust resources and their habitat. The effect of toxins in the food chain and their long-term adverse effects on ecosystem integrity are also largely unknown. These types of scientific information would be valuable for the restoration effort in south Florida.

1. Nutrients -- Fertilizers are widely used in south Florida to maintain high levels of agricultural productivity. From July 1, 1990 through June 30, 1991, fertilizers sold in south Florida, contained 127,000 metric tons (140,000 tons) of inorganic nitrogen and 50,800 metric tons (56,000 tons) of phosphate (McPherson and Halley 1997). Nutrient loading from the Everglades Agricultural Area (EAA) and urban areas have significantly increased nutrient concentrations, particularly phosphorus, in south Florida (Stober *et al.* 1996). This has resulted in increased soil phosphorus content, changed periphyton communities, loss of native sawgrass communities, increased organic matter in water, loss of water dissolved oxygen, conversion of wet prairie plant communities to cattails and loss of important wading bird habitats (Stober *et al.* 1996). Because the Everglades were historically nutrient poor, with phosphorus concentrations less than 10 ppb, nutrient loading from the EAA has been associated with eutrophication in the Water Conservation Areas having greater than 50 ppb phosphorus concentrations.

Atmospheric deposition also contributes to the nutrient load infiltrating the south Florida environment. The highest deposition rates for nutrients occur in agricultural and urban areas, and lowest in coastal and rural areas (Brezonik *et al.* 1983, Hendry *et al.* 1981). Greening (1997) estimated that 29 percent of the nitrogen and 31 percent of the phosphorus entering Tampa Bay come from wetfall and dryfall directly deposited to the bay's surface, making this source second to only stormwater as the largest bay nitrogen loading source, and the largest source of phosphorus. Overall, atmospheric nitrogen is a more important source for the nutrient budget than atmospheric phosphorus (Brezonik *et al.* 1983).

2. Pesticides and Polychlorinated Biphenyls -- Pesticides have also been widely used in agricultural and urban areas in south Florida for more than 50 years to control insects, fungi, weeds and other undesirable organisms. Because of year-round warm temperatures and moist climate, Florida agriculture requires vigorous pest control; thus, while Florida agricultural production ranks approximately 30th in the U.S., pesticide usage per acre is in the top 5. The compounds used vary in their toxicity, persistence, and transport.

Although pesticides are usually applied to specific areas and directed at specific organisms, these compounds often become widely distributed and are potentially hazardous to nontarget species (McPherson and Halley 1997). Since the late 1960s, persistent organochlorine pesticides have been detected in fish that are part of the Everglades food chain (Kolipinski and Higer 1969, McPherson 1973, Haag and McPherson 1997). Some of the more persistent pesticides, such as DDT, chlordane, dieldrin, and aldrin have been banned for use in the state, but their residues still occur in the environment. Herbicides, including atrazine, bromocil, simazine, 2-4-D, and diuron, which have the highest rate of application, are commonly detected pesticides in Florida's surface waters (Shahane 1994). The most frequently detected insecticides in surface waters are the chlorinated hydrocarbons that are no longer used in the State, such as DDD, DDE, DDT, dieldrin, and heptachlor. These insecticides are also the most frequently detected pesticides in bottom sediments (Shahane 1994).

Chlorinated chemicals, such as polychlorinated biphenyls (PCBs), dioxins, and furans, which are generated and used primarily in urban and industrial areas, pose a serious concern to fish, wildlife, and human populations (Colborn *et al.* 1993). Although most uses of PCBs have been banned since the late 1970s, these persistent chemicals are still found in the environment and continue to pose potential threats to fish, wildlife, and humans. In recent years, many organochlorine pesticides and PCBs have been linked to hormone disruption and reproductive problems in aquatic invertebrates, fishes, birds, and mammals (Colborn *et al.* 1993).

3. Mercury -- The evidence of mercury contamination in fish and wildlife in south Florida freshwater and terrestrial ecosystems is extensive. Trends in mercury accumulation in south Florida, as evidenced by sediment profiles, show that atmospheric mercury deposition has increased approximately fivefold since 1900 (Rood *et al.* 1995). The deposition rate of mercury by rainfall measured today is at least double that of other remote sites in North America (Guentzel *et al.* 1995). Piscivorous freshwater sport fish and alligators in many watersheds, especially in the Everglades, have high mercury levels in their tissues (Ware *et al.* 1990, Eisler 1987). After discovering the extent and severity of mercury in fish in 1989 the State Health Officer issued advisories to fishermen warning against consumption of several species of fish in more than 400,000 ha (1,000,000 ac) of the Everglades, and advising restricted consumption of others over most of the state. Besides human health concerns, ecological resources may be at risk as well. In the early 1990s three Florida panthers (*Felis concolor coryi*) inhabiting the Everglades died, with mercury poisoning determined to be the proximate cause of death in one and a contributing cause of death in the other two cases (Roelke *et al.* 1991). High mercury levels have been detected in the endangered wood stork and other birds (Sundlof *et al.* 1994). There is concern that the 50-year decline in wading bird numbers in south Florida may partially be a result of increased mercury exposure. Intensive studies are underway to further define this concern.

CHAPTER IX -- NON-INDIGENOUS SPECIES

Steve Peacock, FWS; and David T. Jones, ENP

A. Introduction

Non-native plants and animals that have been introduced to an ecosystem are referred to as non-indigenous or exotic species. These exotic species have been introduced into the United States through various means. Many of the plant and animal species that have become established in the subtropical climate of Florida were introduced for agricultural or ornamental purposes, escaped to the wild from horticulturists or aquariums, or were transported inadvertently to Florida. "Some introduced species, though persistent, have seemed ecologically innocuous, while others are scourges. Some plant species have changed entire major ecosystems, while others are harmless curiosities." (Simberloff *et al.* 1997, p. xi).

Non-indigenous species incur both direct and indirect impacts on native species. These impacts can be extensive and can result in reducing native populations to a fraction of their status prior to introduction of the non-native species. The C&SF Restudy will affect both native and non-native species in different ways. This chapter is divided into sections providing information on the past and potential future impacts of the C&SF project on various plant and animal taxa.

B. Exotic Pest Plants

1. Existing Conditions Florida's exotic (non-indigenous) plant species, totaling about 1200 taxa (Wunderlin *et al.* 1996), currently constitute nearly 30% of the State's flora (Schmitz *et al.* 1997). These species, many of which are tropical and subtropical in origin, have arrived in Florida by a variety of pathways, mostly with the assistance of man, and often intended for agriculture and the ornamental trade (U.S. Congress 1993, Gordon and Thomas 1997). The majority of these introductions are not known to occur outside cultivation and even those that have spread beyond their planting site are not always invasive (Austin 1978, Science Subgroup 1996). Certain species, however, have not only escaped cultivation and invaded disturbed sites, but have also become established in Florida's natural areas, which are intended for the preservation of native communities and landscapes.

The Florida Exotic Pest Plant Council lists 62 species as invading and disrupting the native plant communities in the State, and an additional 57 species as showing a potential to do the same (Florida Exotic Pest Plant Council 1997). Exotic plants can disrupt native biotic communities in several ways. Examples of the disruptive effects of exotics, which modify the original habitat, include: 1) changes in community structure and composition, 2) alteration of ecological processes, and 3) hybridization between exotic species and their related native ones, resulting in potentially new pests (Austin 1978, Schmitz *et al*. 1997, Simberloff 1997). In addition, exotics can affect the quality of human life in the State by impacting water quality and use, diminishing property values, colonizing agricultural lands, increasing fire risk, and producing less aesthetically-pleasing views (Schmitz *et al*. 1997).

Florida's insularity (the southern third of the peninsula is essentially a "habitat island") and the mosaic of disturbed or novel habitats across its landscape have rendered the State especially susceptible to invasive exotic plants (Simberloff 1997). The State's near tropical conditions, prominence as a transportation hub and center for tourism, and abundance of aquatic habitats, both natural and man-made, have promoted the arrival and establishment of exotic plant species (Simberloff 1997). Disturbed areas such as abandoned farm land, drained wetlands, roadsides, and canals and ditches are sites typically invaded by exotic plants (U.S. Congress 1993). In southern Florida, drainage and development, particularly of the Everglades, have increased the opportunities for exotic species to become established (McPherson and Halley 1996). The modification of the State's waterways for irrigation, water supplies, flood control, and recreation has further facilitated the spread of some of these species (U.S. Congress 1993).

Both wetland and upland habitats in southern Florida are affected by exotic pest plants. Over one million acres of wetlands alone are currently infested with exotic water-tolerant trees and shrubs and aquatic weeds. Estimates for the extent of infestation by the most widespread invasive exotic plants in natural areas of southern Florida are tabulated below (from Schmitz *et al*. 1997):

Table IX-1. Acreage covered by the most widespread species of exotic plants in southern Florida

Species	Acres
Schinus terebinthifolius (Brazilian pepper)	700,000
Melaleuca quinquenervia (melaleuca)	490,000
Casuarina spp. (Australian pine)	375,000
Hydrilla verticillata (hydrilla)	100,000
Eichhornia crassipes (water hyacinth)	1,700
Total	**2,366,700**

Brazilian pepper has invaded a broad range of moist to mesic sites, both disturbed and undisturbed, often forming monotypic, dense stands. It thrives on disturbed, well-drained soils created by natural disruptions (e.g. hurricanes) and is especially invasive in areas affected by human activities, particularly the newly created habitats resulting from agriculture and drainage, such as abandoned farmlands, roadsides, and canal banks (Ewel 1986). In Everglades National Park (ENP), it is commonly found in disturbed tropical hardwood hammocks of Shark Slough and bayhead tree island sites of the East Everglades where over-drainage has created conditions suitable for its establishment. It does not become established in deeper wetland communities and rarely grows on sites with periods of flooding lasting longer than six months, thus it is typically absent from long hydroperiod marshes and prairies (Jones and Doren 1997).

Similarly, Australian pine has invaded well-drained habitats disturbed by human activities and natural events. Once commonly planted to form windbreaks around canals, agricultural fields, houses and roads, it has spread extensively throughout southern Florida (Schmitz *et al*. 1997) and can be found in many of the same habitats invaded by Brazilian pepper. Hybridization occurs between the two most common species, *Casuarina equisetifolia*, widely distributed in coastal areas, and *C. glauca*, typically found in more interior areas.

Melaleuca grows in a variety of habitats – natural and man-made - throughout southern Florida, including roadsides, ditch banks, lake margins, pastures, mesic prairies, sawgrass marshes, cypress forests, and mangrove areas (Bodle *et al.* 1994). Wetter areas are more susceptible to invasion than drier areas. The heaviest infestations are found in Loxahatchee NWR, Big Cypress National Preserve, and the East Everglades portion of ENP. Portions of ENP other than the East Everglades and WCA 2A have the lowest infestations (Bodle *et al.* 1994). Melaleuca has invaded essentially every plant community type known to occur from Lake Okeechobee to southern Miami-Dade County, including healthy, seemingly undisturbed areas. Bodle *et al*. (1994) note that virtually all of these communities could be considered indirectly disturbed (and thus increasingly susceptible to invasion by melaleuca and other exotic plants) because hydrologic patterns in southern Florida have been greatly altered and no freshwater wetlands remain in their natural (historical) state.

Hydrilla and water hyacinth have long been recognized as a problem in aquatic environments throughout the State (Schortemeyer *et al.* 1981). These species have rapidly expanded throughout southern Florida via the hundreds of miles of canals and ditches dug for water management. Excessive growth of hydrilla and other aquatic plants has been linked to increased pollution due to agricultural run-off (Canfield *et al*. 1983). Additional species may not be widespread in southern Florida but can be locally abundant. For example, torpedo grass (*Panicum repens*), which covers over 18,000 acres, forms monospecific stands in the marshes of Lake Okeechobee (Schmitz *et al*. 1997), but is not known to be abundant elsewhere.

Control of exotic plants in southern Florida costs millions of dollars annually. Because of their highly widespread occurrence and disruptive nature, melaleuca, Brazilian pepper, Australian pine, and hydrilla receive top priority in natural areas managed by the NPS, SFWMD, FWS, and GFC. A combination of mechanical and chemical (herbicidal) control methods are currently used to arrest the spread of most species. The Florida Exotic Pest Plant Council has developed management strategies for melaleuca and Brazilian pepper (Laroche 1994, Ferriter 1997). Biological control agents are currently available for melaleuca and hydrilla and are being developed for Brazilian pepper (Center *et al*. 1997).

Fire can be used to control woody exotic plants, but if used incorrectly, it can result in the inadvertent spread of undesirable species. For example, periodic fires in marl prairies of southern Florida can be used to kill Australian pine trees. However, if the fire occurs just before seed maturation and release, establishment of the plant on the improved seed bed may be enhanced (Wade *et al.* 1980). Brazilian pepper seedlings are vulnerable to fire but thickets of the plant are effective barriers to fire and can quickly re-sprout if burned (Jones and Doren 1997). Wade *et al.* (1980) noted that Brazilian pepper is a major component of post-burn vegetation because the fruits of this species are readily eaten by wildlife drawn to burned sites, and wildlife disperse Brazilian pepper seeds through defecation. Melaleuca, on the other hand, is a fire-adapted species: it re-sprouts vigorously after fire and fire induces capsule opening and seed release (Wade *et al.* 1980). The timing of fire, however, can be used to keep it in check (Bodle *et al.* 1994). Application of fire can be timed so that germinating seeds are exposed to fire, because seedlings less than several months old may perish if burned (Wade *et al.* 1980).

2. Effects on Fish and Wildlife Australian pines may disrupt native plant communities by producing a dense litter that smothers vegetation beneath the trees (Mazzotti *et al*. 1981). Melaleuca can also almost totally displace native vegetation, as well as raise soil elevations and cause higher water loss than native sawgrass through evapotranspiration (Woodall 1980). Melaleuca may also affect fire regimes: the combination of its flammable volatile oils and extreme density of stems are conducive to crown fires that can be destructive to surrounding native vegetation (Wade *et al.* 1980, Flowers 1991). Similarly, when Brazilian pepper forms monotypic stands, it can almost completely obliterate the native understory plants. Ewel *et al.* (1982) found only several fern and shrub species, and small numbers of native and exotic tree species, in the understory of the densest stands of Brazilian pepper. Gogue *et al.* (1974) reported that Brazilian pepper has the ability to inhibit the growth of competing vegetation through the production of allelopathic substances.

The effects of exotic plant communities on the local fauna are not well known, but it is generally believed that fewer animals are associated with them Curnutt (1989) found that while a nearly monospecific stand of Brazilian pepper was utilized to some extent for breeding and feeding by native avifauna, both total population density and species diversity were much lower in the Brazilian pepper, compared to the native pineland and forest-edge habitats it replaced. Beever (1994) reported that bird rookeries in mangroves surrounded by Brazilian pepper were abandoned.

On the other hand, the herpetological fauna of Brazilian pepper forests was found to be similar in species numbers and foraging guilds to those of southern Florida's hammock communities, probably due to the fact that both communities have closed canopies and similar soil development (Schmitz *et al.* 1997). In ENP, however, Brazilian pepper threatens nesting habitat of the gopher tortoise (*Gopherus polyphemus*), a State-listed species of special concern (Doren and Jones 1997).

Wildlife studies are lacking for Australian pine forests in Florida. Populations of small mammals in freshwater wetlands invaded by Australian pine may be depauperate compared to those in native plant habitats (Mazzotti *et al*. 1981). In sandy beach communities, where these trees are commonly found, there is evidence that their root system can interfere with the excavation of nests by threatened and endangered sea turtles and the endangered American crocodile (Schmitz *et al*. 1997).

Despite widespread concerns, little research has been conducted regarding the impact of melaleuca on southern Florida fauna. Schortemeyer *et al*. (1981) found that wildlife use of randomly selected melaleuca stands was low, indicating an overall low rate of wildlife utilization of melaleuca. Because melaleuca spreads from isolated patches, the wildlife values of these adjacent native habitats will be diminished due to their loss of and replacement by extensive melaleuca stands (Schortemeyer *et al*. 1981). In their study of wildlife in southern Everglades wetlands invaded by melaleuca, O'Hare and Dalrymple (1997) reported that transient and winter-resident birds occurred at much lower abundances in moderately dense melaleuca infestations compared to native forested habitats such as cypress swamps and hardwood hammocks. They also found that areas with moderate levels of melaleuca retained species composition and productivity typical of the natural wetland community; animal populations were found to persist in areas with disturbed vegetation as long as the hydrologic regime remained unaltered.

Preliminary results of another study indicate that a variety of bird species utilize melaleuca under some circumstances; the trees may provide nesting and roosting sites for native bird species (Schortemeyer *et al*. 1981). While Sowder and Woodall (1985) note that melaleuca generally provides poor habitat for rodent populations, Ostrenko and Mazzotti (1981) found that a mature melaleuca stand was able to enhance a permanent breeding population of one species of rodent, the cotton mouse (*Peromyscus gossypinus*), over that of the surrounding sawgrass community.

Although hydrilla is an exotic species, studies on the littoral zone of Lake Okeechobee indicate that where hydrilla grows at moderate densities, it oxygenates the water column and its complex vegetative structure supports the most abundant and diverse assemblage of above bottom invertebrates among the cover types in the littoral zone (GFC 1991). The rich invertebrate fauna within hydrilla beds is known to attract carnivorous species of game fish (Furse and Fox 1994) and waterfowl (Schmitz *et al.* 1997).. However, when dense hydrilla "tops out", that is, when it completely covers the water surface, light penetration is reduced, the water column below the canopy of leaves is deprived of oxygen, and the benthic invertebrate community is depauperate (GFC 1991). Other adverse effects of extremely dense growths of exotic aquatic plants, like hydrilla and water hyacinth, include, increased water temperature, greater evapotranspiration, higher sediment loading due to leaf decay, lower fish production, and smothering of beds of native submerged vegetation (Schmitz *et al*. 1993). Large floating water hyacinth beds, uprooted by heavy winds, have destroyed emergent plants important to waterfowl (Schmitz *et al.* 1993). Dense hydrilla infestations are known to change the trophic-state classification (based only on water quality) and can shade out native bottom vegetation and altered ecological processes (Schmitz *et al.* 1993). Shifts in zooplankton and macroinvertebrate densities and richness have been linked to hydrilla expansion (Schmitz *et al.* 1997). In water bodies where hydrilla forms a dense canopy, populations of popular game fish species tend to have greater numbers of smaller individuals due to insufficient predator cropping (Colle and Shireman 1980).

3. Mitigating the Continued Threat of Plant Pests According to Moody and Mack (1988), exotic pest plant species may exist in the landscape at low abundances for several decades before experiencing rapid population growth. Many of Florida's widespread exotic plant species were introduced long before they became invasive (Schmitz *et al*. 1997). Examples are Brazilian pepper, which occurred in Florida 50 years before becoming a nuisance species (Ewel 1986), and melaleuca, introduced into Florida in 1906 but not a problem until the 1960s (U.S. Congress 1993). It is reasonable to assume that additional species that have already been introduced, but are now not especially invasive, may become problems in the future (Schmitz *et al.* 1997). As explained by Ewel (1986), certain sites can act as "staging areas" from which exotic species disperse vast quantities of seed into the surrounding landscape, and the resulting exotic populations may eventually produce genetic variants adapted to local conditions. It is also plausible that continued habitat change (destruction of wetlands and alteration of hydrologic regimes) in southern Florida will further enhance conditions for the spread of both current and future species.

Whether a species will be invasive in a new habitat is difficult to predict (Gordon and Thomas 1997). Perrins *et al.* (1992) note that establishment in a new site depends on the life history of the species, the new habitat, and management practices in the habitat, with chance events and timing interacting with these factors to determine establishment success. Rejmanek (1994) and Crawley (1987) noted the following characteristics that enable many exotics to replace native plants: seed size, fruit dispersal by vertebrates, bark thickness, better ability to acquire resources (like nitrogen and light), and ability to form dense thickets. The majority of the plant species placed on the List of Non-native Invasive Species (Florida Exotic Pest Plant Council 1997) have two common traits: 1) mechanism for long-distance seed transport and 2) ability to reproduce vegetatively. These two features allow exotic plants to quickly spread to new sites and form dense stands that make it difficult for other species to penetrate (Gordon and Thomas 1997).

Schmitz *et al.* (1997) note that several exotic plant species seem ready to expand their range greatly in southern Florida wetlands and hammocks. One such species is cat-claw mimosa (*Mimosa pigra*), native to Central America and invasive in many sites around the world, including central Florida. Sutton and Langeland (1993) observed that because of the plant's ability to grow on low-fertility soils, coupled with the conducive hydrological cycle prevailing in southern Florida, the Everglades may be especially susceptible to invasion by cat-claw mimosa. The laurel fig (*Ficus microcarpa*) has been in Florida since the 1930s, but its pollinators have only been introduced within the past 15 years (Nadel *et al.* 1992). More recently, tropical soda apple (*Solanum viarum*) has spread in the State since the early 1980s, typically colonizing ditch banks, roadsides, and pasture lands. It is of interest to note that 39% of the Florida Exotic Pest Plant Council's 1993 list of 94 invasive plant species in Florida, including the laurel fig, were still commercially available in Florida in 1994 (Gordon and Thomas 1997).

The U.S. Congress (1993) reports that the large influx of exotic plants entering the U.S. through various routes has set the stage for potential escapes and unintentional and intentional releases of these organisms. Eighty-five percent of all plant shipments into the U.S. pass through the Miami Inspection Station (U.S. Congress 1993). Florida's woody ornamental industry, worth $1 billion, continues to import large numbers of plants for the nursery and landscaping trades (U.S. Congress 1993). Florida's aquaculture industry is the largest in the U.S. The aquarium trade industry was responsible for introducing hydrilla into canals in central Florida around 1950 and later into Miami canals (U.S. Congress 1993). These industries will continue to threaten native ecosystems if import regulations are not developed, especially for the importation of potentially invasive plants. Without early identification and importation restrictions, the number of invasive species introduced into Florida will continue to rise. The U.S. Congress (1993) recommends that the State of Florida adopt similar legislation and educational programs as those developed in Hawaii and Australia to restrict the importation of exotic plants. Because of the unpredictability of invasiveness that species display, the U.S. Congress (1993) and Gordon and Thomas (1997) have recommended that Florida should consider implementing a policy that essentially states: "...species should be considered invasive and subject to import restrictions until demonstrated otherwise." (U.S. Congress 1993)

4. Effects of the Alternatives and Recommendations (Plants) Total system annual average hydroperiod differences, ponding depth differences, and peak stage differences for Alternatives A, B, C, and D13R were used to determine the possible effects of alternatives on exotic plant species. This evaluation will consider only the effects of these alternatives for five widespread terrestrial and aquatic exotic plant species -- melaleuca, Brazilian pepper, Australian pine, hydrilla, water hyacinth.

Determination of the effects of each alternative on these exotic plant species has been guided by a basic understanding of the ecological conditions that promote or discourage the establishment and spread of terrestrial and aquatic plants in general. For example, Australian pine and Brazilian pepper prefer dry conditions for seed germination and seedling establishment, hence prolonged inundation (long hydroperiods) would limit the success of these two developmental periods, affecting the spatial extent of the species. Established trees of these two species are more tolerant of wet conditions although extended periods of flooding could reduce plant vigor and reproductive capability and may eventually lead to the death of the tree. Melaleuca, on the other hand, prefers wet conditions although invasion of dry areas can occur, especially if these areas become wetter than normal. Continuous flooding of a site may inhibit seed germination in melaleuca, but it does not seem to affect established trees.

Artificial structures, especially canals and levees, represent suitable habitats for both terrestrial and aquatic species. Australian pine and Brazilian pepper are capable of colonizing the elevated, disturbed portions of levees and roadbeds, but melaleuca is not, because these sites are generally not wet enough. The aquatic species (hydrilla, water hyacinth, and others) are widely distributed throughout canals where water levels and conditions are favorable for the establishment of these plants. Thus, the extent that canals, levees, roadbeds and other structures associated with water management operations occur within the system may further influence the occurrence of exotic plants: the more such structures are present, the more habitat becomes available for exotic establishment and spread.

For hydroperiods and ponding depth criteria, Alternatives A, B, C and D13R are similar in the overall hydrological conditions they predict for the system, but they do show some local differences. Lack of water is the main concern, as it can produce localized site conditions favorable for the establishment of Australian pine, Brazilian pepper, and other potentially invasive "upland" species. All four alternatives predict a continuation of short hydroperiods and low ponding depths along the eastern boundary of ENP, especially the area extending from northeast Shark Slough south to northern Taylor Slough. The C-111 basin and the Model Lands show a similar pattern. All of these areas currently support infestations of Australian pine and Brazilian pepper and will continue to do so under the conditions predicted by the four alternatives. On the other hand, an increase in hydroperiods predicted in the East Everglades (Indicator Region 8) may reduce the vigor and spread of these two species that currently inhabit many of the tree islands in this area.

Melaleuca will continue to occur and spread throughout the wetlands under the conditions predicted by the four alternatives except, perhaps, in areas experiencing the hydrological extremes: long hydroperiods and deep ponding or short hydroperiods and low ponding. However, the presence of these conditions at a particular site does not make it immune to melaleuca invasion; reversals in hydrological conditions can make these areas more susceptible. Generally, once melaleuca becomes established at a site, hydrologic changes are ineffective in eliminating it.

Canals, levees, and associated structures function as conduits for the persistence and often rapid spread of both terrestrial and aquatic exotic plants. The filling of canals and the degradation of levees and other raised sites, accomplished by decompartmentalizing the system and eliminating the barriers to water flow, are partially addressed under Alternatives B and D13R. Canals, and the deep water habitats they provide, support the greatest infestations of aquatic weeds (hydrilla, water hyacinth, water lettuce, and others) and are the primary corridors through which these organisms can extend their ranges rapidly from points of introduction and move into wetlands. These structures allow for the distribution and expansion of these pest plants from the north and developed lands to the east. Only Alternatives B and D13R are significantly superior to the present condition with respect to their effect on exotic plants, because they incorporate some removal of structures (canals, levees, roadbeds) from the system.

Levees and other raised earth structures provide prime disturbed “upland” habitat for a wide range of weedy, terrestrial native and exotic plant species, most notably the exotic tree species Australian pine and Brazilian pepper, and exotic grasses such as Burma reed (*Neyraudia reynaudiana*) and napier grass (*Pennisetum purpureum*). They serve as important avenues for the spread of these plants over great areas; their persistence on levees makes them available for dispersal into pristine habitat.

We find that any alternative that approaches NSM conditions, restores natural fluctuations in hydropatterns throughout the landscape, and includes removal of canals and levees in the Everglades Protection Area will reduce exotic plant establishment and spread in the Everglades. Conversely, any alternative that retains or adds to the present array of water management structures in the Everglades Protection Area s should not be viewed as restoration. Alternatives B and D13R come closest to satisfying these conditions.

C. Fish

The Biological Resources Division of the U.S. Geological Survey, Florida Caribbean Science Center, maintains a list of non-native fish in Florida, currently totaling 129 species (USGS 1998). This list is continually growing as more exotics are introduced into the State. The impacts of these fish on native populations in south Florida are far-reaching. Non-indigenous taxa represent well over 50 percent of the State's inland fish fauna south of Lake Okeechobee (Simberloff *et al.* 1997). These introduced species affect native fish populations by using the same food sources and spawning sites, and in many instances, preying upon the native fish.

Non-indigenous fish have been introduced to Florida's waters through a variety of means. Aquaculture operations have intentionally introduced several varieties of fish, including the Nile tilapia (*Oreochromis niloticus*), to ease permitting procedures for their culture as a food fish (Simberloff *et al.* 1997). Other pathways of non-indigenous fish introductions include release from aquarium-fish farms, individual aquariums, dispersal by birds, and intentional stocking. The Florida Game and Fresh Water Fish Commission (GFC) intentionally released the peacock cyclid (*Cichla ocellaris*) to provide biological control of other non-indigenous species and create a new sport fishery (Simberloff *et al.* 1997).

Responding to a request by the South Florida Ecosystem Restoration Working Group, ENP conducted a survey to identify the major species of concern within the NPS managed areas of south Florida (Snow 1998). The major fish species identified as established by the survey included: pike killifish (*Belonesox belizanus*), walking catfish (*Clarius batrachus*), oscar (*Astronotus ocellatus*), black acara (*Cichlasoma bimaculatum*), Mayan cichlid (*Cichlasoma urophthalmus*), blue tilapia (*Oreochromis aureus*), and spotted tilapia (*Tilapia mariae*). Mozambique tilapia (*Oreochromis mossambicus*) and the peacock cichlid, commonly referred to as the butterfly peacock bass (*Cichla ocellaris*) have been recorded but are not known to be breeding on NPS lands (Snow 1998). In addition to those exotic species already located on lands managed by the NPS, several non-indigenous species are established in the canal system adjacent to those parks. These species include the African jewelfish (*Hemichromis letourneauxi*), sailfin catfish(*Liposarchus multiradiatus*), banded cichlid (*Heros severus*), and jaguar guapote (*Cichlasoma managuense*) (Snow 1998).

The largest project element in the Initial Draft Plan that will affect exotic fish is the creation/expansion of canals. Canals provide a means for non-indigenous species which have become established in canals outside the Everglades to move into the natural system. These canals also act as artificial deep-water habitats which provide refuge to non-native aquatic predators in the dry season and during the winter, enhancing their survival and ultimate population sizes. During the dry season, these predators prey heavily on small marsh fishes and invertebrates moving in from the adjacent wetland (Howard *et al.* 1995).

Components SS6, YY6, and O4 involve the construction of two canals approximately 26 miles in length along the eastern border of WCA 3B. These canals could provide a conduit for introduction of non-indigenous species into the periphery of the Everglades. The COE should analyze the impacts of construction of these canals on aquatic species. Under Alternative D13R (Initial Draft Plan), partial removal of the L-67 canals, and the total removal of Miami canal, L-29, and L-28 should reduce the spread of exotic fish species in interior portions of the Everglades and Big Cypress Swamp.

D. Insects

There are approximately 1,000 documented species of non-indigenous insect species in Florida (Simberloff 1997). Pest insects in Florida cause losses of over $1 billion annually, and many of the worst pests are non-indigenous (Simberloff 1997). Many species arrived by walking, flying, swimming, or rafting; more recently, insect immigrants have arrived by hitchhiking or stowing away in cargo (Sailer 1978, Frank and McCoy 1990). These undocumented invaders continue to arrive at a rate of one major new pest species annually, while minor pests and insects that are not pests arrive and become established at a rate of more than 10 species annually (Frank and McCoy 1992). Many other insects in Florida were purposely imported for release as biological control agents (Frank and McCoy 1993). The ENP survey, prepared for the South Florida Working Group, revealed that information is not readily available regarding non-indigenous insects inhabiting NPS lands in south Florida. The report indicated the need to prepare a list of all insects through further surveys so an assessment can be made (Snow 1998). The only significant non-indigenous insect identified in the ENP survey was the imported red fire ant (*Solenopsis invicta*). This ant has the potential to disperse into native habitats and can be expected to spread throughout south Florida parks. It is considered a potential threat to native species, including threatened and endangered species, because it consumes many wildlife species, including alligator eggs, Florida tree snail (*Liguus fasciatus*) nesting individuals and eggs, sea turtle eggs and hatchlings, and has the potential to compete with native ants (Snow 1998).

The impact of the C&SF Restudy on insect species is unknown. However, the removal of levees which serve as a conduit for migration of insects, should reduce the spread of fire ants into the Everglades.

E. Other Invertebrates

A survey conducted by ENP identified two species of non-indigenous aquatic freshwater snails, which were unintentional introductions, and are now considered established in South Florida parks. These are the red-rimmed melania (*Melanoides tuberculata*) and *Marissa cornuarietus*, for which there is no common name (Snow 1998). *M. tuberculata* is considered established in ENP and is found in the mangrove zone, Shark River Slough, and Taylor Slough. This species can serve as the first intermediate host for the human lung fluke (Snow 1998). *Marissa cornuarietus* is found in disturbed habitats, such as canals, adjacent to Everglades and Biscayne National Parks (Snow 1998). The tree snail (*Orthalicus floridensus*), which is a native of south Florida and the Florida Keys was intentionally introduced into inland hammocks for the purpose of future collection by the snail trade. This species is a competitor with the native Florida tree snail (*Liguus fasciatus*). The spike-topped apple snail (*Pomacea bridgesi*) a native of Brazil was introduced by aquarists and aquaculturists into Florida. It is similar in appearance and size to the native Florida apple snail (*Pomacea paludosa*) and researchers working in the Everglades have determined that *P. bridgesi* could displace *P .paludosa (*Warren 1997*)*. Since *P. paludosa* is the primary food source for the endangered snail kite (*Rostrhamus sociabilis plumbeus*), which is unable to feed on *P. bridgesi,* it could create a serious food shortage for the snail kite. Several other mollusks and crustaceans have been identified as non-indigenous species residing in Florida (USGS 1998).

The zebra mussel (*Dreissena polymorpha*), and the Asian clam (*Corbicula fluminea*) pose a potential threat to Florida waters. Zebra mussels have not yet been reported in Florida, but it is believed they will soon enter the State. Zebra mussels have been found to severely impact native freshwater mussel, snail, and crayfish populations (G. Warren, GFC, personal communication 1998). *C. fluminea* is found in many areas of Florida and poses perhaps the greatest threat to native mollusk populations, because it can displace the sand or soft silt used by native mussels with its dense congregation of shells. (G. Warren, GFC, personal communication 1998). The Asian clam has been reported for ENP at the pump station in L-31W in Taylor Slough (W. Loftus, BRD-USGS, personal communication 1998).

Construction of canals may expedite the proliferation of *C. fluminea* and *P. bridgesi* which may directly impact native populations of snails. This will cause indirect impacts to other native species such as the endangered snail kite. Other possible impacts from construction of the project cannot be determined at this time. These impacts should be addressed in the more detailed feasibility studies for discrete phases of the Restudy.

F. Mammals

Several species of non-indigenous mammals were found to occur within the national parks in south Florida. The species identified in the survey include: the nine-banded armadillo (*Dasypus novemcinctus*), Mexican red-bellied squirrel (*Sciurus aureogaster*), Norway rat (*Rattus norvegicus*), black rat (*Rattus rattus*), house mouse (*Mus musculus*), coyote (*Canis latrans*), red fox (*Vulpes vulpes*), feral dogs (*Canis familiaris*), feral cats (*Felis catus*) and feral pigs (*Sus scrofa*) (Snow 1998). Some species have been introduced through accidental introduction from sources such as game ranches, tourist attractions, wild-animal importers, and dealers. Hurricanes may also liberate non-indigenous and domestic species.

The nine banded armadillo and the feral pig seriously impact Florida's native ecosystems. These mammals alter native plant communities through soil disturbance and by eating the eggs of native ground-nesting birds, native reptiles, and native soil invertebrates. Both species also pose a significant localized threat to cultural resources, both surface and sub-surface, as a result of soil disturbance (Snow 1998).

The only exotic aquatic mammal identified in Florida is the nutria (*M. coypus*) (USGS 1998). This mammal burrows into the side of dikes and roads, compromising the stability of the structure. This species does not commonly occur in the project area.

Implementing Alternative D13R will result in negligible impacts to exotic mammals. Other direct and indirect impacts should be addressed in the more detailed feasibility studies for discrete phases of the Restudy.

G. Birds

Several species of non-indigenous birds were found to occur in the National Parks in south Florida. Many non-indigenous birds, including parakeets, macaws, and toucans, have been reported from NPS managed lands in south Florida (Snow 1998). These birds were introduced either unintentionally by escaping from bird cages or intentionally for biological control of insects (Simberloff 1997). The total number of species of avifauna in Florida depends on the criteria chosen for inclusion. One accounting includes 483 species, of which 22 (4.5 percent) are deemed non-indigenous (Stevenson and Anderson 1994). Another more conservative estimate lists 461 species, of which 11 (2 percent) are non-indigenous (Robertson and Woolfenden 1992).
The NPS survey identified 6 non-indigenous species as occurring on NPS lands. Three other species, the cattle egret (*Bubulcus ibis*), shiny cowbird (*Molothrus bonariensis*), and the brown-headed cowbird (*Molothrus ater*) are considered simply to be expanding their natural ranges (Snow 1998). The six species that were identified in the survey, the Muscovy duck (*Cairina moschata*), rock dove (*Columba livia*), Eurasian collared dove (*Streptopelia decaocto*), European starling (*Sturnus vulgaris*), house sparrow (*Passer domesticus*), and the common myna (*Acridotheres tristis*) pose no ecological threat to the NPS areas (Snow 1998). Another six non-indigenous species which have established breeding populations in Florida include: budgerigar (*Melopsittacus undulatus*), monk parakeet (*Myiopsitta monoachus*), canary-winged parakeet (*Brotogeris versicolurus*), red-whiskered bulbul (*Pycnonotus jocosus*), spot-breasted oriole (*Icterus pectoralis*), and the house finch (*Carpodacus mexicanus*) (Simberloff 1997). Of these six species, only *M. monachus*, *B. versicolurus*, *P. jocosus*, and *I. pectoralis* are found in south Florida (Robertson and Woolfenden 1992).

Elimination of levees, which act as corridors for predators, may reduce predation on nesting birds, both native and non-indigenous. Other direct and indirect impacts should be addressed in the more detailed feasibility studies for discrete phases of the Restudy.

H. Amphibians and Reptiles

It has been suggested that the mechanism by which non-indigenous amphibians and reptiles have invaded Florida has changed over the years. The earliest colonizations, prior to about 1930, were by species from nearby islands of the West Indies that immigrated to southern Florida with cargo shipments. During the middle part of the 1900's, additional immigrants from the West Indies were supplemented with intentional and unintentional introductions (King and Krakauer 1966). A survey by ENP found that fifteen species of non-indigenous amphibians and reptiles are of particular concern to NPS management in south Florida. These species include: brown caiman (*Caiman crocodylus*), brown anole (*Anolis sagrei*), giant toad (*Bufo marinus*), spineytail iguana (*Ctenosaura pectinata*), green iguana (*Iguana iguana*), boa constrictor (*Boa constrictor*), Cuban treefrog (*Osteopilus septentrionalis*), greenhouse frog (*Eleutherodactylus planirostris*), Indo-Pacific gecko (*Hemidactylus garnotii*), wood slave gecko (*Hemidactylus mabouia*), tokay gecko *(Gekko gecko*), bark anole (*Anolis distichus*), knight anole (*Anolis equestris*), brahminy blind snake (*Ramphotyphlops bramina*), and Burmese python (*Python molurus*). Other non-indigenous amphibians and reptiles are not yet found in south Florida NPS areas, but occur in canal waters and lands adjacent to the parks, and have the potential to readily disperse into the parks. These include: red-eared slider (*Trachemyus scripta elegans*), crested anole (*Anolis cristatellus*), brown basilisk (*Basiliscus vittatus*), and whiptail lizard (*Cnemidophorus motaguae*). Among the lizards, the brown basilisk is the most closely associated with aquatic ecosystems and therefore has the greatest potential for exploiting canal systems (Snow 1998).

A query for non-indigenous amphibians and reptiles on the USGS Web site resulted in 12 amphibian species and 16 reptiles in Florida (USGS 1998). However, a list compiled by Butterfield *et al.* (1997), included 36 non-indigenous species. Thirty-two of the species originated in tropical regions, two are of temperate origin, and two have wide ranges in both temperate and tropical areas (Simberloff 1997). Butterfield *et al.* (1997), stated that the species that are most likely to colonize natural areas in ENP include the following species: red-eared slider, yellow-headed gecko (*Gonatodes albogularis*), ocellated gecko (*Sphaerodactylus argus*), ashy gecko (*Sphaerodactylus elegans*), bark anole, knight anole, northern curly-tailed lizard (*Leiocephalus carinatus*) and Texas horned lizard (*Phrynosoma cornutum*).

The Initial Draft Plan (Alternative D13R) of the C&SF Restudy involves the removal of existing levees and filling of some canals, and construction of many new canals and levees. Removal of levees will influence migration patterns into the natural areas of the Everglades for many of the reptiles. These levees are used by terrestrial species and aquatic species, expanding the range of their populations. Removal of these levees will reduce the potential for expansion of some species of exotics. However Components SS6, YY6, and O4 involve the construction of two canals approximately 26 miles in length along the eastern border of WCA 3B. Construction of these canals could provide a conduit for introduction of non-indigenous amphibian species to the edge of the remaining Everglades.

I. Summary and Recommendations

All of the Alternatives proposed for the Restudy contain components for the removal or alteration of man-made structures such as canals and levees. The primary difference among the alternatives relative to non-indigenous species is the number and placement of canals and levees that are removed or constructed. Levees provide prime disturbed habitat for almost all of the noxious terrestrial plant species, while acting as a barrier to the dispersal of native marsh plants, thereby artificially affecting plant distribution. Canals are major sites for aquatic exotic infestations, including hydrilla, water lettuce, and water hyacinth. Canals also act as corridors through which non-native animals and plants can extend their ranges rapidly from points of introduction, and can move into wetlands where they can alter habitats and affect food webs (Loftus and Kushlan 1987).

The DOI provides the following summary comments and recommendations:

1. Any alternative that approaches NSM conditions, restores natural fluctuations in hydropatterns throughout the landscape, and includes removal of canals and levees in the Everglades Protection Area will reduce exotic plant establishment and

spread in the Everglades. Conversely, any alternative that retains or adds to the present array of water management structures in the Everglades Protection Area should not be viewed as restoration. Alternatives B and D13R come closest to satisfying these two recommendations

2. During detailed planning for removal of existing structures or construction of new facilities, a plan of action to control exotics should be submitted for review and comment by all interested parties. All practical measures must be taken to control exotic species prior to construction. This is particularly important for detailed design and construction of two canals approximately 26 miles in length along the eastern border of WCA 3A in association with Components SS6, YY6, and O4.

3. We endorse the recommendation of the U.S. Congress (1993) that legislation and educational programs to restrict the importation of exotic plants be adopted for Florida. Because of the unpredictability of the invasive ability that species display, Florida should consider implementing a policy that essentially states: **species should be considered invasive and subject to import restrictions until demonstrated otherwise**.

4. The South Florida Ecosystem Restoration Task Force and Working Group Exotic Pest Plant Task Team are developing a statewide strategic plan for managing and controlling exotic pest plants. This effort should be vigorously supported and implemented. We recommend that an equivalent Task Team for invasive exotic animals be established.

CHAPTER X -- WETLAND MITIGATION, PERMITTING, AND THE C&SF RESTUDY

David L. Ferrell, FWS

A. Introduction

This chapter discusses the ecological, operational, and policy issues surrounding the authorization of section 404 Clean Water Act wetland mitigation activities within project features of the Comprehensive Review Study for the Central and Southern Florida Project (C&SF Restudy). The following discussion is not intended to be all encompassing; rather, it is intended to provide a brief overview of existing guidance, identify where in the C&SF Restudy project boundary wetland mitigation issues lie, stimulate discussion, and provide the DOI's recommendations for the potential resolution of these issues. This section also addresses wetland mitigation accountability associated with the construction of C&SF Restudy project features and provides recommendations which would account for the losses and gains of wetland functions.

B. Wetland Mitigation Banking

Mitigation Banking is a process by which wetland losses are mitigated in advance of the loss in an attempt to achieve "no net loss of wetland function." In Florida, the Mitigation Bank Review Team (MBRT) of Federal and State regulatory agencies reviews applications for banks. At the Federal level, Mitigation Banking is guided by the Federal Guidance for the Establishment, Use and Operation of Mitigation Banks (Federal Register, Vol. 60, No. 228, dated November 28, 1995).

In South Florida, there are currently 30 proposed and/or operational entrepreneurial Mitigation Banks (Table X-2) and Regional Offsite Mitigation Areas (ROMs) encompassing about 60,000 acres of land within the boundary of the South Florida Water Management District (SFWMD). Several of these banks lie within or affect project features of the C&SF Restudy, particularly in the Water Preserve Areas (WPAs) of southeastern Florida (Palm Beach, Dade, and Broward counties).

The primary issues associated with the permitting of Mitigation Banks as related to the C&SF Restudy involve "supplanting public programs planned, or in place," operational compatibility (primarily hydrologic), ecological functional replacement in the C&SF for private wetland losses (zero sum gain issue), relying on private monies to acquire/mitigate in lieu of public monies (shrinking the public revenue stream issue), and mitigating on lands in the public domain (the "level playing field" and "shrinking of the spatial extent of wetlands" issues).

The approach of authorizing Mitigation Banks which fall within planned C&SF project features has been on a case-by-case basis, and has been somewhat inconsistent in regard to the "supplanting" issue. Supplanting involves those instances where the wetland functional lift generated by a Mitigation Bank for future private wetland losses replaces the wetland functional lift generated by a public project (either planned, or in place) which are not subjected to private wetland losses. In effect, a Mitigation Bank generates wetland functional lift at the "expense" of private wetlands losses, and, ideally, "no net loss of wetland function" is realized. Thus, a "zero sum gain" of wetlands is realized (both spatially and functionally).

On the other hand, a public project, funded by public monies and not funds generated by wetland losses, generates wetland functional lift without the "expense" of wetland losses. Thus, a "net gain" in wetlands, both spatially and functionally, is realized.

To date, of the five known Mitigation Banks currently proposing to mitigate in the C&SF study area, the U.S. Army Corps of Engineers (COE) has determined that two banks are inappropriate (they "supplant" the C&SF Restudy) and have not been processed (Overstreet and Lake Okeechobee Mitigation Banks), one has been deemed appropriate since it does not "supplant" the C&SF Restudy, (even though it lies inside the C&SF Restudy boundary and would replace wetland functional lift generated by the C&SF Restudy) and continues to be processed (Loxahatchee Mitigation Bank), and one was deemed partially appropriate (functional lift for hydrologic improvements cannot be calculated until more detailed C&SF Restudy studies are finalized) and continues to be processed (FP&L Mitigation Bank). There are also several new proposals to establish Mitigation Banks inside the C&SF Restudy boundary in Broward County (Buffer Strip Mitigation Bank - Cells 17 and 18) and Palm Beach County (Water Catchment Area) which will involve the "supplanting" issue. There are likely other banking proposals in the planning process, thus additional new banks will need policy review.

There is also concern among the resource agencies involved in C&SF Restudy planning efforts that wetland mitigation authorized by a Mitigation Bank, if eliminated or otherwise altered by a project feature of the C&SF Restudy, can create a situation where previously authorized wetland mitigation will need to be appropriately mitigated by the C&SF Restudy project. Thus, the issue of "mitigating for previous mitigation" arises.

C. Need for Consistent Policy

The DOI recommends that a consistent policy regarding Mitigation Banking inside project features of the C&SF Restudy be implemented as soon as possible, as implementation of the C&SF Restudy is years away, and the need to mitigate for wetland losses will continue and may actually increase as development pressures continue. A potential course of action would be to formally request the South Florida Ecosystem Restoration Working Group, in conjunction with the MBRT, to review this issue and provide recommendations to the South Florida Ecosystem Restoration Task Force. The Task Force would then transmit these recommendations to the COE for implementation.

A primary policy issue which needs clarification is the establishment of a "threshold" when "supplanting" is reached. The DOI is of the opinion that once the Initial Draft Plan is selected for the C&SF Restudy (June 1998) and that alternative is described in the draft PEIS (October 1998), the "threshold" has been reached (the public project is now officially "planned" with defined boundaries). The C&SF Restudy plan should then guide the MBRT in making decisions as to whether a given Mitigation Bank "supplants" the C&SF Restudy and, accordingly, whether that bank is or is not appropriate.

D. Section 404 Permit Program

Similar to the Mitigation Banking program, policy questions regarding the continued practice of issuing section 404 permits inside project features of the C&SF Restudy needs resolution. This is especially true in the WPAs where continued urbanization abuts the Water Conservation Areas. The exact number of individual section 404 permits, issued and proposed, in the C&SF Restudy is unknown, but is very likely considerable (e.g. the Lakebelt/Pensucco Area in Dade County and the WPA in Broward County). The exact acreage of wetland losses for private development mitigated in the C&SF Restudy boundary is likewise unknown at this time.

The DOI recommends that a similar approach to that described above for Mitigation Banking be applied to section 404 permits (including Letter Permits, General Permits and Nationwide Permits). A similar "threshold" applied to Mitigation Banking should also be applied to section 404 permits. First, however, an accounting of pending and issued permits in the C&SF Restudy boundary needs to be tabulated by the Corps of Engineers (COE), Florida Department of Environmental Protection, and SFWMD. Wetland mitigation authorized, by permit, should be discounted from the calculation of ecological benefits attributable to the C&SF Restudy. Likewise, any previous mitigation eliminated or altered by construction activities associated with the C&SF Restudy implementation should be replaced, in-kind, by public monies authorized for the C&SF Restudy.

E. Other Wetland Planning Procedures

The Clean Water Act authorizes other wetland planning procedures which may be applicable in this case. The Advanced Identification (ADID) program administered jointly the COE and the Environmental Protection Agency has been applied to regions of south Florida to guide wetland development/mitigation. The Loxahatchee Slough ADID, Florida Keys ADID, and the Rookery Bay ADID are examples of such wetland planning actions in South Florida. In addition, the COE's Special Area Management Plan (SAMP) program can be applied where wetland mitigation is planned on a regional/watershed basis. A good example of this program is the Bird Drive SAMP in Dade County, which is an on-going wetland mitigation planning program.

In addition, the use of Regional Off-site Mitigation Areas (ROMs) is a State planning process similar to Mitigation Banking. ROMs are designed to "pool" wetland mitigation into larger, well-planned units in order to achieve more wetland functional benefits. While not officially a Mitigation Bank, a ROM functions very similar to a bank, except that a ROM mitigates for wetland losses at the time of permitting, while a Mitigation Bank generates functional lift for future wetland losses.

The DOI recommends that these on-going programs, as well as other watershed approaches, be examined for potential applicability to the C&SF Restudy.

F. Developing a Common Vision for the Water Preserve Areas

There is a growing consensus that a "common vision" for the WPAs is needed. The WPAs are an integral component of the C&SF Restudy. This roughly 100 sq. mi. area stretches from Palm Beach to Dade Counties and is essential for reducing seepage from the remaining Everglades. The WPAs are also important for water supply and maintaining water quality. Public monies are currently being expended to acquire lands in the WPAs. Prior to April 1996, the SFWMD purchased 9,600 acres for WPA implementation. Since April 1996, the SFWMD and the Department of Interior have purchased another 6,100 acres under the Farm Bill.

What is our collective vision of the WPAs in the year 2050, the planning horizon of the C&SF Restudy? Is the use of wetland mitigation to acquire and set aside the necessary lands to implement the WPAs in the overall public interest? If so, what ecological benefits can the C&SF Restudy claim for the WPAs if those benefits have been previously used to mitigate for private wetland losses?

And, who is responsible for "mitigating for previous mitigation" if the C&SF Restudy alters or otherwise eliminates those wetland functions? Finally, should the entire WPA be removed from the C&SF Restudy as a "with -project condition" to avoid these policy issues altogether? If so, what ecological benefits, if any, could the C&SF Restudy claim for the WPAs and how would this effect the overall justification for spending the funds to implement the C&SF Restudy?

The FWS recommends that the regulatory and resource agencies convene to discuss these types of questions in an attempt to reach consensus and to provide consistent guidance for future Mitigation Bank and section 404 permitting decisions as they effect the WPAs.

Table X-1 provides a listing (by cell) of some of the known permitted wetland mitigation areas and their acreages inside the Water Preserve Areas which would require "mitigation for mitigation" if their functional capacity is adversely affected.

Table X-1. Known permitted wetland mitigation sites inside the Water Preserve Areas of Palm Beach, Broward and Dade counties, listed by WPA cell number.

PALM BEACH COUNTY

Cell 4	Loxahatchee Mitigation Bank (proposed)	1,500 acres

BROWARD COUNTY

Cell 10	Arvida Mitigation (residential development)	1,195 acres
Cell 11	Arvida Mitigation (residential development)	228 acres
Cell 18	Sunset Lakes (residential development)	45 acres
Cell 19	Sunset Lakes (residential development)	640 acres

Note: I-75 wetland mitigation and Harbour Lakes wetland mitigation also proposed inside WPAs.

DADE COUNTY

Cell 26	Pennsuco Wetlands (residential development)	1,123 acres
Cell 26	Pennsuco Wetlands (rockmining mitigation)	1,249 acres

G. Wetland Conservation, Permitting, and Mitigation Strategy

One of the stated goals contained in the Interagency Agreement signed by the five Federal Departments creating the South Florida Ecosystem Restoration Task Force in October of 1995 was to develop a Wetland Conservation, Permitting and Mitigation Strategy (Strategy). While the development of the Strategy has been delayed, the need for such a Strategy is increasing clear. The goal of the Strategy is to: "Develop a comprehensive wetlands permit mitigation strategy for South Florida that furthers ecosystem restoration."

The DOI recommends that the South Florida Ecosystem Restoration Task Force, acting through the Working Group, actively pursue the completion of this important and far-reaching effort. The Strategy should embody the collective input of the regulatory and resource agencies and should guide future decision making for wetland conservation and mitigation as the concerted effort to restore the South Florida ecosystem moves forward.

H. Conclusion

The DOI finds that it is imperative, as the C&SF Restudy plans are finalized, that consensus on South Florida wetland conservation and mitigation issues be achieved and a consistent, far-reaching approach be adopted. Today, almost 5 million people reside on the east coast of south Florida, and by 2050 the number is expected to rise to 12 million. Keeping in mind that one-half of the spatial extent of wetland resources of the greater Everglades are irrevocably lost and that human population increases will result in the need for more space and, consequently, more wetland mitigation, we must carefully consider all available means to conserve our remaining wetlands if South Florida ecosystem restoration is to become a reality.

I. Summary Recommendations

1. Mitigation Banking:

The DOI recommends that a consistent policy regarding Mitigation Banking inside project features of the C&SF Restudy be implemented as soon as possible. A primary policy issue which needs clarification is the establishment of a "threshold" when "supplanting" is reached.

2. Section 404 Permit Program:

Similar to the Mitigation Banking program, policy questions regarding the continued practice of issuing section 404 permits inside project features of the C&SF Restudy needs resolution. This is especially true in the WPAs where continued urbanization abuts the Water Conservation Areas. A similar "threshold" applied to Mitigation Banking should also be applied to section 404 permits.

3. Other Wetland Planning Procedures:

The DOI recommends that other wetland planning procedures such as Advanced Identification, Special Area Management Plans, Regional Off-site Mitigation Areas, as well as watershed approaches, be examined for potential applicability to the C&SF Restudy.

4. A Common Vision for the Water Preserve Areas:

The DOI recommends that the regulatory and resource agencies convene to discuss the future of the Water Preserve Areas in an attempt to reach consensus and to provide consistent guidance for future mitigation bank and section 404 permitting decisions as they effect the WPAs and future planning for the C&SF Restudy.

5. Wetland Conservation, Permitting and Mitigation Strategy:

The DOI recommends that the South Florida Ecosystem Restoration Task Force, acting through the Working Group, actively pursue the completion of this important and far-reaching effort. The Strategy should embody the collective input of the regulatory and resource agencies and should guide future decision making for wetland conservation and mitigation as the concerted effort to restore the South Florida ecosystem moves forward.

Table X-2. Approved and Pending Mitigation Banks in the C&SF Restudy Area (April 1998) (Page 1 of 2)

NAME	LOCATION	ACRES
Florida Mitigation Bank Florida Power & Light	Dade County	13,455
Dade County Mitigation Bank Fl. Mitigation Trust Corp.	Dade County	1,640
Pensucco Everglades Bank	Dade County	6,730

CHAPTER XI — LAND ACQUISITION AND THE C&SF RESTUDY

Allen Webb, FWS

A. Federal Programs

Lands can be purchased by Federal agencies either through federal legislation authorizing the purchase of lands for a specific purpose (e.g. congressional action), usually through willing seller programs, or through condemnation of lands for activities that are in the best interest of the general public (eminent domain). Two examples of congressional land purchase authorizations from willing sellers are section 104 of the Everglades National Park Protection and Expansion Act of 1989 (P.L. 101-229) and section 390 of the Federal Agriculture Improvement and Reform Act of 1996 (P.L. 104-127).

The Everglades National Park Protection and Expansion Act of 1989 authorized the purchase of lands to be added to the park that encompass approximately 109,578 acres within northeast Shark River Slough (NESS) and the East Everglades. The purchase of these lands and the hydrological improvements to these lands is critical to restoring ecosystem productivity in the southern Everglades and maintaining adequate freshwater inflow to the downstream estuaries along the Gulf of Mexico and Florida Bay. Acceleration of land purchases in NESS is also required to ameliorate habitat availability for the Cape Sable seaside sparrow. The Everglades National Park requested $58 million in funds in fiscal year 1999 to assist the State of Florida in purchasing lands located within these areas, which are referred to locally as transition lands, and include the Frog Pond, Rocky Glades, and 8.5 Square-Mile Area. The purchase of these lands is necessary to limit further losses suffered by the park due to habitat destruction outside former boundaries and to restore natural water flow patterns that are critical to the long-term viability of the park. Additional land purchases will occur as funds are appropriated and willing sellers are identified. The $58 million requested would be utilized under cost-share terms that require the State of Florida to match the Federal share.

The second example of congressional land purchase authorization is section 390 of the Federal Agriculture Improvement and Reform Act of 1996, referred to as Farm Bill 390. Farm Bill 390 provides two distinct funding programs for land acquisition to support restoration of the Everglades. The first program provided $200,000,000 to the Secretary of the Interior to conduct restoration activities in the Everglades ecosystem in South Florida, including acquisition of real property and interests in real property and resource protection and resource maintenance activities. The second program under the Farm Bill 390 authorization provides for a special account (known as the Everglades Restoration Account). This account receives funds from the sale of surplus real property located in the State of Florida. Any Federal real property located in the State of Florida (excluding lands that are set aside for conservation purposes) shall be identified for disposal or exchange under this legislation and shall be presumed available for public sale, unless the head of the agency controlling the property determines that there is a compelling program need for any property identified as surplus. The total amount of funds deposited in the special account cannot exceed $100,000,000. Provisions of the Farm Bill 390 program require the State of Florida to match the Federal share for this account.

The South Florida Ecosystem Restoration Task Force interagency working group has identified the acquisition of lands in the Everglades Agricultural Area and the East Coast Buffer/Water Preserve Areas as its number one priority for Farm Bill appropriations (South Florida Ecosystem Restoration Task Force Integrated Financial Plan, August 1996). As of January 1998, the Secretary of Interior through the Fish and Wildlife Service has provided approximately $40 million in grants to the South Florida Water Management District resulting in the acquisition of over 4,400 acres in the East Coast Buffer/ Water Preserve Areas and in the Everglades Agriculture Area. These lands will provide important water storage capacity and stormwater treatment. The Secretary of Interior through the Fish and Wildlife Service is also providing financial support to the State of Florida for two additional important acquisitions: 1) purchase of nearly 37,000 acres within the Southern Golden Gate Estates (approximately $25 million), located in the western basin of southwest Florida, and 2) purchase of approximately 50,000 acres of the Talisman Sugar Holdings in the Everglades Agricultural Area (approximately $135 million). The proposed grant monies for these two additional purchases will exhaust the remaining funds available under the $200 million appropriation. Cost sharing and land acquisition expertise are being provided by the SFWMD and DEP for these Federal land purchases.

Limited funds are currently available in the Everglades Restoration Account from the sale of Federal surplus lands. Excess properties in the former Richmond Naval Air Station in Dade County have been tentatively identified as properties that are surplus to Federal needs. Estimated funds generated from these land sales range from $3.4 million to $11.2 million. Once these funds become available, additional lands necessary for Everglades restoration will be purchased. Other properties throughout Florida have also been tentatively identified as potential Federal surplus properties, but land values have not been estimated for these properties.

The Department of Interior's land protection policy is to acquire lands only when other protective means (e.g., zoning or regulation to achieve program goals) are not appropriate, available, or effective. When lands are acquired, the minimum interest necessary to reach land protection and management objectives is retained. The Federal government acquires fee title (control of all property rights) only if control of lesser property interests through easements or leases will not achieve land protection objectives. If fee title is required, full consideration will be given to granting extended use reservations, entering into exchanges, or using other alternatives that will lessen the impact on the owner and the community. Funding for land acquisition can also come from receipts, such as Federal Duck Stamp sales, entrance fees to certain National Wildlife Refuges, import duties on arms and ammunition, and appropriations under the Land and Water Conservation Fund Act of 1965 (P.L. 88-578, as amended) as well as other legislative mandates.

Eminent domain land purchases (lands purchased through condemnation proceedings) can occur under a variety of actions. However, it must first be determined that the purchase is in the best interest of the general public and has been authorized by federal legislation. Examples of these land condemnation purchases are those authorized by section 309(l) of the Water Resources Development Act of 1992 (P.L. 102-580), and by two resolutions passed by the Committee on Public Works and Transportation of the House of Representatives on September 24, 1992. Under these authorizations, the Secretary of the Army can design and construct any features of the C&SF Project that were authorized on or before the date of the enactment of the Water Resources Development Act. The Secretary of the Army also has the authority to modify an authorized project, including features authorized under other Federal actions, where the design and construction will accelerate the restoration, preservation, and protection of the South Florida ecosystem and will generally be consistent with the conceptual framework described for Everglades restoration. The modifications must be compatible with the overall authorized purposes of the Central and Southern Florida Project.

Previously authorized projects are referred to in the Everglades restoration program as Critical Restoration Projects (CPs). Thirteen such project have been currently identified and authorized. CPs have been identified as those projects that are essential to the success of the Restudy. Once these projects are evaluated, they are authorized for approval and funding through the Army Corps of Engineers Headquarters. Following approval, an abbreviated one-year feasibility study is then conducted. This study is followed by a NEPA review and design evaluation. Once the NEPA process is completed, the project undergoes a detailed plan and specification phase, leading to contract award and construction. In general these project require a non-Federal project sponsor and usually will require matching State and/or local funding. Another group of projects are termed Other Project Elements (OPEs). These projects must include the following features: 1) located outside the boundaries of the South Florida Water Management District's Everglades Restoration Hydrological Model, 2) support and be consistent with the C&SF Restudy objectives, 3) contain federal interest, and 4) should not be a stand-alone research or data collection project.

B. State Programs

State land purchases occur through similar mechanisms as those listed for Federal land purchases. The State of Florida's land acquisition program, as administered by the DEP, is the largest and most aggressive in the country, with over $300 million spent annually to purchase environmentally sensitive lands through Preservation 2000 (P2000), Conservation and Recreation Lands Program (CARL), and Save Our Rivers Program (SOR). The State of Florida Bureau of Land Acquisition (Bureau) reviews and evaluates all P2000 and CARL acquisitions for the Board of Trustees of the Internal Improvement Trust Fund. The Bureau also handles land exchanges and negotiates and acquires lands for the DEP and other state agencies. The P2000 program was created in 1990 by the Florida legislature in response to the Governor's Commission on the Future of Florida's Environment that examined the threats to Florida's natural resources. This 10-year, $3 billion land and water conservation program uses funds to purchase endangered species habitat, archaeological and historical sites, water resource areas and public recreation lands. To date, the funds have protected more than 820,000 acres of the State's natural areas. However, funding for the P2000 program is contingent upon annual appropriations from the state legislature. The P2000 program mission of acquiring land to protect ecologically significant areas and the diversity of life supported by those areas is complimentary with the goals of the Restudy. Since its authorizations in 1990, the P2000 program has become the largest state land and water conservation program in the nation. Recent acquisitions include 48,000 acres of rare Florida prairie (once abundant in the Kissimmee River basin) and nesting beaches for the endangered loggerhead and green sea turtles in Indian River County.

The Conservation and Recreation Lands Trust Fund (CARL) was established by Section 259.032, Florida Statutes, as amended. The purpose of the funds is to assure that the citizens of this state shall be provided public ownership of natural areas for purposes of maintaining the state's unique natural resources; protecting air, land, and water quality; and providing lands for natural resource based recreation. It is the intent of the State of Florida to provide public lands for the people residing in urban and metropolitan areas of the state as well as those residing in less populated, rural areas. A high priority is to be given to the acquisition of lands in or near counties exhibiting the greatest concentration of population and within any area designated as an area of critical state concern under Section. 380.05, Florida Statue. The Conservation and Recreation Lands Trust Fund is established within the DEP. The fund shall be used as a nonlapsing, revolving fund exclusively for the purposes of land acquisition and management. An amount up to 1.5 percent of the cumulative total of funds deposited into the Florida Preservation 2000 Trust Fund shall be made available for the purposes of management, maintenance, and capital improvements for lands acquired pursuant to this fund to which title is vested in the State of Florida. The fund shall be credited with proceeds from excise taxes on documents generated under Statue 201.15, Florida Statute and on excise tax generated on the severance of phosphate rock as provided in Statute 211.3103, Florida Statute.

Another state funding program is the Water Management Lands Trust Fund. This documentary tax stamp revenue totals about $12 million per year. The Water Management Lands Trust Fund (WMLTF) was established by Section 373.59, Florida Statutes. The fund is established within the DEP and is to be used as a nonlapsing fund for the purposes of this land acquisition and management. The monies in this fund are continually appropriated for the purposes of land acquisition, management, maintenance, capital improvements, payments in lieu of taxes, and fund administration. By January 15 of each year, each Water Management District shall file with the Florida State Legislature and the Secretary of the DEP a report of acquisition activity together with modifications or additions to its 5-year plan of acquisition. Monies from the fund shall be used for continued acquisition, management, maintenance, and capital improvements on lands identified in the 5-year land acquisition plan developed by the SFWMD. Lands available for purchase by funds generated from the WMLTF program included lands in the water conservation areas and areas adversely affected by raising water levels of Lake Okeechobee in accordance with present regulation schedules, and the Savannahs Wetland area in Martin County and St. Lucie County. The SFWMD receives thirty percent of the monies generated each year by the fund.

The SFWMD also administers funds received from the P2000 program, the CARL program, and the SOR program. In addition to these program funds, the SFWMD also provides funds from their general revenue account that are generated by *ad valorem* taxes. Recent acquisitions by the SFWMD include matching land purchases for Federal lands purchased under the Farm Bill 390 program. Properties in the East Coast Buffer/Water Preserve Areas of Dade, Broward, and Palm

Beach counties were purchased by the District as matching lands. In 1997, the SFWMD purchased approximately 100,000 acres through their various land acquisition programs.

C. County Programs

Land acquisition programs are also available at the local level through county land purchase programs. Counties within the C&SF Restudy provide funds through tax programs, sale of bonds, and other revenue generators. These programs as a whole are often referred to as Environmentally Endangered Lands programs. These land purchases are used to acquire local and county parks, water storage and retention areas, and wildlife preserves. As with both the Federal and State programs, lands are usually purchased from willing sellers. However, lands can be purchased through condemnation when the land purchase is in the public interest and no willing sellers are identified.

D. The Challenge of the Restudy

Many of the land acquisition projects described above were already under way before selection of a preferred plan for the Restudy. To our knowledge, the selected plan for the Restudy does not conflict with any of the ongoing actions; current projects should continue. However, the Restudy adds significantly to the land acquisition needs for restoration of the Everglades. Some of these additional needs are described in Chapters XII, XIII, and VI of this report. These include expansion of the Water Preserve Areas north of C-51 in Palm Beach County; additional reservoirs in the St. Lucie basin, the Caloosahatchee basin, and north of Lake Okeechobee; and many of the Other Project Elements.

As restoration and habitat enhancement concepts and actions are identified in the various basins within the scope of the Restudy, land acquisitions will continue to occur. Lands that can be purchased from willing sellers receive top priority whether the purchase is initiated at the Federal, State, or local government levels. However, once a critical land acquisition component of the Restudy is identified, lands will be purchased through condemnation, if necessary. Funding for land purchases will continue to be provided through the various programs identified above and from new sources of revenue yet to be identified. Specific parcels should be identified as soon as possible, and land acquisition activities should promptly respond. This will minimize the purchase of tracts from willing sellers that would later have to be swapped because the tracts are found to fall outside of the detailed design of the project.

CHAPTER XII -- WATER PRESERVE AREAS

Steve Peacock and David L. Ferrell, FWS

A. Introduction

The Water Preserve Areas (WPAs) Feasibility Study, currently being conducted under the Central and Southern Florida (C&SF) Comprehensive Review Study, is developing a conceptual design for an interconnected series of marshlands, reservoirs, and aquifer recharge basins (Figure XII-1). The objectives of the WPAs are to: 1) hold more water in the natural system by reducing seepage losses from the Everglades; 2) capture, store, and treat stormwater currently lost to tide; 3) provide a buffer between the urban areas and the Everglades; and, 4) protect and conserve wetlands and habitat values outside the Everglades. The WPAs are intended to provide additional regional storage to assist in meeting the future needs of all users - agriculture, urban, and the environment. Ecosystem restoration benefits that are anticipated include: improved water supply for restoring hydropatterns of the Everglades; improved water quality; and preservation of wetland habitat. The WPAs will be located on lands located along the eastern side of the Everglades Protection Area in western Palm Beach, Broward, and Dade counties.

Several studies were completed, reports generated, and many meetings were held by various organizations which focused on the need for establishing a wetland buffer or conservation zone along the eastern Everglades.

The reconnaissance phase of the C&SF Project Comprehensive Review Study clearly demonstrated that WPAs would be an integral part of ecosystem restoration, as authorized by Congressional legislation in 1992. The purpose of the legislation was to reexamine the C&SF system for ecosystem restoration benefits, while enhancing other project purposes. WPAs were identified as critical to system-wide restoration of the south Florida ecosystem of the Everglades for the following reasons: 1) natural system modeling indicates that additional historic runoff must be returned to the Everglades hydrologic system; 2) development continues to encroach on the areas identified as being sensitive to ecosystem restoration, and 3) water supply to the urban and agricultural areas must be maintained at existing levels to ensure a sustainable south Florida. In addition, the WPAs will address other water-related needs such as water supply and water quality. The WPAs could provide a mechanism for increased aquifer recharge and surface and subsurface water storage capacity to enhance regional water supplies for the lower east coast urban areas.

The South Florida Water Management District (SFWMD) has investigated numerous alternatives for the WPAs. These range from a continuous Everglades buffer, consisting of an interconnected system of marshlands (proposed by the National Audubon Society as Water Supply Preserves) to individual “cells” that were combined to form wetland areas, reservoirs, and aquifer recharge basins, termed the East Coast Buffer. In 1994 the U.S. Army Corps of Engineers (COE) endorsed the East Coast Buffer concept as “Water Preserve Areas.” These alternatives will be assessed in more detail in the Water Preserve Areas Feasibility Study. The timely implementation of the WPAs has been identified as an early action item for Everglades restoration. In July 1995, the COE proposed, and the SFWMD Governing Board approved, the Water Preserve Areas Feasibility Study.

A preliminary land suitability analysis was conducted in 1994 by CH2M Hill for the SFWMD, in conjunction with the East Coast Buffer study, to identify lands which could be used as or converted to water preserve areas, including reservoirs and marshes. A more detailed study was conducted in 1996 by CH2M Hill for the SFWMD Restudy Team. The study utilized databases from the National Wetlands Inventory and soil-surveys. The total area of the current study is 1,643,000 acres (2,567 square miles) which was subdivided into 2.5 acre grids for analysis (SFWMD 1997).

The National Audubon Society (NAS), the SFWMD, and the U.S. Environmental Protection Agency sponsored a scientific conceptual design workshop for the eastern Everglades WPAs on September 19-20, 1996, in Miami, Florida, which convened 31 biologists and experts in the ecology of eastern Everglades wetlands. The purpose of this meeting was to identify: 1) functions or values in the WPAs, 2) spatial extent of the WPAs, and 3) high value areas which should be protected (NAS 1997).

Both the reconnaissance report, which was completed in November 1994, and the project study plan, which was completed in July 1995 for the Comprehensive Review Study of the C&SF, identified WPAs as a major element of the C&SF Restudy in the area between the Everglades and the Atlantic Ocean (SFWMD 1997).

B. Habitat Characteristics of the Water Preserve Areas

Several areas adjacent to the WPAs have been identified and recommended for the expansion of the spatial extent of wetlands, to provide additional buffer zone, and to enhance biological connectivity and hydrological connectivity to the Everglades. The WPAs have been grouped into cells for the East Coast Buffer project. These cells begin with cell 1 at the northeast corner of Loxahatchee National Wildlife Refuge in Palm Beach County, and end at cell 32 south of the Bird Drive recharge area in Dade County, with larger areas south of the Lakebelt identified by letters D thru G and/or associated components. Components of the C&SF project associated with these cells assist in identifying the location within the project boundary. The Florida Land Use, Cover and Forms Classification System (FLUCCS) was used in evaluating existing conditions within the WPAs. A cell-by-cell habitat analysis of the WPAs is found in Table XII-1.

1. Palm Beach County

Water Storage Areas: Components GGG6 (L-8 Basin), VV6 (Areas A&D), and M4 (Cells 7&8) have been identified as storage areas. These storage areas range from 1,200 acres and 40 feet deep in component GGG6 to 1,660 acres and 12 feet deep in component VV6, and 1,660 acres and 6 feet deep in component M4, for a total of 4,500 acres of storage. These areas have been designated as storage based on the Land Suitability Analysis, which identified minimal environmental impacts and maximum potential for storage capacity. Location of these storage components in rock mining areas or agricultural areas will result in negligible impacts to fish and wildlife. In addition, if features for fish and wildlife enhancement, as discussed below, are incorporated into the design, an overall ecological benefit could result in these areas.

Stormwater Treatment Areas: Components Y6, K6, and X6 have been identified as Stormwater Treatment Areas (STAs). Component Y6 is a proposed 600 acre area south of the M-Canal and west of the Water Catchment Area. A location and size for component K6 has not been determined. Component X6 is a proposed 550 acres STA to be located east of the Water Catchment Area. No information on existing habitat conditions at these sites has been obtained. A detailed analysis of environmental impacts associated with these components will be conducted in the Fish and Wildlife Coordination Act Report for the Water Preserve Areas Feasibility Study.

2. Broward County

Water Storage Areas: Component Q5 (cell 11/area B) has been identified as a storage area. This component will inundate 1,600 acres up to 4 feet deep. Conservation easements of 114 and 118 acres are included in this component as preservation areas for wetland mitigation for the Sunset Lakes permit. Inundating with up to 4 feet of water will impact sawgrass marsh and freshwater wetlands. Incorporating fish and wildlife enhancement features into the design will reduce the overall impacts to fish and wildlife. However, an overall negative impact to native vegetation and wetlands will occur in this area. An analysis of wetland acreage impacted by various components in the WPAs needs to be conducted, and a determination of impacts/benefits made, in order to determine if mitigation will be required.

Stormwater Treatment Areas: Component R4 (cells 17, 18, 19 and area D) has been identified as an STA. This component will impound 2,500 acres 4 feet deep. This component will impact a large section of freshwater marsh. The use of this area as an STA for water quality treatment will introduce nutrients which may cause displacement of native vegetation by non-indigenous species.

Seepage Control: Components SS6, YY6, and O4 involve the rerouting of water supply deliveries to North New River Canal, diversion of water to NE Shark River Slough and Central Lake Belt, and reducing seepage from WCAs 3A and 3B. This will be accomplished through widening and converting two borrow area canals in cells 9, 12, 13, 14, 15 and 16. This provides several opportunities to enhance fish and wildlife values in those sections of the WPAs. Manipulation of water levels, construction of small islands and removal of *Melaleuca* and Brazilian pepper can all provide great benefits to fish and wildlife. However, the construction of canals also pose a threat to the dispersal of exotic fish to new areas. An analysis of impacts on aquatic species associated with construction of these canals should be conducted during the Feasibility Study.

3. Dade County

Water Storage Areas: Components XX6 (cell 20), S6 (cell 21) and HHH6 (cell 28) have been identified as water storage areas. A total of 11,700 acres will be impounded by these three components. Component XX6 is a 4,500 acre impoundment also known as the North Lake Belt Storage. This impoundment will be operated on a schedule which can fluctuate by 20 feet. The FLUCCS codes for this area indicate that a section of pine flatwoods will be impacted by this component. This area is considered a Resource Category 2 which is described as "of high value for evaluation species and is scarce or becoming scarce on a national basis or in the ecoregion section." The mitigation goal for Resource Category 2 is no net loss of in-kind habitat value. If this area cannot be avoided, the FWS recommends compensation by replacement of the same type of habitat value.

Component S6, also known as the Central Lake Belt, will inundate 5,200 acres, and will fluctuate as much as 36 feet. This component will inundate existing lakes, rock quarries, and *Melaleuca* and appears to be best suited for this area.

Component HHH6 will impound 2,877 acres up to a depth of 4 feet. This component will impact approximately 2,000 acres of freshwater marsh. Existing conditions include both short and long hydroperiod wetlands with predominant vegetation being spikerush (*Eleocharis* spp.), sawgrass (*Cladium jamaicense*), muhly grass (*Muhlenbergia* spp.), punk tree (*Melaleuca quinquenervia*) and scattered tree islands with willow (*Salix* spp.). The change in water levels will alter the plant and wildlife communities from those associated with prairie and freshwater wetlands to species associated with deeper aquatic systems. Inundation of the area will help reduce the spread of *Melaleuca;* however, the dense patches that exist on the northern fringe of the component will remain in their current state.

Stormwater Treatment Areas: Component XX6 includes the construction of 3 STAs. Two of the units are located south of the North Lake Belt impoundment and are 250 and 235 acres in area, respectively. These STAs are to be situated on what is mainly agricultural land with some freshwater marsh located within the boundaries. The third STA of 640 acres will be located northeast of the impoundment and will impact according to FLUCCS codes will impact a large pine flatwood area. Recommendations for this area will be the same as mentioned above for the impoundment portion of component XX6, which also impacts pine flatwoods.

Buffers: A section of privately owned land located in sections 9, 15, and 16, township 35 south, range 39 east which is located between the Pennsuco wetlands and the wellfield in Dade County is recommended for acquisition. This land would provide a wildlife corridor from the wellfield to the Pennsuco wetlands as well as acting as a buffer to the wellfield.

A section of land located in sections 23, 24, 25, and 26, township 35 south, range 39 east currently not included in the comprehensive plan should be acquired. These parcels, which are existing lakes located south of the wellfield, are currently owned by mining companies. Acquisition of this property would provide an opportunity for wetland creation/enhancement and expand the spatial extent of the project in that area, as well as further buffer adjacent developed areas.

C. Project Effects

Impacts of the WPAs on the natural resources of the area are both positive and negative. The positive aspects of the project include: 1) acquisition of land to act as a buffer from nearby developed areas, 2) control of exotic plant species, 3) recharge the aquifers to restore natural hydroperiods to the Everglades and provide vital urban water supply, and 4) improve water quality. Negative impacts associated with the project include: 1) loss/degradation of freshwater wetlands and other Resource Category 2 habitats, and 2) spread of exotic species to other areas.

The DOI recommends that a full ecological trade-off analysis be conducted of the WPAs during the Feasibility Study. A wetland functional assessment such as the SFWMD's Wetland Rapid Assessment Procedure (WRAP) or the COE's Hydrogeomorphic Methodology (HGM) should be utilized to quantify wetland functional losses and gains. Further, an accounting of the effects of constructing the WPAs on previously permitted mitigation under the section 404 program is necessary.

D. Mitigation

Mitigation for losses of previously permitted mitigation areas through the section 404 permit program will be required. In accordance with the FWS Mitigation Policy (Federal Register, Vol. 46, No. 15; Pp. 7644-7663; January 23, 1981), the loss of Resource Category 1, 2, or 3 habitats will require mitigation. A Resource Category 1 designation requires no loss of existing habitat and the FWS will recommend that all losses of existing habitat be prevented as these unique habitats cannot be replaced. A Resource Category 2 designation is an area of high value for evaluation species and is scarce or becoming scarce on a national basis or in the ecoregion. The mitigation goal for Resource Category 2 is no net loss of in-kind habitat value. If Resource Category 2 areas cannot be avoided, the FWS recommends compensation by replacement of the same kind of habitat value. A Resource Category 3 designation has a mitigation goal of no net loss of habitat value while minimizing loss of in-kind habitat. The FWS recommends ways to avoid or minimize losses of Resource Category 3 habitat; however, if losses are likely to occur, then the FWS will recommend ways to rectify those losses or reduce or eliminate them over time. The FWS will recommend that these losses be compensated by replacement of habitat value.

E. Fish and Wildlife Enhancement Features

The marshes of the East Everglades have been systematically eliminated due to agricultural and urban development over the last several decades. Large acreage of short-hydroperiod marshes, critical to the life-cycle of many water birds when water levels in the WCAs are high, no longer exist. Exotic invasive species, particularly *Melaleuca* and Brazilian pepper, now occupy significant portions of the WPAs. It is essential that fish and wildlife resources be integrated into the planning for the management of the WPAs.

The DOI recommends that fish and wildlife enhancement features be included in WPA project design (Figure XII-2). Priority fish and wildlife planning objectives for the WPAs include: 1) devising an aggressive plan for the perpetual removal of invasive exotics (both plants and animals); 2) managing the WPAs to maximize short-hydroperiod marshes for foraging water birds, particularly during high water events in the WCAs; 3) designing project features to enhance fish and wildlife resources, such as vegetated buffer zones between developed and natural areas and creation of vegetated islands within the deeper impoundments for as refugia for nesting/foraging water birds and other wildlife; and, 4) ensuring adequate water quality. Public access to the WPAs should be carefully planned to avoid and minimize sensitive nesting/breeding areas during critical periods.

F. Unresolved Issues

Outstanding unresolved issues which will require additional review include: 1) mitigation for permitted mitigation areas which will be impacted as a result of the project, 2) spread of exotic plant and animal species through construction of canals and storage reservoirs, 3) prioritization of land acquisition prior to development, 4) degradation of existing wetlands through construction of storage areas and STAs, and 5) maintenance of adequate water quality.

G. Recommendations

The DOI recommends the following actions be integrated into the design and operation of the WPAs:

1. Remove exotic vegetation in all of the identified WPAs;

2. Identify and implement applicable wetland mitigation to off-set previously permitted mitigation through the issuance of section 404 wetland permits in order to achieve "no net loss of wetland functions and values;"

3. Provide a detailed accounting of other habitat losses in the PEIS and utilize a functional assessment (e.g., WRAP, HGM) to address these losses during the Feasibility Study.

4. Incorporate a feature for fish and wildlife enhancement into the design of storage areas and STAs to make them more environmentally compatible and to off-set habitat functional losses;

5. Maximize flow-ways (e.g., the two-canal area in Broward) and other short-hydroperiod wetlands whenever possible to benefit fish and wildlife and to expand the spatial extent of wetlands to the east of the WCAs;

6. Minimize deep water impoundments (greater than four feet deep) that support little or no wetlands and wetland-dependent wildlife; and,

7. Recognize that a Management Plan will be needed for fish and wildlife resources and potential recreational uses.

TABLE XII-1
WATER PRESERVE AREAS HABITAT ANALYSIS (Page 1 of 5)

	HABITAT CHARACTERISTICS			
COMPONENT/ LOCATION	EXISTING CONDITIONS	WITH PROJECT CONDITIONS	NAS/FWS VALUE	COMMENTS
Palm Beach County				
GGG6	Mined area	40' storage depth; 1,200 acres with a slurry-wall	Low	A rock mine, currently being mined, used for storage to restore natural hydroperiods to Loxahatchee NWR.
Y6 /K6 and X6 (L-8 Basin)	Unknown	Unknown	Unknown	Components K6 and Y6 include a 600 acre STA but a location has not been determined and only one of the components may be implemented (Y6 to be located north of M-canal). Component X6 includes a 550 acre STA.
Other Project Element (OPE) (Cells 1,2,3)	Sawgrass marshes and cypress habitat	Levied sawgrass marshes and cypress habitat, 1.5' max depth	High	Managed to enhance/protect the unique habitat; minor hydrologic restoration may be considered. Cell 1 is currently managed by Loxahatchee NWR on a lease agreement, and the Refuge owns cell 3. Recommend hydrology not be altered.
VV6 (Area A and a portion of Area D)	Agriculture	1,660 acre impoundment, 12' deep with ASR.	Low	Impoundment 12' deep, with ASR. Area D has been reduced from 21,000 acres and is included in VV6.
No component Cells 4, 5 and Area B	A mixture of temperate, tropical and wetland hardwoods, sawgrass, Brazilian pepper.	Withdrawn from comprehensive plan by COE.	Moderate/ High	Proposed SFWMD Loxahatchee Mitigation Bank, pending review of agencies. Recommend it remain in Comp Plan and be restored with project funds instead of permitted wetland losses.
No component Area C	Improved pasture, under construction for a county park.	County Park	Moderate	The acquisition of this site would provide vital connectivity/wildlife corridor. This site is in the NAS report but not designated for acquisition by SFWMD on the latest maps. Recommend acquisition.
M4 (Cells 7 and 8)	Improved pasture; pine flatwoods with Melaleuca, fallow cropland.	Site 1 storage area = 1,660 acres; max depth= 6 ft.	Ranked low in NAS report	The creation of a water storage area in this agricultural location is appropriate. Permitted for rock mining.

TABLE XII-1
WATER PRESERVE AREAS HABITAT ANALYSIS (Page 2 of 5)

COMPONENT/ LOCATION	HABITAT CHARACTERISTICS: EXISTING CONDITIONS	HABITAT CHARACTERISTICS: WITH PROJECT CONDITIONS	NAS/FWS VALUE	COMMENTS
Broward County				
QQ6 Cell L68A	Dense sawgrass marsh; some cattails on south end of L-68A.	Dense sawgrass. Levee to be removed and Miami Canal filled in.	High	Will reconnect this area with WCA-3. It appears that cattails have infested the WCA west of the levee. Removal of the levee will allow spread of cattails throughout this cell. Recommend aggressive management of cattails/noxious plants prior to levee removal.
SS6 , YY6, O4 (Cell 9)	Dense sawgrass marsh	Area will be situated with a canal on each side	High	Will reroute water supply deliveries to N. New River Canal; divert water to NE Shark River Slough and Central Lake Belt; and reduce seepage from WCAs 3A and 3B.
Weston Development mitigation site	Moderate/dense sawgrass	Moderate/dense sawgrass. Levee on the eastern boundary	High	Weston development mitigation site. Will remain intact.
Q5 Cell 11/Area B (reduced size)	Sawgrass, dense/moderate *Melaleuca*, wetlands, dry pasture	1,600 acre impoundment; 4' deep. Levee on the eastern boundary.	Variable	Proposed for water storage. Will impact wetlands south of cell 10. Contains conservation easements of 114 and 118 acres for Sunset Lakes mitigation.
SS6 and YY6 (Cells 12, 13, 14) Also 15 and 16 in Dade Co.	Cells12/13/16- serious *Melaleuca* problem . Cells 14/15 - valuable marshes and mixed shrub	Canal on each side of the cells.	Moderate	No change to existing uses. A canal will be placed on either side of the cells. Recommend treatment/removal of *Melaleuca* prior to implementing and construction of managed marsh in these areas. May disperse exotic fish population through new canals.
Trailer park (Area C)	Trailer park	Flood control around trailer park	None	Recommend acquisition to provide contiguous wildlife corridor. Would provide high wildlife value.

R4 (Cells 17, 18 and 19 and area D)	Cell 17- dense Melaleuca Cell 18- dense *Melaleuca* in north half with freshwater marsh in south Cell 19- rock quarries in north with improved pasture	Will become part of C-9 STA 2,500 acre impoundment 4' deep. Upper third of Cell 19 (rock quarries) proposed for mitigation. 185 acres of mitigation for Sunset Lakes will be inundated.	Moderate	An analysis of lost mitigation will be required. If a permitted mitigation area is lost, then mitigation for that site will be required. Cell 19 has been reduced in size and Area D eliminated from the plan since it would be fragmented from other property in the plan.
Dade County				
XX6 (Area A)	Agriculture, airport Melaleuca, pine flatwoods and freshwater marsh	2 STAs North of Miami Canal and 1 STA in adjacent to Florida Turnpike and Canal 9 Ext	Low except for moderate in pine flatwoods	Much of this area has been scheduled as a 1997 project addition by Save Our Rivers. The 2 southern STA's total approximately 500 acres. The north STA (pine flatwoods) totals about 640 acres. A portion of the pine flatwoods will become part of the North Lake Belt Storage (see below).
XX6 (Cell 20)	Pine flatwoods, improved pasture and borrow pits	Inundated, North Lake Belt Storage	Low except for moderate in pine flatwoods	Will be inundated by a 4,500 acre water storage area with a 20' variance in depth. Some of the proposed land acquisition has been completed. Recommend pine mitigation for flatwood habitat with short hydroperiod wetlands.
Area B	No baseline information	Unable to determine	Unknown	This parcel was proposed for acquisition in NAS for water storage but has been dropped from consideration for acquisition. Potential mitigation site for mitigation required as a result of the project. Adjacent to pine flatwood area.

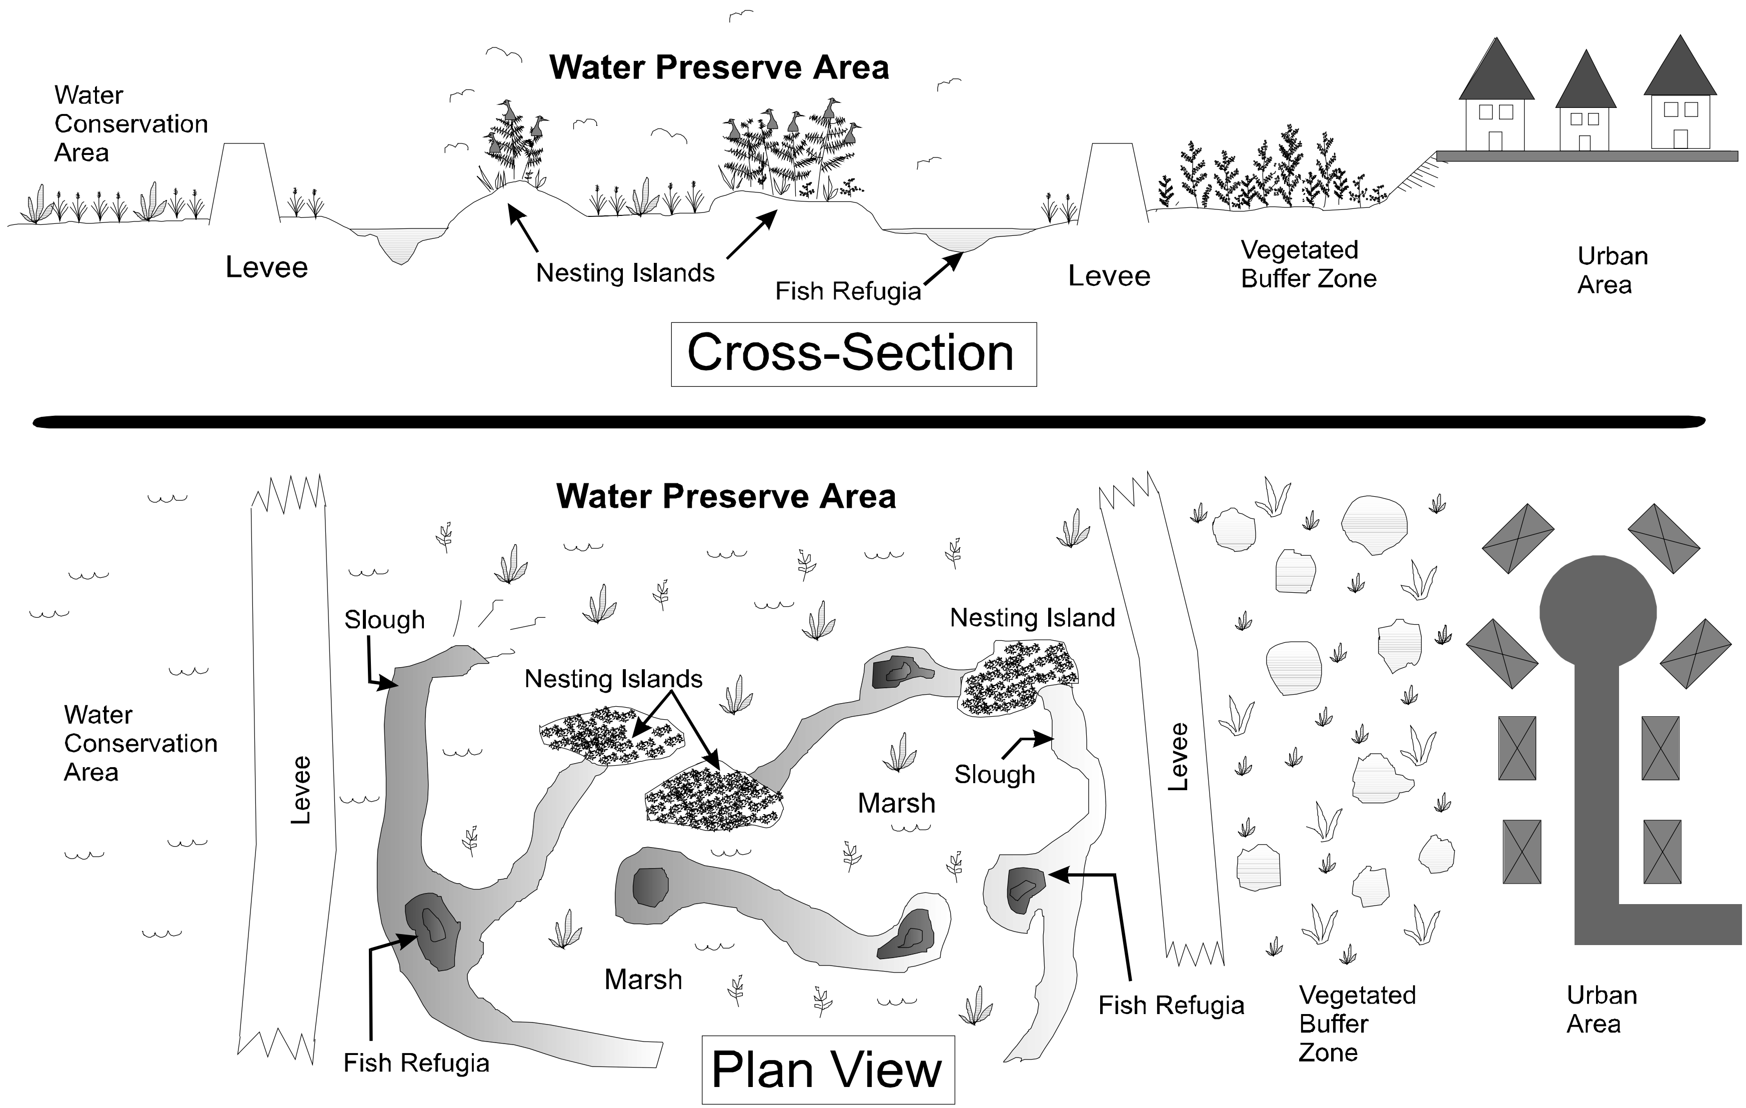

Figure XII-2. Conceptual diagram of fish and wildlife habitat enhancement features in the Water Preserve Areas.

CHAPTER XIII -- EFFECTS OF STORAGE RESERVOIRS AND STAs ON HABITAT CONDITIONS (EXCLUDING WATER PRESERVE AREAS)

Robert Pace, FWS

A. Introduction

The present design of Alternative D13R includes conversion of approximately 151,200 acres of uplands and wetlands for water storage and treatment (Table XIII-1). The degree to which the COE and the SFWMD have determined locations for these facilities varies greatly among the components. For example, the Indian River Lagoon Feasibility Study has already screened sites for suitability and has defined options for sites, which would apply, in part, to Restudy components B and UU in the St. Lucie basin. The COE has also identified preliminary locations for the facilities north of Lake Okeechobee (2 options for siting Restudy Component A) , storage in the Caloosahatchee basin (Component D), and an STA in the Caloosahatchee basin (Component DDD). However, other storage and treatment facilities have only been screened for their hydrologic effects on the C&SF system through coding in the SFWMM, without an analysis of the availability of suitable lands. Examples include both of the W Components in the Taylor Creek/Nubbin Sough basins, and the three storage compartments in the EAA (Component G). Because the EAA has relatively homogeneous and has low habitat value and is relatively homogeneous, we are not especially concerned about the siting of the 60,000 acres of storage in the EAA as long as it produces the desired restoration benefits. Although we understand the conceptual level of detail in the Restudy, we have attempted to provide as complete an analysis as the present information allows.

An accounting of impacts is needed to assess the loss of habitat functions versus gains in habitat functions through ecosystem restoration in the C&SF system as a whole. These gains and losses should be discussed in the PEIS and appropriate methods to avoid or minimize these impacts should be identified during subsequent detailed project planning. Although the restoration benefits of the Restudy **may** offset the construction impacts, an accounting of the habitat gains and losses should be included in the PEIS. The ecological benefits of the Restudy are principally in the form of improved hydrologic functioning in existing (primarily herbaceous) wetlands. In contrast, the storage reservoirs will impact a variety of upland and wetland habitats, including some forested wetlands. Therefore, in order to accept the premise that the ecological benefits of the Restudy far outweigh the impacts on existing habitat values in the areas to be converted to storage reservoirs and treatment facilities, it will be necessary to assess and accept "out-of-kind replacement" of habitat function and value as defined in the FWS' mitigation policy (Federal Register, Vol. 46, No. 15; Pp. 7644-7663; January 23, 1981).

Table XIII-1. Water storage and treatment areas proposed in the Restudy, excluding the Water Preserve Areas.

Component	Location	Area (Acres)	Max. Depth (Ft)
A	N. of Lake Okeechobee	20,000	10
B	St. Lucie drainage (C-44)	10,000	4
UU	St. Lucie drainage (C-23, C-24, North and South Forks)	26,200	8
D	Caloosahatchee drainage (Storage)	20,000	8
G	EAA (3 compartments)	60,000	6
W	Taylor Creek/Nubbin Slough (Storage)	5,000	10
W	Taylor Creek/Nubbin Slough (STA)	5,000	4
DDD	Caloosahatchee drainage (STA)	5,000	4
Total		151,200	

We have performed preliminary analyses of the cover types and the threatened, endangered, or rare species present in the areas so far identified as potential storage areas. This analysis was performed to assist the COE in evaluating the habitat impacts discussed above. We must express caution that the cover type analyses are based on classification of a satellite image, which is subject to variable levels of error, depending on the habitat type. (For an assessment of the accuracy of the specific GFC classification we used, see Kautz *et al.*, 1993.) The data we reviewed for presence of threatened, endangered, and rare species of plants and animals have been compiled from a variety of sources. Some of these sources have not been updated in recent years. Site-specific field surveys must be performed before final decisions are made regarding location of the proposed storage areas so that the presence of habitat types and sensitive species can be confirmed. The results presented here should be considered as indications of what resources **might** be expected to occur in these areas. We have also reviewed siting proposals to determine whether the facilities would occur in the Strategic Habitat Conservation Areas (SHCAs) defined by Cox *et al.*(1994) in their publication entitled, “Closing the Gaps in Florida’s Wildlife Habitat Conservation System.”

B. Storage in the EAA (Component G)

The DOI finds that locating storage areas in the EAA will have relatively less impact on fish and wildlife resources than elsewhere in the C&SF Restudy area. The EAA presently provides habitat for wading birds, particularly during periods of high water in the late rainy season (Sykes and Hunter 1978). The principle wading bird species include the federally endangered wood stork (*Mycteria americana*) and three wading bird species listed by the GFC as species of special concern: little blue heron (*Egretta caerulea*), tricolored heron (*Egretta tricolor*), and snowy egret (*Egretta thula*).

However, the EAA contains little native habitat and is not a stable, sustainable ecosystem. The cover types in the EAA are almost entirely classified as "grassland", whether these are sugarcane fields or other crops. The scarcity of native cover types within the EAA led to Cox *et al.* (1994) not including any portion of the EAA in their designation of SHCAs. We therefore recommend that as detailed design proceeds for the features of the Restudy, storage in the EAA take priority in implementation over storage elsewhere in the study area.

C. Storage north of Lake Okeechobee and in the Caloosahatchee Basin (Components A and D)

The COE has identified preliminary locations for these facilities; a single site was identified in the Caloosahatchee basin and two options were identified for the region north of Lake Okeechobee.

The cover types, as defined by Kautz *et al.* (1993), within the three potential storage reservoir sites are provided in Table XIII-2. In general, grassland (most likely improved pasture) is the predominant cover type in both of the storage locations for storage north of Lake Okeechobee. The location provided for Option 2, which lies between the Paradise Run section of the lower Kissimmee River and the Indian Prairie Canal, has a greater area classified as dry prairie than the Option 1 location, to the northeast (east of the Kissimmee River). Because dry prairie is a native community and pasture is not, we would prefer selection of Option 1, although either of the sites appears to be acceptable. The proposed reservoir site north of the Caloosahatchee River is substantially more diverse in cover types than either of the two options for storage north of the lake. It displays greater spatial heterogeneity in a rather complex pattern of cover types, including grassland, dry prairie, pineland, freshwater marsh, and hardwood hammock. The following paragraph includes a discussion of why we suspect that the area remotely sensed as dry prairie in Option 2 may in fact contain more xeric oak scrub or sand pine scrub than was classified as the latter two land cover types.

The two optional locations for storage north of Lake Okeechobee are similar with respect to the presence of threatened, endangered, or rare species. Each of these has a relatively low density of observations for these species, compared to other parts of south Florida. Both sites contain records of nesting by the federally threatened bald eagle (*Haliaeetus leucocephalus*); some of these nest sites are active, while others are older records. The federally threatened Audubon's crested caracara (*Polyborus plancus audubonii*) is present within and around both sites. We have found that the caracara occurrence database is biased towards reporting a greater number of observations near public roads. It is therefore likely the occupied caracara home ranges on private properties away from roads are underestimated. We recommend that a thorough survey for the distribution of caracara habitat must be conducted within and outside the proposed storage reservoirs before they are finally selected. Caracara observations are also reported around the periphery of the proposed site north of the Caloosahatchee River, and we find it likely that caracara territories also occur within the site. Although we have no record of bald eagle nesting within the Caloosahatchee reservoir area, eagle nest locations change over time, and we would recommend a detailed search for nests in this area prior to any construction. According to a survey conducted by Archbold Biological Station (Fitzpatrick *et al.* 1994), the threatened Florida scrub jay (*Aphelecoma coerulescens coerulescens*) occupies habitat in two locations within the proposed Caloosahatchee reservoir site. Their survey characterized the habitat at both locations as "moderately overgrown." The reported locations for scrub jays in the Caloosahatchee reservoir site overlay areas remotely sensed as dry prairie; we believe that xeric oak scrub and sand pine scrub habitat types are likely dominant in this area, but were not classified as such. State-listed species within any of the three sites may include the Florida sandhill crane (*Grus canadensis pratensis*), threatened; and the burrowing owl (*Speotyto cunicularia*), species of special concern. We anticipate that the gopher tortoise (*Gopherus polyphemus*), which is also a species of special concern, may be present in the scrub habitat within the Caloosahatchee reservoir site.

The proposed storage sites differ substantially with respect to potential impacts on the SHCAs described in Cox *et al.* (1994). Option 1 for storage north of Lake Okeechobee contains a relatively small area designated as a SHCA. Roughly the southern third of the Option 2 site north of the lake is designated as such, coinciding with clusters of native cover types, primarily dry prairie and hardwood forest, which are more abundant than in the Option 1 site (Table XIII-2). The storage area north of the Caloosahatchee River is almost entirely designated as a SHCA, and more importantly, forms part of a much larger contiguous region designated as a SHCA in western Glades County. In contrast, smaller and more fragmented areas are designated as SHCAs south of the Caloosahatchee River in Hendry County, which should be examined as an alternative to the COE's currently recommended site.

We find that within the three possible storage sites north of Lake Okeechobee or in the Caloosahatchee basin, only the Caloosahatchee storage area contains xeric scrub habitat, which we consider to be "unique and irreplaceable," as described in the FWS' mitigation policy as Resource Category 1. The Resource Category 1 designation calls for no loss of existing habitat value, that is, avoidance of adverse impact. Because it is not practical to create compensatory scrub habitat, this habitat should be avoided in siting the proposed storage. The COE can avoid this habitat either by splitting the storage impoundment in two around the scrub habitat or by shifting the storage elsewhere in the Caloosahatchee basin. Other potential sites where the storage reservoir could be relocated include portions of Glades County, east of the COE's currently recommended location, or south of the Caloosahatchee River in selected portions of Hendry County. We are ready to assist the COE in siting this facility in a less sensitive location. Although impacts on crested caracara habitat may be unavoidable in these other sites, they appear to have less habitat heterogeneity than the currently recommended site, and impacts to the scarcer scrub habitat could be avoided.

In summary, the Option 1 site is preferred over Option 2 north of Lake Okeechobee, but either of these options is most likely acceptable. The COE should seek an alternative to the currently selected site north of the Caloosahatchee River. Less sensitive sites appear to be available east of the currently recommended location (north of the river) and in selected areas south of the Caloosahatchee River.

D. Proposed Storage Sites as Part of the Indian River Lagoon Feasibility Study (Components B and UU)

Fourteen potentially suitable sites have been proposed under the Indian River Lagoon Feasibility Study, seven sites in St. Lucie County, and seven in Martin County (Figure XII-1--The numbers in this figure have been assigned strictly as points of reference for this document.) These sites were selected following a series of GIS-based land suitability analyses and workshops attended by experts on regional environmental conditions. This planning has resulted in a relative lack of concern with respect to impacts of the facilities on fish and wildlife habitat. The Restudy modeling runs assumed 10,000 acres of storage, at a maximum depth of 4 feet, along C-44 (Component B); and a total of 26,200 acres of storage, up to 8 feet deep, along C-23, C-24, and the North Fork and South Fork of the St. Lucie River. We determined that a total of 72,957 acres (bottom of Table XIII-3) of potentially suitable area has thus far been defined through the Indian River Lagoon Feasibility Study. Modeling of the Restudy alternatives suggests that the desirable salinity envelope for the St. Lucie estuary will be maintained much more often than under the current C&SF system, but extreme high and low flows (outside of the desired salinity regime) will not be entirely eliminated. The Restudy modeling assumed a total of 36,200 acres of storage out of a potential 72,957 acres of suitable land. Depending on the outcome of future studies, it may be necessary to increase the total water storage areas beyond the 36,200 acres to achieve the ecological goals. It also should be noted that much of the Upper East Coast drainage into the St. Lucie estuary originates from areas outside the geographic scope of the SFWMM. This indicates the need for more detailed hydrological modeling under the Indian River Lagoon Feasibility Study which may in turn confirm the need for a greater total acreage of storage than that modeled in the Restudy alternatives.

Land cover designations in each of the 14 proposed sites is summarized in Table XIII-3. In general, the site selection effort mentioned above has been successful in limiting the extent of impact on fish and wildlife habitat. The majority of the existing cover types that would be affected by the storage areas were classified as grassland or barren, with smaller areas of freshwater marsh. The prevalence of freshwater marsh ranges from less than 1 percent to about 9 percent of the total area of each site. The area classified as grassland would include citrus groves, which are common in the region. The proposed sites have low habitat heterogeneity.

The potential storage areas identified to date in the Indian River Lagoon Feasibility Study are not known to be located in habitats of particular significance to threatened, endangered, or rare species, based on the survey data we have available. One record of the crested caracara has been reported from Site 2 in northern St. Lucie County. Site 6 has been delineated to avoid impacts to a valuable, complex, wetland along its western boundary. Two nesting colonies in a cypress swamp just west of Site 6 have historically supported several species of waterbirds. In various years, these have included the federally endangered wood stork (*Mycteria americana*) and three

State-listed species of special concern: little blue heron (*Egretta caerulea*), tricolored heron (*E. tricolor*), and white ibis (*Eudocimus albus*) . Other species that have nested there include great blue heron (*Ardea herodias*), great egret (*Casmerodius albus*), anhinga (*Anhinga anhinga*), and cattle egret (*Bubulcus ibis*). If Site 6 becomes part of the storage needed for the C&SF system, extreme caution would be required to avoid adverse impacts on surrounding wetlands during levee construction, and the construction schedule might need to be managed to avoid construction during the nesting season close to any active waterbird nesting colonies. In the long term, storage of no more than 4 feet of water in this area could enhance foraging capabilities for birds nesting in the area, compared to the site's current land use as a citrus grove.

None of the proposed sites for storage from the Indian River Lagoon Feasibility Study would affect SHCAs.

E. Storage/Treatment in the Taylor Creek/Nubbin Sough Basins (Component W)

The Restudy proposes 5,000 acres of storage at 10 feet deep and a 5,000-acre STA in the Taylor Creek and Nubbin Slough basins, but the COE has not provided maps of proposed locations. The DOI supports these features because these basins currently export the highest nutrient loads to Lake Okeechobee. The chapter of this report dealing with Other Project Elements (OPEs) includes a section entitled "Lake Okeechobee Water Retention/Phosphorus Removal." That project will also assist in retention of phosphorus in the basin, and that endeavor can, if adequately planned and coordinated, be complimentary to the facilities discussed here. The individual projects that make up the Lake Okeechobee Water Retention/Phosphorus Removal critical project should occur outside the areas to be converted to the larger storage and treatment areas. Therefore, the COE should identify as soon as possible potential sites for the two 5,000-acre storage and treatment areas. This will ensure that efforts related to the Lake Okeechobee Water Retention/Phosphorus Removal are not expended in areas that will become the larger storage and treatment areas.

Although we have not been provided potential locations for the storage and treatment facilities in these basins, we have conducted a preliminary analysis on the availability of suitable sites. We found three areas in the Taylor Creek/Nubbin Slough basins that may be suitable for water storage and treatment (Figure XII-2). All of the sites are dominated by grassland, with some inclusions of freshwater marsh and dry prairie, similar to the two options for storage north of Lake Okeechobee described above. Site 1 (Figure XII-2) is comprised of approximately 6,165 acres in an area north of State Road 68 and west of U.S. Highway 441. Site 2 is just east of the first, across U.S. Highway 441. Because Site 2 contains about 3,612 acres, it is not capable by itself of accommodating either of the two 5,000-acre facilities, but it may be possible to split the facility on either side of the highway. Site 3, measuring 7938 acres, is located in the southeastern portion of the Taylor Creek drainage basin and the northern end of the Nubbin Slough basin, north of State Road 70.

Preliminary screening indicates that known occurrences of threatened, endangered, or rare species are not abundant in these sites. Sites 1 and 2 have one record each of the presence of the federally threatened Audubon's crested caracara, and Site 3 has no records for any of the species in our databases. Sites 1 and 2 have relatively small scattered portions designated as SHCAs (not part of any larger contiguous areas), and Site 3 has virtually no portion designated as a SHCA.

In summary, areas with relatively low environmental sensitivity appear to be available for the proposed facilities, but the two 5,000-acre sites for the storage area and the STA may have to be separated within the two basins to avoid adjacent more sensitive areas.

F. STA in the Caloosahatchee Drainage Near Lake Okeechobee (Component DDD)

The COE has identified a preliminary location for this 5000-acre facility. Table XIII-4 indicates the cover types that will be affected if that site is finally selected. The area appears to be situated well away from the rarer habitat types. No records of endangered, threatened, or rare species are present within the COE's recommended site, but there are records for the federally threatened Audubon's crested caracara in the area around the site. We recommend that more detailed surveys be performed to determine caracara habitat use within the site prior to detailed project planning. The proposed site has negligible effect on SHCAs. Therefore, we find that the currently recommended site has low environmental sensitivity and would generally appear to be suitable.

G. Effects of the Initial Draft Plan

The focus of this chapter has been an assessment of the existing habitat conditions in the areas that may be converted to storage areas and STAs. We can confidently predict that habitat value for upland species (such as gopher tortoise and scrub jay) would be lost in conversion of these areas. However, it is more difficult to predict the net effect on wetland-dependent species (wading birds) or species that primarily are found in upland habitats but are known to forage in wetlands (Audubon's crested caracara) or use wetlands for breeding (Florida sandhill crane).

A principal reason for this uncertainty is that some of facilities proposed here are unprecedented in south Florida in terms of size and hydrologic regime. It is difficult to predict what vegetative communities, and other habitat characteristics, will be present in most of the storage areas, because these act as large "surge tanks" to buffer the effects of flood and drought on the Everglades Protection Area. The SFWMM predicts the most extreme hydrologic regimes for the 20,000-acre storage area north of Lake Okeechobee and the 5,000-acre storage area in the Taylor Creek/Nubbin Slough basins. In the storage area north of Lake Okeechobee, the surface is either dry or nearly dry for periods as long as 1.75 years, and is filled with water 10 feet deep for periods ranging from a few days, to several months, to as long as 1.25 years. Other storage areas also experience less extreme, but still unnaturally large, fluctuations in water levels. We are presently unable to determine what wildlife species might find habitat in these areas; however, we are concerned that not only might these areas have low intrinsic habitat value, but also that they may become "traps" or "population sinks" for certain opportunistic species. These impacts can include direct mortality when the areas are flooded and/or population declines caused indirectly by the loss of suitable habitat in some years.

A second uncertainty arises for the STAs. Although we have several years of data on the habitat conditions in the existing Everglades Nutrient Removal Project, which is similar to the proposed facilities, the long-term habitat conditions in these areas are uncertain. Even if water levels are normally suitable for many species of fish and wildlife, it is likely that the areas will become filled with sediment, cattails, and other nutrient-tolerant vegetation. In this event, the STAs most likely will have to be periodically drained and cleaned of accumulated sediment and vegetation to achieve long-term efficiency in nutrient removal. Thus, although they may provide temporarily suitable habitat conditions for some species, they will not be stable high quality habitats for a variety of species. STAs that do not exceed 4 feet deep, and that are not in a stage in their maintenance cycles when they are clogged with vegetation, would be expected to provide foraging habitat over many years for widely ranging species, such as the federally endangered snail kite (*Rostrhamus sociabilis plumbeus*) and wading birds.

These unprecedented facilities will serve as experiments that must be closely monitored. Scientific studies should be focused on information that will be useful to decision-makers in an adaptive management framework.

H. Recommendations

1. Water storage or treatment areas should be developed first in the EAA before affecting more valuable wildlife habitats in other parts of the C&SF system.

2. For water storage north of Lake Okeechobee, the site identified by the COE as Option 1 (east of the Kissimmee River in southeastern Okeechobee County) is somewhat preferable over Option 2 (west of the Kissimmee River in northwestern Glades County) to avoid impacting more valuable wildlife habitat.

3. We strongly recommend that the COE seek an alternative to the site currently recommended for water storage in the Caloosahatchee River drainage. Environmentally less sensitive sites appear to be available in some areas south of the Caloosahatchee River. If the currently identified site cannot be avoided entirely, we recommend that detailed design should avoid any impact on occupied scrub jay habitat.

4. Adaptive management of both the storage areas and the STAs should be based on focused scientific study of their intrinsic and external effects on wildlife, including their potential threat as “traps” or “sinks” to wildlife populations normally supported in adjacent habitats.

CHAPTER XIV -- ADAPTIVE MANAGEMENT

Cheryl Buckingham, FWS

A. Introduction

A conceptual adaptive management strategy was developed for the South Florida Restoration Program (Figure XIV-1). Its purpose is: a) to strengthen the overall role of science in the planning, implementation and evaluation phases of restoration programs, b) to suggest a logical sequence of points during the restoration planning process where science can contribute, c) to follow a more structured and predictable scientific process during the development of restoration programs, and d) to create the framework of ecological models and hypotheses that will be necessary to build adaptive management feedback loops into the restoration programs. This strategy for a science-based process is designed to operate over a range of scales, from local to regional. It can be applied to ecological activities in a variety of habitats in south Florida; it applies equally well to defining proper fire management practices for scrub on the Lake Wales Ridge as it applies to assessing the hydrologic changes anticipated from the C&SF Restudy.

Adaptive management focuses on the importance of building in the ability to learn about systems and to incorporate new information into the restoration process. Hypotheses are formed, tested, and revised in a systematic way to produce the greatest amount of useful information. Classical adaptive management strategies consist of a continuing cycle of conducting true experiments, monitoring the results, and revising both the hypotheses and the experiments with the ultimate goal of discovering new information. When adaptive management is applied to restoration projects, the goal of reaching restoration targets is added to that of discovering new information. Additionally, the step of modifying or revising the restoration projects in light of new information is added to the cycle.

In the Everglades, there may never be enough management flexibility to conduct true experiments. To do so would require the ability to manipulate the system on large enough spatial and temporal scales to test major hypotheses. Nevertheless, this adaptive management strategy has created a very strong scientific framework for guiding restoration planning and for evaluating system responses. The key to achieving this goal is to reach consensus on a strong set of hypotheses that describe causal relationships affecting the altered south Florida ecosystems.

Because the scale of the program makes conducting experiments improbable, the adaptive management process will need to depend on the combined influences of large scale changes in management practices and variation in climatological patterns as the means for "testing" the hypotheses and, at the same time, evaluating the management actions. One avenue for using management practices to "test" hypotheses will come with the development of the implementation plan. The same interdisciplinary consensus will be needed to properly sequence the order in which components go on-line. The additions of components must be carefully orchestrated to act as experiments, to test hypotheses, to help evaluate the effects of management plans, and to generate as much information as possible, although it is understood that the information will be limited in scale and time. This new information will be used to refine future actions. An example of treating climatological events as experiments was seen during the high water years of 1994-1995 where the responses of wildlife and wildlife habitat to extreme depths and extended hydroperiods were carefully recorded both during and in the years following those events. Although this does not constitute a controlled experiment, the information obtained from those years gave a great deal of insight into what might occur in a much wetter ridge and slough system.

B. Implementing the Adaptive Management Strategy

The following four steps are being used to implement the Restudy's restoration adaptive management strategy:

1. Develop Conceptual Models. Representatives of a number of essential disciplines held several workshops and charettes over the period of two years. From these came a set of landscape-scale, conceptual ecological models of the south Florida ecosystems. These ecological models explain how the natural systems functioned in terms of **stressors** on the system, the **effects** of those stressors, the **attributes** or **endpoints** that felt the effects, and the **measures** of those endpoints that were altered in the managed system. The models integrated information from empirical studies, modeling and monitoring and best professional judgement of the participants. While many conceptual models already existed, this was the first time they were integrated among and across multi-disciplinary and institutional lines to the degree that they could be used as driving forces for restoration planning and adaptive assessment. Consensus on the characteristics of these conceptual models was an essential step in the process of refining the list of restoration endpoints, also called success criteria.

2. Develop Causal Hypotheses. A set of hypotheses were generated from the conceptual models to explain why changes occurred in each of the major ecological functions and components of the natural systems. Many causal relationship hypotheses had been described before this process, but again, they needed to be integrated across disciplinary and institutional lines. These hypotheses are relatively specific in their explanations of causal relationships even though those relationships operate at a range of different scales. They serve to define the sources of ecological problems in the system and therefore suggest what management actions need to be taken to correct the problems. During the plan formulation process, these hypotheses drove the development of a large number of **performance indicators** and **performance measures**. Performance indicators and measures are the standards and rationale against which model outputs are evaluated. Performance indicators do not have specific targets but are useful to show whether restoration plans are causing changes in a particular direction in relation to the existing conditions and future without project conditions. Performance measures have targets that were approved by the AET and were used to determine whether restoration objectives have been achieved. Performance measures were helpful in a) predicting how the systems would respond as a result of each restoration action modeled, b) evaluating how well each of these management actions appeared to accomplish its objectives, and c) gaining new information and insights into how the systems operate.

3. Develop a Robust Monitoring Program. An ecological monitoring program is being developed to collect data, determine baseline conditions, and monitor the attributes that the hypotheses predict will be affected by specific management plans within the restoration program. The monitoring program will measure the responses of the attributes at the same range of scales as those addressed by the array of hypotheses.

4. Adaptive Assessments Multi-disciplinary teams of scientists will conduct periodic, regular (at least annual), assessments of system responses to compare the actual responses as seen in the monitoring program to the pre-determined sets of responses predicted by the hypotheses. These comparisons will provide a means to: a) evaluate the effectiveness of the management action, b) test and evaluate the causal hypotheses, and c) recommend any revisions to the conceptual ecological models, the causal hypotheses, or to the management action. The report cards prepared by these teams create the feedback loop that characterizes an adaptive strategy, in that revisions to the conceptual models and hypotheses can and should lead to revisions in the restoration plans.

The use of a strong set of widely accepted causal hypotheses as the technical framework of restoration planning has improved the linkage between science, effective management, and policy actions. This strategy also avoids the lack of consistent support adaptive management has fallen prey to in the past. Specifically, because an interdisciplinary group has developed the program, the monitoring program will generate research that is consistent with and has the backing of policy-makers. Political consensus will help ensure the program's continued existence. Subjects of study will be determined by the needs of the program rather than just the interests of scientists. Proper baselines will be established (as much as possible) so that the changes made to the system will be measured against the proper references. Natural events will be used as test cases to glean further information and to test hypotheses. Because the monitoring program is an integral part of the restoration program, the problem of inadequate institutional commitment to monitoring will be less of a problem and the lengthy timetable will be determined and approved in advance. Also, as the list of subjects to be monitored will develop from the conceptual models and be agreed upon by an interdisciplinary group, the problem of "trying to measure everything," will be less likely to occur.

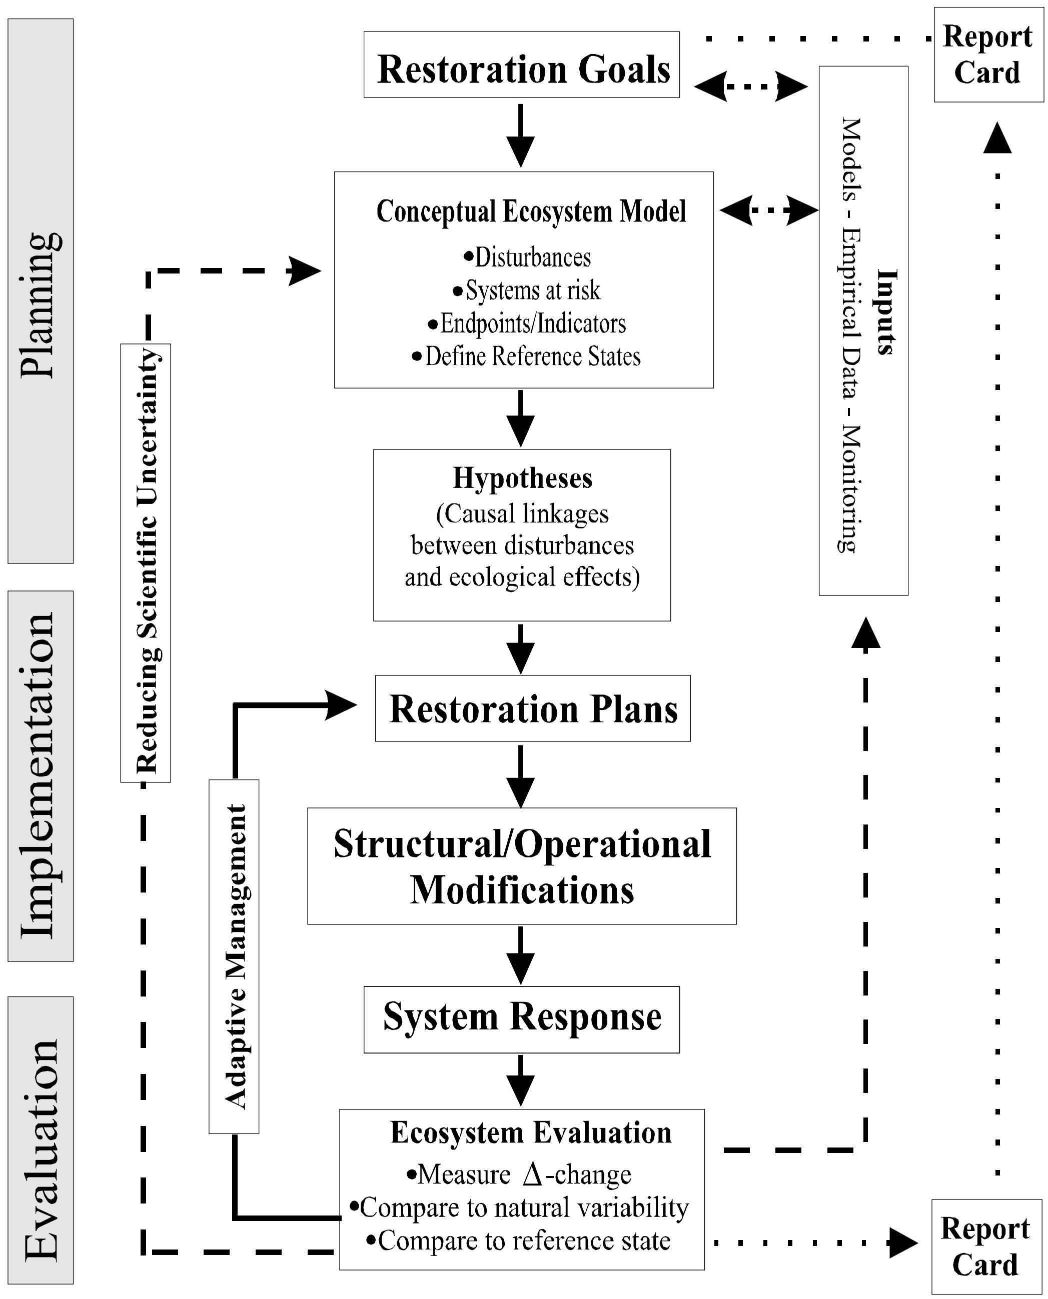

Figure XIV-1. A science-based strategic process for the south Florida restoration program.

CHAPTER XV -- SCHEDULING, SEQUENCING, AND PRIORITIES

David L. Ferrell, FWS

A. Integrating Currently Authorized Projects

There are currently several congressionally authorized federal projects within the C&SF Restudy planning boundary. While authorized projects are considered a "future without project" condition in planning ecosystem restoration in South Florida, consideration must be given as to how these authorized projects are integrated into the larger restoration envisioned by the C&SF Restudy. Planning for a smooth integration of authorized projects will be critical during implementation of the larger C&SF Restudy.

Viewing the entire ecosystem, the northern Kissimmee River Basin and the southern Water Conservation Areas/Everglades have been subject to recent environmental restoration planning, reporting, and authorization. In the headwaters of the Kissimmee/Okeechobee/Everglades ecosystem lie the authorized Kissimmee Headwater Lakes Revitalization Project and Kissimmee River Restoration Project, while at the southern end of the ecosystem, some 200 miles south, lie the authorized Modified Water Deliveries Project and the C-111 Project. The C&SF Restudy is intended to provide a system-wide view of restoring and enhancing ecological conditions throughout south Florida. This entails further improvement on conditions in areas, such as the Kissimmee River and Shark River Slough, that are presently covered by congressionally authorized studies, and includes investigation of opportunities for solving hydrologic problems in all the portions of the C&SF system that lie between its northern and southern ends.

1. Kissimmee Headwater Lakes Revitalization Project

Authorized by Section 1135 of the Water Resources Development Act (WRDA) of 1986, the purpose of this project is to restore fish and wildlife resources and to provide the volume and timing of water discharges to enable restoration of the Kissimmee River. By elevating lake regulation schedules in five major lakes to between 52.5 feet and 54 feet NGVD, restoration of the necessary storage (an increase in seasonal storage capacity of 100,000 acre-feet) and discharge characteristics to restore flow to the Kissimmee River would be realized. Additionally, breaching the confining levees surrounding three lakes would restore an estimated 6,000 acres of short hydroperiod wetlands. Implementation of this project would supply a continuous minimum flow of 250 cfs to the restored Kissimmee River.

Based on the 1998 Save Our Rivers Land Acquisition and Management Plan, 3,222 acres of land remain to be acquired to fully implement the Kissimmee Headwater Lakes Revitalization Project. Completion of land acquisition is critical to realize restoration benefits and to restore flow to the Kissimmee River.

The DOI recommends that the Kissimmee Headwater Lakes Revitalization Project be given priority and, if at all possible, be implemented prior to the construction and operation of the major project features of the C&SF Restudy in the central and southern Everglades. To accomplish this, remaining land acquisition in the headwaters area must be accelerated before lake levels are elevated. An estimated additional 100,000 acre-feet of water, delivered according to seasonal flow characteristics, is a significant amount of water to be stored, potentially contributing to enhancement of the natural system south of Lake Okeechobee.

2. Kissimmee River Restoration Project

The Kissimmee River Restoration Project was authorized by Section 1135 of the WRDA of 1986, and funding for preparation of a Feasibility Report/Environmental Impact Statement was authorized by WRDA of 1990. Backfilling the 30-foot deep Canal 38 and restoring flow to over 25 miles of presently isolated river channel would restore an estimated 24,000 acres of floodplain wetlands and associated fish and wildlife resources. The project would also provide more natural seasonal flow to Lake Okeechobee.

Land acquisition necessary to restore the Kissimmee River in accordance with the Level II Backfilling Plan is nearly complete. Of a total project area of 62,628 acres, only 334 acres remain to be purchased.

The DOI recommends that the current scheduled completion date of 2011 be adhered to, as the completion of river restoration is not anticipated to disrupt restoration efforts to the south, provided the additional water is delivered to the remaining natural system in an uninterrupted seasonal flow pattern.

3. Modified Water Deliveries Project

This project has been in the planning stage for a number of years. Authorized by the Supplemental Appropriations Act of 1984, the purpose of the project is to improve the timing, quantity, and distribution of water delivered to Everglades National Park by redirecting water in the Water Conservation Areas to Shark River Slough according to a rain-driven schedule.

Now under the direction of the interagency Southern Everglades Restoration Alliance (SERA), the project is undergoing additional modifications and is subject to closer scrutiny due to its direct hydrological and structural connection with project components of the C&SF Restudy. For example, authorized structural modifications to the L-67A and L-67C levees for the Modified Water Deliveries Project by constructing gated culverts and spillways needs to be re-examined in light of the proposed series of notched weirs proposed for the C&SF Restudy. Additionally, passage of flow under the Tamiami Trail, critical for rehydrating northeast Shark River Slough, needs to be re-assessed to meet the restoration goals of the Initial Draft Plan of the C&SF Restudy.

4. C-111 Project

This authorized project has a lengthy planning history. Originally authorized as an addition to the C&SF Project by the Flood Control Act of 1962, the C-111 Project has been further modified by authorization of the ENP-South Dade Conveyance System in 1968 and the Everglades National Park Expansion Act of 1989. The purpose of the project is to restore natural values in the ENP and maintain flood protection within the C-111 basin east of the L-31N and C-111 canals. A Final Integrated Reevaluation Report/Environmental Impact Statement was completed in May 1994 and recommended a preferred alternative to meet these project purposes. The C-111 Project is also managed by SERA.

A significant assumption utilized in formulating the preferred alternative was that the volume of water entering the C-111 basin was not expected to increase. Additionally, it was recognized that the C&SF Restudy, Modified Water Deliveries Project, the SFWMD's Lower East Coast Water Supply Study, and on-going Everglades litigation would likely effect the operations in the C-111 basin in the future.

Similar to the Modified Waters Delivery Project, the C-111 Project is directly connected, hydrologically and structurally, to C&SF Restudy plans to restore Shark River Slough. Thus, the project features described for the C-111 Project will likely change as the C&SF Restudy is implemented. To avoid potentially removing structures and changing operational criteria for the C-111 Project as authorized, plans to implement the C-111 Project should reflect components (specific structural and operational features) described in the Initial Draft Plan for the C&SF Restudy.

DOI recommends that the identified project features of the C&SF Restudy be included in the C-111 Project and Modified Water Deliveries Project to ensure smooth integration of the two projects and to achieve maximum ecosystem restoration in the C-111 basin. Integrating these projects will require close coordination between the C&SF Restudy and SERA.

B. Water Preserve Areas

The Water Preserve Areas (WPAs) Feasibility Study, currently being conducted under the Central and Southern Florida (C&SF) Comprehensive Review Study, is developing a conceptual design for an interconnected series of marshlands, reservoirs, water treatment areas, and aquifer recharge basins. The objectives of the WPAs are to 1) hold more water in the natural system by reducing seepage losses from the Everglades; 2) capture, store, and treat stormwater currently lost to tide; 3) provide a buffer between the urban areas and the Everglades; and 4) protect and conserve wetlands and habitat values outside the Everglades. The WPAs are intended to provide additional regional storage to assist in meeting the future needs of all users - agriculture, urban, and the environment. Ecosystem restoration benefits that are anticipated include: improved water supply for restoring hydropatterns of the Everglades; improved water quality; and preservation of wetland habitat. The WPAs will be located on lands located along the eastern side of the Everglades Protection Area in western Palm Beach, Broward, and Dade counties.

Both the reconnaissance report which was completed in November 1994, and the project study plan which was completed in July 1995, for the Comprehensive Review Study of the C&SF, identified water preserve areas as a major element of the C&SF Restudy in the area between the Everglades and the Atlantic Ocean. The total area of the current study is 1,643,000 acres (2,567 square miles) which was subdivided into 2.5 acre grids for analysis (Water Preserve Areas: Land Suitability Analysis) (SFWMD 1997). The C&SF Restudy will initiate a separate Water Preserve Area Feasibility Study in the year 2000, leading to a Integrated Feasibility Report/EIS for the design and construction of this important project component.

1. Sequencing of Implementation. Before the full benefits of restoration of the Everglades can be attained, the WPA's must be operational. With the WPA's subject to a separate Feasibility Study, it is anticipated that the implementation of construction, subject to land acquisition efforts, of the estimated 43,492 acres of various water impoundments and new canals will be accelerated early in the next century. Implementation of the WPA plan should be timed to occur prior to, or at least concurrent with, the implementation of the other C&SF Restudy project features.

2. Land Acquisition. According to the 1997 Save Our Rivers report (SFWMD 1998), 66,400 acres of land are required to implement the conceptual design. Currently, approximately 10,627 acres have been purchased or are in public ownership, leaving 55,773 acres yet to be purchased. With continued development pressure in the western portions of Palm Beach, Broward and Dade counties, it is imperative that land acquisition be given a high priority to ensure the benefits of the WPA's are realized before the "window of opportunity" for land acquisition is foreclosed. Priority land acquisition areas, based on factors such as importance of location and the level of development potential, need to be identified. Land acquisition funding then needs be secured and these critical areas purchased.

3. Prioritizing Management of Fish and Wildlife Resources within the WPA's. Over the last 100 years, the marshes of the East Everglades have been systematically eliminated due to agricultural and urban development. Large acreage of short-hydroperiod marshes, critical to the life-cycle of many water birds when water levels in the WCAs are high, no longer exist. Exotic invasive species, particularly *Melaleuca* and Brazilian pepper, now occupy significant portions of the WPA's. It is essential that fish and wildlife resources be integrated into the planning for the management of the WPA's. Priority fish and wildlife planning objectives include: 1) devising an aggressive plan for the perpetual removal of invasive exotics (both plants and animals), 2) managing the WPA's to maximize short-hydroperiod marshes for foraging water birds, particularly during high water events in the WCAs, 3) designing project features to enhance fish and wildlife resources, such as vegetated buffer zones between developed and natural areas and creation of vegetated islands within the deeper impoundments for as refugia for nesting/foraging water birds and other wildlife, and 4) ensuring adequate water quality. Public access to the WPA's should be carefully planned to avoid and minimize sensitive nesting/breeding areas during critical periods.

C. Water Conservation Areas

1. Adaptive Management. The remaining Everglades are now contained in the Water Conservation Areas of central and southern Florida. Establishing the priorities for ecological restoration of this estimated five million acre area will be complex, and will be subject to the process of adaptive management. Adaptive management focuses on the importance of building upon the ability to learn about ecological systems and to incorporate new information into the restoration process. Hypotheses are formed, tested, and revised in a systematic way to produce the greatest amount of useful information which is utilized to guide future restoration efforts.

The adaptive management process entails four basic steps: 1) develop conceptual models (landscape-scale ecological models of south Florida have been developed), 2) develop causal hypotheses (hypotheses have been developed to define the sources of ecological problems and to identify management actions necessary to correct those problems), 3) develop a monitoring program (currently under development), and, 4) conduct adaptive assessments (compare actual ecological responses to the hypotheses, evaluate effectiveness and adjust restoration efforts as necessary).

The DOI recommends that the adaptive management process be formalized and that at each step in the restoration process, appropriate modeling/testing be conducted and adjustments to restoration be implemented. This process would ensure that the most available scientific information is integrated into restoration decision making.

2. Sequencing of Implementation. Sequencing the necessary actions to restore the WCAs will require linking hydrologic performance to ecological performance. Priority for implementation should focus on increasing water storage and reducing seepage. Three basic steps, conducted in the following order, would accomplish this:

a) <u>Optimize operation of existing infrastructure</u>: This would be the first step in improving hydrologic, and concurrently, ecologic performance. Establishing new operational criteria to begin returning hydrologic conditions to NSM targets inside the WCAs is the focus of this step;

b) <u>Construct and begin operating the necessary infrastructure outside the WCAs</u>: This important step, conducted concurrently with step 1, involves the construction of such features as the water preserve areas north of Lake Okeechobee and in the Caloosahatchee and St. Lucie basins to store water for restoration, the Storm Water Treatment Areas to the north of the WCAs to provide clean water and distribute water in a more historical manner, and the Water Preserve Areas of Palm Beach, Broward and Dade counties to reduce seepage to the coast and to provide flows to northeast Shark River Slough, the ASR facilities to store water for release during the dry season, and water re-use facilities to conserve water lost to the coast and returned to the natural system;

c) Decompartmentalize and construct/operate infrastructure inside the WCAs: This final step, which could be phased in near the end of step two, would build on the first two steps and would lead to fulfillment of established restoration goals. With seepage reduced and adequate water storage realized, the internal infrastructure of the WCAs and decompartmentalization could then proceed. Attention should be given to the fact that decompartmentalization will result in less control for managing water in the WCAs. Therefore, adequate storage and seepage control are essential before decompartmentalization begins in earnest.

D. Indian River Lagoon Feasibility Study

The Indian River Lagoon Feasibility Study is the second feasibility study to be authorized under the Comprehensive C&SF Restudy. The purpose of the study is to examine alternatives which address the water resource problems and needs within the C&SF project canal watersheds in Martin and St. Lucie counties. The three watersheds in the 1,160 square mile study area include the C-44 (St. Lucie Canal) and the C-23, C-24 and C-25 canal system. Currently, sixteen sites totaling 58,000 acres are under review as WPAs (COE 1996). Several flow-ways, designed to improve water quality, increase short-hydroperiod wetlands, and reduce sediment loading to the estuaries are also proposed.

The study will determine the feasibility of making structural and operational modifications to the C&SF project for environmental quality, water supply and other project purposes. The study is anticipated to conclude in 2001.

1. Implementation Timing and Priorities. Similar to the WPAs discussed above, it is critical to identify and purchase available land before opportunities are foreclosed. The DOI recommends that **siting WPAs and flow-ways and land acquisition**, in that order, be identified as the top priorities for the Indian River Lagoon Feasibility Study.

While the C-44, the primary discharge canal from Lake Okeechobee to the east coast of Florida, is hydrologically and structurally linked to Lake Okeechobee, the remaining WPAs are separable and can be constructed and operated independently from the remainder of C&SF Restudy components. Thus, the DOI recommends that the Indian River Feasibility Study proceed as scheduled and not be delayed until all C&SF Restudy component features are planned and/or implemented. The exception to this is the C-44 canal, which is tied to Lake Okeechobee regulation schedules. Until the Headwater Lakes Revitalization Project and Kissimmee River Restoration projects are implemented and additional flows (estimated at 100,000 acre-feet) are delivered to Lake Okeechobee, the final operation of WPAs in the C-44 basin will be difficult to finalize.

2. Sediment Removal. The SFWMD studied the feasibility of removing muck from the estuary to enhance fishery production and overall productivity in the estuary (SFWMD 1984). While this study identified the ecological benefits of muck removal, it recommended additional study and initiation of a muck removal demonstration project. On a larger scale, however, the St. Johns

River Water Management District (SJRWMD) is examining a similar muck removal program in the northern portions of the Indian River Lagoon. The DOI recommends that, in addition to studying a pilot muck removal demonstration project, a more holistic approach to muck removal, including both the SFWMD and SJRWMD and other agencies, be pursued. System-wide muck removal priorities and funding needs should be identified.

3. Environmental Considerations for Siting WPAs and Flow-ways. The DOI recommends that environmental considerations be included in the siting process. The principles of avoiding important habitats, expanding the spatial extent of wetlands, improving water quality and compensating for unavoidable habitat losses are important to keep in mind. These are summarized as follows:

a) Avoid Areas of High Habitat Value: These habitats, both wetland and upland, should be avoided to the maximum extent possible. Particular attention is needed for areas supporting threatened and endangered species. The DOI will implement the FWS Mitigation Policy (FWS 1981) to designate resource values and compensation needs during future planning;

b) Compensate for Unavoidable Habitat Losses: For those unavoidable habitat losses, a mitigation plan should be developed and appropriate measures incorporated to off-set those losses;

c) Implement Fish and Wildlife Enhancement Measures: As discussed in the Water Preserve Areas section above, the DOI recommends that fish and wildlife enhancement features such as water bird nesting islands, foraging sloughs, and deeper water fish refugia, vegetated buffer zones and water quality maintenance be factored into the WPAs and flow-ways. An exotic species removal program should also be included in these measures.

E. Southwest Florida Feasibility Study

For the southwest Florida region, the Restudy alternatives include components that will provide storage reservoirs in the Caloosahatchee River basin for capturing basin runoff and regulatory releases from Lake Okeechobee. While these facilities may provide improvements to this basin, additional water resource problems and opportunities exist for southwest Florida that, to date, have not been fully examined in the Restudy. The COE and SFWMD have proposed a separate feasibility study for southwest Florida as a part of the Comprehensive C&SF Restudy. In Fiscal Year 1999, a reconnaissance study will be initiated to identify water resource problems and opportunities, leading to the initiation of a full feasibility study in Fiscal Year 2000.

Several initiatives with public and private interests have formed to address the problems associated with the increasing development pressure being experienced in southwest Florida. Some of these include the Southwest Florida Project Coordination Team, Southwest Issues Group of the Governor's Commission for a Sustainable South Florida, Southwest Coast Ecosystem Management Team, Estero Bay Agency for Bay Management, Southern Golden Gate

Technical Committee, Big Cypress Basin Science Steering Committee, Southwest Focus Group and others. In addition, the COE is conducting a Programmatic EIS to address the cumulative effects of section 404 wetland permitting in the region. The DOI recommends that the feasibility study incorporate the findings of these types of initiatives in future planning efforts.

Most of southwest Florida lies outside the spatial extent of the South Florida Water Management Model (SFWMM) and the Natural System Model (NSM). The SFWMM covers the Big Cypress National Preserve and the southern fringing mangrove system east of State Road 29, but does not include most of Hendry County nor those portions of Lee and Collier counties west of State Road 29. The NSM has slightly broader coverage, including a larger part of Hendry County, but not the western portion of Lee and Collier counties. Existing hydrological models used by the SFWMD, Big Cypress Basin, and others primarily focus on stormwater management and are inadequate in providing essential information regarding how changes in the hydrologic regime will affect the ecosystem.

Because the existing models do not provide adequate coverage for southwest Florida, a Southwest Florida Water Management Model (SWFWMM) and expanded coverage of NSM should be developed (Figure XV-1). The models should be characterized by 1) a grid-based (spatially explicit) connected surface and surficial groundwater model that includes existing water control structures and 2) a corollary model without control structures that simulates the natural response of the system to rainfall. The model should be designed to seamlessly connect to both the SFWMM and NSM to minimize boundary effects and address boundary issues. As recommended in Chapter XX of this report, development of the new SWFWMM should integrate water quality modeling.

In the interim, there are a number of identified Critical Projects (CPs) and several Other Project Elements (OPEs) in southwest Florida that DOI recommends not be delayed pending completion of the feasibility study. In particular, the Southern Golden Gate Estates Hydrologic Restoration, a CP, would restore an estimated 100 square miles of over-drained habitat and would help stabilize base flows to the Ten Thousand Islands National Wildlife Refuge. This project and others should move forward as planned and be integrated into a larger restoration plan developed during the feasibility study.

1. Restoration Planning Objectives. The Working Group of the South Florida Ecosystem Restoration Task Force has identified the following restoration objectives for Southwest Florida. The DOI supports these objectives and recommends they be used to guide the feasibility study:

a) Restoration of more natural timing, distribution, and quantities of fresh water into the coastal estuaries;

b) Improvement to water quality by addressing point source and non-point source discharges;

c) Restoration of degraded habitat and minimization of further habitat loss;

d) Protect of floodplains from further development to minimize needs for additional drainage projects;

e) Improvement of aquifer recharge, and protection of ground water from pollutant loading and saltwater intrusion;

f) Promotion of best management practices for agriculture, development, local governments and the general public; and,

g) Protection, buffering and management of existing public lands.

2. Planning Priorities. The DOI provides the following recommended planning priorities for the Southwest Florida Feasibility Study:

a) Priority should be given to developing a comprehensive hydrologic model for southwest Florida to define regional restoration needs;

b) Identified CPs and OPEs should not be delayed by completion of the feasibility study; rather, these projects should move forward to derive more immediate ecological restoration benefits; and,

c) The feasibility study should integrate the best science-based knowledge from the initiatives described above, ecological experts, engineers, and others.

Successful watershed planning in southwest Florida would reduce the threat of additional fragmentation and compartmentalization and avoid a repetition of the impoundment of the remnant Everglades that has taken place to the east.

F. Uncertain Technologies

It is extremely important that, early in the Restudy planning process, technologies upon which the Restudy relies upon for implementation and ecological restoration be proven and demonstrated to work. Pilot studies and demonstration projects will be necessary to document with some level of confidence that uncertain technologies will meet DOI expectations.

1. Aquifer Storage and Recharge (ASR) ASR is an important water management component of the C&SF Restudy. Pumping water down deep wells into the underground aquifer during the wet season allows for water to be retrieved during the dry, high-demand periods. ASR can accelerate restoration by reducing dependency on the natural system during periods of drought, reduce peak flows to tide, manage saltwater intrusion, and generally restore more environmentally compatible water levels in the remaining Everglades.

Before ASR can be widely adopted, however, technical issues need to be resolved. There remain concerns about adequate characterization of the storage zones and confining layers, hydraulic characteristics of aquifers with test wells, uncertainty regarding recovery rates, water quality and regulatory issues, effects on subterranean invertebrates, and long-term effects of cycling water, to name a few.

The proposed ASR program for Lake Okeechobee involves over 200 ASR wells to store significant amounts of water to be used during the dry season. The results of a recent ASR test well in Okeechobee County was deemed inconclusive by some researchers, demonstrating the need for more rigorous testing of ASR feasibility.

The DOI, with the USGS as the lead, recommends that two major ASR initiatives be given priority:

a) Development of a regional hydrogeologic model to predict the areas of greatest potential for successful site-specific ASR feasibility projects based on information collected from regional hydrogeologic characterization of receiving waters and injection water sources; and

b) ASR pilot wells to test the injection rates and recovery rates of injected waters.

2. Water Reuse The need for water reuse has been subject to extensive debate by the C&SF Restudy Team. Reuse water (treated wastewater) has been modeled as the only means of meeting some of the ecological restoration goals (e.g. Biscayne Bay). Additionally, there is a general recognition that the more water that is reused, the more water there will be for restoration of the remaining system. Reuse, however, is expensive, and must be justified. The DOI continues to recommend that opportunities to wisely reuse water, particularly in Dade, Broward, and Palm Beach counties, be pursued in the C&SF Restudy.

G. South Miami-Dade County

1. Model Lands Acquisition The Model Lands, a body of wetlands in Miami-Dade County that form a wedge between Palm Drive on the north and US 1 on the west, have been identified by the county as eligible for the Environmentally Endangered Lands (EEL) Program. This area has been degraded by canals and exotic plants to varying degrees, but remains a significant feature in providing surface flow into Barnes and Card Sounds. Hydrologically these two bodies of water are upstream extensions of Biscayne Bay.

The EEL Program authorizes and funds willing seller purchases of private lands for environmental purposes, and Miami-Dade County has begun to purchase tracts in the Model Lands. A large segment of the Model Lands also constitutes a mitigation bank operated by Florida Power and Light. Once most of the private lands are purchased by the county, the combined acreage of EEL properties and the FP&L mitigation bank will offer outstanding opportunities for storing and redistributing surface water that flows into the coastal estuaries.

Progress on EEL purchases in the Model Lands has languished in recent years. If this program were accelerated, it could significantly enhance and complement Restudy efforts to achieve restoration goals.

Completing this land acquisition effort will make possible a range of restoration activities in concert with the Restudy, that will not otherwise be possible. The best scientific knowledge and the most effective scientific modeling will be meaningless without a land base upon which to apply them. This EEL project should be completed no later than 2003.

2. South Dade Wetlands Addition As with the Model Lands, the South Dade Wetlands Addition is a body of somewhat degraded wetland parcels eligible for purchase by the county under the Environmentally Endangered Lands program. These wetlands, interspersed with similar tracts that are already under county ownership, are largely west of Biscayne National Park and north of the Model Lands and form part of the Biscayne Bay drainage. Surface water flows from these lands into canals that discharge into the bay. These wetlands provide opportunities to store and distribute surface water that is vital to Biscayne Bay's estuarine restoration and, like the Model Lands, provide opportunities to enhance and complement Restudy objectives. This EEL project should be completed no later than 2003.

3. L-31-E Redistribution Project This project will add culverts and spreader canals to the L-31-E levee that now forms a barrier to sheetflow into Biscayne Bay. This project has been ranked high as a critical project for Corps of Engineers funding, but is not yet funded. Because it does not depend on land acquisition, this rare opportunity to replicate sheetflow directly into Biscayne Bay can be the first true restoration project to be completed in this drainage. It should be targeted for completion by 2002.

4. Study of Groundwater Discharge into Biscayne Bay The US Geological Survey is conducting a study to create a model of groundwater flows into Biscayne Bay. This study examines the significance of present groundwater flows into the bay and how those flows might be altered by changes in canal flows in the same area. Little is now known about groundwater flows into the bay, and a successful model will be able to answer questions that are fundamental to any effort to restore estuarine conditions. To ensure timely application, the model should be available by 2000.

5. Biscayne Bay Hydrodynamic Model This project is funded by the Corps of Engineers and involves Miami-Dade County and Biscayne National Park, is developing a circulation model for Biscayne Bay. It will be an essential tool in the effort to manage groundwater and surface water inflows to replicate pre-development estuarine conditions. Until this model is completed, decisions to alter freshwater delivery to the bay will continue to be based more on estimates of the consequences than on scientific evaluation. A second phase of this effort will examine water quality in the same area. As with the groundwater model, this circulation model should be ready to use by 2000.

The EEL Program authorizes and funds willing seller purchases of private lands for environmental purposes, and Miami-Dade County has begun to purchase tracts in the Model Lands. A large segment of the Model Lands also constitutes a mitigation bank operated by Florida Power and Light. Once most of the private lands are purchased by the county, the combined acreage of EEL properties and the FP&L mitigation bank will offer outstanding opportunities for storing and redistributing surface water that flows into the coastal estuaries.

Progress on EEL purchases in the Model Lands has languished in recent years. If this program were accelerated, it could significantly enhance and complement Restudy efforts to achieve restoration goals. Completing this land acquisition effort will make possible a range of restoration activities in concert with the Restudy, that will not otherwise be possible. The best scientific knowledge and the most effective scientific modeling will be meaningless without a land base upon which to apply them. This EEL project should be completed no later than 2003.

H. Lake Okeechobee

The COE is currently re-evaluating the regulation schedule for Lake Okeechobee. Three time frames are applicable for possible modification of the lake's regulation schedule. The meteorological forecasting described by Zhang and Trimble (1996) could be applied in any of these three phases, and the options available to modify the regulation schedule will be less constrained as water managers move through the three phases. The DOI recommends that immediate modification to the schedule should only be allowed if it can be demonstrated that no additional phosphorus loading to the Everglades Protection Area will occur. Compliance with the Everglades Settlement Agreement will restrict the options available to water managers until STAs 3 and 4 are brought on-line. A second phase of potential changes to the lake's regulation schedule will open up new possibilities once STAs 3 and 4 are operating, but will still be constrained by lack of water storage options outside of the lake. This will allow Lake Okeechobee to discharge more water to the Everglades Protection Area without violating the Settlement Agreement. The third phase will involve construction of the additional storage around the lake and the implementation of large-scale ASR around the lake, as projected in the Restudy's Initial Draft Plan. If fully implemented, this phase should culminate in the projected benefits to the lake's littoral zone.

I. Estuaries

Altered and unnatural flow situations in coastal waters have created a loss of historically abundant estuarine species such as red drum (*Sciaenops ocellata*), black drum (*Pogonias cromis*), and eastern oyster (*Crassostrea virginica*), the loss of juvenile fish habitat, and an increase in stress tolerant species such as the gulf toadfish (*Opsanus beta*) (Serafy *et al.*, 1997).
In addition to loss of species, many fishes in Biscayne Bay exhibit tumors and deformities, probably as a result of water and/or sediment quality factors. As discussed in Chapter V, fish with tumors, lesions, and scale and deformities have also been found in the St. Lucie River and estuary. The Restudy project design should benefit all the coastal receiving waters by providing the

quantity and quality of flow needed to support optimum quality habitat for wildlife, fish, and other aquatic resources.

1. Implementation Priorities A priority objective for coastal waters in the Restudy is to maintain adequate mean monthly flows in order to maintain favorable salinities and water quality conditions for estuarine organisms. This involves input of fresh water and nutrients into the systems in appropriate quantities and timing to support primary and secondary productivity. High volume discharge events such as those in the St. Lucie estuary, Lake Worth Lagoon, and Caloosahatchee estuary that damage aquatic environments should be eliminated.

With or without the Restudy, several projects should be accomplished to benefit coastal waters. A Critical Project proposed for Ten Mile Creek Water Preserve Area should be funded, planned, and implemented as soon as possible to provide protection for the St. Lucie estuary. Two Other Project Elements (OPEs) can immediately benefit Biscayne Bay and should be given priority: 1) South Dade Agriculture: Rural Land Use and Water Management Plan and 2) Biscayne Bay Coastal Wetlands.

Many concerns for the estuaries have to be addressed in the detailed design phase. The assumption made for Biscayne Bay has been that "re-use" water or tertiary treated domestic wastewater will be available and appropriate for use in this sensitive and valuable marine environment. Alternative sources of water other than "reuse" water and ASR well water should be identified and investigated as part of the detailed design process.

Additional flow is also needed through Shark River Slough to Florida Bay to reach NSM targets. In the Model Lands/C-111 Area, additional flow is needed to reach Joe Bay and Long Sound in Florida Bay. The water should be of appropriate quality and timed so as not to cause further perturbations in Florida Bay.

2. Further Environmental Considerations The DOI has two recommendations regarding the Miami River and the estuaries in southwest Florida. The Miami River is experiencing reduced flows; we recommend that if extra water is ever available in this area of the project, moderate flows should be sent down the Miami River to keep the water flushing out into Biscayne Bay, without transporting contaminated bottom sediments. For southwest estuaries, modeling of Restudy alternatives predicted better flows overall under Alternative D13 than under Alternative D13R. Flow dynamics need to be modeled in greater detail for the southwest coast to determine the cause of this apparent decrease in flow to this region.

CHAPTER XVI -- THREATENED AND ENDANGERED SPECIES

Heather McSharry and Robert Pace, FWS

Detailed findings and recommendations regarding the effects of the C&SF Restudy on Federally-listed threatened and endangered species are found in the Biological Opinion that accompanies this FWCA Report. This chapter provides a brief summary of those findings.

The Florida panther (*Felis concolor coryi*), red-cockaded woodpecker (*Picoides borealis*), Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), and five species of pine rockland plants in Dade County are not likely to be affected by the Restudy.

The bald eagle (*Haliaeetus leucocephalus*), Audubon's crested caracara (*Polyborus plancus audubonii*), eastern indigo snake (*Drymarchon corais couperi*), and the Florida scrub jay (*Aphelocoma coerulescens*) may be adversely affected by the Restudy, but we do not anticipate that the level of adverse effect will be likely to jeopardize the continued existence of any of these species.

The snail kite (*Rostrhamus sociabilis plumbeus*) would likely be slightly benefitted overall by the Restudy through improved quality in foraging habitat and a reduction in high water damage to nesting substrate. Although these beneficial effects would slightly improve the species' chances for recovery, it must be noted that recovery of the snail kite in Florida is considered to be more dependent on maintaining or expanding widespread suitable habitat in the Kissimmee Chain of Lakes and in the St. Johns marsh. The Kissimmee Chain of Lakes will not be significantly affected by the Restudy, and the St. Johns marsh is outside its geographic scope. Although the Restudy may provide moderate net gains in habitat quality for the snail kite, the proposed changes are not beneficial in all areas; some areas will likely be improved, while others will be degraded. Therefore, **sequencing of project elements** will be crucial in assuring that improved habitat quality is already available to offset anticipated losses in other areas. This will give the species time to adjust to the changing landscape with a low level of risk.

The wood stork (*Mycteria americana*) should be benefitted overall due to improved timing and volume of water flow that should substantially increase nesting success, particularly in the estuarine areas of Everglades National Park, adjacent to Florida Bay.

Higher water levels in the northeastern portion of the Cape Sable seaside sparrow's (*Ammodramus maritimus mirabilis*) range are expected to improve habitat quality through a reduction in the fire frequency and a reversal in the invasion of shrubs in an area that was previously more suitable habitat. The central population of the Cape Sable seaside sparrow near Mahogany Hammock is not likely to be affected by the Restudy. The crucial subpopulation west of Shark River Slough should be benefitted by the Restudy.

The Okeechobee gourd (*Cucurbita okeechobeensis okeechobeensis*), American crocodile (*Crocodylus acutus*), and West Indian manatee (*Trichechus manatus*) are expected to be greatly benefitted by the Restudy.

The Initial Draft Plan appears to be the most favorable overall to promote recovery of listed species.

Literature citations supporting these findings are available in the Biological Opinion.

CHAPTER XVII -- FISHING AND WILDLIFE - RELATED RECREATION

D. Timothy Towles, Florida Game and Fresh Water Fish Commission

A. Introduction

The C&SF Restudy encompasses a very large geographic area delimited by the South Florida Water Management District (SFWMD) boundary and includes a number of public properties that are managed by the Florida Game and Fresh Water Fish Commission (GFC) for their recreational value related to fish and wildlife. Those areas that are presently thought to be little affected, if at all, by the Initial Draft Plan (Alternative D13R), but which lie within the drainage basin, include six Type I wildlife management areas: Three Lakes Wildlife Management Area (WMA) and Kicco WMA in Osceola County, Arbuckle WMA in Polk County, Kissimmee River WMA in Highlands and Okeechobee counties, Fred C. Babcock/ Cecil M. Webb WMA in Charlotte County, and Frog Pond WMA in Dade County; and one Type II wildlife management area (Avon Park Air Force Base) in Polk and Okeechobee counties. Type I wildlife management areas are public hunting and recreation areas operated by the GFC in cooperation with private, State, and Federal landowners. Type II wildlife management areas are public hunting and recreation areas operated by the landowner in cooperation with the GFC. Those wildlife and (WEAs) that are presently not expected to be affected include the John G. and Susan H. Dupuis WEA in Palm Beach and Martin counties and the CREW WEA in Lee and Collier counties. Other areas managed by the GFC that are not expected to be influenced by the C&SF Restudy include the Lake Harbor and Terrytown Public Waterfowl Areas (PWA). However, the use of Terrytown as a Public Waterfowl Area may be temporary, because this area was acquired by the SFWMD for use as a stormwater treatment area as part of the Everglades Forever Act. The remaining wildlife management areas detailed in this report are the ones that we thought had the most potential for being affected if Alternative D13R were implemented.

A measure of the amount of recreational hunting in each of those wildlife management areas that are anticipated to change under the C&SF Restudy is portrayed in Table XVII-1. The level of monitoring for harvest pressure varies among wildlife management areas due to budgetary and staffing constraints, and to differences between areas in check station operation and amount of hunter use. For example, the highest 5-year mean (13,306 man-days) for harvest pressure recorded in the Everglades region was for the Big Cypress Wildlife Management Area (Big Cypress WMA) (Table XVII-1). Harvest pressure information for this area was derived from vehicle counts on Saturdays of every weekend during the 93 days comprising the archery, muzzle-loading, and general gun seasons. By contrast, harvest pressure data were not collected in the Holey Land and Rotenberger WMAs during portions of some hunting seasons. For instance, during the 1997-98 season, harvest pressure data were gathered only on the opening weekends of muzzle loading and general gun-walk seasons. Consequently, the 5-year mean figures for harvest pressure in the Holey Land (635 man-days) and Rotenberger (766 man-days) WMAs should be viewed as minimal estimates of harvest pressure that are not directly comparable to areas such as the Big Cypress WMA, where the hunting pressure is more consistently measured.

B. Everglades and Francis S. Taylor Wildlife Management Area

The Everglades Wildlife Management Area (EWMA) is a Type I wildlife management area located in southwestern Palm Beach, western Broward, and northwestern Dade counties, Florida. The EWMA consists of Water Conservation Areas (WCAs) 2 and 3 and encompasses approximately 671,831 acres (Figure XVII-1). Different hydrological regimes exist due to the division of WCA 2 into two compartments forming WCA 2A and WCA 2B, and the division of WCA 3 into two compartments forming WCA 3A and WCA 3B (Francis S. Taylor Wildlife Management Area). Consequently, wildlife populations and associated recreational opportunities vary considerably between these compartments, necessitating the implementation of an array of management strategies that also varies with regional weather patterns. The principal landowners of the EWMA are the South Florida Water Management District (SFWMD) and the State of Florida's Board of Trustees, with the remainder owned by other public agencies and private individuals. Water Conservation Areas 2 and 3 were designated as the EWMA in 1952 and are operated by the GFC under the terms of a cooperative management agreement with the SFWMD.

The Everglades WMA has traditionally been used by the public for a variety of recreational activities including hunting, fishing, frogging, airboating, camping, and nature appreciation. Utilization of the interior marsh is limited due to physical constraints and lack of access. Airboats are the primary mode of transportation into the marsh when surface water is present, whereas all-terrain vehicles (ATVs), tracked vehicles, and swamp buggies are used to access the area when water levels recede below ground.

Several other recreation areas are located along the boundary of the EWMA: Loxahatchee Recreation Area, Sawgrass Recreation Area, Everglades Holiday Park, and Mac's Fish Camp. These facilities, along with several others operated by the Miccosukee Indians on the Tamiami Trail, provide amenities such as boat ramps, camping facilities, boat rentals, airboat tours, fishing guides, bait and tackle supplies, and food to the general public. During 1997, commercial airboat tours out of Everglades Holiday Park transported 116,306 tourists into nearby Everglades canals and marsh.

Frogging is permitted throughout the year. This is a favorite past-time of many airboaters. Although frogging occurs throughout the EWMA, the portion of WCA 3A south of Alligator Alley has traditionally harbored the best frog populations and consequently has received the most use (GFC 1960).

Hunting for selected game species is allowed during the fall-winter period. However, check stations erected to monitor harvest pressure and collect biological information are only operated during the fall deer season. Consequently, there is no information for hunting pressure on other game species. The mean time spent on deer hunting in the EWMA, based on the five-year period of 1989-93, was 1,984 man-days (Table XVII-1). However, this level of hunting pressure is exceptionally low for the EWMA due to the unprecedented high water event of 1994-95 that nearly eliminated the area's deer herd and necessitated the complete closure of the deer season for three years (Table XVII-1). Other game often sought by hunters in the EWMA, when hydrological conditions are favorable, include waterfowl, snipe, and wild hogs.

The canal system of the EWMA also supports a very popular sport fishery, with fishing permitted throughout the year. Two of the areas that have traditionally supported some of the best fishing and consequently have been monitored by the GFC's Everglades fisheries program through creel surveys are the L-35B/ L-38E canals and the L-67A Canal. Creel survey data collected for the five-year period of 1985-89 in the L-35B/L-38E canals estimated a fishing effort ranging from 55,659 hours in 1985-86 to 128,430 hours in 1986-87, with an annual mean of 81,665 hours (Table XVII-2). A five-year mean total of 79,755 fish were harvested, with a harvest success rate of 0.91 fish per hour (Table XVII- 2). Any body of water in Florida that maintains a harvest success rate of at least 0.5 bass per hour is considered to be a quality fishery (GFC 1998c). A no-consumption advisory is in effect for bass due to high levels of mercury in the EWMA. Consequently, anglers routinely release their fish, which has resulted in high populations of 2- to 5-pound bass (J. Fury, GFC, personal communication 1998).

Fishing effort in the L-67A Canal for the seven-year period of 1990-97 ranged from 25,848 hours in 1992-93 to 58,150 hours in 1995-96, with an annual mean of 43,167 hours. The seven-year mean total recorded harvest was reported to be 41,765 fish, with a mean success rate of 0.98 fish per hour. The results from these creel surveys are derived from a six-month sampling period during each of the years, so these data do not include fishing effort expended during the remainder of those years. Although creel surveys were discontinued for the L-35B/L-38E in 1990, observations by fisheries personnel indicated that the fishing effort in this canal system appeared to be comparable to that expended for the L-67A for the time period of 1992-97. High water levels in the EWMA since 1993, however, have contributed to below-normal fishing effort due to the dispersion of fish into the adjoining marsh, resulting in lower catch rates. It should also be noted that even though the year 1995-96 experienced the highest amount of fishing effort in the L-67A canal over the past seven years (Table XVII-2), access was greatly curtailed due to the closure of the boat ramps at the primary access site of Everglades Holiday Park for about three months and the closure of the canal itself for about one month.

Although these two canal systems represent no more than 16% (assuming a total of 330 miles) of the total canal mileage within the EWMA, they receive a disproportionate amount of the fishing pressure from boats. Due to staffing and budgetary constraints, no recent creel survey data have been collected for the rest of the canal system within the EWMA. There is also a considerable amount of bank fishing in the canals adjacent to State Road 27, I-75, and the Tamiami Trail.

Due to the institution of slot possession limits on largemouth bass in 1996, it became necessary to issue regulation exemption permits for bass tournament participants. Outside of Lake Okeechobee, the canal system within the EWMA has proven to be the most popular location for holding bass tournaments. There are approximately 65 fishing clubs in the Everglades region, many of which periodically host tournaments. In fiscal year 1996-97, 91 of the 116 bass tournaments (78%) in the Everglades region (excluding Lake Okeechobee) were held in the EWMA. During that year, 3,202 participants landed 5,061 bass, with a combined weight of

13,906 pounds. Thirty-seven of these bass caught in WCA 3A weighed more than 8 pounds, and the largest weighed almost 10 pounds. During fiscal year 1997-98, 117 of the 180 bass tournaments (65%) in the Everglades region (excluding Lake Okeechobee) were conducted within the canal system of the EWMA. In that fiscal year, 4,312 anglers landed 6,759 bass, with a combined weight of 16,920 pounds. Of these bass, 54 caught in WCA 3A weighed more than 8 pounds, and the largest weighed in at nearly 11 pounds. It is estimated that approximately 95% of the WCA 3A tournaments originate at Everglades Holiday Park, with most of the fishing pressure concentrated in the L-67A canal (J. Fury, GFC, personal communication 1998).

There are currently more than 65 privately constructed camps scattered throughout the EWMA. These camps consist of permanent buildings constructed by private individuals on tree islands or on pilings over the water. These camps are primarily used as weekend retreats and hunting camps.

C. Holey Land Wildlife Management Area

The Holey Land Wildlife Management Area is a tract of Everglades marsh encompassing approximately 35,350 acres in the southwest corner of Palm Beach County (Figure XVII-1). Title to this tract is held by the State of Florida's Trustees of the Internal Improvement Trust Fund, and the area is leased to the GFC for fish and wildlife management purposes.

The Holey Land WMA was a popular deer hunting area prior to its rehydration under the Holey Land Restoration Project. Since hydrological restoration was begun in 1991, the Holey Land WMA has undergone a transition in recreational use that has been more strongly oriented towards fishing in the perimeter canal and waterfowl hunting (GFC 1997g). Recreational access to the marsh areas may be achieved by airboat, ATVs, or tracked vehicles. Vehicle use is permitted in the Holey Land WMA from May 1 to the end of the duck season, except during specified big game hunts when further restrictions apply. Tracked vehicle deer hunts may be conducted under appropriate hydrological conditions if deer population indices indicate a sufficient population level.

The hunting pressure on the Holey Land WMA has ranged from 214 to 972 man-days during the time period extending from the 1993-94 through the 1997-98 seasons (Table XVII-1). However, due to a severe reduction in the deer herd as a result of the higher water regulation schedule adopted for the Holey Land WMA and above-average amounts of rainfall, the gun-vehicle hunt season was closed from the 1993-94 through the 1996-97 seasons. Also, only the archery season was open during the 1994-95 season. Consequently, the annual mean hunting effort for the years 1993-98 in the Holey Land WMA, using only the figures for those hunts that were open each season, was calculated to be 635 man-days.

Although waterfowl hunting has become popular in the Holey Land WMA since hydroperiod restoration began in 1991, no data on duck hunter use was collected until the 1996-97 season. During that season, a minimum of 266 man-days of hunting pressure were estimated for duck hunters, which surpassed the minimum estimate of 156 man-days expended by deer hunters during that season. During the 1997-98 season, man-days attributed to hunting in Holey Land were 392, with a reported harvest of 382 ducks and two deer. Although frogging is permitted in the Holey Land WMA, the hydrological regime and vegetative structure is not conducive to an exploitable frog population; the area therefore receives little pressure from recreational froggers (B. Sasse, GFC, personal communication 1998).

No creel surveys have been conducted in the Holey Land WMA by the GFC's Fishery Division; however, an attempt was made in 1996 by Division of Wildlife personnel to estimate fishing pressure by counting vehicles at boat ramps whenever they visited the management area. Fishing pressure was estimated to be 5,054 angler-days in 1996, with the majority of fishermen using the G-200 and G-201 boat ramps. From this survey, it was concluded that fishing had apparently become the primary recreational use in the Holey Land WMA(GFC 1997g).

D. Rotenberger Wildlife Management Area

The Rotenberger Wildlife Management Area is a tract of Everglades marsh comprising approximately 27,810 acres in the southwest corner of Palm Beach County, bordered to the east by the Miami Canal and to the south by WCA 3A (Figure XVII-1). The area is owned by the State of Florida under fee-simple title to the Trustees of the Internal Improvement Trust Fund and leased to the GFC for fish and wildlife management purposes (GFC 1997e).

The primary public use of the Rotenberger WMA has been deer hunting. Other game commonly sought include wild hogs and snipe. Although frogging and fishing are also permitted, these resources are in limited supply due to the short hydroperiods that presently exist in the area (GFC 1997e). Recreational access to the area can be achieved by ATVs, airboats, swamp buggies, or tracked vehicles during designated times of the year (May 1 to the end of the waterfowl season) when hydrological conditions are appropriate for each particular mode of transportation.

The hunting pressure on the Rotenberger WMA has ranged from 106 man-days during the 1994-95 deer hunting season to 946 man-days during the 1996-97 season. The low hunting pressure during 1994-95 could be attributed to the combined effects of extremely high water levels in the adjacent EWMA, a low deer population index, and the closure of all big game seasons except the archery season. The mean hunting effort for the five-year period from 1991-96 was reported as 766 man-days, using only those figures for the hunts that were open during that particular season (GFC 1998b).

E. Big Cypress National Preserve

The federally owned Big Cypress Wildlife Management Area comprises approximately 565,848 acres in northwestern Dade, eastern Collier, and northwestern Monroe counties (Figure XVII-1) with the game animal populations managed by the GFC under a cooperative agreement with the Big Cypress National Preserve (BICY).

Due to the great diversity of both upland and wetland habitats in the BICY, a wide array of game species are harvested from the area. A significant amount of the hunting pressure within the Big Cypress WMA takes place in the Corn Dance, Loop Road, and Stairsteps units, which, since 1991, have together accounted for almost half of the total hunting pressure during those years when all units are open to hunting (Table XVII-3). Due to the high level of interest in the big game general gun hunting season, this hunt is regulated by a weekly quota that has been consistently reached during the past six years for the Corn Dance and Loop Road units, but not in the Stairsteps unit (E. White, GFC, personal communication 1998). The number of permits allocated to the Stairsteps unit, however, is also usually three to four times the number issued to either the Corn Dance or Loop Road units. Although deer and hog hunting constitutes a significant component of recreation in the BICY (Jansen 1986), wild turkey, waterfowl, and small game (including doves, snipe, quail, marsh rabbits, grey squirrels, and racoons) provide additional recreational opportunities. Fishing is a popular activity in the canals accompanying roadways through the Big Cypress WMA (U.S. 41, SR 94, and Turner River Road) (J. Schortemeyer, GFC, personal communication 1998) although the use of outboard motor boats is limited due to the narrowness and generally densely vegetated nature of the canals (Duever *et. al* 1986). Most frogging activity occurs in the wet prairie and dwarf cypress forest habitats in the Stairsteps unit south of US 41 (Duever *et. al* 1986).

There are several established seasons for different user groups for the harvest of deer and wild hogs. These include a 30-day archery season extending from early September until early October that has been in effect since 1990, a 16-day muzzle-loading gun season in the latter half of October, and a 47- to 51-day general gun season extending from mid-November through the first of January (GFC 1997b). Access to the interior of the preserve is attained by the use of wheeled swamp buggies, all-terrain vehicles, and airboats, depending on hydrological conditions and the regulations for a particular management unit. Wheeled swamp buggies are the most commonly employed mode of transportation in most of the Big Cypress WMA, including the Corn Dance unit. On the other hand, airboats are the preferred type of transportation into the Everglades type habitats of the Stairsteps unit (Duever *et. al* 1986).

F. Southern Glades Wildlife and Environmental Area

The Southern Glades Wildlife and Environmental Area (WEA) consists of 30,080 acres of Everglades marsh in southeastern Dade County that is bisected by the C-111 and C-109 canals and associated levees (Figure XVII-1). Most of the area was acquired by the SFWMD through the Save Our Rivers program (although small private in holdings are present), with the GFC given the responsibility of managing the fish and wildlife resources of the area. The Southern Glades WEA is divided into four management units. Unit 1 is that portion of the area lying west and south of the C-111 canal; unit 2 is that portion of the area located between the C-111 canal and the C-110 canal; unit 3 is that portion of the area located between the C-110 canal and the C-109 canal north of the C-111 canal; and unit 4 is that portion of the area north of the C-111 canal that is located between the C-109 canal and highway U.S. 1. All motorized vehicles are prohibited, except airboats in units 1 and 4 from December through March 1 and outboard motor boats within the canals.

Fishing, primarily within the C-111 canal, is the primary recreational use within the Southern Glades WEA. A public use survey conducted from September through November 1997 revealed weekend use by the public that averaged 7 people per day (GFC 1997h). Fishing was shown to be the most common use, followed by sightseeing, hunting, and biking. A foot trail has been established along the area's levees, and horse gates have been installed to improve access for equestrian groups to the trail system.

Fishing is permitted throughout the year within the Southern Glades WEA, while frogging is restricted to the period of December 1 through March 1. An annual deer season is open 30 days from early September through early October for archery hunters; 3 days in mid-October for muzzle-loaders, and approximately 35 days from late October to late November for general gun hunting participants. Due to low deer populations and limited access, however, hunter participation has been low (Table XVII-1). Waterfowl hunting is limited because of low densities and wide year-to-year variation in the local populations (GFC 1997f).

G. J. W. Corbett Wildlife Management Area

The J.W. Corbett Wildlife Management Area, a Type I wildlife management area located northwest of West Palm Beach (Figure XVII-1), comprises only 60,224 acres but receives a disproportionately high amount of recreational use for the Everglades region. Most popular among hunters is the big game season, which consists of an archery season that begins the end of August and lasts for about 22 days, followed by a muzzleloading gun season that lasts for about 16 days, and a general gun season that extends from early November into early January. Although deer and wild hogs are the favored big game species, the Corbett WMA possesses a relatively good mixture of habitat types that support a wide array of other game species. The Corbett WMA is one of the most popular management areas in the Everglades region for snipe hunting (GFC Florida wildlife management area harvest data report, 1997). Other game sought on the Corbett WMA include grey squirrels, wild turkeys, puddle ducks, bobwhite quail, rabbits, and racoons. Since low flatwoods swamp is poor habitat for terrestrial species, populations of upland species like wild turkeys, bobwhite quail, and grey squirrels are low; consequently, hunting pressure on these species is also low (GFC 1997c). During the racoon night-hunting season, racoons may be pursued with dogs for about 40 days as part of the winter small game season. Fishing and frogging are permitted throughout the year. Due to the seasonal nature of most natural ponds on Corbett WMA, fishing is limited to drainage canals, some of the deeper marshes, and six ponds excavated for fishing.

Access to hunting areas in the Corbett WMA is attained most commonly by swamp buggies and ATVs. Vehicular recreational access is also allowed on designated grades from late April through mid-August. Tracked vehicles, airboats, motorcycles, and ATVs having a wheelbase less than 60 inches are not permitted in the management area at any time. Primitive camping is allowed at designated campsites both during the big game season and on weekends following the end of the general gun season.

The Corbett WMA provides other nature-oriented recreational opportunities such as bird watching, horseback riding, hiking, and nature study (GFC 1997c). The Hungryland boardwalk and self-interpretive nature trail is used by those who wish to become better educated about the natural history of the area. Those hiking the Florida Trail also pass through the Corbett WMA. Prior to fiscal year 1997-98, there was no way to track use of the Corbett WMA by users in the non-hunting season. However, with the institution of a daily use permit in July of 1997, the area has been estimated to receive on average about 30 to 40 people per week. Most of these users are reported to be interested in either observing or photographing wildlife (J. Schuette, GFC, personal communication 1998).

Although the John G. and Susan H. Dupuis Jr. Wildlife and Environmental Area lies to the west of the Corbett WMA within the L-8 basin, no impacts on recreation have been predicted for the Restudy at this time and no analyses were conducted in this area.

H. Lake Okeechobee

Lake Okeechobee is nationally recognized as supporting high quality largemouth bass and black crappie fisheries (Bell 1987). For the four-year period from the 1992-93 creel survey period through the 1995-96 period, creel estimates of fishing effort ranged from 742,347 angler hours in 1992-93 to 1,003,508 hours of effort in 1995-96 (Table XVII-4). This estimate equates to an annual mean fishing effort of 879,616 hours for this four-year period. Creel surveys were conducted each year during the peak six-month period extending from December through May. During that four-year period, the black crappie fishery received the most use, with an annual mean creel estimate of fishing effort of 510,403 hours, followed by largemouth bass with 312,722 hours, and bream with 56,492 hours. It should be noted that these creel survey data are based on four high use areas, with each area covering approximately 20,000 acres, for a total creel survey area of 80,000 acres. This creel survey area thus amounts to only about 10% of the areal extent of the lake; but it is estimated that these areas receive approximately 70% of the fishing pressure on the lake (D. Fox, GFC, personal communication 1998). If the summer-fall months were included, the estimated annual fishing effort would undoubtedly be greater. Bell (1987) used creel survey data collected during the summer-fall period in the late 1970s, and found the low-season fishing pressure to constitute approximately 23.8 % of the total annual fishing effort. Assuming that this relationship has continued until the present, the four-year period from 1992 to 1996 would have had an annual mean fishing effort totaling 1,088,965 hours.

Bass fishing tournaments have become very popular events on the lake, but prior to 1996, no permitting system existed for conducting bass tournaments on Lake Okeechobee, and consequently, no monitoring of this activity occurred. Between April 1996 and March 1997, a total of 520 bass tournaments consisting of 28,128 anglers were permitted through the GFC's Division of Fisheries. These anglers caught 25,164 bass, yielding a total weight of 55,486 pounds, with an average weight of 2.2 lb/ fish. Between April 1997 and March 1998, a total of 484 bass tournaments were held on Lake Okeechobee consisting of 33,021 anglers. Angler success during these two years was considered to be low due to extremely high water levels that reduced fish vulnerability to capture (D. Fox, GFC, personal communication 1998).

Pleasure boating (including airboats) on Lake Okeechobee is also a popular activity. As of 1987, there were 18 marinas on Lake Okeechobee supplying a total of 705 wet slips and 315 dry slips. Boat access to the lake is achieved through the use of 40 boat ramps with 65 lanes (Bell 1987). In addition to recreational fishing and boating, Lake Okeechobee serves as a popular duck hunting and frogging area.

Lake Okeechobee is probably the most important freshwater recreational fishery in the state of Florida, with an asset value assessed at nearly $100 million in 1987 dollars and an annual economic impact of approximately $28 million (Bell 1987). It was also estimated that tourists spend $65.51 (1986 dollars) per fishing day, compared to $24.23 for residents of Lake Okeechobee counties, on largemouth bass fishing (Bell 1987).

The lake is divided into four alligator management units, and a set number of alligator harvest permits, based on annual alligator population survey data, are issued for the lake each year. Interest in the alligator harvest program remains high and, statewide, only about 5% of the applicants are randomly selected to participate each year. During the most recent alligator harvest in 1997, 1,256 permits were issued to 251 participants, resulting in the harvest of 981 alligators on Lake Okeechobee (Table XVII-5). The number of alligator harvest permits issued for Lake Okeechobee in 1997 accounted for approximately 40% of the permits issued for the entire state of Florida. The only other public body of water in the Everglades region where regulated alligator harvests still occur is on Lake Trafford, a relatively small lake located near Immokalee. This lake has had a rather modest annual harvest quota ranging from 30 to 70 permits over the last five years (Table XVII-5).

I. Waterfowl Hunting in the C&SF Project Area

Waterfowl hunting is an important outdoor recreational activity in central and southern Florida with a significant economic impact. A Midwinter Waterfowl Inventory is conducted by the GFC. Data from the years 1994-1997 were included in this report for those survey routes within the scope of the C&SF Restudy that were consistently covered in those years (Table XVII-5; Figure XVII-2). Although these data should not be interpreted as representing a comprehensive count of waterfowl in central and southern Florida, they provide useful comparisons of the relative abundance of different species (or groups of species) in a particular area and their relative abundance among areas. The data could also be used to identify inter-annual variability in waterfowl abundance, and if consistently surveyed and analyzed over many years, might indicate long-term trends. The most abundant species found on the surveys were the American coot (*Fulica americana*); ringnecked duck (*Aythya collaris*); either blue-winged (*Anas discors*) or cinnamon (*Anas cyanoptera*) teal, which were counted together; and mottled duck (*Anas fulvigula*). The survey routes with the highest total waterfowl counts, averaged over the four years, were, in order of decreasing abundance: Lake Okeechobee, Lake Weohyakapka, Lake Hatchineha, Lake Istokpoga, and Fisheating Bay in Lake Okeechobee.

Migratory bird hunting stamp sales data (Table XVII-6) and harvest data (Table XVII-7) for counties within the scope of the Restudy were obtained from the Office of Migratory Bird

Management, Laurel, Maryland. These data demonstrate the economic importance of waterfowl hunting in central and southern Florida.

J. Potential Impacts of the Interim Draft Plan (D13R) on Recreation

1. Everglades Wildlife Management Area

The unauthorized construction and augmentation of camps on tree islands in WCAs 2 and 3 has been a controversial issue almost since the inception of the original C&SF Project in 1949 (GFC 1958). Prior to the construction of the eastern perimeter levees, hydroperiods were relatively short, airboat access to interior portions of much of the Everglades was limited primarily to the rainy season, and no camps were present. Wetter conditions following levee construction led to longer periods of accessibility by airboat, and camps started to appear in the EWMA in the mid-1950s, with more than 20 camps by 1958 (Wallace 1958). Similarly, there has been a resurgence of new camp construction on tree islands over the last five relatively wet years (1993-97). Under Alternative D13R, WCA 3B and northern WCA 3A will be wet for a greater proportion of the year; thus airboat access would probably be increased in these areas. The increased accessability of tree islands in this area may lead to an increase in privately constructed camps. Although the construction of permanent structures is prohibited in all wildlife management and environmental areas in the Everglades region, the continued erection of hunting camp structures in the EWMA remains a problematic issue.

Although airboat activity may increase as a result of the longer hydroperiods predicted by Alternative D13R, the use of vehicles that require relatively little or no surface water for operation (tracks, swamp buggies, ATVs, etc) would be expected to decline. The use of tracked vehicles in the Everglades appears to be steadily declining due to the high maintenance requirements of these vehicles; a decline in operator opportunities to use them for hunting because of higher water levels in recent years; and lower deer densities, which in turn resulted in the closure of the area to vehicle hunting seasons. During the 1997-98 hunting season on Rotenberger WMA, only 64 track permits were issued, with 50 tracked vehicles reportedly participating in the hunt (B. Sasse, GFC, personal communication 1998). Information derived from hunter questionnaires revealed that an average of 4 hunters occupied a track on any one occasion (GFC 1998a). In the last big track hunt that occurred in WCA 3A north of I-75 in 1990, 109 track permits were issued. The number of tracks for which hunting applications have been submitted in the Everglades during the past six years has ranged from as few as 83 in 1996 to as many as 165 in 1992 (E. White, GFC, personal communication 1998). It is evident, however, that not all track owners have decided to participate in the vehicle hunts during recent years, perhaps because of limited opportunities due to the continued closure of the northern part of WCA 3A to track hunting because of depressed deer population levels. During the 1996-97 season, only 83 of the 123 tracks that had their tags renewed applied for a hunting permit. At present, it has been estimated that probably no more than 100 to 200 tracked vehicles (although many are in various stages of disrepair) remain in south Florida (B. Sasse, GFC, personal communication 1998). The number of tracks has probably dwindled even more, because the track hunting season has remained closed in WCA 3A since 1994, and in Holey Land WMA from 1993 through 1996.

Although tracked vehicle use may continue to decline, hydrological conditions in Holey Land WMA and Rotenberger WMA, and perhaps the northern portion of WCA 3A in drier years would probably still be suitable for tracked vehicle operation. The use of swamp buggies is currently minimal on Everglades mucky soils, and would likely disappear altogether under the elevated water table proposed under the 2050 Base (which assumes that the Everglades Forever Act and Modified Water Deliveries to Everglades National Park are fully implemented). Thus, the use of swamp buggies is not expected to be affected under the Initial Draft Plan.

The adoption of Alternative D13R would result in a very large decline in the mileage of canals available to fishermen. The decrease in canal mileage as modeled in the SFWMM was 19 miles for the 2050 Base, but with the increased decompartmentalization under Alternative D13R, an additional 127 miles of canals would be backfilled. Although many of these canals may not be easily accessible with an outboard motorboat, or provide exceptionally good fishing opportunities, other more accessible canals do receive a considerable amount of fishing pressure. This projected decline in the mileage of canals available to fishermen will most definitely have an impact on recreational fisheries in south Florida. However, the planned addition of 6,977 acres of water preserve areas with maximum water depths of 4 feet; 9,700 acres of above-ground water storage areas with variable depths in the Lakebelt region; and a 1,600-acre stormwater treatment area of an unspecified depth in Broward and Dade and counties may offer some potential for the development of new fisheries resources in this region.

Of particular concern is the L-67A canal. Alternative D13R proposes to backfill approximately six miles of the southern end of this canal. The “three pines” area, located near the proposed end of the canal, has been a particularly productive fishing spot, and may be eliminated if this portion of the canal is backfilled. In general, the southern half of the L-67A canal receives the most fishing pressure, probably due in part to the prolonged hydroperiod in the southern portion of WCA 3A (J. Fury, GFC, personal communication 1998) Although access to the remaining portion of the L-67A canal would be reduced due to a loss of access from the Tamiami Trail, this effect may not be so pronounced. Due to a lack of security at the somewhat isolated boat ramp on the L-67 canal off the Tamiami Trail, most fishermen prefer to launch from Holiday Park, at the northern end of the L-67A canal, and motor south to their favorite fishing holes. Information gathered by GFC from creel surveys on the L-67A canal during 1991-97 found that 75% of those anglers interviewed launched their boat at Holiday Park with the remaining 25% launching their boat at the southern end of the L-67A levee (J. Fury, GFC, personal communication 1998). Regardless of what access problems may exist, modeled hydrological conditions for the WCA 3A marsh adjacent to the L-67A canal predict somewhat lower mean water depths than would exist under the 2050 Base and considerably lower mean depths (more than 1 ft lower) than would occur under the 1995 Base. Consequently, the areal extent and duration of water depths in WCA 3A sufficient to maintain a productive marsh/canal bass fishery are expected to decline dramatically with implementation of the Modified Water Deliveries Project in the 2050 Base, and even further under Alternative D13R. At this time, it is not clear how the weir design and operations across the L-67A levee will affect the fishery in the L-67A canal.

The L-67C canal, although not as popular a fishing area as the L-67A canal, also receives fishing pressure, especially when marsh water levels recede during the dry season. A count of the boat trailers parked at the L-67C boat ramp during the 6-month period extending from December 1996 through May 1997 yielded a total count of 2,900 boats using this canal, with an average of two persons per boat (J. Fury, GFC, personal communication 1998). This canal would be backfilled entirely in Alternative D13R, and this fishery would be lost as well.

Under Alternative D13R, the areal extent of upland refugia in the form of tree islands and levees is expected to decline in WCA 3B. The removal of the entire length of the L-67C levee and portions of the L-67A levee would significantly reduce the areal extent of existing high elevation habitats in this portion of the Everglades. Such habitats in the current remnant Everglades, where suitable upland refugia have been lost to development east of the L-30 levee and to devastating muck fires in the northern portion of WCA 3A and in WCA 2, have high wildlife value and function. For example, following the recent high water episode of 1994-95 in WCA 3B, the deer population was essentially eliminated from the marsh interior, with the only known survivors persisting on the levee system. The L-67C was one of the most used levees by deer seeking relief from high water levels, which may have been due in part to the movement of deer to the northwest along the natural elevation gradient and to the relatively close proximity of several "low" elevation tree islands that were vacated when submergence occurred. The L-67C also serves as a corridor for expediting deer immigration from the levee back to tree island habitats following water level recession in the area.

Due to increased water levels in WCA 3B, recreational opportunities in terms of huntable deer populations is likely to decline in this area, where tree islands occur at lower densities and many are at relatively low elevations. Conversely, the areal extent and duration of emergence of tree islands above ambient water levels is expected to increase in the southern portion of WCA 3A upon the removal of the impounding effects of the L-28, L-29, and partial removal of the L-67 levees, and this situation would allow a relatively large number of tree islands to remain above ambient water levels for much longer periods of time. The greater density of tree islands in southern WCA 3A and a considerable reduction in the length of time that slough water levels remain above 30 inches deep in Alternative D13R may permit a more stable environment for upland game animals. Hence, deer hunting opportunities should improve in the southern portion of WCA 3A. Although the removal of the L-28 levee would result in the loss of dry habitat that has served as relief for deer and other upland-dependent wildlife in the past, lower water levels and reduction in prolonged high water events predicted by Alternative D13R would make this levee less critical as an upland refugium. In addition, the removal of the L-28 levee and its associated borrow canal will help to recreate the natural hydrological gradient based on the region's topography and allow longer periods of time for deer to move "upslope" to areas of higher elevation in the Big Cypress WMA during times of rising water.

The removal of the L-29 levee and canal by Alternative D13R could have negative impacts on recreational access into WCA 3A and WCA 3B from U.S. 41, since the roadway would have to be elevated in some way. Three public boat ramps provide airboat access into WCA 3B, and three public boat ramps provide airboat and jon boat access into the L-29 canal and the WCA 3A.

marsh. One of the boat ramps for WCA 3B also provides jon boat access into the L-67C canal, which would be backfilled in Alternative D13R. Therefore, it will be necessary to construct on and off ramps to these recreational areas and provide ample parking space for vehicles and boat trailers.

2. Big Cypress Wildlife Management Area

The AET's summary evaluation of those geographic regions encompassing the Stairsteps and Loop Road units suggests that the hydrology of these areas would more closely resemble NSM conditions under Alternatives D and D13R. The ATLSS Cape Sable Seaside Sparrow Model and Breeding Potential Index output for Alternative D13R predict a slight decrease in average hydroperiod relative to the 2050 Base in the Stairsteps and Loop Road units. Ponding depths in the eastern portion of the Stairsteps unit also are projected to be slightly less in Alternative D13R than under the 2050 Base. Although the ATLSS White-tailed deer Breeding Potential Index was not run for Alternative D13R, output was available for Alternative B, which was structurally similar to Alternative D13R in that both the L-28 and L-29 levees were removed. The analysis for Alternative B projected a slightly higher mean deer breeding potential in the Stairsteps and Loop Road units under Alternative D13R when compared to the 2050 Base. The index remained relatively unchanged in the Corn Dance unit with Alternative B.. Assuming the results would be similar for Alternative D13R, somewhat more favorable hydrological conditions will likely exist for deer and other upland game animals in the Stairsteps and Loop Road units of the Big Cypress WMA than would occur in the 2050 Base, and conditions will probably remain relatively stable in the Corn Dance unit.

Table XVII-1. Wildlife Management Area harvest pressure data for the years 1993 to 1998, in those areas that could be affected by the Restudy.

Harvest Pressure (Man-Days)

Harvest Season	Big Cypress	Corbett	Roten-berger	Holey Land	Everglades	Southern Glades
1993-94	15,910	11,431	800	972	2,232	6
1994-95	9,735[a]	10,801	106	214	0	15
1995-96	11,290[a]	10,280	416	294	0	27
1996-97	15,185	10,961	907	274[c]	0	4
1997-98	14,410	11,298	944	281[c]	294	8
5-Year Mean	**13,306**	**10,954**	**766**[b]	**635**[d]	**1,984**[f]	**12**

Total Mean Harvest Pressure = 28,030 Man-Days

[a]Hunting seasons were shortened during these years due to the closure of some units because of high water.

[b]Those hunting seasons closed during 1994-95 were omitted from the 5-year mean.

[c]Includes opening weekend of the regular waterfowl hunting season..

[d]All closed hunts were omitted when calculating the 5-year mean.

[e]The 1997-98 season was open for only 15 days as a gun-vehicle season in WCA 3A south of Alligator Alley.

[f]The five year average for the EWMA was based on the years 1989-93, since the area has remained closed since the 1994 season due to low deer population levels resulting from the 1994-95 flood event.

TABLE XVII-2. Expanded harvest, effort, and harvest success estimates for all fish categories obtained from the roving angler use surveys in WCA 2A (L-35B and L-38E canals) and WCA 3A (L-67A Canal) between 1985 and 1997.

Year	Harvest	Effort	Harvest Success
WCA 2A			
1985-86	46,698	55,659	0.84
1986-87	167,444	128,430	1.30
1987-88	90,115	90,925	0.99
1988-89	59,129	77,617	0.76
1989-90	35,389	55,693	0.64
WCA 3A			
1990-91	51,312	49,536	1.04
1991-92	82,176	52,414	1.54

CHAPTER XVIII -- ESSENTIAL FISH HABITAT

Dawn Whitehead, FWS

The Magnuson-Stevens Fishery Conservation and Management Act of 1996 (PL 104-208) establishes in part, an ecosystem approach to conserving fisheries habitat. It includes a framework for conserving and enhancing essential fish habitat (EFH) which is defined as "the waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity." Waters include aquatic areas and associated physical, chemical, and biological properties that are utilized by fish. Some examples are open waters, wetlands, estuaries, and rivers. Substrate includes sediment, hard bottom, under water structures, and associated biological communities.

The National Marine Fisheries Service (NMFS) published an Interim Final Rule in December, 1997 to clarify the EFH concept and to set the general process for State and Federal agencies and Fishery Management Councils to coordinate, consult, or provide recommendations on Federal and State activities that may adversely affect EFH. Using existing environmental review procedures, NMFS is to coordinate with and provide information to other Federal agencies to further the conservation and enhancement of EFH. When it is determined that an action would adversely effect any EFH, measures will be recommended that can be undertaken by the agency to conserve such habitat. Exact coordination mechanisms and levels have yet to be determined for agencies to consult with NMFS on EFH.

EFH can be affected by non-fishing related activities such as dredging, fill, excavation, mining, oil and gas exploration, shipping, impoundment, discharge, water diversions, thermal additions, pollution, sedimentation, introduction of exotic species, and conversion of aquatic habitat. Some general conservation and enhancement for EFH includes enhancement of rivers, streams, and coastal areas; protection of water quality and quantity; recommendations to local and state organizations to minimize destruction and degradation of wetlands; restoration and maintenance of the ecological health of watersheds, and replacement of lost or degraded EFH.

EFH will be a consideration as Restudy plans are refined. Both the Gulf of Mexico and the South Atlantic Fishery Management Councils have jurisdictions in South Florida and much information on EFH. The Councils have each prepared extensive source documents on the range of managed fish species, their habitat requirements by life stage, and the distribution and characteristic of those habitats. This includes some mapping of EFH by species and by life stage.

CHAPTER XIX -- HYDROGEOLOGIC ISSUES FOR AQUIFER STORAGE AND RECOVERY

Kevin Cunningham and Ronald S. Reese, WRD, USGS

A. Introduction

Assuring adequate water supply to meet the demands of natural systems, agriculture, and urban areas in southern Florida presents an enormous challenge to water managers. The current regional water supply system meets the needs of urban areas and agriculture fairly well, while large portions of the Everglades and important estuarine environments do not receive sufficient quantity, timing, or distribution of water. A key objective to the C&SF Restudy is to assure adequate water supply for all stakeholders while providing restoration of natural systems.

In general, aquifer storage and recovery (ASR) is a water management technique implemented during the wet season in which excess potable water is pumped down a deep well for storage in underground aquifers. During the dry, high-demand season, when consumption of water is high, the stored water is withdrawn and distributed to users. ASR is currently used in southern Florida as a water management strategy and is under consideration for augmentation of future water supplies. The South Florida Water Management District has proposed to meet the goals of the C&SF Restudy with as many as 225 deep storage wells as an option to improve water supply. The critical issues concerning the implementation of cost-effective ASR are: 1) selection of suitable hydrogeologic storage zones, 2) location of injection water sources, and 3) treatment requirements.

Ideal conditions for hydrogeologic storage zones include: 1) good confinement, 2) adequate thickness, porosity, and permeability, and 3) appropriate distribution of pore space and permeability. Good confinement reduces loss of injected freshwater while adequate thickness, porosity, and permeability ensure that water can be injected at a high enough rate over a long enough period of time. The distribution of pore space and permeability need to be defined within the strata such that flow is fairly uniform and steady over the entire interval of injection. Thin zones of high permeability may provide poor recovery because of rapid lateral movement of most of the injected water away from the injection well. Additionally, a low ambient hydraulic gradient is desirable so that the injected water does not move such a substantial distance from the injection well that it prevents recovery.

B. Future Needs for Information or Design

Assessment of technical issues in any hydrogeologic evaluation of ASR requires the following data on the receiving aquifer and injected water: 1) inventory of existing data, 2) core analysis, 3) lithology, 4) aquifer characterization, 5) characterization of confining layers, 6) lithostratigraphy and sequence stratigraphy, 7) hydraulic characteristics, 8) mineralogy of geologic materials, 9) geophysical logs, 10) well construction, 11) water quality of aquifer water and injection source water, 12) geologic structure, 13) potentiometric surface, 14) recharge and discharge boundaries, 15) groundwater velocity and direction, and 16) proximity to potential sources of contamination.

In southeastern Florida, the Floridan aquifer is used for storage. However, other shallower and potentially more cost effective aquifers such as the gray limestone (lower Tamiami), Hawthorn Group, and Miocene-Pliocene quartz sands have been inadequately tested and need to be rigorously evaluated. In southern Florida, municipal ASR projects have been completed in the Upper Floridan aquifer. Based upon test results from wells in Dade, Broward, and Palm Beach counties, it appears that the Upper Floridan aquifer can be productive (D. Pyne, CH2M Hill, personal communication, 1998).

Two major studies, at different scales, are needed: 1) regional hydrogeologic characterization of receiving aquifers and injection water sources and 2) ASR pilot projects. The USGS has begun mapping the top of the Floridan aquifer in southeastern Florida. However, other potential storage aquifers need to be defined by intensive mapping using interpretive results from well data and reflection seismic surveys. A reconnaissance and mapping study of the gray limestone aquifer in central southern Florida is in progress by the USGS and needs to be augmented with an ASR feasibility study.

A multi-disciplinary regional analysis of all potential storage aquifers (Floridan, Hawthorn Group, gray limestone, and Miocene-Pliocene quartz sands) should be implemented. This would involve the collection and interpretation of geologic, geophysical, hydrologic, and geochemical data. These data can be used in creating a regional hydrogeologic model to predict the areas of greatest potential for successful site-specific ASR feasibility projects, which is the second major study identified. At each ASR feasibility project, injection rate and efficiency of recovery of injected water needs to be determined and integrated with hydrogeologic data and interpretations. Hydrogeologic modeling will be **critical** to long-term management of each ASR site and expanded project development in each area.

Very little information exists concerning the effects of pumping large volumes of water into the Floridan aquifer, including how additional water pressure will effect the integrity of the aquaclude, or confining layers at the top of the Floridan. There are also questions relative to the draw down of water in well clusters, particularly if simultaneous draw downs create a negative pressure or suction in the aquifer causing the confining layer of the aquifer to implode (T. Corcoran, National Audubon Society, personal communication 1998).

C. Feasibility of the Lake Okeechobee ASR Component

The C&SF Restudy has proposed large-scale ASR for the area around Lake Okeechobee in the Floridan aquifer system. An ASR test well was drilled in Okeechobee County, but was completed in the Lower Floridan aquifer over a large interval. Because of the large vertical extent of the interval completed and the high permeability of thin zones within it, some researchers believe the results from this test well are inconclusive. The Upper Floridan aquifer was not tested. Limited mapping of the Upper Floridan aquifer on the eastern and southern sides of the Lake has been completed and indicates that there are significant variations in the thickness, hydrologic character, and water quality of the aquifer, dependent on the proximity to and direction from Lake Okeechobee.

D. Water Quality Concerns

Current EPA drinking water standards require that water pumped into an aquifer must meet promulgated drinking water standards. Within the Everglades, most water meets the state primary standards except for coliform bacteria (T. Corcoran, National Audubon Society, personal communication 1998). To meet these standards, the water would require treatment prior to injection into an ASR well. If chlorine is used as the treatment technology, there is a potential that a chemical reaction may occur between chlorine and organic matter naturally present in the water, producing a class of chemical compounds known as trihalomethanes or THMs. Chloroform, a carcinogenic compound, is one type of trihalomethane. Because both Lake Okeechobee water and the Everglades/Biscayne aquifer water commonly contain organic material, there is a concern that the use of ASR in the Restudy alternatives will create harmful THMs if chlorination is used to treat water pumped into an ASR well. Furthermore, water removed from ASR wells should be placed into a "buffer zone" before being discharged into the natural environment in order to provide aeration and pH adjustment (D.Pyne, CH2M Hill, personal communication 1998).

Regional ASR at the scale proposed in the Restudy is unprecedented in central and south Florida; regulators must consider water quality data from ASR pilot studies and data that will be available after implementation of regional-scale facilities to determine if modification of existing water quality requirements governing use of ASR is warranted.

E. Summary

ASR as a water management tool should be used in combination with surface storage reservoirs since the reservoirs would modulate peak flows to the wells. It would be preferable to recover the water from ASR wells into a buffer zone area designated for this purpose rather than directly into natural environments. As an example, marginal EAA land could be utilized for this purpose. It is important to keep in mind that the overall time frame from feasibility study to demonstration well to expansion of the program is approximately 3.5 years (T. Corcoran, National Audubon Society, personal communication, 1998). Other water storage options should be investigated in the event that ASR cannot be implemented on the scale proposed for the Restudy.

CHAPTER XX -- RECOMMENDATIONS FOR IMPROVEMENTS IN HYDROLOGIC MODELS AND TOPOGRAPHIC DATA

Eric Swain, WRD, USGS

The hydrologic models that will be used in detailed planning for Restudy components must represent water depths and flows with a degree of accuracy compatible with desired objectives and performance measures. All current models represent water depths with a greater degree of accuracy than flow values; this is an inherent property of numerical models in low gradient regimes. The relationship of flow to water level gradient must be refined as much as possible in order to optimize the predictive capabilities of the models. Other model enhancements are required to more accurately represent flow in the surface-water system, groundwater system, and the interaction between the two systems. The dominant surface-water regime requires high-accuracy topography to correctly model the flow.

Refining the models involves both the computational algorithms and the input data. This refinement has several aspects, which are discussed below:

1. Accounting for smaller scale features - One of the primary sources of model uncertainty is the fact that parameters must be discretized and averaged for the model grid size. In almost all cases, data is sparser than the actual variability in any parameter, so even if a smaller grid is implemented in a model, the data do not exist to support it. It is impractical to collect data over the entire study area or to construct a model grid with dimensions of several feet. The best approach is to collect intensive data in important or highly variable areas and use these data to develop insight into appropriate spatial means for the model . Identifying areas where more data are needed, both for determining better spatial means and determining optimum grid size, is therefore an important priority.

2. Refining functional flow relationships, flow depths - The hydrologic models with surface-water components in the south Florida area are all sensitive to ground surface elevation. High-order topographic measurements are needed for the entire model domain. However, simply refining the average elevation in a model cell is not sufficient. The effective average cell elevation for flow computation is not the same as the elevation below which flow ceases. This difference in elevations accounts for depression storage. The depression storage term is very important in sporadically inundated areas. Intensive topography data in test areas is needed to develop representative depression storage numbers.

3. Refining functional flow relationships, frictional terms - The surface-water friction coefficient (Manning's *n* or Chezy's *c*) has been notoriously difficult to define. Several studies have been implemented in south Florida to develop more accurate friction coefficients and define factors which affect frictional resistance. The findings of these studies must be transferred to the restoration models and further study needs defined. Field scale studies are needed to investigate the space-averaged characteristics of the friction coefficients.

4. Groundwater flow representation - Model enhancements are required to properly represent groundwater flow in the C&SF Project area. The coastal saltwater interface affects the freshwater flow to the coast. Its location can threaten water supply, and the upwelling of groundwater flow over the saltwater wedge intrudes on the surface-water regime. Numerical representation of variable-density flow at the coast should be included in future modeling efforts.

5. Evapotranspiration (ET) and rainfall - These two major components of the water budget have been the subject of studies in the south Florida area, especially ET. All new findings should be integrated into the modeling efforts and several other topics need to be addressed. For example, rainfall/runoff in urban areas differs from that in agricultural or wetlands areas. Drainage and developed areas control the distribution of infiltration in the urban environment. This also has implications in the water quality components of any model. The ET in agricultural areas is likewise affected by irrigation and plant uptake. The relative significance of the unsaturated zone in ET and rainfall recharge needs to be resolved.

6. Surface water/ground water interactions - The exchange of water between the surface and sub-surface is an important part of the hydrology in south Florida. Studies of the leakage phenomena indicate the aquifer flow fields in close proximity to surface-water bodies are more complex than most model representations. Further model enhancements are required in the area of localized leakage phenomena. Vertical leakage in lake and wetland areas must be represented with the same degree of accuracy as horizontal leakage to canals.

7. Large scale topography - The importance of parameterizing the small scale topographic variations was discussed under item 2 above, but large scale topographic measurements to a common datum are also needed. Many model users reference elevations to the NGVD 1929 datum. However, the best accuracy can be obtained by converting all elevations to NAVD 1988 and using this datum for all new measurements. Error bounds on existing stations and benchmarks should be established to properly define the uncertainty in the models.

8) Water quality modeling - Two types of numerical models, dealing with water quality and quantity, have generally developed separately, with minimal information transfer between them. Rather than using the flows computed by the quantity models as input to chemical and biological models, coupled flow and transport codes need to be implemented and expanded. Because the primary Restudy objectives involve ecological restoration, water quality concerns must be addressed. More detailed hydrologic studies required for project design should use this integrated approach to assess water quality impacts.

CHAPTER XXI -- THE EFFECTS OF DECOMPARTMENTALIZATION AND THE C&SF RESTUDY

Sue Perry, ENP; Cheryl Buckingham, FWS; Bill Loftus, BRD, USGS

The C&SF Project has imposed extensive physical changes on the Everglades landscape in the form of canals and levees to meet its goals of providing water supply and flood protection. While the effects of canals and levees in draining wetlands and impounding waters is well understood, there has been less information available concerning what the presence of those structural features has meant to the ecology of the system. In planning for the restoration of the Everglades, emphasis has shifted toward finding non-structural solutions to problems whenever possible and toward removal of structures that offer few benefits to the natural system.

There are three general categories of beneficial effects to the Everglades system expected to result from adopting a decompartmentalization approach (i.e. filling canals or degrading levees): 1) the restoration of wetland sheetflow, 2) the reconnection of fragmented wetlands, and 3) the elimination of artificial habitats that support introduced plants and animals. Descriptions of these effects follow:

1. The restoration of **sheetflow** across marshes, instead of rapid canal routing of water will provide the advantage of slowing the flow of water on the landscape. Allowing water to flow slowly across the landscape rather than sending it to tide through artificial canals alleviates the adverse effects of flood releases on the estuaries while maintaining persistent dry-season flows in the interior marshes, an aspect of the present system that is deficient. A water quality benefit of increasing sheetflow in the central Everglades is the further reduction of phosphorus and other nutrients. Sheetflow moves particulate and dissolved materials across wetlands to allow more natural cycling of nutrients and energy. The flow of water across wetlands also fosters the passive dispersal of plant and animal species and their propagules.

2. By degrading **levees** that act both as barriers and terrestrial corridors into the wetlands, several important restoration goals will be approached. The unnatural pooling of water, caused by levees that impound water flow, would be reduced or eliminated. That action would lessen the incidence of tree island flooding and reduce the need for regulatory flood releases downstream. Flood releases have been implicated in the destruction of alligator nests and the disruption of wading bird prey concentrations.

Contiguous wetlands, now isolated by the C&SF Project levee system, would be reconnected so as to not restrict the movement of aquatic animals and plants. There is evidence that genetic divergence in populations of mosquitofish and grass shrimp is related to levee barriers. The community composition and standing stocks of aquatic animals also differ in the wetlands of Shark Slough and the Water Conservation Areas, in part as a result of the hydropatterns created by the compartmentalization of the C&SF Project. As wetlands are reconnected, natural disturbance processes, such as fires, would be able to operate without interruption across the landscape.

Levee deconstruction will also eliminate artificial terrestrial corridors in the wetland landscape that act as habitats and dispersal conduits for exotic animals and plants

3. **Canals** represent a dramatic change in the landscape of the Everglades. Few net ecological benefits can be attributed to this artificial habitat. Removal of canals by infilling with levee material will eliminate the major habitat for exotic floating and submersed aquatic plants, fishes, and snails in the ecosystem. The non-indigenous plants alone require a substantial annual expense to control and result in the addition of unwanted herbicides to the Everglades system. Because the canals act as pathways for dispersal for exotic plants and animals, their filling would slow the colonization of introduced aquatic organisms that presently occur east of the Everglades with the interconnected canal system.

The filling of canals would help to restore the natural populations of native predatory fishes, small forage fishes and invertebrates that have been altered by the presence of the spatially extensive canal system. Canals act as long, deep drought and thermal refuges in which large native and introduced species achieve higher numbers than in natural, shallower water habitats. When open to adjacent marshes, canals are thought to alter energy flow in the wetland system by acting as sinks for wetland secondary production in the dry season. As marshes begin to dry, large fishes move into canals to feed on smaller, native fishes. This process depletes marsh fish stocks, reducing the number of fish available to recolonize the marsh, and suppressing reproductive effort and available prey base for competing predators such as wading birds. Filling the canals should result in a greater prey base for those wading birds that feed in drying marshes.

The continual accumulation of data for Everglades community structure and functioning fails to demonstrate positive benefits for the system resulting from fragmentation. On the contrary, many of the demonstrated factors contributing to degradation of the system can be tied directly to the structural components of the C&SF system and their secondary effects of drainage and flooding. Removal of as much of this infrastructure as possible can be expected to provide many benefits.

We realize that some infrastructure is necessary to meet the C&SF system demands in the highly modified system and that man-made structures are destined to remain a fact of life in south Florida for several reasons. The natural system has been reduced to approximately half of its historic spatial extent. It can no longer handle the tremendous volumes of water necessary to maintain hydroperiods in Shark River Slough and proper salinities in Florida Bay without increasing the severity of damaging extreme depths and hydroperiods in the Water Conservation Areas. Canals are capable of conveying water to the south quickly and efficiently, substituting for the missing part of the Everglades. Other structures pay for themselves ecologically by protecting the natural system from developed areas. The east coast protective levee may aggravate the exotic species problem, for example, but it allows water to remain in the Everglades that would otherwise flow into canals and eventually out to sea. Other structures serve water quality functions. For example, the canal along the interior perimeter of Loxahatchee National Wildlife Refuge is important for routing lower quality water around the pristine center of the Refuge. The levees surrounding the refuge protect it from over-drainage during dry years and allow for future adaptive management options. The C&SF Project canals can be used to move floodwaters quickly into storage areas to prevent sending harmful flows through the estuaries. New storage areas are an essential feature in all of the restoration alternatives. These extremely large, man-made features can have serious ecological impacts for many habitats. However, their regional benefits to the Everglades are expected to far outweigh the local ecological costs.

Ecologists strongly favor minimizing the number of ecologically disruptive structures **within** the natural areas while searching for non-structural solutions to problems whenever possible. When structures are inevitable, they should be located, whenever feasible, outside natural areas, either on the perimeter or in less environmentally sensitive areas. Structures should be designed and redesigned so that their impacts to the ecology are minimized. Substantial justification should be required for adding structures because they are needed for adaptive management strategies.

Fortunately, there is much more information available today on the effects of canals, levees, and structures on the ecological system than during the 1940s when the C&SF Project was conceived. As a result, the Everglades' restoration planners have become sensitized to the issues and no longer automatically search for structural solutions to every problem. Each proposed structure must face close scrutiny in the upcoming years and prove to be invaluable to the greater restoration effort or it can and should be removed. The adaptive management strategy being developed for the C&SF Project will provide a systematic way to continue to examine the role of structures in the greater Everglades ecosystem and for modifying or removing them in light of new information.

CHAPTER XXII -- CONFLICTING GOALS AND TRADE-OFFS

Robert Pace, FWS; Sue Perry, ENP

A. The Need to Address the Present Constraints of the C&SF System

It has often been assumed that restoration or enhancement of natural areas in south Florida may conflict with other societal values, such as water supply and flood control. In addition, the current operational and physical constraints of the C&SF system seem to prevent attainment of all ecological goals in the various portions of the system. Chapter VII of this report deals with water supply issues, while the following discussion includes apparent conflicts in reaching all ecological restoration goals. Regulation of water in Lake Okeechobee provides an example of the inability to meet the four key objectives for managing the lake: 1) protection of the lake's littoral zone, 2) water supply, 3) protection of the St. Lucie and Caloosahatchee estuaries, and 4) Everglades hydroperiod restoration (Trimble and Marban 1988, Neidrauer *et al.* 1997). Another example is the need to store water in the Water Conservation Areas to meet water supply demands for the Lower East Coast; this leads to frequent low and high water extremes in the WCAs and alters the timing of drying and wetting of the wetlands from the seasonal patterns these areas experienced prior to construction of the C&SF system. The Restudy was initiated to explore ways to rectify these problems and constraints and many others of a similar nature.

The Alternative Evaluation Team (AET) and Alternative Development Team (ADT) initially approached the problem primarily by increasing water storage outside the Everglades Protection Area. Some constraints were considered irremovable, including: 1) the Herbert Hoover Dike around Lake Okeechobee, 2) the Eastern Protective Levee, and 3) portions of the EAA will remain in agriculture. The third assumption means that storage/treatment will be the purposes for any land acquired in the EAA, rather than attempt to restore remaining portions of the EAA to wetlands similar to those found in the pre-drainage condition. Despite these remaining constraints, the AET and ADT attempted to define and achieve ecological goals in all of south Florida's natural areas.

B. Efforts to Eliminate or Minimize Anticipated Conflicts Through Alternative Design

Continued refinement of the alternatives throughout the Restudy evaluation process indicated that many of the presumed conflicts among objectives could be either eliminated or minimized. The majority of the design components put in the Restudy alternatives are based on simple proven technology. These include the Water Preserve Areas and additional seepage control features between the Everglades and the Lower East Coast urban area, storage/treatment areas in other portions of the C&SF system, removal or modification of certain structures and canals in the Everglades Protection Area, and modification of operational rules. These features are essential pieces of the Restudy, but the AET determined during plan development that these were still not adequate to meet all restoration objectives. Subsequent Restudy designs included features that are more dependent on presently uncertain technologies, and in many cases are more energy-dependent, because they rely more on pumping large volumes of water.

Entering the Restudy, some participants were concerned that the health of Lake Okeechobee's littoral zone would have to be sacrificed to meet future water demands or to provide the necessary volume of water to restore the Everglades. Modeling indicated that complete decompartmentalization of Loxahatchee NWR or WCA 2 was not possible without harming the lake's littoral zone. Even the partial decompartmentalization scenarios required large volumes of surface water storage and 200 ASR wells around the lake to meet ecological goals in the lake, the estuaries, and the Everglades, while also meeting projected water supply demands. The modeling demonstrated that the constraints of the present system could be surmounted, but this conclusion is highly dependent on the feasibility of the 200 ASR wells around Lake Okeechobee.

C. Potentially Remaining Trade-offs

Lake Okeechobee provides just one example of the uncertainty surrounding assumptions that the Restudy will resolve many of the trade-offs in the current C&SF system. The following brief summaries discuss trade-offs that may be unavoidable in carrying out the Initial Draft Plan, particularly if uncertain technologies do not prove feasible for technical, regulatory, or financial reasons:

1. Lake Okeechobee littoral zone health versus urban and agricultural water supply; Lake Okeechobee versus St. Lucie and Caloosahatchee estuaries; and Lake Okeechobee versus water for Everglades restoration. As noted above, full decompartmentalization of the Everglades jeopardizes the littoral zone of the lake with periods of extremely low water. Other modeled scenarios indicate that even if L-39 (which separates Loxahatchee NWR from WCA 2A) is not removed, adoption of a rain-driven schedule for Loxahatchee NWR also has a less severe, but significantly adverse, effect on water levels in Lake Okeechobee. Implementation of the Initial Draft Plan, which does not include either full decompartmentalization of the WCAs or a rain-driven schedule for Loxahatchee NWR, requires the high volumes of pumping associated with the surface storage around Lake Okeechobee and the 200 ASR wells. If these prove to be infeasible, some level of trade-off will remain among the ecological goals and between ecological goals and other societal goals.

2. Water quantity versus water quality. The Restudy has attempted to provide additional STAs (beyond those provided by the Everglades Construction Project) in some locations where water quality is known to be a problem. However, in the Restudy's attempts to capture more water to deliver to the natural system, we remain uncertain that the proposed facilities will be adequate to meet ecologically-based water quality standards for the Everglades, including the removal not only phosphorus, but a full range of potential pollutants. As a general principle, water in the natural system should be retained in the natural system. Detailed design of the Restudy should minimize the import of water to the natural system from surrounding urban and agricultural lands, particularly when these sources are known to contain high concentrations of nutrients, mercury, pesticides, or other pollutants.

3. Matching hydroperiod versus decompartmentalization. Because roughly half of the original extent of the Everglades has been lost, and because none of the Restudy alternatives propose restoration of the EAA or the urban east coast, physical constraints (most notably the

Eastern Protective Levee) remain in place, preventing full restoration of Everglades. Attempting to restore NSM-like inundation patterns in one portion of the system has consequences elsewhere in the remaining natural system. Decompartmentalization of the remaining natural system causes water to accumulate along certain portions of the eastern levee during high rainfall periods, and lacking the full storage capacity of the original Everglades, water is often not available to hydrate the southern Everglades during periods of low rainfall. Early model runs for the Restudy showed that a highly managed system can produce a high percentage of hydroperiod matches relative to NSM. However, ecologists pointed out that such a highly managed and fragmented system was not in keeping with the concept of ecosystem restoration. Therefore, subsequent models attempted to find a balance between hydroperiod matches and removal of barriers in the system. The Initial Draft Plan appears to have the most desirable balance of the two, but as the Restudy enters detailed design, components should be analyzed in terms of this trade-off.

4. Ecosystem management versus species management. The DOI generally supports the principles of ecosystem management, but must point out that special recommendations will still be necessary on a case-by-case basis to comply with provisions of the Endangered Species Act. We find no fundamental conflict for any particular species in achieving the hydrologic conditions predicted to occur after full implementation of the Initial Draft Plan. However, arriving at the final conditions will involve a series of interim actions that must be evaluated in a step-wise manner to ensure that they do not jeopardize listed species and to recommend ways to reduce adverse effects that do not reach the jeopardy threshold. Proper sequencing of projects should minimize potential conflicts, and priority should be given to preferentially protect those species that are : 1) most imperiled, 2) most limited in their distribution to areas affected by the action, and 3) least able to adjust to proposed changes. Seasonal timing of construction activities to protect particular species or groups of species will also remain a concern, even when the cumulative effect of the interim actions do not reach the level of jeopardy. For example, if disturbance of a wading bird colony containing nests of the endangered wood stork (*Mycteria americana*) can be avoided by scheduling construction activity outside the nesting season of the wood stork, such scheduling changes are justified regardless of whether the long-term effects of the project will benefit the species as a whole.

5. Benefits to the whole system or to one portion of the system versus potential harm to other portions of the system. The Initial Draft Plan has minimized these types of trade-off, which were more evident in earlier iterations of design. However, trade-off issues that have been diminished by features of the plan will return to prominence if some of the components of the Initial Draft Plan prove to be infeasible. We have provided below two examples of these types of issues--one dealing with WCA 3 and the other dealing with Biscayne Bay.

Initial attempts at partial decompartmentalization of WCA 3 indicated that attempting to reach the wet season water levels in Shark River Slough was not entirely possible, and that the frequency and duration of both high water stages and low water stages were detrimental to eastern WCA 3A and WCA 3B. The AET asked the ADT to increase the use of Central Lake Belt storage and to design a variable crest weir along L-67, both of which were intended to extend the period of continuous flooding through the dry season in Shark River Slough and reduce the severity of extreme drying and flooding events in eastern WCA 3A and WCA 3B. There was general agreement that areas, such as WCA 3B, that appear to be functioning well ecologically should not be allowed to deteriorate significantly from the 1995 Base condition in order to restore other areas of the system. The Initial Draft Plan is much improved over the other alternatives in avoiding detrimental conditions in WCA 3, but it has not been completely successful. Sensitivity analyses must be performed to determine to what degree the minimization of extreme high and low water stages in WCA 3 is attributable to the provision of variable crest weirs along L-67 and to the use of Central Lake Belt storage. If Central Lake Belt storage does not prove to be feasible, the trade-off between approaching restoration targets for Shark River Slough and reducing the frequency of detrimental high and low water stages in WCA 3 could be more significant.

6. Surface flows of fresh water to Biscayne Bay versus level of treatment proposed for southern Dade County water reuse. Increased water supply demands in the 2050 Base would reduce the surface water flows of fresh water available to maintain a desirable salinity regime in nearshore portions of southern Biscayne Bay below the current levels of flow, which are already considered inadequate. The iterations of Restudy alternatives through Alternative B involved increased storage of fresh water in the C&SF system. The increased storage seemed to benefit the percentage of demands met for agricultural and municipal water supply and also partially restored the hydrology of the remnant Everglades. However, to that point, surface flows to southern Biscayne Bay had not met targets. In Alternatives C and D, water reuse facilities were modeled for south Dade County. This component was effective in reaching surficial fresh water inflow targets for southern Biscayne Bay without compromising urban water supply or restoration of the Everglades. Rather than place ecological restoration goals (fresh water retained in the Everglades versus flows to Biscayne Bay) in apparent competition, we find that other provisions must be made to achieve restoration goals in both areas, should water reuse plans fall short of expectations. We are concerned that, because the presently recommended reuse facilities are among the most expensive components in the Restudy, actions may be delayed in this area. Part of the high projected cost may be the intent to treat the water to the quality standards for drinking water; less costly treatment may make captured water suitable for reuse as irrigation for household lawns, golf courses, and agriculture. Priorities should not be established on the basis of what is politically or financially uncomplicated, but on the need for action to resolve environmental problems.

7. Water storage versus existing habitat values (central versus disjunct natural areas). The Restudy has concentrated largely on improving hydrologic conditions in remnant natural areas of south Florida. A primary principal in restoration of the Everglades had been the need to rectify the loss of its spatial extent (Science Subgroup 1993, Davis and Ogden 1994), but the Initial Draft Plan does not propose restoration of large areas of existing agricultural or urban areas to natural areas. Facing the realities of increased human population in south Florida's future, the emphasis has shifted to restoring or enhancing remaining "core" natural areas, while limiting the impact of the features of the Initial Draft Plan on the more peripheral natural areas. These "core" natural areas include the remnant Everglades, Florida Bay, Big Cypress National Preserve, Lake Okeechobee, the St. Lucie and Caloosahatchee estuaries, the Kissimmee River, and the

Kissimmee Chain of Lakes. Other chapters of this report describe the efforts to reduce the environmental impact of the Water Preserve Areas and the other water storage and treatment facilities, which collectively total close to 200,000 acres of land. Some of these areas are of limited habitat value for fish and wildlife (e.g. improved pasture, citrus groves). The Restudy has attempted to minimize impacts on native cover types (marshes, swamps, dry prairie, pine flatwoods, and others), but some impacts on significant fish and wildlife habitats will be unavoidable. We have recommended that the COE avoid unique and irreplaceable habitats, such as the xeric oak scrub vegetative community, particularly when this habitat is occupied by the Florida scrub jay. If the Initial Draft Plan is completed and functions as a whole as we anticipate, the impacts on disjunct natural areas should be outweighed by the benefits to the "core" natural areas. However, the conceptual plan will likely evolve from our current design, and we must continually re-assess the anticipated benefits of the total plan versus adverse impacts of individual components.

8. Passive systems versus active control. Many new structures have been added in the Restudy alternatives outside of the Everglades Protection Area, including additional pump facilities, reservoirs, wells, curtain walls, canals, and levees. Some of these structures are designed to have environmental benefits, such as increased storage of water that is currently lost to tide so that it can be delivered to natural areas during the dry season. All of the restudy alternatives except Alternative A involve removal of some levees, water control structures, and canals within and around WCA 3. Alternative B removed more structures and canals than any of the other alternatives and would be favored strictly on this basis. However, modeling results indicated that a series of weirs had to be placed along the present location of the L-67 levee to reduce the amount of water ponding in WCA 3B and along the eastern side of WCA 3A, and to prevent the too rapid flow of water to the south. Water is retained by the levee when water stages drop below the control elevations of the weirs and is available to be delivered to Shark River Slough during periods of lower rainfall.

Alternative A was unfavorable not only in its failure to provide even partial decompartmentalization of the Everglades Protection Area, but also in its inclusion of large pumps designed to deliver water south of Tamiami Trail to Shark River Slough. In addition to the enormous operating costs for such pumps, pumping can kill and injure fish and invertebrates through direct injury, reduction of dissolved oxygen in water delivered through pumping, and temperature shock.

The passive weirs along the present location of L-67 (included in Alternative D and refined in Alternative D13R) are preferable over levees and water control structures because they provide a continuous flow of water and aquatic organisms during periods of high water, and only lead to a discontinuity in water levels during periods of low water. Alternative D13R is preferable to Alternative D in that it includes removal of the western portion of L-28 and all of L-29.

In addition to the environmental costs of an actively managed system, the questions of maintenance cost, energy consumption, and vulnerability to natural disasters should be considered. Depletion of fossil fuels may play a role in increasing energy costs in the future unless new power generation technologies become available. The additional energy costs of pumping water from one area to another, backpumping into reservoirs and into Lake Okeechobee, and pumping into and recovery from ASR wells, are large and should be evaluated and reduced whenever possible. Adverse weather conditions (e.g. hurricanes, intense thunderstorms, and tornados) may impair the ability to operate pumps and may result in severe damage to ecosystems if maintenance of these ecosystems is highly dependent on pumping operations.

Among the evaluated alternatives, Alternative D13R appears to provide a better balance between our attempts to remove structures from the C&SF system and the avoidance of the unintended consequences of full decompartmentalization (periods of extreme high and low water in some portions of the Everglades Protection Area). However, the COE should reassess these issues as each portion of the C&SF Restudy enters detailed design. Design plans should be chosen based upon the ability to achieve the most environmentally beneficial patterns of inundation with the lowest practical level of active control.

CHAPTER XXIII -- SUMMARY OF THE DOI's POSITION

The DOI has cooperated closely in this multi-agency, multi-disciplinary effort to meet ecological targets throughout the C&SF system. Alternative D13R has shown significant progress towards achieving ecological restoration throughout the C&SF project and we endorse the majority of the elements in the Initial Draft Plan. However, Alternative D13R needs improvement to fully reach restoration goals. The DOI recommends further refinement of the Initial Draft Plan prior to the release of the Final PEIS in the spring of 1999.

The DOI concurs with the South Florida Ecosystem Restoration Task Force's appraisal of the issues most in need of continued analysis and refinement in the Restudy:

1. Total overland flow volumes to Florida Bay, through Shark River Slough, and Taylor Slough should be increased to reach NSM targets.

2. While accomplishing the above, the hydrologic characteristics in Water Conservation Area 3 (particularly northeastern WCA 3A, all of WCA 3B, and WCA 2B) should also reach ecological targets. Alternative D13R was not able to entirely eliminate potentially damaging high water and low water conditions in those areas. We should continue to seek full restoration of hydrologic characteristics in Florida Bay, Shark River Slough and Taylor Slough without compromising full restoration of WCA 3. Water flow should be delivered as naturally as possible in the remaining Everglades.

3. Whether or not wastewater reuse on the scale proposed by the Restudy is feasible for Dade County, we should continue to seek opportunities that are not dependent on this technology to restore more natural flows to Biscayne Bay. Chapter VI of this report describes two Other Project Elements (OPEs) that would benefit Biscayne Bay with or without the additional water that may be available through reuse facilities. These two OPEs are entitled: South Dade Agriculture Rural Land Use and Water Management Plan and Biscayne Bay Coastal Wetlands. The DOI believes that these projects and any others developed to improve ecological conditions in Biscayne Bay should be given priority. Under any future circumstances, total flow volumes to Biscayne Bay should be no less than those simulated in the 1995 Base.

4. Restoration goals for minimum flows of fresh water to the St. Lucie estuary and the elimination of regulatory releases to the estuary from Lake Okeechobee would be generally met in the Initial Draft Plan. However, the runoff generated within the St. Lucie drainage basin is still significantly greater than the restoration target. The DOI recommends that efforts to fully restore the St. Lucie estuary

5. The DOI understands that the Water Resources Development Act of 1996 authorized the protection of water quality as a project purpose of the C&SF Project. As such, water quality protection must be addressed throughout the entire Kissimmee/Okeechobee/Everglades watershed. The DOI remains concerned that the C&SF Restudy may not include adequate facilities for treatment of water destined to be returned to the natural system. The DOI recommends that specific pollutant loading targets be established and an implementation plan developed to reach those goals within the watershed. Finally, planning should not be limited to nutrient loading; a variety of water quality parameters and pollutants also need to be addressed (e.g. pesticides and mercury contamination).

Detailed findings and recommendations can be found throughout the preceding chapters of this report. The following general findings and recommendations provide a reference to the reader for the appropriate chapters:

1. The hydrologically restored wetland habitats of central and south Florida will not have the same distribution, abundance, and diversity of fish and wildlife as the pre-drainage Everglades. Given resolution of the issues presented above, we are reasonably certain that it will be sustainable in the long term and have the necessary structure and function **(Chapter II)**.

2. The Water Preserve Areas are an essential feature of the Restudy that should proceed rapidly to detailed design, preserving areas of existing high habitat value, and providing habitat enhancing features in others **(Chapter XII)**.

3. Water storage and treatment in other portions of the study area should also minimize impacts on fish and wildlife habitat. We have provided recommendations for relocation of the currently proposed storage location in the Caloosahatchee basin and for siting of storage and treatment in the Taylor Creek/Nubbin Slough basin **(Chapter XIII)**.

4. Land acquisition requirements are substantial in the Initial Draft Plan. We have provided a review of our current understanding of the issues. Although current activity is largely dependent on willing sellers, we find that eminent domain procedures will likely be required to complete the plan **(Chapter XI)**.

5. As the COE proceeds to detailed planning of components, we may find that some of the features are not feasible from technical, regulatory, or financial standpoints. Trade-offs will become more prominent in decision-making and fallback positions will need to be devised to address ecological problems that would be compromised by these trade-offs. Detailed design of all components should continually consider approaches that will promote passive systems over intensely active management **(Chapter XXII)**. Opportunities for removal of

structures that impede restoration should be a guiding principle; addition of structures must be clearly demonstrated to be unavoidable before being included in designs **(Chapter XXI)**. Proper sequencing of presently authorized projects and the components to be authorized in the Restudy must be determined and followed **(Chapter XV)**.

6. Policies governing authorization of wetland mitigation within the study area must be consistent with the goals of the Restudy. Enhancement of wetland functions and values attributable to the Restudy should not be credited to others. Information on the location of features proposed in the Restudy must be made accessible to reviewers of permit applications, and decisions must be compatible with the design of the Restudy **(Chapter X)**.

7. We have provided a review of the ecological benefits expected from implementation of the Other Project Elements. Many of these projects will provide ecological benefits at a regional scale **(Chapter VI)**.

8. We anticipate that the Restudy will promote recovery of several Federally-listed threatened and endangered species. Other listed species will either not be affected, or will be adversely affected, but not jeopardized, by implementation of the Initial Draft Plan **(Chapter XVI)**.

9. Recreational uses in the natural areas of south Florida must be considered in detailed project design and in policy development. Issues involved with access for hunting and fishing, management of fish and wildlife resources in the Water Conservation Areas, and the perception that federal lands are receiving restoration priority over state lands are issues that must be addressed with the Florida Game and Fresh Water Fish **(Chapter XVII)**.

10. Effective sequencing of actions proposed by the Restudy (relative to each other and to existing authorized projects) must be thoroughly analyzed and integrated in construction schedules. We strongly support the completion of the Water Preserve Areas, the Indian River Lagoon, and the Southwest Florida Feasibility Studies **(Chapter XV)**.

11. Control and management of invasive non-indigenous plants and animals is a critical aspect of ecosystem restoration in the central and south Florida. The South Florida Ecosystem Restoration Task Force and Working Group Exotic Pest Plant Task Team are developing a statewide strategic plan for managing and controlling exotic pest plants. This effort should be vigorously supported and implemented. We recommend that an equivalent Task Team for invasive exotic animals be established **(Chapter IX)**.

12. The DOI recommends that all progress toward achieving ecosystem restoration be continuously evaluated in a scientific forum. A peer-reviewed science-based adaptive management strategy, coupled with a sound monitoring program, is the recommended means for integrating all the past knowledge of the south Florida ecosystem with recent findings of the scientific community. Based on the monitoring information, the interagency adaptive management team will prepare annual reports and provide recommendations to decision-makers on how to proceed. This strategy will ensure that refinements to the Initial Draft Plan will be based on the best and most recent information. The annual reports will also be an avenue for keeping the general public informed on the progress of the restoration **(Chapter XIV**).

13. We have provided a review of some of the principal issues relating to water supply that have arisen during the Restudy **(Chapter VII)**.

14. We have provided recommendations regarding necessary studies on ASR **(Chapter XIX)** and on improvements to hydrologic models **(Chapter XX)**.

Without the actions proposed in the Restudy, we are certain that ecological conditions will continue to decline to a level where recovery will be improbable. Although no single plan has been shown to fully meet all targets, we support the Initial Draft Plan (Alternative D13R), with further refinements, as an effective conceptual strategy as we continue to refine and carry out the components of the Restudy.

Re: Central and Southern Florida Project Comprehensive Review Study (Restudy), Multiple Counties

Dear Colonel Miller:

The Florida Game and Fresh Water Fish Commission has reviewed the draft Integrated Feasibility Report and Programmatic Impact Statement ("integrated report") for the Central and Southern Florida Project Comprehensive Review Study (Restudy), dated October 15, 1998; and the scenario D13R4, which was developed after the draft integrated report was released. We have provided a series of three letters under the Fish and Wildlife Coordination Act (FWCA) of 1973 on the results of the Central and South Florida Project Comprehensive Review Study (Restudy). The first letter, dated August 6, 1998, addressed Alternative D13R; the second letter, dated January 19, 1999, addressed the draft integrated report; and this last letter addresses information (specifically, scenario D13R4) that has become available since the release of the draft integrated report. We have also received your letter dated February 19, 1999 in which you attempted to provide some level of assurance and commitment that the comprehensive plan would not further degrade Everglades habitats in the water conservation areas in the process of meeting other natural systems' restoration goals.

The preferred alternative, Alternative D13R, would partially alleviate flooding in southern WCA-3A and excessively dry conditions in northern WCA-3A; however, problems in some regions remain unresolved. Extreme high-water events would occur in eastern WCA-3A, and extreme high- and low-water events would occur in WCA-2B. Other sources of concern include increased water depths in WCA-3B, the frequency of extreme high-water events in northeastern WCA-3A, a shift toward long durations of marsh inundation throughout southern WCA-3A, and increased number and/or intensities of droughts in southern WCA-2A. Future development of this alternative must correct these deficiencies. We have addressed these issues in more detail in the first two parts of our FWCA report.

Effects of Scenario D13R4

Since the draft integrated report was released, the Alternative Evaluation Team developed scenario D13R4 to increase water deliveries to Everglades National Park and Biscayne National Park. This goal would be accomplished by capturing stormwater runoff from the basins that contribute to the C-51, C-13. C-14, C-15, C-16, Hillsboro, and North New River canals, and diverting it both west, through the Site 1 Reservoir/Stormwater Treatment Area (STA) and the Agricultural Reserve, into Water Conservation Area (WCA) 2A; and south, through the Water Preserve Areas and Lakebelt Reservoirs, to both parks. A number of other structural modifications were also modeled, including making WCA-2B more of a flow-through system and improving water delivery from Stormwater Treatment Area 3/4 into northern WCA-3A.

The result of developing scenario D13R4 was that Biscayne National Park and Everglades National Park (specifically, Shark River Slough) are predicted to receive water volumes that more closely approximate the target preferred by Everglades National Park than they would have received under the preferred alternative. In addition, very modest improvements would be made in the hydrologic regimes in eastern WCA-3A and in WCA-2B, although both areas still fall well short of their targets. On the other hand, these improvements would come at great cost to WCA-2A and WCA-3B, which would fare even worse than they do under the 1995 or 2050 Base Cases. In southern WCA-2A, scenario D13R4 would double the number of high-water events, while providing no relief from the increased drought frequencies predicted by the preferred plan. It would also double the frequency of high-water events throughout WCA-3B, and the frequency of extreme water depths would exceed that predicted by the Natural System Model for any portion of the Everglades characterized by a ridge and slough landscape. This effect in WCA-3B is of special concern to us, since this is one of the last parts of the WCA system that contains tree islands that have not been substantially damaged by flooding. The net result of scenario D13R4 is to increase the total area of the WCA system that is predicted to be worse off than if the project were not implemented. Clearly, this situation does not constitute "restoration" under any guise, and is not acceptable. The preferred alternative, Alternative D13R, is far superior in this respect.

In terms of the feasibility of implementing scenario D13R4, our conclusion is that it is problematic at best. One of the greatest areas of uncertainty is whether it would be possible to treat the stormwater captured through this scenario to a standard that would cause no "imbalance to flora and fauna." The water quality subteam of the Alternative Evaluation Team for the Restudy has calculated that the combined flow-weighted mean concentration of phosphorus in the water to be stored in the Site 1 Reservoir STA, and thence into WCA-2A, would be 166 ppb. Their calculations indicate that this STA would have to be enlarged from 2,160 to 6,892 acres in order to reduce this concentration to 50 ppb; no estimate is made as to the size required to meet the ultimate concentration that will be required by the Everglades Forever Act of 1994. Whether there is sufficient land available in this rapidly urbanizing portion of south Florida is highly uncertain. More importantly, by including urban runoff in the diversion of water to the natural system, chemical constituents (e.g., pesticides, oils, grease, and metals) other than phosphorus become a concern. While STAs appear to hold promise for reducing phosphorus loads, their efficacy at treating other contaminants is unknown.

A second significant source of uncertainty is the accuracy of the topographic information that led to the conclusion that substantially more water than that provided by the preferred alternative is needed in Shark River Slough, and that therefore led to the development of scenario D13R4. The Natural System Model assumes that no subsidence has occurred south of the Tamiami Trail, whereas lowered water levels in the northeastern portion (the "Expansion Area") of Everglades National Park, which had been drained for agriculture and development before its inclusion into the park and continues to be overdrained due to flood concerns to the east, would logically have caused some loss of soil to occur. If soil subsidence is factored into the model assumptions, then it is very possible that less water would be necessary to achieve desirable water depths in Shark River Slough. This issue is critical to the future of WCA-3B, and until it is resolved we would oppose any plan that includes maintaining extreme water depths in WCA-3B as a means to achieve restoration in other parts of the system.

Scenario D13R4 has been useful to the extent that it shows that the preferred alternative has the flexibility to capture 274,000 acre-feet of previously unused water in Palm Beach and Broward counties. If this water is to be shunted to natural areas (e.g., the WCAs or either national park), then it must be fully treated before it is discharged into them. Future efforts should (1) explore the possibility of reducing the negative effects in WCA-2A by incorporating a system to allow excess water to be moved south without passing it through WCA-2A and -2B when doing so would create flood events and a provision for using the Site 1 STA to deliver water to WCA-2A to alleviate the overly dry conditions that would otherwise occur; and (2) conduct an analysis to determine the extent to which topographic assumptions of the Natural System Model affect model outcome.

Conclusions

To summarize our major findings for this three-part FWCA report, we provide the following statements.

1. Alternative D13R remains the array of plan components that thus far has the most potential to be refined into a more detailed plan that could support the assemblage of fish and wildlife species that characterize south Florida. The exaggerated effects of dry and wet years in the

WCAs convince us that a "no-action" alternative would not be in the best interest of the state's fish and wildlife resources, and we believe that action needs to be taken as soon as possible to eliminate the conditions that have led to the unnatural pattern of water-level fluctuations that has been seen since the impoundment of the WCAs.

2. In its present form, Alternative D13R will require substantial refinements, particularly in portions of the WCAs, in order for it to realize its potential to provide adequate habitat for those fish and wildlife species, and to allow people to pursue recreational amenities that support a healthy Everglades.

3. Scenario D13R4 is troubling in that it continues a trend that has been in place since the conception of the Central and South Florida Project. This trend has consistently been one of ensuring water supply and flood control for agricultural uses and an ever-growing urban population at the expense of the natural system, and the part of the natural system that has borne the bulk of this cost has been the WCAs. To continue this trend in the name of restoration is unacceptable, particularly in light of the fact that these WCAs represent one-half of a system that itself has already been reduced by half. If true restoration of the Everglades as a whole is ever to occur, this trend must be reversed.

4. To ensure that the area affected by the Central and South Florida Project provides the kind of habitat that supports the fish and wildlife species of south Florida, we are committed to continue working with the U.S. Army Corps of Engineers and the South Florida Water Management District to develop the promise that we believe is contained in Alternative D13R. The challenge to you is to maintain your commitment to the Restudy's goal of enhancing ecologic values. To do so will necessitate maximizing benefits to the *entire* natural system. To do otherwise would result in an unacceptable loss to the future of Florida.

Sincerely,

Allan L. Egbert, Ph.D.
Executive Director

Re: Central and Southern Florida Project Comprehensive Review Study (Restudy), Multiple Counties

Dear Colonel Miller:

The Florida Game and Fresh Water Fish Commission (GFC) has reviewed the draft Integrated Feasibility Report and Programmatic Impact Statement ("integrated report") for the Central and Southern Florida Project Comprehensive Review Study (Restudy), dated October 15, 1998. This report is submitted under the authority of the Fish and Wildlife Coordination Act (FWCA) of 1973.

On August 6, 1998 we sent the U.S. Army Corps of Engineers (COE) the first portion of our FWCA report, which addressed concerns and made recommendations on the performance of the preferred alternative, D13R, which only covers hydrologic changes that can be modeled using the South Florida Water Management Model. At that time, we had expected that the issues that fell outside of the domain of the South Florida Water Management Model would be available in the draft integrated report for review. We had anticipated that we would address these other aspects through this letter, which constitutes the second and final portion of our FWCA report. Specifically, we had planned to provide input as to how water quality, the implementation plan, and the Other Project Elements would affect fish and wildlife. Although the draft integrated report contained sections on these topics, they are undergoing significant revision. In addition, even Alternative D13R is being revised. Even recognizing that a draft will likely be subject to some degree of revision, the work that is currently underway contains changes that are of sufficient magnitude that we cannot responsibly provide a FWCA report on what has become a moving target. Specifically, we will have to wait until the results of this month's revision of Alternative D13R, the five issue papers (adequacy of water deliveries to Shark River Slough, performance of Alternative D13R in portions of the Water Conservation Areas, discharges to the St. Lucie estuary, adequacy of water to Biscayne Bay, and the feasibility of water reuse), the revised implementation plan, and the white paper on water quality impacts are available for review. Although staff of the GFC have been involved with the development of some of these documents, their informal participation does not constitute a sufficient basis on which the GFC can provide a FWCA report.

In the meantime, we are providing you with a summary of some of our major concerns, most of which have been described in more detail in the August 6, 1998 section of our FWCA report.

Performance of Alternative D13R in Natural Areas. The performance of Alternative D13R is, at this point in the planning process, flawed with respect to the extent to which much of the Everglades is restored. We have supported this alternative in concept in that, of all of the alternatives, it appears to provide the array of hydrologic tools that will probably be necessary to improve the hydropatterns within the natural areas; however, much work remains to be done to determine how to best use these tools to approximate restoration. Of particular concern are the fates of portions of the Water Conservation Areas, Shark River Slough in Everglades National Park, and the St. Lucie estuary.

Our major concerns with the performance of Alternative D13R, with respect to the WCAs, include the extremely high and low water levels predicted to occur in WCA-2B; deep water in eastern and northeastern WCA-3A; and extended hydroperiods in much of WCA-3A, particularly south of Alligator Alley. Water Conservation Area 2B is particularly problematic, with conditions drying out in the northeastern corner (where the drier conditions have aided an invasion of melaleuca) and consistent ponding in the south.

Staff of Everglades National Park contends that Alternative D13R provides only 70% of the historic flow volumes to Shark River Slough, as predicted by the Natural Systems Model, and our rough calculations based on their data tend to agree with this conclusion. Since the slough is the major delivery route for fresh water to Florida Bay, the implications are on a larger scale than just the southern Everglades. We note, however, that Appendix B ("Hydrology and Hydraulics Modeling") cautions "against using NSM [Natural Systems Model] flow volumes as hydrologic restoration targets, and recommend[s] that it is more appropriate to use water depths and patterns as targets due to the relatively large uncertainty in NSM overland flow estimates compared to those from the [South Florida Water Management Model]" (Subsection B.3.2.4 "Proper Interpretation of Overland Flow," p. B-63). Since there is an intuitive link between flow and water depth, we are concerned that the reduction in flow cited by Park staff may indeed reflect a problem area, but the extent to which it is a problem in an ecological sense is not yet clear. Future efforts should be directed toward assessing the performance of Alternative D13R on Shark River Slough through indicators other than overland flow volume before actions are taken to adjust the plan. These assessment tools should not only be used to evaluate conditions within the slough, but also the timing and delivery of fresh water to Florida Bay.

Need to Treat Water through the New S-140 Structure. We have been concerned that immediately discharging a large amount of water directly into northern WCA-3A, where muck fires and oxidation have caused substantial soil subsidence, would result in the same situation as we have seen in Holey Land Wildlife Management Area, where cattails proliferated almost immediately after it was fully rehydrated. The expansion of the S-140 would allow the system to be operated so that some of the water that would eventually be discharged in to northern WCA-3A could be shunted, at least initially, to areas further south. This flexibility would allow northern WCA-3A to be rehydrated gradually, while still providing water to southern and central WCA-3A and Everglades National Park. This design comes at a price, however, in that it would involve the discharge of untreated water off of agricultural lands in the basin to be served by the new S-140 structure. Our preliminary review of the impacts of Alternative D13R led us to recommend a water-quality treatment facility be added to treat water that would be discharged through the new S-140 structure.

Key Information Needs for Planning in the Future. The single most important information need for future hydrologic restoration is accurate topographic information. During the Restudy process, there has been much debate over issues such as the "real" height of tree islands (which we define as the spectrum of islands of woody vegetation ranging from willow strands, islands dominated by swamp bay or dahoon holly, and islands with flood-intolerant native vegetation within a larger landscape of marsh and slough), the degree to which parts of the Water Conservation Areas have subsided, and whether there would be a sufficient hydraulic head to move water farther south. The information that exists may have been adequate for the conceptual level of planning that has gone on until now, but planning in the future will be severely hampered unless more accurate and detailed topographic information is obtained.

Other Project Elements. Although the list of Other Project Elements (actions that cannot be modeled through the use of the South Florida Water Management Model) do not appear to contain projects that would be detrimental to fish and wildlife, most of the individual project descriptions do not contain enough information on which to base an assessment of their potential impacts on fish and wildlife in any detail. The entire section of the draft integrated report dealing with the Other Project Elements lacks a critical review of the projects that have been proposed as "restoration" projects when various funding opportunities have arisen during the past several years. One of the projects appears to be mitigation for impacts already required under an existing permit, and another has value only as a demonstration project to determine if hardwood hammock vegetation can be reestablished on rock-plowed lands along two 200-foot-wide strips along the main road to Everglades National Park. Clearly, these projects must be investigated further if they are to be accepted as a restoration project on anything more than a conceptual level. The Other Project Elements will have to be reviewed under the FWCA individually as they are further developed.

Importance of Recreational Amenities. Societal values are the driving force behind the extent to which a project such as the Restudy can be carried out. It stands to reason, then, that it will be important to provide people with the opportunity to interact with the systems that we are restoring. Everglades National Park provides an excellent place where nature lovers can go to appreciate fish and wildlife in a way that minimizes disturbance to these resources, and we also have started a program, Watchable Wildlife, that promotes nature watching. The popularity of nature watching should not, however, eclipse the need to provide people with the opportunity to enjoy part of the system for the more traditional recreational activities of hunting and fishing, at least to the extent that they do not compromise restoration of the system as a whole. For instance, the L-67 canals support an enormously popular area for recreational fishing, including tournament fishing. We are concerned that not enough is known yet to support the contention that canals are a significant detriment to system-wide restoration, other than for hydrologic reasons. Because providing quality hunting and fishing opportunities consistent with restoration is an important mission of the GFC, it is important that canal removal be well justified in terms of hydrological and ecological results. Retaining public access to WCAs-2 and -3, which we manage as the Everglades Wildlife Management Area, is an integral part of this mission, so we are concerned about the potential to lose existing access points, particularly off the Tamiami Trail. We therefore oppose removal of existing access points without providing alternative suitable locations.

New Opportunities Provided by the Restudy. In addition to the benefits to the natural system and to water supply predicted by the integrated report, implementing the Comprehensive Plan may provide new opportunities for managing the Everglades Wildlife Management Area in ways that would benefit native wildlife. For instance, we recommend retaining portions of levees internal to the WCAs in such a manner that would not inhibit the restoration of sheetflow, and grading their sides to provide a gradual slope not unlike that of a natural tree island. This design would provide us with areas that we would then plant with appropriate native vegetation. Our aim would be to provide "tree island-like" habitat, particularly in areas where tree islands have disappeared. It would also provide an opportunity to test the hypothesis that the functions that lost tree islands provided can be restored by artificial means.

Authorization Process. The draft integrated report does not clearly address how the COE intends to request authorization of the Comprehensive Plan. Because it is expected to involve 50 years of construction and operational changes, we believe that it will be essential to obtain up-front Congressional endorsement, at least at a conceptual level, for the entire plan in order to provide the kind of support that will be needed if the Federal government is to ensure that it is committed to implementing the plan in full.

Although we strongly recommend that the COE request that the entire Comprehensive Plan be endorsed in concept, we would object if individual authorization packages resulted in a process that short-circuited the intent of the FWCA. Although we have no objection to the COE having the flexibility needed to implement the Comprehensive Plan, it will be important to maintain close coordination under the FWCA at all points during this large and complex project in order to ensure that intended benefits are indeed realized by native fish and wildlife communities.

We continue to support the restoration of the natural areas that the Restudy aims to accomplish, and look forward to continued coordination with the COE during the refinement and implementation of the Conceptual Plan.

Sincerely,

Allan L. Egbert, Ph.D.

Re: Central and Southern Florida Project Comprehensive Review Study (Restudy), Multiple Counties

Dear Colonel Miller:

The Florida Game and Fresh Water Fish Commission (GFC) has reviewed the description of the initial draft plan, Alternative D, for the Central and Southern Florida (C&SF) Project Comprehensive Review Study (Restudy), sent to us by the U.S. Army Corps of Engineers (COE) on 11 June 1998; and the description of the refined version (Alternative D13), sent to us in an undated letter (received in our Vero Beach office on 25 June 1998). Since we received the second letter, we understand that Alternative D13 has been further refined (Alternative D13R) to correct a modeling error that our staff had detected and in order to further improve the performance of the alternative with regard to the St. Lucie estuary. We have also reviewed the Alternative Evaluation Team's (AET) report (posted on the Restudy website on 24 July 1998) on the performances of Alternatives A, B, C, D, and D13R relative to the 1995 Base and the 2050 Base.

While Alternative D13R comprises an integral part of the Comprehensive Plan for the Restudy, as authorized by the Water Resources Development Acts of 1992 and 1996, it does not constitute the entire plan. For example, the Comprehensive Plan will also include a series of restoration projects, termed Other Project Elements (OPEs), that cannot be evaluated through the use of the South Florida Water Management Model (SFWMM) or its companion model, the Natural System Model (NSM). It is our understanding that a definitive list of these OPEs may not be available until the draft Programmatic Environmental Impact Statement (PEIS) is released on 15 October 1998. For that reason, this letter constitutes our Fish and Wildlife Coordination Act Report (FWCAR) for Alternative D13R, and we anticipate sending the COE a separate FWCAR once there is a definitive set and description of the OPEs. In addition, the AET's evaluation of water quality is not yet available; therefore, we will defer an assessment of the performance of Alternative D13R with regard to impacts of water quality on fish and wildlife to a later FWCAR.

This report is submitted under the authority of the Fish and Wildlife Coordination Act (FWCA) of 1973 (48 Stat. 401, as amended: 16 U.S. C. 661 et seq.). We intend to send additional reports as necessary to address significant changes to Alternative D13R resulting from the public review process.

Development of the Initial Draft Plan (Alternative D13R)

In October 1997, the COE and the South Florida Water Management District (SFWMD) began a planning process that was aimed at developing a broadly conceived Comprehensive Plan for the C&SF Project, intended for submission to Congress in July 1999. In order to accomplish this, they convened a multiagency team, composed of planners, modelers, hydrologists, biologists, and water-quality experts, that has met for the past year in an intensive, iterative process of developing and refining plans for hydrologic improvements to the C&SF Project to cover demands projected through the year 2050, with the assumption that the Everglades Construction Project, Modified Water Deliveries to Everglades National Park, and the C-111 Project would already have been implemented. It was also assumed that water conservation practices outlined by the Lower East Coast Regional Water Supply Plan would be in place. This team was divided into an Alternatives Development Team (ADT), made up primarily of modelers and hydrologists, and an Alternatives Evaluation Team (AET), made up primarily of biologists, water-quality experts, and water-supply planners. A starting plan was first developed by the modelers, and, ultimately, six alternatives were built upon it. Four of these plans were deemed worthy of further evaluation, and one, Alternative D, was chosen by the AET and the overall multiagency Restudy team as the one to be investigated intensively for refinement. The result of this refinement is Alternative D13R, also termed the “initial draft plan.”

Alternative D13R has approximately 50 components, which include both operational and structural changes to the present C&SF Project (excluding the Upper St. Johns River portion). It includes a massive amount of water storage through regional Aquifer Storage and Recovery (ASR) wells [1,665 million gallons per day (MGD)], regional surface reservoirs (1.5 million acre-feet), stormwater treatment areas (STAs; 60,000 acre-feet in addition to that supplied by the Everglades Construction Project), and the Water Preserve Areas (at least 42,400 acre-feet; these Water Preserve Areas will be more fully explored by a separate feasibility study due September 2001). It would partially decompartmentalize Water Conservation Area (WCA)-3 by filling in the Miami Canal and removing the L-67C, L-28, L-28 tieback, and L-29 levees and canals. The L-67A levee would remain, but three S-345 structures would be placed farther south than would the two now planned under Modified Water Deliveries to Everglades National Park. Eight fixed-crest weirs, six north of and two south of the S-345 structures, would be placed along the length of the

L-67A levee. The southern six miles of the L-67A canal would be filled, so that it would terminate at a control structure just upstream of the S-345 structures. The purposes of this design are to transport excess water from eastern WCA-3A and to avoid excessively deep water in WCA-3B, while delivering water to a point in southern WCA-3B where it could flow eastward to rehydrate northeast Shark River Slough. Alternative D13R is designed to route excess water from WCA-2B, WCA-3A, and WCA-3B, to the east of the L-30, L-33, and L-37 levees through the Water Preserve Areas into a proposed Central Lake Belt Reservoir, where it would be available for further improvements to the eastern part of Everglades National Park. It includes a rainfall-based operational plan for the entire system, except for the A.R.M. Loxahatchee National Wildlife Refuge.

Evaluation of Alternative D13R

This letter summarizes some key results of Alternative D13R in terms of ecological restoration of the south Florida ecosystem. Although the GFC is responsible for all of the wildlife and freshwater fish within the Restudy area, this letter focuses on the northern half of the remaining Everglades and Lake Okeechobee, for two reasons. First, these are areas where water supply and flood control have for many years taken precedence over the conservation of fish and wildlife. As a result, they have been significantly damaged by the C&SF Project, and they are at risk of continued deterioration unless their environmental needs receive sufficient priority as part of the Restudy effort. Second, because participating federal agencies have done an outstanding job advocating for the environmental restoration of federal trust lands within the A.R.M. Loxahatchee National Wildlife Refuge, Big Cypress National Preserve, Everglades National Park, and Biscayne Bay National Park, this letter focuses on issues confronting the other major parts of the Everglades ecosystem (i.e., the WCAs and Lake Okeechobee). An evaluation of Alternative D13R for all natural areas is attached to this letter (Attachment A).

The C&SF Project has caused a massive shift in water flows from their natural pattern. Flood waters were allowed to rise within Lake Okeechobee, and then were diverted in large releases to the east and west via the Caloosahatchee and St. Lucie canals. In the Everglades, the volume of water flowing through the watershed decreased; canals caused over-drainage of northern areas; levees created deep ponds at the lower elevations of the WCAs; and overall flows into Everglades National Park and Florida Bay were dramatically decreased. Alternative D13R makes substantial progress toward remedying this situation. The fundamental result of Alternative D13R for the overall natural system is that it restores an enormous amount of fresh water to a southward flow, using storage to achieve improvements in timing, while reducing unnatural flows to the east and west in the form of flood releases to the Caloosahatchee and St. Lucie estuaries. It accomplishes this without undue reliance on storage in Lake Okeechobee.

Northern and Central Everglades

The northern and central Everglades are composed of Holey Land and Rotenberger wildlife management areas (WMAs), A.R.M. Loxahatchee National Wildlife Refuge (WCA-1), and the Everglades and Francis S. Taylor WMA. Together, these areas constitute roughly 900,000 acres of Everglades landscape. The two most significant problems that have been caused by the C&SF Project in this region are (1) the loss of peat soils as a result over-drainage, followed by microbial oxidation and muck fires; and (2) the destruction of tree island vegetation as a result of a combination of muck fires in over-drained regions, such as northern WCA-3A, and prolonged high water in deeply ponded areas, such as southern WCA-2A. Overall, Alternative D13R appears to make major steps toward solving these two critical problems. Although all of the final alternatives developed by the Restudy team perform well in relieving drought conditions that could damage peat soils, Alternative D13R provides the best overall reduction in extreme high-water conditions that would flood tree island vegetation communities in southern WCA-3A and throughout WCA-3B.

Three physical features of the current Everglades make full hydrologic restoration difficult. First, the Everglades proper (i.e., the landscape composed of sawgrass plains, sawgrass ridge and slough, and shorter hydroperiod marl marshes) is much smaller than it was historically, with greater loss of extent as one proceeds northward. In order to restore historical flows and depths to the southern Everglades, it is therefore necessary to route more water through the smaller, narrower channel formed by today's northern portion of the Everglades. Second, current reconstructions of the predrainage system indicate that the portion of the Everglades now lost to development east of the Dade-Broward levee included some of the deepest areas, where substantial flow may have occurred (NSM 4.5 Final version, SFWMD). Third, the natural slope of the land directs water toward the eastern boundary of the remnant system in what is now WCA-3, and toward the southern boundary of WCA-2B. These changes in the landscape create a persistent problem in all the alternatives: a tendency for water to pond in WCA-2B and on the eastern sides of WCA-3A and -3B, while depths and inundation durations within Shark River Slough in Everglades National Park remain below NSM values. The Restudy team explored three basic methods of increasing conveyance so that excess water in the WCAs could be routed to Shark River Slough, where it was needed to restore the marsh and provide flows to Florida Bay: (1) use the existing L-67A canal to speed flow south; (2) remove levees that were impediments to flow, specifically the L-28, L-28 tieback, and L-29; and (3) develop a conveyance system (the Central Lake Belt reservoir component) east of the L-30 and L-33 levees in order to compensate at least partially for the lost eastern portion of deeper Everglades that fed Shark River Slough. Alternative A explored the first of these components, while Alternatives B, C, and D evaluated the second and third approaches in varying proportions. None of these alternatives managed to approach restoration goals sufficiently either north or south of Tamiami Trail. Only Alternative D13R has come close to providing hydrologic conditions that are more NSM-like throughout the northern, central, and southern Everglades, and it does this by using all three methods to move water from the ponded northern areas of eastern WCA-3A and WCA-2B toward the south.

A number of issues remain. One of the most serious issues is the potential ecological effect of the large hydrologic change predicted by Alternative D13R within WCA-3B. Water depths and inundation durations in WCA-3B will increase concomitant with restoring flows in Shark River Slough, through modification to L-67 structures and the removal of the L-29 levee. Overall, this would be a substantial deviation both from current conditions in WCA-3B and from NSM predictions of the predrainage hydrologic conditions. It would impose on WCA-3B an inundation and depth pattern that more closely matches NSM predictions for mid-Shark River Slough than for WCA-3B itself; therefore, WCA-3B is neither restored in an historical sense, nor are its current ecological values conserved under Alternative D13R. Only the compelling need to restore freshwater flows through Shark River Slough and Florida Bay and to provide more natural hydrologic conditions for the entire Everglades justifies tolerating this deviation from what would otherwise be suitable restoration objectives for this area. However, of all of the alternatives, only Alternative D13R manages to approximate restoration goals for the entire Everglades ecosystem with the least degradation of the ecological values in WCA-3B. At this time, Alternative D13R's performance appears to be at the limit of hydrologic change that could responsibly be advocated for WCA-3B in the near term, as any greater depths would push the region beyond the range of conditions currently predicted by NSM to have existed in *any* part of the historic River of Grass. Extreme caution will be needed in implementing changes that carry such a high degree of biological uncertainty. Maintaining even this minimally acceptable hydroperiod depends on the ability to move water to Shark River Slough through the Lake Belt system east of WCA-3B. The Lake Belt system is therefore an essential component of D13R.

A second major issue is the potential long-term biological effect of a shift in the overall hydrologic pattern toward longer periods of inundation with fewer drying events than those predicted by the NSM. The best overall match to NSM inundation patterns is Alternative A, where it appears that maintenance of the WCAs as compartments provides more control over water depths in different sections of the Everglades; however, what amounts to a highly controlled series of dammed pools is not consistent with the idea that one of the defining characteristics of a restored Everglades system is dynamic sheetflow. With partial decompartmentalization, such as modeled in Alternatives B and D13R, exact matches to local NSM predictions within WCA-3 no longer appear to be possible, given the reduced overall extent of the Everglades watershed north of Tamiami Trail. Hence, the benefits of decompartmentalization in promoting sheetflow and reducing the frequency and duration of flooding appear to conflict with the ability of water management to match local NSM targets. In considering this apparent trade-off, we believe that long-term sustainability of the northern and central Everglades marshes probably depends more on the avoidance of extremes of drought and flood than on exact restoration of local predrainage hydropatterns. Only Alternatives B and D13R manage to avoid extreme high water in southern and central WCA-3A, and only Alternative D13R accomplishes this in WCA-3B as well.

A third significant issue is the effect of altered hydrologic conditions within eastern WCA-3A on wading bird nesting and foraging areas. On the one hand, northeastern WCA-3A is predicted to become wetter and to experience an increased occurrence of depths in excess of 2.0 feet, as compared to the 1995 and 2050 bases. On the other hand, the area south of the 3A-3 gage and east of the Miami Canal will still remain deeper than the NSM values, but will have far fewer high-water events than would occur under the 1995 Base. Since both of these areas include important wading bird rookery sites, the changed conditions could be expected to improve breeding habitat in some areas (such as the Andytown rookery) but possibly damage it in others (such as Rescue Strand rookery). Furthermore, the distribution of suitable foraging areas for wading birds will undoubtedly be changed. Although overall restoration of the Everglades watershed is expected to improve habitat for nesting wading birds regionally, the timing of development of suitable breeding sites to the south, relative to changes in current nesting sites, could have significant effects on regional wading bird populations. We believe that improvement of performance measures that can evaluate the response of wading bird populations to changes in hydrologic conditions, combined with a plan for system-wide monitoring, will be extremely important components in implementing the plan.

In northwestern WCA-3A, as well as in Holey Land and Rotenberger WMAs, performance under Alternative D13R appears adequate to provide for sustainable marsh conditions. There is a beneficial decrease in the frequency of extreme drought conditions in northwestern WCA-3A and in Rotenberger WMA. Although hydrologic performance appears satisfactory at the level of resolution that can be provided by the SFWMM, it is not clear whether the structural components being considered in Alternative D13R are sufficient to (1) support a sufficiently natural hydrologic pattern, and (2) meet a 10-ppb phosphorus standard (the current default standard under the Everglades Forever Act). Specifically, it is our understanding from discussions with SFWMD staff that Rotenberger WMA is being modeled to receive dry-season water deliveries from the regional water supply system, as needed, via STA 5, and that Holey Land WMA includes additional discharge capacity to meet outflow operations aimed at minimizing depths above 1.5 feet (C. Neidrauer, pers. comm.). These structural and operation details are not formally documented in the descriptions of alternative components (Components DD5 and EE5). In addition, it is unclear as to whether or not STA 5, which discharges into Rotenberger, and the S-140 structure, which discharges into western WCA-3A, will be able to meet the 10-ppb phosphorus standard assumed by the alternative.

In conclusion, Alternative D13R provides inundation patterns within the WCA system that are similar to those thought to have occurred in the pre-drainage Everglades and that seem likely to promote a sustainable marsh ecosystem. There nonetheless remain many questions about the biological responses that will occur, and these uncertainties can only be overcome by a suitable plan for adaptive management that will allow timely and informed changes in water management that promote biological restoration goals.

Lake Okeechobee

The model results indicate that Alternative D13R would provide improvements to Lake Okeechobee, particularly for the littoral zone. It performs well due primarily to the addition of two types of water-storage strategies. First, storage and attenuation would be provided by the construction and operation of surface-water reservoirs (250,000 acre-feet; sites yet to be identified) and a stormwater treatment area in the Nubbin Slough/Taylor Creek basin (20,000 acre-feet). Second, and perhaps more significant, is heavy reliance on Aquifer Storage and Recovery (ASR) wells to achieve the benefits to the lake. The concept behind the use of ASR wells is to store water in the Floridan Aquifer when there is excess water in the system, and then to draw it back up for use when more water is needed. Alternative D13R proposes 200 ASR wells around the lake, each with a capacity of 5 MGD.

Recreation

One issue that merits attention is the potential impact of Alternative D13R on the recreational amenities provided by Lake Okeechobee, J.W. Corbett WMA, Rotenberger WMA, Holey Land WMA, Everglades and Francis S. Taylor WMA (WCAs-2 and -3), Big Cypress WMA, and Southern Glades Wildlife and Environmental Area. Please refer to the attached interim report (Attachment B) for a more in-depth description of the recreational values (hunting, fishing, and wildlife viewing) for which the GFC manages these natural areas. To our knowledge, the overall economic impact of the recreational uses, and in the case of Lake Okeechobee, commercial use, has not been fully evaluated; however, the growth of ecotourism would only escalate the economic benefits of fishing, hunting, and nature watching in the non-developed areas. To the extent that Alternative D13R approaches restoration, we anticipate benefits in recreational uses as well, since sustainable recreation depends on sustainable natural resources. For example, the elimination of extreme high-water events in WCA-3A may greatly reduce strandings of white-tailed deer, and allow them to move to and from higher ground in the Big Cypress National Preserve and other lands just west of WCA-3A. On the other hand, the removal of over 100 miles of canals would, without replacement of fishing opportunities elsewhere in Dade and Broward counties, eliminates much of the opportunity for this popular sport in southeastern Florida.

Concerns and Recommendations

1. <u>Concern:</u> The heavy reliance on ASR to meet performance goals for Lake Okeechobee is of concern for two reasons. First, although ASR technology is currently in use elsewhere in Florida, its use on a regional scale has not yet been tried. We understand that the PEIS will address a contingency plan should this solution fail to perform as modeled, and we are heartened to hear that the U.S. Environmental Protection Agency may be able to permit the use of ASR wells

without expensive treatment at the wellhead. Nevertheless, other obstacles (e.g., geological formations in the aquifer) may pose more technical problems. The implications of failure to identify a successful replacement for this technology are of grave concern with regard to the future of the lake.

Recommendation: Although we may have doubts as to the efficacy of regional-scale ASR facilities around Lake Okeechobee, we have no doubt as to how we want to see the lake look in the future. Both Alternative D and D13R perform very well for the lake; however, if regional ASR fails to perform adequately, we strongly recommend that the contingency plans avoid transferring the brunt of the storage lost to any part of the natural system.

2. Concern: We are concerned about the impact of impingement and entrainment of fish in pipelines and pumps used to move water from Lake Okeechobee to the reservoirs and ASR wells. Larval fishes, in particular, lack the ability to avoid entrainment. If there is at least one high-capacity connection to the lake for each reservoir and each ASR well, then their use could affect the fish communities in the lake.

Recommendation: We recommend that the COE work closely with staff of the GFC's Division of Fisheries to reduce or eliminate the potential for impingement and entrainment of fishes by new pumping facilities.

3. Concern: None of the alternatives manage to restore hydrologic conditions in WCA-2B to anything that approximates those that would sustain an Everglades-like landscape. During the course of the alternatives analysis, the reason for this poor performance was never well understood. We are concerned that continued dry-outs and high-water events that currently occur in WCA-2B will lead to further deterioration of this area to the extent that it no longer contributes to the overall populations of fish and wildlife that characterize the Everglades.

Recommendation: In order to rectify hydrologic problems in WCA-2B, every attempt must be made in the future to identify why the modeled alternatives, particularly Alternative D13R, have failed to provide hydropatterns that would be conducive to an Everglades landscape. We suggest that the first area to be investigated is the operations of WCA-2A and -2B.

4. Concern: Alternative D13R predicts hydrologic changes in northeastern WCA-3A that may harm nesting habitat for wading birds in areas that have been among the most productive nesting sites in the Everglades within recent years. The increase in extreme high water in this area can be credited, at least partly, to operational assumptions about STA 3/4.

Recommendation: Hydrologic performance in this area should be improved during further modeling efforts. It is possible that changes in STA3/4 operational rules alone could lead to improved performance. Additional storage to the north, or the development of structures that would provide a more balanced distribution of inflows to the WCAs during high rainfall periods, may also need to be included in the final plan.

5. Concern: One area of serious concern that remains with respect to Alternative D13R is the fact that approximately 6 miles of the southernmost end of the L-67A canal would be removed, as would the entire L-29 canal. We understand that the reason for the design of the L-67 system is to use the S-345 structures and the expanded weirs 7 and 8 to shunt water eastward into northeastern Shark River Slough, while avoiding extreme high-water events in the bulk of WCA-3B. On the other hand, the entire length of this canal is heavily used for recreational fishing, and in fact is one of Florida's premier recreational fishing areas. For example, in 1997 there were 106 organized fishing tournaments, with nearly 3,000 participants, held in WCA-3A. The catch rate for those tournaments was 0.67 largemouth bass per man-hour, as compared to the statewide goal of 0.5 (F. Morello, GFC, pers. comm.). The entire length of the L-67A canal is used, with a slightly higher observed use in the southern reaches. In addition, six GFC boat ramps associated with the L-29 canal and the southern end of the L-67 canals would be eliminated. Some of these ramps are quite popular. For example, during a six-month period from December 1996 though May 1997, GFC staff of the Division of Fisheries counted 2,900 boats launched from the boat ramp at the lower end of the L-67C canal.

We are aware of concerns that exotic fishes in canals may cause problems for native marsh communities, if not now, then possibly in the future. On the other hand, such impacts, specifically for the L-67A and L-29 canals, remain hypothetical, whereas the adverse effects of canal removal on recreational fishing would clearly occur. Thus, we cannot presently support the removal of these canals on the basis of the presence of non-native fish species alone. The GFC is prepared to support actions necessary for ecological restoration, but significant negative impacts to human use of these resources require clear justification.

Recommendation: While we fully support a design that would accomplish ecologic restoration, we recommend that the COE and the SFWMD run a sensitivity analysis to determine whether the L-67A canal can be extended farther south and still capture the hydrologic benefits that the currently proposed design is anticipated to accomplish. In addition, it is our understanding that the removal of the L-29 levee automatically included removal of the L-29 canal, as well. It does not appear that the effect of leaving in the canal, or parts of it, was investigated. Since the L-29 canal also provides a fishery resource with sufficient use that its elimination would pose a serious concern for our recreational fishing program, we recommend that the COE and SFWMD also model a scenario in which the L-29 levee is removed, but the L-29 canal is retained. In short, we would strongly support a design that clearly aids in restoring the overall hydrologic characteristics of the predrainage system; however, we would be opposed to removing canals that currently provide recreational fishing benefits when that removal provides little or no hydrologic restoration benefit. We recommend that the COE work in close cooperation with the GFC's Division of Fisheries during the detailed design phase in order to determine the degree to which recreational amenities can be maintained and to fully mitigate for any losses (e.g., by designing the Water Preserve Areas so that they support recreational fishing).

6. Concern: The northern and central Everglades are predicted under Alternative D13R to shift toward hydroperiods that are longer than those predicted by the NSM. The long-term ecological effects of such a change are not known. One significant uncertainty is the possibility of large scale cattail proliferation within the northern areas of WCA-3A.

Recommendation: Further modeling and design of the preferred alternative should include an effort to develop operational flexibility within the Everglades watershed. Operational and structural details should be explored that will allow hydroperiods within the remnant Everglades to be reduced in some regions without causing an overall loss of flow to more downstream parts of the system. The use of the S-140 structure and an associated spreader-canal system would be an example, as it might allow more water to be discharged into central WCA-3A, if it became desirable to send less water into northern WCA-3A as a means of discouraging cattail expansion.

7. Concern: An issue that continues to plague efforts to predict ecosystem response to hydrologic changes is that much of the SFWMM relies on topographic information that is derived from data collected before much of the subsidence and peat loss that has occurred over the past 40 years. Unless up-to-date information that captures the extent of subregional subsidence and local peat loss due to muck fires is utilized, we are concerned that the predicted flow vectors and extent of ponding may be inaccurate.

Recommendation: The COE and local sponsor should work with the U.S. Geological Survey and others to expedite the collection of high-resolution topographic data in Rotenberger and Holey Land WMAs and throughout the WCAs and Everglades National Park.

8. Concern: A variety of performance measures were used to evaluate the Restudy alternatives. These measures were deliberately designed to function as a minimal set of evaluation tools that could compare model results on the accelerated schedule of the Restudy alternative development process. These measures, therefore, cannot and should not be interpreted as management objectives for any or all parts of the Everglades ecosystem. Specific reasons why the AET performance measures should not be viewed as management criteria were detailed in a previous planning aid letter of 24 February 1998.

Recommendation: A concerted effort is needed to ensure that performance measures are developed that can more accurately predict the responses of peat soils, tree island vegetation communities, and wildlife (including wading birds) to hydrologic changes. Such measures should be scientifically supportable as best current estimates of ecological responses to changed hydrologic conditions, and they will need to be developed prior to detailed design of structures and operations that will alter hydrologic conditions within the Everglades watershed.

9. Concern: The Everglades has been subjected to hydrologic regimes that are far different than were the conditions under which they were originally formed. They have been drained to some extent for roughly 100 years, and have been even more intensively managed over the past 40 to 50 years. It is reasonable to hypothesize that, to some extent, today's landscape has adjusted to these changes. We are therefore concerned that abrupt changes to a more "restored" landscape may in fact result in unintended shifts in community structure. As an example, when the GFC, South Florida Water Management District, Florida Department of Environmental Regulation (now Florida Department of Environmental Protection), and the Board of Trustees of the Internal Improvement Trust Fund decided in 1983 to impound Holey Land Wildlife Management Area and restore it to a 0- to 2-foot water regulation schedule, the result was a proliferation of cattails, particularly in areas that had a history of muck fires.

Recommendation: The Comprehensive Plan should include two well-crafted sections: (1) an implementation plan that allows for careful staging of hydrologic changes so as to avoid large environmental "shocks" that could induce ecological damage to the marsh communities; and (2) an adaptive management strategy that ensures that monitoring is well designed and comprehensive over the total system. It will be crucial for monitoring results to be evaluated within an objective scientific framework, and to be acted upon expeditiously. Maintaining flexibility in water management actions in response to monitoring results will be critical during project implementation. Water management changes likely to be identified as part of an adaptive management process would generally take place on a time scale of months-to-years; hence, operational flexibility need not be incompatible with a system in which passive forms of water management play a dominant role.

10. Concern: No plan for adaptive management of the Everglades ecosystem can succeed unless it has the "teeth" that allow water management policy for the natural system to be responsive to input from the resource management agencies that would be responsible for much of the monitoring effort. We are concerned that, as the population of south Florida grows, there will be increasing conflict between the responsibilities of the agencies that manage water resources and those that manage natural resources.

Recommendation: We recommend that, if ecological restoration is to become a reality, a process be established to coordinate and balance the responsibilities and goals of the many resource- and water-management agencies responsible for different parts of the south Florida ecosystem.

Conclusion

The development of Alternative D13R has been the result of an intensive, multiagency planning process that has been underway since last October. The GFC has been very involved in this process, leading the AET subgroup that developed performance standards and evaluated model output for all of the Everglades landscape north of Tamiami Trail, an area that has been the most heavily impacted part of the natural system. Because the scope and complexity of the Comprehensive Plan that will be sent to Congress next July is unprecedented, we commend the COE and the SFWMD for taking this multiagency approach, which incorporates a wide spectrum of agency and government expertise.

In conclusion, the GFC finds Alternative D13R to be the alternative that shows the most promise for restoring the natural areas that lie within the SFWMM domain. We therefore support it as an alternative that merits further development during the detailed design phase. Concerns and issues expressed in this letter are intended to provide guidance for improvements during the future development of practical applications to effect restoration. We understand that the plan is still conceptual in nature, and we look forward to continuing our role in the Restudy team as it continues to design more detailed plans in order to turn the concept into actual restoration actions. To that end, we anticipate this FWCAR to be the first in an on-going series of FWCARs that we intend to provide the COE as it enters the detailed design phase.

Sincerely,

Allan L. Egbert, Ph.D.
Executive Director

SUMMARY OF THE PERFORMANCE OF ALTERNATIVE D13R IN THE NATURAL AREAS

Office of Environmental Services
Everglades Protection and Restoration Section
Florida Game and Fresh Water Fish Commission

This section provides a summary of the performance of Alternative D13R with respect to the natural system, since these are the areas that most directly pertain to fish and wildlife resources. The Alternatives Evaluation Team (AET) divided the domain of the South Florida Water Management Model into eight geographic subunits: the total system, Lake Okeechobee, the Lake Okeechobee Service Area, the Lower East Coast Service Areas, the northern and central Everglades [Rotenberger and Holey Land wildlife management areas (WMAs), WCAs-1, -2A, -2B, -3A, -3B, and the Pennsuco wetlands], southern Everglades (Everglades National Park, including Florida Bay; the Model Lands; and the C-111 basin), Big Cypress National Preserve, and the estuaries and bays (Caloosahatchee estuary, St. Lucie estuary, Lake Worth Lagoon, and Biscayne Bay). Our report is based in part on a review of the AET's report with regard to these regions, with the exception of the northern and central Everglades. For this critical portion of the Everglades, we have provided a much more in-depth analysis of the performance of Alternative D13R, since staff was deeply involved with its evaluation.

Total System (Decompartmentalization)

Because many of the effects of compartmentalization and fragmentation are at this time hypothetical, it is not possible to determine conclusively whether all of the benefits anticipated will be realized. For example, the extent to which canals play a role in the introduction of exotic fishes into "healthy" natural marshes, as opposed to remaining primarily in disturbed areas, is much debated [P. Shafland, Florida Game and Fresh Water Fish Commission (GFC), pers. com.]. On the other hand, exotic catfish have been well documented in Lake Okeechobee, where they disturb benthic habitat used by native fish species (G. Warren, GFC, pers. com.). The hypothesis that managing the WCAs as discrete pools such that "false cues" are given to wading birds in terms of when to initiate nesting is plausible, but as of this time, we are unaware of any definitive studies to support this concept.

On the other hand, much can be accomplished by the removal of some of the levees. For example, the removal of the L-29 levee has dramatically reduced dependence on WCA-3 for storage, and eliminates the damaging high-water events that have plagued southern WCA-3A during the past six years.

Lake Okeechobee

Alternatives B, C, D, and D13R all performed well in terms of nearly eliminating the number of undesirable events. These results are largely because all of these alternatives assumed that 200 regional-scale Aquifer Storage and Recovery (ASR) wells would be placed around the lake, although some lesser benefit is also accrued by incorporating above-ground reservoirs north of the lake. In addition, the inclusion of a large reservoir in the Everglades Agricultural Area would lessen its dependence on the lake, and therefore reduce the number of extreme drawdowns. All of the alternatives were improvements over the 1995 Base and the 2050 Base.

Alternative D13R would provide hydrologic conditions that would be beneficial to the littoral zone, particularly in the west and northwest. The littoral zone cannot be underestimated in terms of its importance to the fisheries of the lake. The littoral zone community of Lake Okeechobee includes most of the wading bird, waterfowl, and herpetofauna characteristic of the Everglades as a whole. One possible negative impact of Alternative D13R is the potential for impingement and entrainment of fishes in the pumps and pipelines used to move water from Lake Okeechobee to above-ground storage and ASR wells.

Southern Everglades

For the most part, Alternative D13R represented a significant improvement over the 1995 and 2050 bases. The overall performance of Shark River Slough indicated an 82% match with the NSM target, as opposed to 28% for the 1995 Base and 38% for the 2050 Base. The rockland marl marsh fared slightly less successfully, with an overall match of 76%, as opposed to 22% for the 1995 Base and 60% for the 2050 Base. The Florida Bay coastal basins showed an 80% match, as opposed to 20% for the 1995 Base and 50% for the 2050 Base. The overriding problem was the lack of sufficient water to fully meet the performance targets; however, the extent to which these shortfalls are ecologically significant is as yet undetermined.

The results for Model Lands were mixed, indicating that Alternative B performed better for lands west of U.S. 1, whereas Alternatives C, D, and D13R performed better for lands east of U.S. 1. As was the case for the rest of the southern Everglades, the issue was a lack of sufficient water, particularly of an adequate quality, to meet the restoration objectives. As a whole, however, the AET report deemed Alternatives C, D, and D13R to be preferable for the region as a whole, since all of these alternatives spread the available water across the region more equitably. Moreover, these three alternatives would provide the infrastructure to furnish the needed water, should a source be identified during the detailed design phase.

The ecological significance of the gap between the target performance measures is not clear at this time. Many other parts of the natural system likewise do not fully meet their targets. One thing that is certain is that it will not be possible to return the south Florida ecosystem, let alone the Everglades and Lake Okeechobee, to their predrainage condition. Since the first canals were dug in the late 1800s, roughly half of the spatial extent of the Lake Okeechobee-Everglades system has been lost; the system of levees that protect the developed and agricultural lands east of the Everglades has changed the shape of the natural flowage system, and therefore changed the range of possible flow vectors; peat has been lost, and whole regions have subsided; sea level appears to be rising over the long term; and exotics have invaded. Many of these changes are irreversible, while others are reversible only by restoring long-term processes. In general, any movement in the direction of meeting the performance measures beyond the performance of the 1995 Base and the 2050 Base would be expected to be positive for fish and wildlife. More problematic than the shortfalls predicted for hydrologic conditions within Everglades National Park are the long-term effects of shortened hydroperiods and water quality within the Model Lands. Invasion of exotic and brushy plants due to shortened hydroperiod may have to be approached aggressively through fire management and herbicidal treatment in order to maintain the relatively low, open plant community that supports the easternmost subpopulations of the endangered Cape Sable seaside sparrow. These issues will have to be sorted out at the detailed design stage.

Big Cypress National Preserve

The AET assessed the effects of the alternatives on the Big Cypress National Preserve by comparing the performance in each of the three regions (north Big Cypress, south Big Cypress, and southeastern Big Cypress) most likely to be affected by the changes being modeled with the SFWMM with the values predicted by the NSM. The results were not conclusive, possibly due in part to the use of an indicator region that did not adequately reflect the alternatives' performance in the north Big Cypress region, and also due to a disagreement as to how to interpret performance at the boundary with Everglades National Park (southeastern Big Cypress region). The summary results for the southern and southeastern Big Cypress regions, however, do indicate that Alternatives D and D13R perform the best of all of the alternatives, including the 1995 and 2050 bases. Due to uncertainties mentioned above, the impacts to fish and wildlife are not clear.

Estuaries and Bays

The greatly improved performance of the Caloosahatchee estuary under Alternative D13R would benefit all estuarine species. Reducing these freshwater pulses would stabilize seagrass beds, and would benefit members of the drum family (Sciaenidae), such as the seatrout. Damaging discharges to the St. Lucie estuary would be reduced, resulting in fewer stressful events on the estuarine fish species and productive seagrass beds; however, the Comprehensive Plan will have to defer to the results of the Indian River Lagoon Feasibility Study to fully address the St. Lucie estuary. Anticipating impacts to Lake Worth Lagoon and to Biscayne Bay are problematic at this time, due to the uncertainty in performance uncovered by both analyses of these coastal waterbodies.

Northern and Central Everglades

Holey Land and Rotenberger Wildlife Management Areas

Holey Land and Rotenberger WMAs constitute about one-half of the remnant sawgrass plains landscape of the Everglades, the remainder of which occurs in northeastern WCA-3A. The principle hydrological restoration needs for these areas are: the provision of clean water during both wet and dry seasons, in quantities suitable to provide natural hydropatterns; the avoidance of extreme high-water events that would drown remaining tree islands and promote cattail proliferation; and the prevention of extreme drought conditions that cause soil oxidation and risk of muck fires. Although the Restudy alternatives do no include significant structural alterations to these WMAs, Alternative D13R, like Alternatives A through D, contains some potentially beneficial components, including: (1) an inflow/outflow operational schedule that would deliver water to both Holey Land and Rotenberger WMAs during dry as well as wet seasons; (2) rainfall-based operational rules that provide for natural depth variations, but with high and low limits imposed to prevent extreme flood or drought conditions; and (3) improvement of additional outflow structures in Holey Land WMA as need to support the outflow operations (C. Neidrauer, pers. comm.).

The overall performance of Alternative D13R appears to be largely satisfactory in these areas. The model results for Rotenberger WMA show a reduced frequency of drought conditions relative to both the 1995 and 2050 bases. For Holey Land WMA, however, any comparison of Alternative D13R to the revised 1995 and 2050 bases is not realistic, because the revised bases modeled a 0- to 2-foot regulation schedule that has been abandoned and is unlikely ever to be re-implemented in the future. For this reason, we interpreted Alternative D13R for Holey Land WMA by comparing performance to the unrevised 1995 Base, which assumed a 0- to 1-foot regulation schedule more like that which is currently in use. When this comparison is made, the performance of Holey Land WMA in Alternative D13R is overall similar to the revised 1995 Base. Advantages of using the rainfall-based operations, as opposed to the fixed schedule in the 1995 Base, cannot be discerned at the level of resolution of the SFWMM.

Four concerns remain. First, the predicted quality of inflow water seems uncertain. Stormwater Treatment Area (STA) 5 may not be sufficiently large to meet a target of 10 ppb phosphorus, or even the 50-ppb interim standard, with the increased flows predicted for the Restudy. Second, it is not yet understood what exact operational limits on high and low water depths will provide the biologically best balance between the need protect peat soils and the need to discourage cattail proliferation. Current operational assumptions in Alternative D13R are only an estimate to support modeling of structural performance. It will be essential for the restoration of these areas that operational rules be evaluated with more detailed modeling, followed by monitoring and adjustment as needed. Third, one disadvantage of rainfall-based operations is that they can create higher water demands than do fixed regulation schedules because water is brought in and discharged more frequently in an attempt to emulate natural depth patterns. While this strategy may improve flow through the system, it may also increase overall phosphorus loading. Hence, it will be important to balance development of operational rules with possible constraints imposed by water quality. The fourth concern is that in both WMAs, drought conditions (when the water table drops to more than one foot below the ground surface) occur about 3-4% of the simulation period in Alternative D13R. The minimum depths and durations needed to protect peat soils are still not well understood; however, so long as the plan provides for dry season deliveries of adequately treated water via the STAs, it should be possible to adjust operational details so as to avoid further soil loss.

The hydrological performance of Alternative D13R for both Holey Land and Rotenberger WMAs is generally similar to that in the unrevised 1995 Base for Holey Land WMA. Predicted conditions are largely consistent with overall current management goals for these areas. Nonetheless, there remain uncertainties about the ability of the STAs to provide sufficient water quality, and these uncertainties raise concern about the potential for continued cattail expansion within these areas. The flexibility to adjust water management regimes in these areas will likely be the most important component for insuring long-term sustainability of marsh conditions favorable for wildlife.

Water Conservation Area 1 (A. R. M. Loxahatchee National Wildlife Refuge)

The current regulation schedule for A. R. M. Loxahatchee National Wildlife Refuge (LNWR) was used by all of the Restudy alternatives. Earlier examination of decompartmentalization scenarios had shown that removal of the L-39 levee would lead to severely damaging low water levels in Lake Okeechobee. Current refuge management goals are to maintain present conditions, comparable to the 1995 Base. For this reason, the only structural components included in Alternative D13R were weirs placed within the perimeter canal in order to reduce over-drainage of the northern part of the refuge.

Overall, LNWR would be expected under Alternative D13R to maintain marsh conditions favoring deeper-water species such as snail kites and waterfowl, as well as substantial populations of marsh fishes. However, it is possible that a continuation of the existing schedule, which maintains deeper water in the southern part of the refuge, could lead to adverse effects on tree island communities and the wildlife that depend on them.

Water Conservation Areas -2A and -2B

The marsh ecosystem in WCA-2A has suffered substantial damage as a result of past water management. In the south, most of its tree islands have been lost to prolonged high waters (Dineen 1974), while many acres of northeastern WCA-2A have been overtaken by cattails. The highest quality marsh occurs in central WCA-2A in the vicinity of the 2-17 gage and to the northwest of the gage, where a small number of intact tree islands persist. Principle hydrological restoration needs are a reduction in over-drainage in the north and in extreme high-water events that have drowned tree islands in the south.

Under all of the Restudy alternatives, WCA-2A exhibited problematic performance. In Alternatives A-D, southern WCA-2A experienced more frequent extreme high-water events than would occur under 1995 and 2050 bases while northern WCA-2A had durations of inundation that were much longer than those predicted by the NSM. Alternative D13R introduced operational changes that improved inundation patterns in the north, but in so doing increased the frequency of extreme drought conditions in the south. It appears that water management in WCA-2A imposes trade-offs between providing improved marsh conditions in some areas but worse conditions in others. It is also possible that restoration of a more natural hydropattern to this portion of the Everglades is hampered by constraints imposed by water management elsewhere, notably the fixed regulation schedule in LNWR, that may be amplifying high and low water conditions in WCA-2A. If LNWR adopts rainfall-based operational rules in the future, such unnatural fluctuations in depth may be alleviated.

Water Conservation Area-2B was one of the two most problematic regions in the northern and central Everglades from the standpoint of restoration to more natural hydrologic conditions. Although the overall hydroperiod in this area is similar to that in the NSM, all the alternatives exhibit too-frequent extremes of high water, low water, or both. In Alternative D13R, the occurrence of extreme high-water events is substantially less than it is in the 1995 and 2050 bases; however, there still remains a combination of frequent drought conditions and frequent extreme high-water events that occupy 16% of the total simulation period. Such frequent extremes imply that this area will not be able to function sustainably as either a shorter- or a longer-hydroperiod Everglades wetland.

The overall most significant component affecting performance in WCAs-2A and -2B is the Central Lake Belt storage facility, which takes water from southern WCA-2B (as well as from eastern WCA-3A and -3B) and routes it to the Central Lake Belt reservoir for later delivery to Everglades National Park or other areas. This design leads to continued flow-through and a very different set of water management issues than those of the present C&SF Project. Rather than exhibiting high water in the south combined with overdrainage in the north, as is currently the case in all of the WCAs, Alternative D13R predicts longer hydroperiods near the STA-2 input in the north, increased drying in the south, and accumulation of water at the “bottom” in WCA-2B. As a result, those areas that most closely match target hydrologic performance are those nearest to the locations of gages that trigger inflow/outflow operations. A more detailed study of the effects of different operational rules will be needed in order to identify the ecologically most beneficial method of water management for this region.

The ability of Alternative D13R to support appropriate densities of Everglades fish and wildlife within WCAs -2A and -2B will depend strongly on the results of detailed project design and the operational rules that accompany it. On the one hand, it is possible that water management could promote protection of remaining tree islands in northern WCA-2A along with recovery of previously damaged islands in southern WCA-2A. Such protection would provide nesting areas for wading birds and reptiles, as well as improved wading bird foraging habitat. On the other hand, it is also plausible that extremes of high and low water could result in soil loss in southern WCA-2A, deterioration of remaining tree islands, and spread of cattails throughout the north. Similarly, the deep water in WCA-2B might support fish and apple snail populations and provide refuges for aquatic organisms during all but the most extreme dry periods; however, if water management in this area allows WCA-2B to dry out for extended periods, it will not be able to serve such ecological functions.

Water Conservation Area-3A

A number of components in Alternative D13R lead to significant predicted changes in hydrologic conditions in WCA-3A. Those components having the most direct effects on the conservation area are (1) the changes in the location and magnitude of water deliveries along the northern and western boundaries; (2) the Central Lake Belt reservoir and its operation; (3) the L67-A canal and levee changes; and (4) the removal of the L-28, L-28 tieback, and L-29 levees. The hydrologic changes that result from these components fall into three general classes, corresponding to different sub-regions of the conservation area that differ both in their current restoration needs and in the changes predicted for Alterative D13R.

The first hydrologically distinct area is northwestern WCA-3A, north of Alligator Alley and west of the Miami Canal.   This area is within the part of the WCA that has been most affected by over-drainage, which in turn has led to substantial soil loss through oxidation and muck fires. A major restoration priority in this area is the protection of existing peat soils and the reinitiation of peat accumulation. Alternative D13R predicts improved hydrologic conditions in this respect, with a reduction in the frequency of extreme dry-outs (defined as groundwater depths in excess of 1.0 feet below ground) from 7-11% of time in the 1995 Base, and 4-5% of time in the 2050 Base, to 1-3% of time in Alternative D13R.

The second hydrologically distinct area in WCA-3A is the region south of Alligator Alley and west of the Miami Canal. This area includes some of the most deeply ponded parts of the WCA, where substantial damage to tree island vegetation has occurred as a result of flooding during the past 30 years (McPherson 1973). Southern WCA-3A also includes the portions of the central Everglades that have suffered the least damage as a result of C&SF Project operations (McPherson 1973; Schortemeyer 1980). Under Alternative D13R, southern WCA-3A is predicted to see a substantial reduction in the frequency and duration of extreme high-water events. The most dramatic improvement is in the southernmost part, corresponding to Indicator Region 14 in SFWMM output. Here the occurrence of extreme high-water events is reduced from 36% of time in the 1995 Base, and 6% of time in the 2050 Base, to only 1% of time in Alternative D13R.   These benefits are clearly owing to the removal of the L-29 levee along the southern boundary of WCA-3A, since significant reduction in the intensity of flooding occurs only in Alternatives D13R and B, the two alternatives in which this levee is removed. On the other hand, although extreme depths are largely eliminated from southern WCA-3A, the overall hydroperiod of the area is increased, with periods of inundation that are much longer than those predicted by the NSM. These extended hydroperiods are most pronounced in the area immediately to the south of Alligator Alley, corresponding to Indicator Region 18 in SFWMM output. Here the model predicts only 11 marsh dry-outs during the 31-year simulation, as compared with 18 events in the 1995 Base and 24 events in the NSM. This lengthening of hydroperiods is a result of the relocation and increased operational capacity of the S-140 structure, which leads to greatly increased discharges directly northwest and upstream of Indicator Region 18. Hence, although the reduction in predicted tree island flooding would be a dramatic step toward ecological restoration of southern WCA-3A, the ecological effects of a general shift toward longer hydroperiods is uncertain.

The third hydrologically distinct area in WCA-3A is the region to the east of the Miami Canal. This is the area in which the most successful wading bird nesting has occurred in recent years, although rookery vegetation was substantially damaged by the high-water event of 1994-95 (T. Towles, GFC, pers. comm.). The performance of Alternative D13R is problematic in this area. In the northeastern region, north of Alligator Alley, the frequency of extreme high-water events is larger than it is in either the 1995 or 2050 bases, and simulated depths and durations during the high-rainfall years of 1994-95 are predicted to be worse than in the 1995 Base. This increase in predicted flooding raises concerns about potential negative effects on wading bird nesting habitat in this region, which already suffered damage during the 1995-96 high-water event. The problem in Alterative D13R appears to result from excess discharges from STA 3/4 during high rainfall years. In contrast, to the south of the 3A-3 gage, northeastern and eastern WCA-3A are predicted to experience reduced depths and flooding compared to the 1995 Base. Since eastern WCA-3A has suffered from extreme high-water events in recent years, rookery sites in eastern WCA-3A might be expected to do better under Alternative D13R than under current conditions. In addition to uncertainty about the effect of hydrologic changes on rookery vegetation in this region, Alternative D13R also predicts that northeastern WCA-3A will continue to experience drought conditions frequently enough to raise concern about continued impacts to peat soils.

Alternative D13R makes substantial progress toward remedying the two most significant causes of habitat degradation for wildlife within WCA-3A. The first of these is flood damage to tree islands, with attendant loss of upland tree species, willow strands that serve as wading bird nesting sites in northeastern WCA-3A, tropical hardwood hammocks in southwestern WCA-3A, and habitat throughout the WCA for island-dependent organisms such as nesting reptiles, white-tailed deer, and migratory and nesting songbirds. The second major cause of habitat degradation has been the destruction of peat soils, marsh vegetation, and tree islands as a result of wildfires brought on by drought conditions in the north. Together, the reduction in the frequency and intensity of these two sources of environmental damage should be expected to lead to substantial restoration within this large portion of the remnant Everglades ecosystem.

Nevertheless, there continues to be uncertainty about several aspects of the predicted hydrologic change. First, the ecological effect of prolonged inundation periods on the overall functioning of the Everglades ecosystem is not known. Comparison of predicted hydroperiods for the overall WCA-3A and -3B region indicates that the entire landscape will, on average, be shifted toward inundation durations that are longer than those predicted by the NSM. Second, it is uncertain whether hydropattern restoration will lead to cattail proliferation in the north, as a possibly inevitable consequence of antecedent soil conditions and changed topography. Third, it is difficult to predict how wading bird nesting and foraging will be affected by changes in depth patterns in northeastern WCA-3A. The more northerly parts of this area (represented by model output for the 3A-4 gage and Indicator Region 21) are predicted to become wetter, while to the south, areas east of the Miami Canal will remain deeper than the NSM values, but will have much reduced high-water frequencies compared to the 1995 Base. These conditions could be expected to improve suitable rookery sites in some areas but, possibly, damage others; and the distribution of suitable foraging areas will undoubtedly be changed. Although overall restoration of the Everglades watershed is expected to improve nesting habitat for wading birds regionally, the timing of development of suitable breeding sites to the south, relative to changes in current nesting sites, could have significant effects on regional wading bird populations. A more detailed analysis of anticipated effects of Alternative D13R on wading bird breeding and foraging habitat, combined with a plan for system-wide monitoring, will be important components in implementing the plan.

A final area of uncertainty is water quality. The alternatives modeling process has assumed that all environmental water deliveries would meet a 10 ppb phosphorus standard; however, given the large inflows into and through the WCA system, it is not clear that this goal will be achieved. As currently modeled, most inflows into WCA-3A involve water that will be coming through the STAs (those currently under construction under the Everglades Construction Project and additional STAs proposed by Alternative D13R). However, an area of concern is the water entering WCA-3A South via the relocated S-140 structure. There is a possibility that the plan may not include adequate STA treatment capacity for flows of this magnitude in this area.

Water Conservation Area-3B

Water Conservation Area-3B is the second of two remaining high-quality marsh areas within WCA-2 and -3, the other being central WCA-3A. Although generally drier than it was prior to construction of the C&SF Project, the area is characterized by good water quality, intact wet prairie and sawgrass communities, and hardwood hammock and bayhead tree islands that are largely undamaged by flood, fire, or modern human activity. Southeastern WCA-3B is part of the predrainage channel of Shark River Slough. Overall, the area is slated to receive increased depths as part of the effort to restore natural hydropatterns to Shark River Slough and freshwater flows to Florida Bay.

Achieving acceptable Everglades conditions within WCA-3B has been a major planning challenge for the Restudy. Water Conservation Area-3B exhibits increased depths in all four alternatives, with weekly mean depths that exceed the NSM values by 0.5-0.75 feet year round. Of greater concern than the increased average depth pattern, however, has been the predicted high occurrence of prolonged depths in excess of 2.5 feet. Alternative B had the most extreme high water, with 12% and 17% of the simulation period having depths greater than 2.5 feet in western and eastern WCA-3B, respectively. These values for duration of high-water events range from 25% to 76% larger than those predicted by the NSM for northeast Shark River Slough, historically the deepest part of the natural system. Hence, Alternative B actually pushes WCA-3B not only well beyond the range of the predicted predrainage depths for that area, but outside the maximum depths and durations estimated to have occurred anywhere predicted within the historical River of Grass.

Alternatives D13R and A were the only alternatives that succeeded in holding the frequency of extreme high-water events within the bounds defined for the natural system, overall, by the NSM. In both alternatives, this performance can clearly be credited to the barrier provided by the L-67 levee, which prevents excess build up of water within the northern and central sections of the WCA. Alternative D13R was the only "decompartmentalization" alternative that avoided excessive flooding in WCA-3B. In addition, Alternative D13R predicts a lower frequency of extreme high-water events than that predicted for the 2050 Base, although 2050 Base conditions in northeast Shark River Slough are far drier than their restoration targets.

Under Alternative D13R, WCA-3B is neither restored in an historical sense, nor are its current ecological values conserved. Overall, D13R leads to an inundation and depth pattern in WCA-3B that more closely matches NSM predictions for mid-Shark River Slough than it does for WCA-3B itself. This pattern represents a substantial deviation from both current conditions in WCA-3B and from NSM predictions of the pre-drainage hydrology. The rationale for this deviation from what would otherwise be the defined restoration targets for WCA-3B is the need to restore freshwater flows through Shark River Slough to Florida Bay, and to provide more natural hydrologic conditions for the entire Everglades landscape. The long-term effect of increased depths in WCA-3B is uncertain.

Water Conservation Area-3B is one of the least impacted portions of the northern and central Everglades. Although it is substantially drier, at least in its southeastern reaches, than in predrainage estimates, and has suffered significant soil loss in this area, it has good water quality and tree islands that have been largely unimpacted by flood, drought, or human activity. Hence, although Alternative D13R appears likely to prevent damage to higher hammock tree islands in WCA-3B, impacts on less-elevated tree islands still may occur. It is doubtful that WCA-3B could tolerate much deeper conditions than those seen in Alterative D13R without causing a net degradation in fish and wildlife resources in this area.

Pennsuco Wetlands

The Pennsuco wetlands lie in a region that once included some of the deepest parts of the predrainage Everglades. Today the area supports a drier marsh with extant tree islands. Under Alternative D13R, extreme low-water and extreme high-water conditions occur relatively rarely, and the reduction in drought conditions is dramatically improved over the 1995 and 2050 bases. Overall hydroperiods are longer than under the base models, and the hydrologic conditions appear likely to support "NSM-like" ridge and slough conditions, with reduced drought frequencies. These hydrologic conditions would be expected to protect marsh soils and provide for a sustainable marsh in the area, even though it would not return this area to its historical condition.

Given the increased depths predicted in Alterative D13R for both Shark River Slough and WCA-3B, an important potential function of the Pennsuco marsh might be to provide shallower water suitable for wading bird foraging during periods when both Shark Slough and WCA-3B are too deep.

Everglades Protection and Restoration Section
Florida Game and Fresh Water Fish Commission

Introduction

The C&SF Restudy encompasses a very large geographic area delimited by the South Florida Water Management District (SFWMD) boundary and includes a number of public properties that are managed by the Florida Game and Fresh Water Fish Commission (GFC) for their recreational value related to fish and wildlife. Those areas that are presently thought to be little affected, if at all, by the initially preferred alternative (Alternative D13R), but which lie within the drainage basin, include six Type I wildlife management areas consisting of Three Lakes Wildlife Management Area (WMA) and Kicco WMA in Osceola County, Arbuckle WMA in Polk County, Kissimmee River WMA in Highlands and Okeechobee counties, Fred C. Babcock/ Cecil M. Webb WMA in Charlotte County, and Frog Pond WMA in Dade County; and one Type II wildlife management area (Avon Park Air Force Base) in Polk and Okeechobee counties. Type I wildlife management areas are public hunting and recreation areas operated by the GFC in cooperation with private, state, and federal landowners. Type II wildlife management areas are public hunting and recreation areas operated by the landowner in cooperation with the GFC. Those wildlife and environmental areas (WEAs) that are presently not expected to be affected include the John G. and Susan H. Dupuis WEA in Palm Beach and Martin counties and the CREW WEA in Lee and Collier counties. Other areas managed by the GFC that are not expected to be influenced by the C&SF Restudy include the Lake Harbor and Terrytown Public Waterfowl Areas (PWA). Nevertheless, the use of Terrytown as a Public Waterfowl Area may be temporary since this area was acquired by the SFWMD for use as a stormwater treatment area as part of the Everglades Forever Act. The remaining wildlife management areas detailed in this report are the ones that we thought had the most potential for being affected if Alternative D13R were implemented.

A measure of the amount of recreational hunting in each of those wildlife management areas that are anticipated to change under the C&SF Restudy is portrayed in Table 1. The level of monitoring harvest pressure varies between wildlife management areas due to budgetary and staffing constraints, and to differences between areas in check station operation and amount of hunter use. For example, the highest 5-year mean (13,306 man-days) for harvest pressure recorded in the Everglades region was for the Big Cypress Wildlife Management Area (Big Cypress WMA) (Table 1). Harvest pressure information for this area was derived from vehicle counts on Saturdays of every weekend during the 93 days comprising the archery, muzzle-loading, and general gun seasons. By contrast, harvest pressure data was not collected in the Holey Land and Rotenberger WMAs during portions of some hunting seasons. For instance, during the 1997-98 season, harvest-pressure data were gathered only on the opening weekends of muzzle loading and general gun-walk seasons. Consequently, the 5-year mean figures for harvest pressure in the Holey Land (635 man-days) and Rotenberger (766 man-days) WMAs should be viewed as minimal estimates of harvest pressure that are not directly comparable to wildlife management areas such as the Big Cypress WMA, where the hunting pressure is more consistently measured.

Everglades and Francis S. Taylor Wildlife Management Area

The Everglades and Francis S. Taylor Wildlife Management Area (EWMA) is a Type I wildlife management area located in southwestern Palm Beach, western Broward, and northwestern Dade counties. The EWMA consists of Water Conservation Areas (WCA)- 2 and -3, and encompasses approximately 671,831 acres (Figure 1). Different hydrological regimes exist due to the division of WCA-2 into two compartments forming WCA-2A and WCA-2B, and the division of WCA-3 into two compartments forming WCA-3A and WCA-3B. Consequently, wildlife populations and associated recreational opportunities vary considerably between these compartments, necessitating the implementation of an array of management strategies that also varies with regional weather patterns and water management operations. The principal landowners of the EWMA are the SFWMD and the State of Florida's Board of Trustees, with the remainder owned by other public agencies and private individuals. Water Conservation Areas-2 and -3 were designated as the EWMA in 1952, and are operated by the GFC under the terms of a cooperative management agreement with the SFWMD.

The EWMA has traditionally been used by the public for a variety of recreational activities including hunting, fishing, frogging, airboating, camping, and nature appreciation. Utilization of the interior marsh is limited due to physical constraints and lack of access. Airboats are the primary mode of transportation into the marsh when surface water is present, whereas all-terrain vehicles (ATV), tracked vehicles, and swamp buggies are used to access the area when water levels approach ground level.

There are several recreation areas located along the boundary of the EWMA: Loxahatchee Recreation Area, Sawgrass Recreation Area, Everglades Holiday Park, and Mac's Fish Camp. These facilities, along with three regularly operated concessions by the Miccosukee Tribe on the Tamiami Trail, provide amenities such as boat ramps, camping facilities, boat rentals, airboat tours, fishing guides, bait and tackle supplies, and food to the general public. During 1997, commercial airboat tours out of Everglades Holiday Park transported 116,306 tourists into nearby Everglades canals and marsh.

Frogging is permitted throughout the year. This is a favorite pastime of many airboaters. Although frogging occurs throughout the EWMA, the southwestern and central portions of WCA-3A have traditionally harbored the best frog populations, and consequently have received the most use (Ligas 1960).

Hunting for selected game species is allowed during the fall-winter period; however, check stations erected to monitor harvest pressure and collect biological information are only operated during the fall deer season. Consequently, there is no information as to the hunting pressure on other game species. The mean time spent on deer hunting in the EWMA, based on the five-year period of 1989-93, was 1,984 man-days (Table 1); however, this level of hunting pressure declined precipitously following the unprecedented high water event of 1994-95 that practically eliminated the area's deer herd and necessitated the complete closure of the deer season for three years (Table 1). Other game species that are often sought by hunters in the EWMA, when hydrological conditions are favorable, include waterfowl, snipe, and wild hogs.

The canal system of the EWMA supports an important recreational fishery, with fishing permitted throughout the year. Two of the areas that have traditionally supported some of the best fishing and consequently have been monitored by the GFC through creel surveys are the L-35B/L-38E canals and the L-67A canal. Creel survey data collected for the 5-year period of 1985-89 in the L-35B/L-38E canals yielded a fishing effort ranging from 55,659 hours in 1985-86 to 128,430 hours in 1986-87, with an annual mean of 81,665 hours. A five-year mean total of 79,755 fish were harvested with a harvest success rate of 0.91 fish per hour (Table 2). There is a no-consumption advisory on bass due to high levels of mercury in the EWMA. Consequently, anglers routinely release their fish, which has resulted in high populations of 2- to 5-pound bass (Jon Fury, pers. com.).

Fishing effort in the L-67A canal for the seven-year period of 1990-97 ranged from 25,848 hours in 1992-93 to 58,150 hours in 1995-96, with an annual mean of 43,167 hours. The seven-year mean total recorded harvest was reported to be 41,765 fish, with a mean success rate of 0.98 fish per hour. The results from these creel surveys are derived from a six-month sampling period during each of the years, so these data do not include fishing effort expended during the remainder of these years. Although creel surveys were discontinued for the L-35B/L-38E canals in 1990, observations by staff of the Division of Fisheries indicated that the fishing effort in this canal system appeared to be comparable to that expended for the L-67A for the time period of 1992-97. High water levels in the EWMA since 1993, however, have contributed to below-normal fishing effort due to the dispersion of fish into the adjoining marsh, resulting in lower catch rates. It should also be noted that even though the year 1995-96 experienced the highest amount of fishing effort in the L-67A canal over the past seven years (Table 2), access was greatly curtailed due to the closure of the boat ramps at the primary access site of Everglades Holiday Park for about three months and the closure of the canal itself for about one month. Although these two canal systems represent no more than 16% (assuming about 330 miles total) of the total canal mileage within the EWMA, they receive a disproportionate amount of the fishing pressure from boats. Due to staffing and budgetary constraints, no recent creel survey data have been collected for the rest of the canal system within the EWMA. There is also a considerable amount of bank fishing in the canals adjacent to S.R. 27, I-75, and the Tamiami Trail (Tim Towles, pers. com).

Due to the institution of slot possession limits on largemouth bass in 1996, it became necessary to issue regulation exemption permits for bass tournament participants. Outside of Lake Okeechobee, the canal system within the EWMA has proven to be the most popular location for holding bass tournamentsin south Florida. There are approximately 65 fishing clubs in the Everglades region, many of which periodically host tournaments. In the fiscal year 1996-97, 91 of the 116 (or 78%) bass tournaments in the Everglades region (excluding Lake Okeechobee) were held in the EWMA. During this year, 3,202 participants landed 5,061 bass, with a combined weight of 13,906 pounds. Also, 37 of these bass caught in WCA-3A weighed more than 8 pounds, and the largest weighed almost 10 pounds. During the fiscal year of 1997-98, 117 of the 180 (or 65%) bass tournaments in the Everglades region (excluding Lake Okeechobee) were conducted within the canal system of the EWMA. In this fiscal year, 4,312 anglers landed 6,759 bass, with a combined weight of 16,920 pounds. Of these bass, 54 caught in WCA-3A weighed more than 8 pounds, and the largest weighed in at nearly 11 pounds. It is estimated that approximately 95% of the WCA-3A tournaments originate at Everglades Holiday Park, with most of the fishing pressure concentrated in the L-67A canal (Jon Fury, pers.com).

There are currently more than 65 privately constructed camps scattered throughout the EWMA. These camps consist of permanent buildings constructed by private individuals on tree islands or on pilings over the water. These camps are primarily used as weekend retreats and hunting camps.

Holey Land Wildlife Management Area

The Holey Land Wildlife Management Area (Holey Land WMA) is a tract of Everglades marsh encompassing approximately 35,350 acres in the southwest corner of Palm Beach County (Figure 2). Title to this tract is held by the State of Florida's Trustees of the Internal Improvement Trust Fund, and the area is leased to the GFC for fish and wildlife management purposes.

The Holey Land WMA was a popular deer hunting area prior to rehydration under the Holey Land Restoration Project. Since hydrological restoration was begun in 1991, the Holey Land WMA has undergone a transition in recreational use that has been more strongly oriented towards fishing in the perimeter canal and waterfowl hunting (GFC 1997g). Recreational access to the marsh areas may be achieved by airboat, ATVs, or tracked vehicles. Vehicle use is permitted in the Holey Land WMA from May 1 to the end of the duck season, except during specified big game hunts when further restrictions apply. Tracked vehicle deer hunts may be conducted under appropriate hydrological conditions if deer population indices indicate a sufficient population level.

The hunting pressure on the Holey Land WMA has ranged from 214 to 972 man-days during the time period extending from the 1993-94 through the 1997-98 seasons (Table 1). However, due to a severe reduction in the deer herd as a result of the higher water-regulation schedule adopted for the Holey Land WMA and above-average amounts of rainfall, the gun-vehicle hunt season was closed from the 1993-94 through the 1996-97 seasons. Also, only the archery season was open during the 1994-95 season. Consequently, the annual mean hunting effort for the years 1993-98 in the Holey Land WMA, using only the figures for those hunts that were open each season, was calculated to be 635 man-days.

Although waterfowl hunting has become popular in the Holey Land WMA since hydroperiod restoration began in 1991, no data on duck hunter use were collected until the 1996-97 season. During this season, a minimum of 266 man-days of hunting pressure was estimated for duck hunters, which surpassed the minimum estimate of 156 man-days expended by deer hunters during that season. During the 1997-98 season, man-days attributed to hunting in Holey Land WMA were 392, with a reported harvest of 382 ducks and two deer. Although frogging is permitted in the Holey Land WMA, the hydrological regime and vegetative structure is not conducive to an exploitable frog population; the area therefore receives little pressure from recreational froggers (Blake Sasse, pers. com).

No creel surveys have been conducted in the Holey Land WMA by the GFC's Division of Fisheries; however, an attempt was made in 1996 by staff of the Division of Wildlife to estimate fishing pressure by counting vehicles at boat ramps whenever they visited the management area. Fishing pressure was estimated to be 5,054 angler-days in 1996, with the majority of fishers using the G-200 and G-201 boat ramps. From this survey, it was concluded that fishing had apparently become the primary recreational use in the Holey Land WMA (GFC 1997g).

Rotenberger Wildlife Management Area

The Rotenberger Wildlife Management Area (Rotenberger WMA) is a tract of Everglades marsh comprising approximately 27,810 acres in the southwest corner of Palm Beach County, and is bordered to the east by the Miami Canal and to the south by WCA-3A (Figure 3). The area is owned by the State of Florida under fee-simple title to the Trustees of the Internal Improvement Trust Fund and leased to the GFC for fish and wildlife management purposes (GFC 1997e).

The primary public use of the Rotenberger WMA has been deer hunting. Other game species that are commonly sought include wild hogs and snipe. Although frogging and fishing are also permitted, these resources are in limited supply due to the short hydroperiods that presently exist in the area (GFC 1997e). Recreational access to the area can be achieved by ATVs, airboats, swamp buggies, or tracked vehicles during designated times of the year (May 1 to the end of the waterfowl season) when hydrological conditions are appropriate for that particular mode of transportation.

The hunting pressure on the Rotenberger WMA has ranged from 106 man-days during the 1994-95 deer hunting season to 944 man-days during the 1997-98 season. The low hunting pressure during 1994-95 could be attributed to the combined effects of extremely high water levels in the adjacent EWMA, a low deer population index, and the closure of all big game seasons except the archery season. The mean hunting effort for the five-year period from 1993-98 was reported as 766 man-days, using only those figures for the hunts that were open during that particular season (GFC 1998b).

Big Cypress Wildlife Management Area

The federally owned Big Cypress Wildlife Management Area (Big Cypress WMA) comprises approximately 565,848 acres in northwestern Dade, eastern Collier, and northwestern Monroe counties (Figure 4), with the game animal populations managed by the GFC under a cooperative agreement with the Big Cypress National Preserve. The Big Cypress WMA is subdivided into six different management units (Figure 4), where the amount of hunting pressure is regulated based on deer population indices, hydrological conditions, and the maintenance of a food base for the Florida panther. Of these management units, the Corn Dance, Loop Road, and Stairsteps units are more likely to be influenced by hydrological changes due to their close proximity to WCA-3A.

Due to the great diversity of both upland and wetland habitats in the Big Cypress WMA, a wide array of game species is harvested from the area. A significant amount of the hunting pressure within the Big Cypress WMA takes place in the Corn Dance, Loop Road, and Stairsteps units, which, since 1991, have together accounted for almost half of the total hunting pressure during those years when all units are open to hunting (Table 3). Due to the high level of interest in the big game general gun hunting season, this hunt is regulated by a weekly quota that has been consistently reached during the past six years for the Corn Dance and Loop Road units, but not in the Stairsteps unit (Eddie White, GFC, pers. com.). The number of permits allocated to the Stairsteps unit, however, is also usually three to four times the number issued to either the Corn Dance or Loop Road units. Although deer and hog hunting constitutes a significant component of recreation in the Big Cypress WMA (Jansen 1986), wild turkey, waterfowl, and small game (including doves, snipe, quail, marsh rabbits, grey squirrels, and raccoons) provide additional recreational opportunity. Fishing and frogging are permitted throughout the year. Fishing is a popular activity in the canals accompanying roadways through the Big Cypress WMA (U.S. 41, SR 94, and Turner River Road) (Jim Schortemeyer, pers. com.) although the use of outboard motor boats is limited due to the narrowness and generally densely vegetated nature of the canals (Deuver et.al 1986). Most frogging activity occurs in the wet prairie and dwarf cypress forest habitats in the Stairsteps unit south of US 41 (Deuver et.al 1986).

There are several established seasons for different user groups for the harvest of deer and wild hogs. These include a 30-day archery season extending from early September until early October that has been in effect since 1990, a 16-day muzzleloading gun season in the latter half of

October, and a 47- to 51-day general gun season extending from mid-November through the first of January (GFC 1997b). Access to the interior of the preserve is attained by the use of wheeled swamp buggies, ATVs, and airboats, depending on hydrological conditions and the regulations for a particular management unit. Wheeled swamp buggies are the most commonly employed mode of transportation in most of the Big Cypress WMA including the Corn Dance unit. On the other hand, airboats are the preferred type of transportation into the Everglades type habitats of the Stairsteps unit (Deuver et.al 1986).

Southern Glades Wildlife and Environmental Area

The Southern Glades Wildlife and Environmental Area (Southern Glades WEA) consists of 30,080 acres of Everglades marsh in southeastern Dade County and is bisected by the C-111 and C-109 canals and associated levees (Figure 5). Most of the area was acquired by the SFWMD through the Save Our Rivers program, although small, private in-holdings do occur, with the GFC given the responsibility of managing the fish and wildlife resources of the area. The Southern Glades WEA is divided into four management units. Unit 1 is that portion of the area lying west and south of the C-111 canal; Unit 2 is that portion of the area located between the C-111 canal and the C-110 canal; Unit 3 is that portion of the area located between the C-110 canal and the C-109 canal north of the C-111 canal; and Unit 4 is that portion of the area north of the C-111 canal that is located between the C-109 canal and U.S. 1. All motorized vehicles are prohibited, except airboats in units 1 and 4 from December through March 1 and outboard motor boats within the canals.

Fishing, primarily within the C-111 canal, is the primary recreational use within the Southern Glades WEA. A public-use survey conducted from September through November in 1997 revealed a weekend use that averaged 7 people per day (GFC 1997h). Fishing was shown to be the most common use, followed by sightseeing, then hunting, and biking. A foot trail has been established along the area's levees, and horse gates have been installed to improve access for equestrian groups that wish to use the trail system.

Fishing is permitted throughout the year within the Southern Glades WEA, while frogging is restricted to the period of December 1 through March 1. An annual deer season is open 30 days from early September through early October for archery hunters; 3 days in mid-October for muzzle loaders, and approximately 35 days from late October to late November for general gun hunting participants. Due to low deer populations and limited access, however, hunter participation has been low (Table 1). Waterfowl hunting is limited because of low densities and wide year-to-year variation in the local populations (GFC 1997f).

J.W. Corbett Wildlife Management Area

The J.W. Corbett Wildlife Management Area (Corbett WMA), a Type I wildlife management area located northwest of West Palm Beach (Figure 6), comprises only 60,224 acres but receives a disproportionately high amount of recreational use for the Everglades region. Most popular among hunters is the big game season, which consists of an archery season that begins the end of August and lasts for about 22 days, followed by a muzzleloading gun season that lasts for about 16 days, and a general gun season that extends from early November into early January. Although deer and wild hogs are the favored big game species, the Corbett WMA possesses a relatively good mixture of habitat types that support a wide array of other game species. The Corbett WMA is one of the most popular management areas in the Everglades region for snipe hunting (GFC Florida wildlife management area harvest data report, 1997). Other species that are sought on the Corbett WMA include grey squirrels, wild turkeys, puddle ducks, bobwhite quail, rabbits, and raccoons. Since low flatwoods swamp is poor habitat for terrestrial species, populations of upland species like wild turkeys, bobwhite quail, and grey squirrels are low; consequently, hunting pressure on these species is also low (GFC 1997c). There is a raccoon night-hunting season during which raccoons may be pursued with dogs for about 40 days during the winter small game season. Fishing and frogging are permitted throughout the year. Due to the seasonal nature of most natural ponds on Corbett WMA, fishing is limited to drainage canals, some of the deeper marshes, and six ponds excavated for fishing purposes.

Access to hunting areas in the Corbett WMA is attained most commonly by swamp buggies and ATVs. Vehicular recreational access is also allowed on designated grades from late April through mid-August. Tracked vehicles, airboats, motorcycles, and ATVs having a wheelbase less than 60 inches are not permitted in the management area at any time. Primitive camping is allowed at designated campsites both during the big game season and on weekends following the end of the general gun season.

The Corbett WMA provides other nature-based recreational opportunities such as bird watching, horseback riding, hiking, and nature study (GFC 1997c). The Hungryland Boardwalk and self-interpretive nature trail is used by those who wish to become better educated about the natural history of the area. Those hiking the Florida Trail also pass through the Corbett WMA. Prior to fiscal year 1997-98, there was no way to track use of the Corbett WMA by users in the non-hunting season; however, with the institution of a daily-use permit in July of 1997, the area has been estimated to receive on average about 30 to 40 people per week. Most of these users are reported to be interested in either observing or photographing wildlife (James Schuette, GFC, pers. com.).

Although the John G. and Susan H. Dupuis Jr Wildlife and Environmental Area lies to the west of the Corbett WMA within the L-8 basin, no impacts on recreation have been predicted at this time, and no analyses were conducted for this area.

Lake Okeechobee

Lake Okeechobee is nationally recognized as supporting high-quality largemouth bass and black crappie fisheries (Bell 1987). For the four years from the 1992-93 creel survey period through the 1995-96 period, creel estimates of fishing effort ranged from 742,347 angler hours in 1992-93 to 1,003,508 hours of effort in 1995-96 (Table 4). This estimate equates to an annual mean fishing effort of 879,616 hours for this four-year period. Creel surveys were conducted each year during the peak six-month period extending from December through May. During this four-year period, the black crappie fishery received the most use, with an annual mean creel estimate of fishing effort of 510,403 hours, followed by largemouth bass with an estimated annual mean fishing effort of 312,722 hours, and bream with an estimated annual mean fishing effort of 56,492 hours. It should be noted that these creel survey data are based on four high-use areas, with each area covering approximately 20,000 acres, for a total creel survey area of 80,000 acres. This creel survey area thus amounts to only about 10% of the areal extent of the lake; but it is estimated that these areas receive approximately 70% of the fishing pressure on the lake (Don Fox, GFC, pers. com.). If the summer-fall months were included, the estimated annual fishing effort would undoubtedly be greater. Bell (1987) used creel survey data collected during the summer-fall period in the late 1970s, and found the season fishing pressure to constitute approximately 23.8 % of the total annual fishing effort. Assuming that this trend has continued until the present, the four-year period from 1992 to 1996 would have had an annual mean fishing effort equating to 1,088,965 hours.

Bass fishing tournaments have also become very popular events on the lake, but prior to 1996, no permitting system existed for conducting bass tournaments on Lake Okeechobee and, consequently, no monitoring of this activity occurred. During the year extending from April 1996 through March 1997, however, a total of 520 bass tournaments consisting of 28,128 anglers were permitted through the GFC's Division of Fisheries. These anglers caught 25,164 bass, yielding a total weight of 55,486 pounds, with an average weight of 2.2 lb/ fish. During the past year extending from April 1997 through March 1998, there was a total of 484 bass tournaments on Lake Okeechobee consisting of 33,021 anglers. Angler success during these two years was considered to be low due to extremely high water levels that reduced fish vulnerability to capture (Don Fox, GFC, pers. com.).

Lake Okeechobee is probably the most important fresh water recreational fishery in the State of Florida, with an asset value assessed at nearly $100 million in 1987 dollars and an annual economic impact of approximately $28 million for the local economy (Bell 1987). It was also estimated that tourists spend $65.51 per fishing day compared to $24.23 for residents of Lake Okeechobee counties on largemouth bass fishing based on 1986 dollars (Bell 1987).

Pleasure boating (including airboats) on Lake Okeechobee is also a popular activity. As of 1987, there were 18 marinas on Lake Okeechobee supplying a total of 705 wet slips and 315 dry slips. Boat access to the lake is achieved through the use of 40 boat ramps with 65 lanes

(Bell 1987). In addition to recreational fishing and boating, Lake Okeechobee serves as a popular duck hunting and frogging area.

The lake is divided into four different alligator management units, and a set number of alligator harvest permits, based on annual alligator population survey data, is issued for the lake each year. Interest for participating in the alligator harvest program remains high and, statewide, only about 5% of the applicants are randomly selected to participate each year. During the most recent alligator harvest in 1997, 1,256 permits were issued to 251 participants, resulting in the harvest of 981 alligators on Lake Okeechobee (Table 5). The number of alligator harvest permits issued for Lake Okeechobee in 1997 accounted for approximately 40% of all permits issued for the entire state of Florida. The only other public body of water in the Everglades region where regulated alligator harvests still occur is on Lake Trafford, a relatively small lake located near Immokalee. This lake has had a rather modest annual harvest quota ranging from 30 to 70 permits over the last five years (Table 5).

Waterfowl

[This section was provided by Robert Pace, U.S. Fish and Wildlife Service, Vero Beach, FL]

Waterfowl hunting is an important outdoor recreational activity in central and southern Florida with a significant economic impact. A Midwinter Waterfowl Inventory is conducted by the GFC, and data have been compiled from the years 1994-1997 for those survey routes within the scope of the C&SF Restudy and which were consistently covered in those years (Table 6). Although these data should not be interpreted as representing a comprehensive count of waterfowl in central and southern Florida, they provide useful comparisons of the relative abundance of different species (or groups of species) in a particular area and their relative abundance among areas. The data could also be used to identify inter-annual variability in waterfowl abundance, and if consistently surveyed and analyzed over many years, might indicate long-term trends. The most abundant species found on the surveys were the American coot (*Fulica americana*); ringnecked duck (*Aythya collaris*); either blue-winged (*Anas discors*) or cinnamon (*Anas cyanoptera*) teal, which were counted together; and mottled duck (*Anas fulvigula*). The survey routes with the highest total waterfowl counts, averaged over the four years, were, in order of decreasing abundance: Lake Okeechobee, Lake Weohyakapka, Lake Hatchineha, Lake Istokpoga, and Fisheating Bay in Lake Okeechobee (Figure 7). Migratory bird hunting stamp sales data (Table 7) and harvest data (Table 8) for counties within the scope of the Restudy were obtained from the Office of Migratory Bird Management, Laurel, Maryland. These data demonstrate the economic importance of waterfowl hunting in central and southern Florida.

Potential Impacts of the Initially Preferred Alternative (D-13R) on Recreation

Everglades Wildlife Management Area

The unauthorized construction and augmentation of camps on tree islands in WCAs- 2 and -3 has been a controversial issue almost since the inception of the original C&SF Project in 1949 (GFC 1958). Prior to the construction of the eastern perimeter levees, hydroperiods were relatively short, and airboat access to interior portions of much of the Everglades was limited primarily to the rainy season and no camps existed. However, wetter conditions following levee construction led to longer periods of accessibility by airboat and camps started to appear in the EWMA in the mid 1950s with greater than 20 camps present by 1958 (Wallace 1958). Similarly, there has been a resurgence of new camp construction on tree islands over the last five relatively wet years (1993-97). Under Alternative D13R, WCA-3B and northern WCA-3A will be wet for a greater proportion of the year; thus airboat access would probably be increased in these areas. The increased accessibility of tree islands in this area may lead to an increase in privately constructed camps. Although the construction of permanent structures is prohibited in all wildlife management and environmental areas in the Everglades region, the continued erection of hunting camp structures in the EWMA remains a problematic issue.

Although airboat activity may increase as a result of the longer hydroperiods predicted by Alternative D13R, the use of vehicles that require relatively little or no surface water for operation (tracks, swamp buggies, ATVs, etc) would be expected to decline. The use of tracked vehicles in the Everglades appears to be steadily declining due to the high maintenance requirements of these vehicles; a decline in operator opportunities to use them for hunting because of higher water levels in recent years; and lower deer densities, which in turn resulted in the closure of the area to vehicle hunting seasons. During the 1997-98 hunting season on Rotenberger WMA, only 64 track permits were issued, with 50 tracks reportedly participating in the hunt (Blake Sasse, GFC, pers. com). Information derived from hunter questionnaires revealed that an average of 4 hunters occupied a track on any one occasion (GFC 1998a). In the last big track hunt that occurred in WCA-3A north of I-75 in 1990, 109 track permits were issued. The number of tracks for which hunting applications have been submitted in the Everglades during the past six years has ranged from as few as 83 in 1996 to as many as 165 in 1992 (Eddie White, GFC, pers.com.). It is evident, however, that not all track owners have decided to participate in the vehicle hunts during recent years, perhaps because of limited opportunities due to the continued closure of the northern part of WCA- 3A to track hunting because of depressed deer population levels. During the 1996-97 season, only 83 of the 123 tracks that had their tags renewed applied for a hunting permit. At the current time, it has been estimated that there are probably no more than between 100 and 200 tracked vehicles (although many are in various stages of disrepair) still remaining in South Florida (Blake Sasse, GFC, pers. com.) The number of tracks has probably dwindled even more since the track hunting season has remained closed in WCA-3A since 1994, and in Holey Land WMA from 1993 through 1996. Although tracked vehicle use may continue to decline, hydrological conditions in Holey Land WMA and Rotenberger WMA, and perhaps the northern portion of WCA-3A in drier years would probably still be suitable for tracked vehicle operation. The use of swamp buggies is currently minimal on Everglades mucky soils, and would likely disappear altogether under the elevated water table proposed under the 2050 Base (which assumes that the Everglades Forever Act and Modified Water Deliveries to Everglades National Park are fully implemented). Thus, the use of swamp buggies is not expected to be affected under the current preferred Restudy alternative.

The adoption of Alternative D13R would result in a very large decline in the mileage of canals available to fishermen. The decrease in canal mileage as modeled in the SFWMM was by 19 miles for the 2050 Base, but with the increased decompartmentalization under Alternative D13R, an additional 127 miles of canals would be backfilled. Although many of these canals may not be easily accessible with an outboard motorboat, or provide good fishing opportunities, other more accessible canals do receive a considerable amount of fishing pressure. This projected decline in the mileage of canals available to fishermen will most definitely have an impact on recreational fisheries in South Florida. However, the planned addition of 6,977 acres of water preserve areas with maximum water depths of 4 feet; 9,700 acres of above-ground water-storage areas with variable depths in the Lakebelt region; and a 1,600-acre stormwater treatment area of an unspecified depth in Broward and Dade and counties may offer some potential for the development of new fisheries resources in this region.

Of particular concern is the L-67A canal. Alternative D13R proposes to backfill approximately six miles of the southern end of this canal. The “three pines” area, located near the proposed end of the canal, has been a particularly productive fishing spot, and may be eliminated if this portion of the canal is backfilled. In general, the southern half of the L-67A canal receives the most fishing pressure, probably due in part to the prolonged hydroperiod that normally exists in the southern portion of WCA-3A (Jon Fury, GFC, pers. com.) Although access to the remaining portion of the L-67A canal would be reduced due to a loss of access from the Tamiami Trail, this effect may not be as pronounced as it could be. Due to a lack of security at the somewhat isolated boat ramp on the L-67 canal off the Tamiami Trail, most fishermen prefer to launch out of Holiday Park, at the northern end of the L-67A canal, and motor south to their favorite fishing holes. Information gathered by GFC Everglades Fisheries personnel while conducting creel surveys on the L-67A canal during the time period of 1991-97 found that 75% of those anglers interviewed launched their boat at Holiday Park with the remaining 25% launching their boat at the southern end of the L-67A levee (Jon Fury, GFC, pers. com.). Regardless of what access problems may exist, modeled hydrological conditions for the WCA-3A marsh adjacent to the L-67A canal predict somewhat lower mean water depths than would exist under the 2050 Base and considerably lower mean depths (> 1 ft.) than would occur under the 1995 Base. Consequently, the areal extent and duration of water depths in WCA-3A sufficient to maintain a productive marsh/canal bass fishery is expected to decline dramatically with implementation of Modified Water Deliveries in the 2050 Base, and even further under Alternative D13R. At this time, it is not clear how the weir design and operations across the L-67A levee will affect the fishery of the L-67A canal.

The L-67C canal, although not as popular a fishing area as the L-67A canal, also receives fishing pressure, especially when marsh water levels recede during the dry season. A count of the boat trailers parked at the L-67C boat ramp during the 6-month period extending from December 1996 through May 1997 yielded a total count of 2,900 boats using this canal, with an average of two persons per boat (Jon Fury, GFC, pers. com.). This canal would be backfilled entirely in Alternative D13R, and this fishery would be lost as well.

Under Alternative D13R, the areal extent of upland refugia in the form of tree islands and levees is expected to decline in WCA-3B. The removal of the entire length of the L-67C levee and portions of the L-67A levee would significantly reduce the areal extent of high elevation habitats that exist in this portion of the Everglades. Such habitats in the current remnant Everglades, where suitable upland refugia have been lost to development east of the L-30 levee and to devastating muck fires in the northern portion of WCA-3A and in WCA-2, have high wildlife value and function. For example, following the recent high water episode of 1994-95 in WCA-3B, the deer population was essentially eliminated from the marsh interior, with the only known survivors persisting on the levee system. The L-67C was one of the most used levees by the deer seeking relief from high water levels, which may have been due in part to the movement of deer to the northwest along the natural elevational gradient and to the relatively close proximity of several "low" elevation tree islands that were vacated when submergence occurred. The L-67C also serves as a corridor for expediting deer immigration from the levee back to tree island habitats following water level recession in the area.

Due to increased water levels in WCA-3B, recreational opportunities in terms of huntable deer populations are likely to decline in this area, where tree islands occur at lower densities and many are at relatively low elevations. Conversely, the areal extent and duration of emergence of tree islands above ambient water levels is expected to increase in the southern portion of WCA-3A upon the removal of the impounding effects of the L-28, L-29, and partial removal of the L-67 levees, and this situation would allow a relatively large number of tree islands to remain above ambient water levels for much longer periods of time. The greater density of tree islands in southern WCA-3A and a considerable reduction in the length of time that slough water levels remain above 30 inches deep in Alternative D13R may permit a more stable environment for upland game animals. Hence, deer hunting opportunities should improve in the southern portion of WCA-3A. Although the removal of the L-28 levee would result in the loss of dry habitat that has served as relief for deer and other upland-dependent wildlife in the past, lower water levels and reduction in prolonged high-water events predicted by Alternative D13R would make this levee less critical as an upland refugium. In addition, the removal of the L-28 levee and its associated borrow canal will help to recreate the natural hydrological gradient based on the region's topography and allow deer longer periods of time to move "upslope" to areas of higher elevation in the Big Cypress WMA during times of high water.

The removal of the L-29 levee and canal by Alternative D13R could have negative impacts on recreational access into WCA-3A and WCA-3B from U.S. 41, since the roadway would have to be elevated in some way. There are three public boat ramps providing airboat access into WCA-3B and three public boat ramps providing airboat and jon boat access into the L-29 canal and marsh of WCA-3A. One of the boat ramps for WCA-3B also provides jon boat access into the L-67C canal, which would be back-filled in Alternative D13R. Therefore, it will be necessary to construct on and off ramps to these recreational areas and provide ample parking space for vehicles and boat trailers.

Big Cypress Wildlife Management Area

The summary evaluation of those geographic regions encompassing the Stairsteps and Loop Road units suggests that these areas would most closely resemble NSM conditions under Alternatives D and D13R. Under the ATLSS Cape Sable Seaside Sparrow Model and Index output for Alternative D13R versus the 2050 Base, the hydroperiod length was shown to decrease somewhat in the Stairsteps and Loop Road units. Ponding depths in the eastern portion of the Stairsteps unit also appeared to be slightly less in Alternative D13R than under the 2050 Base. Although no ATLSS output for the White-tailed Deer Breeding Potential Index was generated for Alternative D13R, output was available for Alternative B, which was structurally similar to Alternative D13R in that both the L-28 and L-29 levees were removed. Under this modeled output, the overall deer breeding potential mean was slightly higher in the Stairsteps and Loop Road units under Alternative D13R when compared to the 2050 Base, but remained relatively unchanged in the Corn Dance unit. In conclusion, these evaluations tend to suggest that somewhat more favorable hydrological conditions will exist for deer and upland game animals in the Stairsteps and Loop Road units of the Big Cypress WMA with the adoption of Alternative D13R than would occur in the 2050 Base, and that deer populations in the Corn Dance unit will probably remain relatively stable.

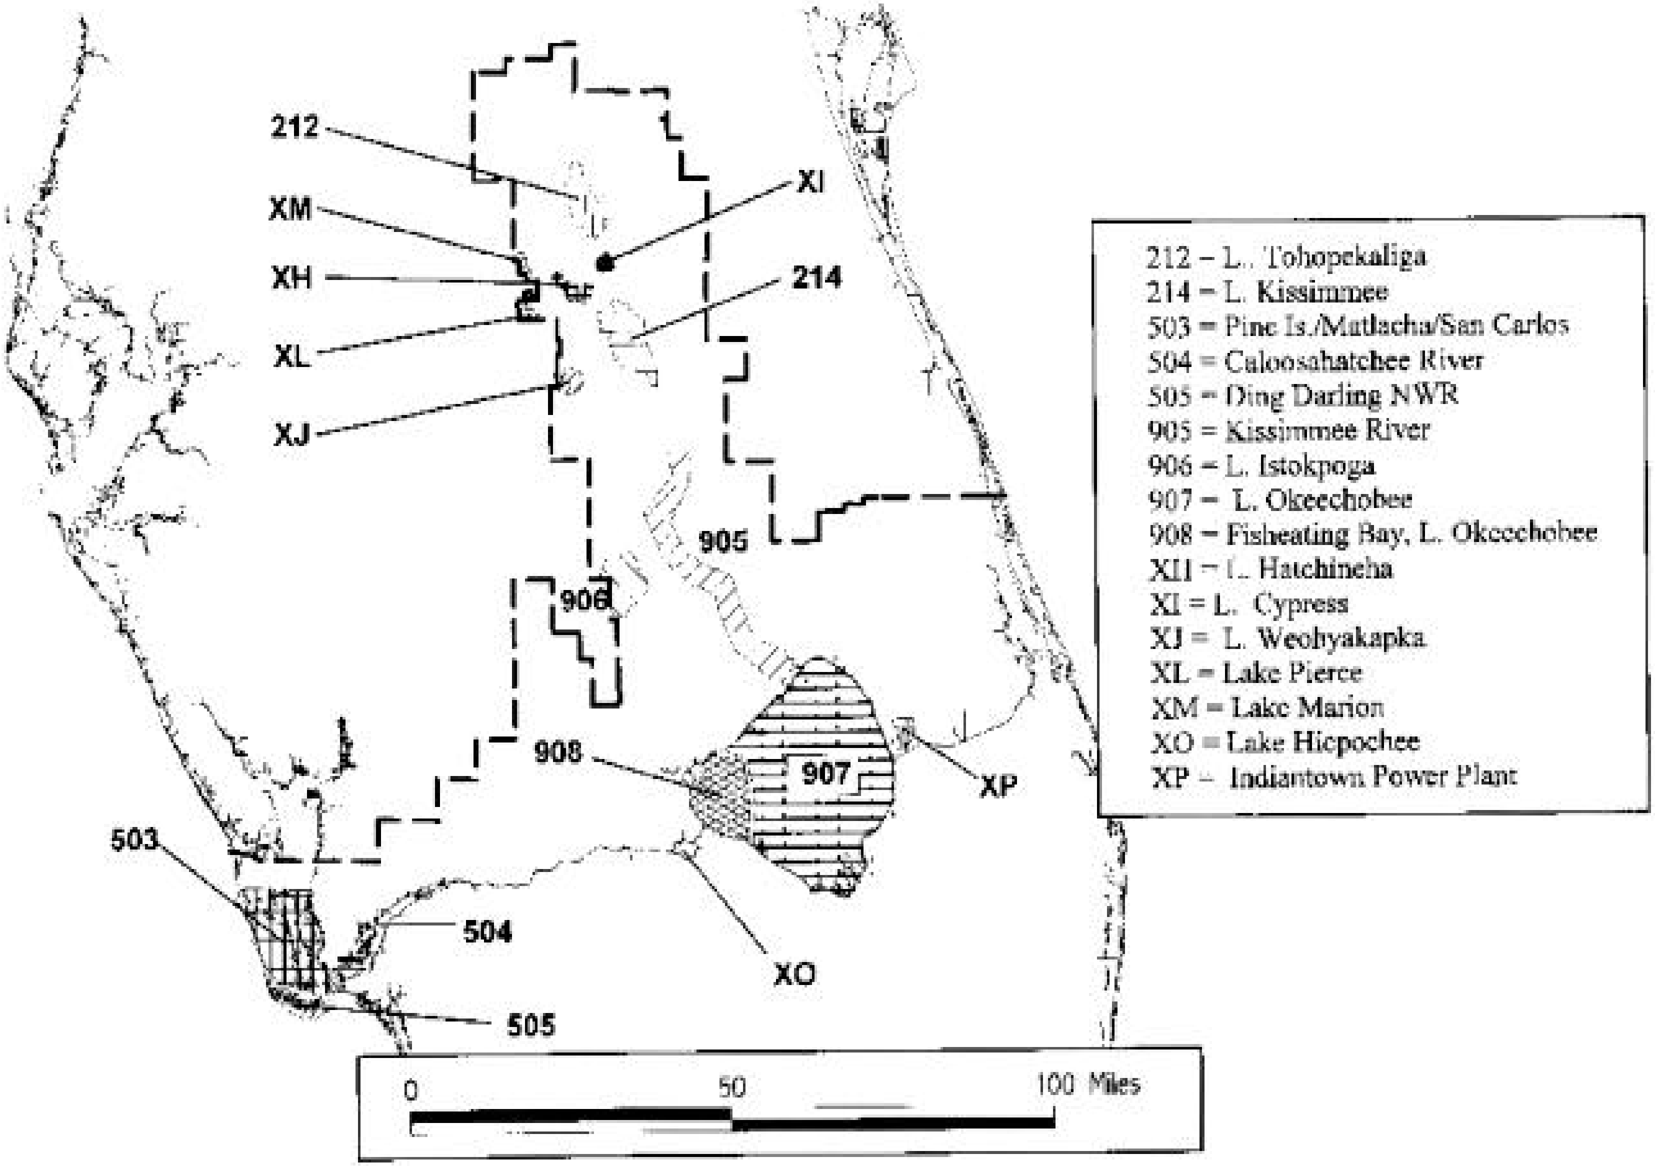

Figure 7. Location of the Midwinter Waterfowl Inventory survey routes that were consistently surveyed in central and south Florida in the years 1994-1997.

Table 1. Wildlife Management Area harvest pressure data for the years 1993 to 1998 in those areas that could be affected by the Restudy.

HARVEST PRESSURE (Man-Days)

Harvest Season	Big Cypress	Corbett	Rotenberger	Holey Land	Everglades	Southern Glades
1993-94	15,910	11,431	800	972	2,232	6
1994-95	9,735[a]	10,801	106	214	0	15
1995-96	11,290[a]	10,280	416	294	0	27
1996-97	15,185	10,961	907	274[c]	0	4
1997-98	14,410	11,298	944	281[c]	294[e]	8
5-Year Mean	**13,306**	**10,954**	**766**[b]	**635**[d]	**1,984**[f]	**12**

Total Mean Harvest Pressure = 28,030 Man-Days

[a]Hunting seasons were shortened during these years due to the closure of some units because of high water.

[b]Those hunting seasons closed during 1994-95 were omitted from the 5-year mean.

[C] Includes opening weekend of the regular waterfowl hunting season

[d]All closed hunts were omitted when calculating the 5-year mean.

[e]The 1997-98 season was open for only 15 days as a gun-vehicle season in WCA- 3A south of Alligator Alley.

[f]The five-year average for the EWMA was based on the years 1989-93, since the area has remained closed since the 1994 season due to low deer population levels resulting from the 1994-95 flood event.

Table 2. Expanded harvest, effort, and harvest success estimates for all fish categoriesobtained from the roving angler use surveys in WCA- 2A (L-35B and L-38E canals) and WCA-3A (L-67A canal) between 1985 and 1997 (GFC 1992, 1993, 1994, 1998c).

Area	Year	Harvest (# of Fish)	Effort (Hours)	Harvest Success (Fish Per Hour)
WCA-2A	1985-86	46,698	55,659	0.84
	1986-87	167,444	128,430	1.30
	1987-88	90,115	90,925	0.99
	1988-89	59,129	77,617	0.76
	1989-90	35,389	55,693	0.64
WCA-3A	1990-91	51,312	49,536	1.04
	1991-92	82,176	52,414	1.54
	1992-93	24,471	25,848	0.95
	1993-94	37,475	28,709	1.31
	1994-95	33,520	41,244	0.81
	1995-96	30,846	58,150	0.53
	1996-97	32,557	46,265	0.70

U.S. FISH AND WILDLIFE SERVICE
PROGRAMMATIC BIOLOGICAL OPINION

United States Department of the Interior

FISH AND WILDLIFE SERVICE
South Florida Ecosystem Office
P.O. Box 2676
Vero Beach, Florida 32961-2676

August 7, 1998

Colonel Joe R. Miller
District Commander
Jacksonville District
U.S. Army Corps of Engineers
400 West Bay Street
Jacksonville, FL 32232

Project:	Central and Southern Florida Project Comprehensive Review Study Initial Draft Plan.
FWS Log No.:	4-1-98-F628
Agency:	U.S. Army Corps of Engineers

Dear Col. Miller:

This document transmits the U.S. Fish and Wildlife Service's (FWS) preliminary programmatic biological opinion based on our review of the Central and Southern Florida Project Comprehensive Review Study (C&SF Restudy) alternative D13R (Initial Draft Plan), and its effects on threatened and endangered species in accordance with section 7 of the Endangered Species Act of 1973 (ESA), as amended (16 U.S.C. 1531 *et seq*.). Our analysis considered effects on the following species: the endangered West Indian manatee *(Trichechus manatus*), Florida panther (*Felis concolor coryi*), snail kite (*Rostrhamus sociabilis plumbeus*), wood stork *(Mycteria americana*), Cape Sable seaside sparrow *(Ammodramus maritimus mirabilis)*, American crocodile (*Crocodylus acutus*), Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), red-cockaded woodpecker *(Picoides borealis)*, Okeechobee gourd (*Cucurbita okeechobeensis)*, crenulate lead-plant (*Amorpha crenulata*), deltoid spurge (*Euphorbia deltoidea)*, Small's milkpea (*Galactia smallii*), and tiny polygala (*Polygala smallii*), and the threatened bald eagle (*Haliaeetus leucocephalus)*, Audubon's crested caracara (*Polyborus plancus)*, eastern indigo snake (*Drymarchon corais couperi*), Florida scrub jay (*Aphelocoma coerulescens*) and Garber's spurge (*Euphorbia garberi*). Our analysis also considered effects on designated critical habitats for the West Indian manatee, snail kite, Cape Sable seaside sparrow and American crocodile. We have assigned FWS log number 4-1-98-F628 to this consultation.

This preliminary programmatic biological opinion is based on information provided by the U.S. Army Corps of Engineers (COE), the South Florida Water Management District (SFWMD), Everglades National Park (ENP), the U.S. Geological Survey's Biological Resources Division (USGS-BRD), the Florida Game and Fresh Water Fish Commission (GFC), the Institute for Environmental Modeling at the University of Tennessee, and information available in our files on the C&SF Restudy and other published and unpublished sources of information. A complete administrative record of this consultation is on file in the FWS's South Florida Restoration Projects Office in Vero Beach, Florida.

CONSULTATION HISTORY

In a November 20, 1996, letter, the COE initiated informal section 7 consultation and requested a list of threatened and endangered species expected to occur in the C&SF Restudy project area.

On January 22, 1997, the COE and the FWS met to discuss how to proceed with section 7 consultation for the C&SF Restudy and agreed to integrate section 7 consultation with preparation of a Fish and Wildlife Coordination Act report and programmatic Environmental Impact Statement.

In a February 20, 1997, letter, the FWS provided the COE with a list of 17 threatened and endangered species that occur in the project area that may be affected by the C&SF Restudy.

On November 24, 1997, the COE and the FWS met to further discuss how to proceed with section 7 consultation. The FWS presented several alternative consultation methods and explained the relative benefits of each.

In a December 19, 1997, letter, the FWS provided the COE with a written summary of the options for section 7 consultation that were discussed in the November 24th meeting, and asked the COE to notify the FWS of their preferred course of action.

In a February 2, 1998, letter, the COE notified the FWS that they would continue informal consultation at present and that they would initiate early programmatic consultation when an Initial Draft Plan for the C&SF Restudy had been chosen.

From November 1997 - June 1998, the FWS provided technical assistance and recommendations regarding listed species impacts during the COE's C&SF Restudy alternatives development process through participation in the COE's interagency C&SF Restudy Alternatives Evaluation Team.

In a February 24, 1998, letter, the FWS provided extensive recommendations for maximizing benefits to threatened and endangered species resulting from the C&SF Restudy that would fulfill the COE's affirmative conservation obligations in accordance with section 7(a)(1) of the ESA.

In an April 8, 1998, letter, the FWS informed the COE that, due to new information on possible impacts resulting from the C&SF Restudy, the FWS had determined that an additional threatened species, the Florida Scrub Jay, may be affected by the C&SF Restudy.

In an June 11, 1998, letter, the COE initiated formal consultation on the C&SF Restudy for the 18 threatened and endangered species referenced in the FWS's February 20, 1997, and April 8, 1998 letters. This letter indicated that Alternative D had been chosen as the official Initial Draft Plan. However, a significantly refined alternative, Alternative D13R, was developed and endorsed by the C&SF Restudy Alternatives Evaluation Team after June 11, 1998.

In a June 22, 1998, letter, the COE confirmed that Alternative D13R had been selected as the Initial Draft Plan.

PRELIMINARY PROGRAMMATIC BIOLOGICAL OPINION

DESCRIPTION OF PROPOSED ACTION

C&SF Restudy components can be divided into those that have been modeled using the SFWMD's South Florida Water Management Model (WMM), and those that could not be modeled in this way for various reasons. <u>This biological opinion addresses the first group of components only</u>. The second group, called Other Project Elements, will be addressed in separate section 7 consultations, as necessary. In this document, the phrase "proposed action" means those C&SF Restudy components modeled by the WMM as part of the C&SF Restudy Initial Draft Plan. Critical Projects and other Feasibility Studies associated with the C&SF Restudy will also require separate section 7 consultation.

In general, the proposed action seeks to restore the biological integrity of the remaining natural areas within the project boundaries through modifications to the existing C&SF Project while also providing for the water supply and flood control needs in this area. A detailed description of the means for accomplishing these goals contained in the proposed action is available on the C&SF Restudy World Wide Web Site (http://www.sfwmd.gov/org/pld/restudy) as of this writing, and will be contained in the Draft Programmatic Environmental Impact Statement (DPEIS) for the C&SF Restudy, which is currently scheduled to be published and available to the public by late October 1998.

Because the current proposed action, despite its complexity, provides only a conceptual description of individual project features, detailed analyses of impacts associated with each project feature will be conducted in the future when detailed design and engineering information has been developed. This means that the COE will likely need to reinitiate section 7 consultation on this action many times as detailed planning and implementation progress. A general description of some of the major features of the proposed action is provided below and this biological opinion will analyze and address the effects the proposed action may have on threatened and endangered species in general terms wherever possible. This is appropriate because of the programmatic nature of the proposed action and is consistent with FWS policy governing programmatic section 7 consultations. Figures 1, 2 and 3 illustrate the major features of the action area.

Water Storage Areas: New water storage reservoirs are proposed in the following general areas: 20,000 acres in the Kissimmie River Basin near Lake Okeechobee; 10,000 acres in the St. Lucie River Basin near Lake Okeechobee; 20,000 acres in the Caloosahatchee River Basin near Lake Okeechobee and 60,000 acres in the Everglades Agricultural Area. These reservoirs will store excess water when it is not needed in the natural system or for water supply, so that it may be used later. Currently, much of this excess water is discharged to the Atlantic Ocean and Gulf of Mexico where it often causes adverse impacts to estuarine environments. Other new water storage areas, called Stormwater Treatment Areas and Water Preserve Areas, would help to improve water quality and improve water supply and flood control.

Additional Water Control Structures: Several new water control structures are proposed in the Initial Draft Plan. These structures provide additional flexibility in the control of timing, direction and volume of water flow necessary to improve and maintain natural habitats and water supply and flood control. For example, new structures proposed for the southern border of Water Conservation Area (WCA) 2B and eastern border of ENP will allow the movement of excess water from WCA 2B to the Taylor Slough area in ENP where it is needed to restore natural conditions. Another example is a new weir that would partially replace the existing L-67A canal and levee, allowing more natural free flow of water from WCA 3A to WCA 3B.

Removal of Existing Structures: The proposed action would remove several existing water control structures, including large portions of the L-28 and Tamiami Trail canals and levees. This would provide more natural free flow of water between large areas that are currently separated and would allow many fish and wildlife species to move more freely between habitats.

Operational Changes: Numerous changes are proposed for the way new and existing water control structures are operated. Examples include different rules for opening and closing gates and different rules for turning pumps on and off. Each of the proposed changes would help to make the timing, distribution and volume of water flow more like natural conditions and/or would help provide for water supply and flood control.

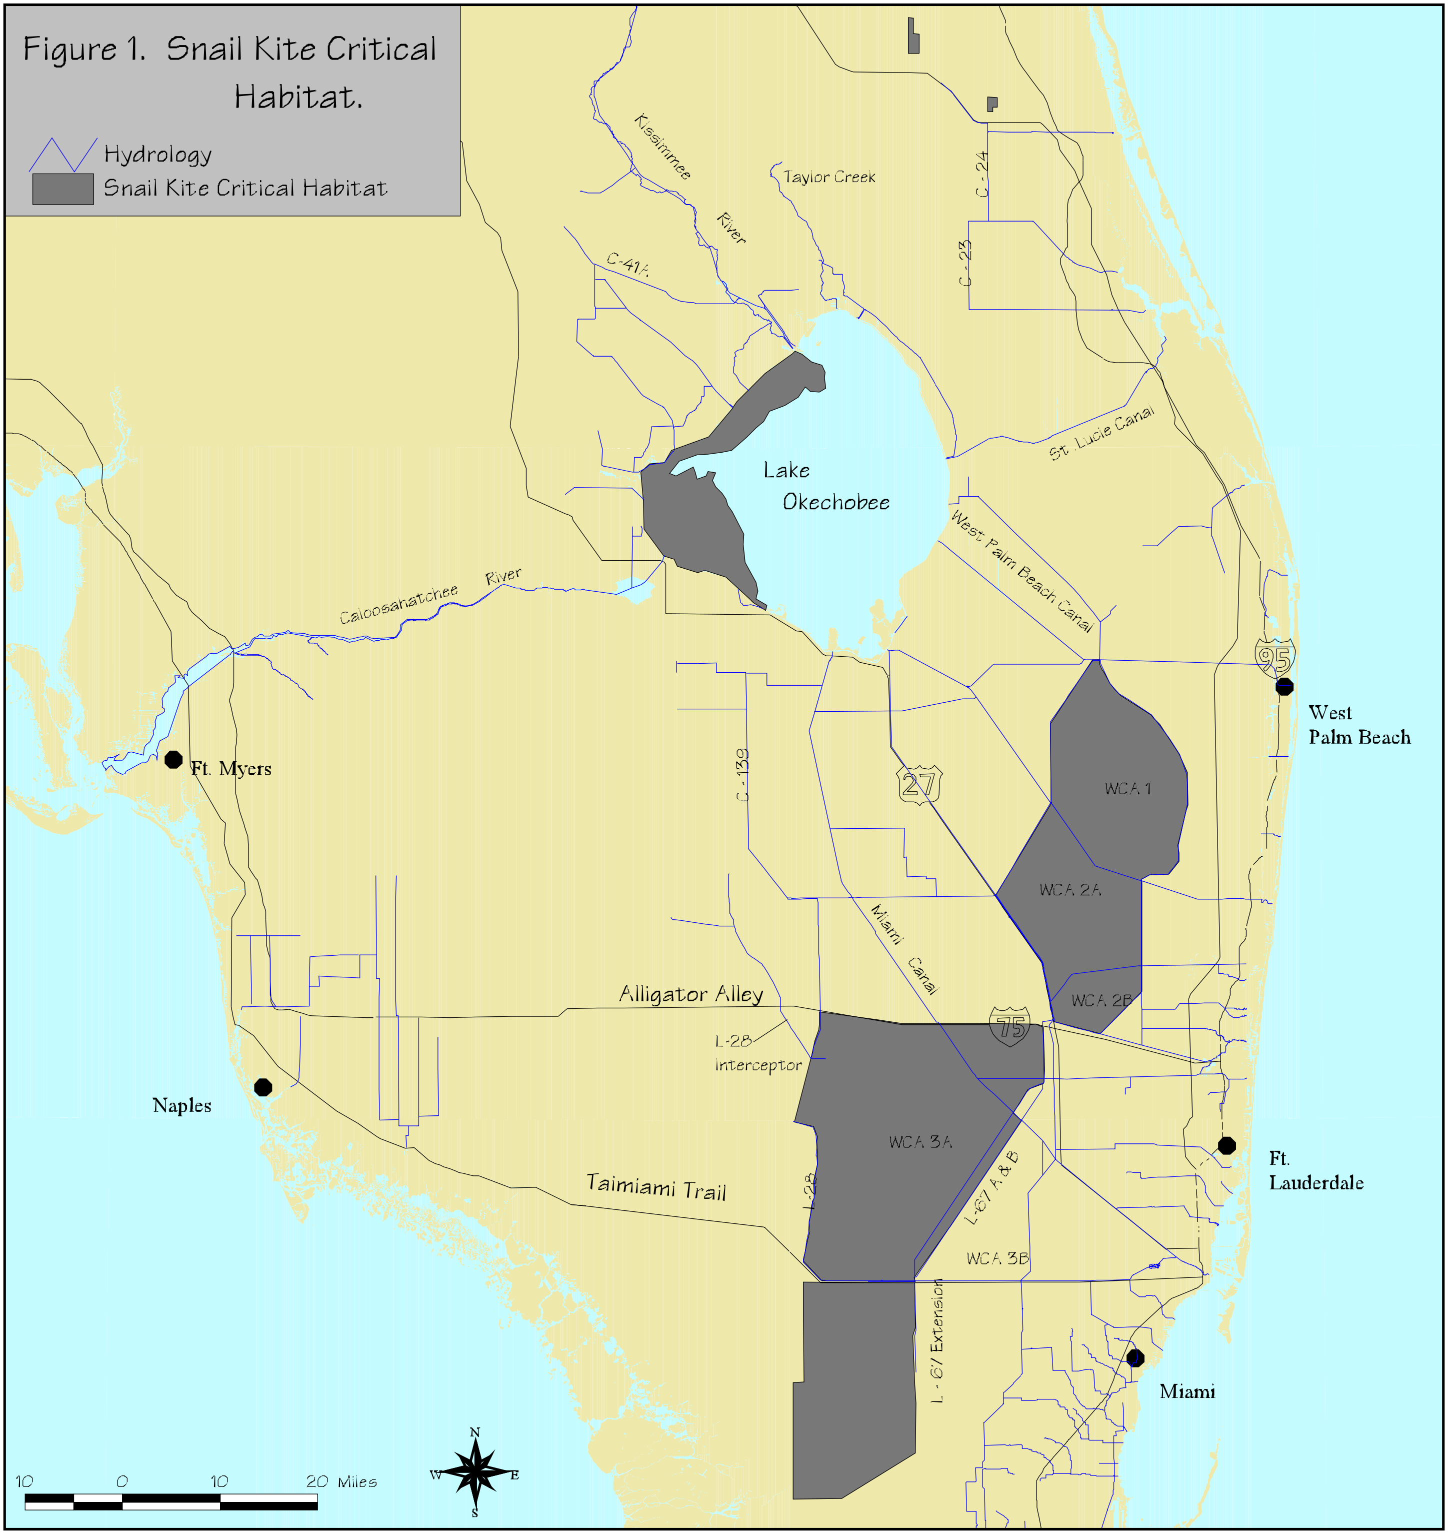

Figure 1. Snail Kite Critical Habitat.

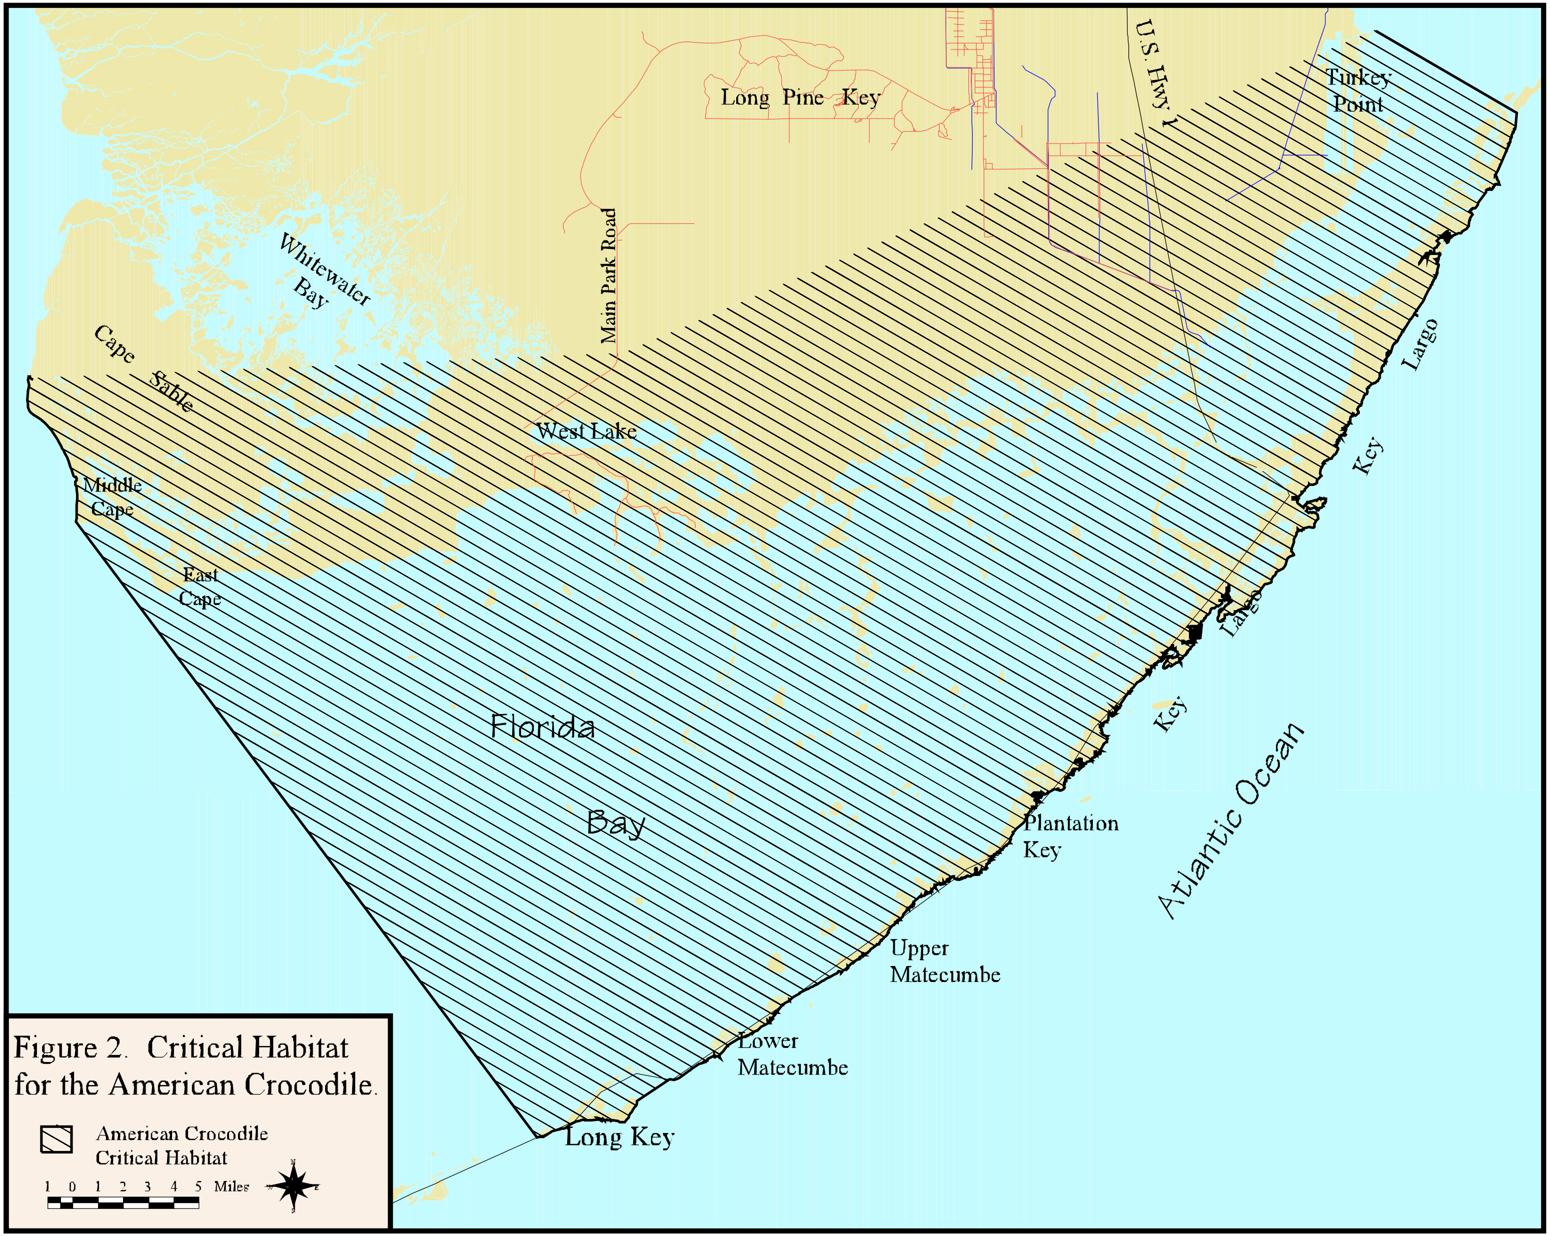

Figure 2. Critical Habitat for the American Crocodile.

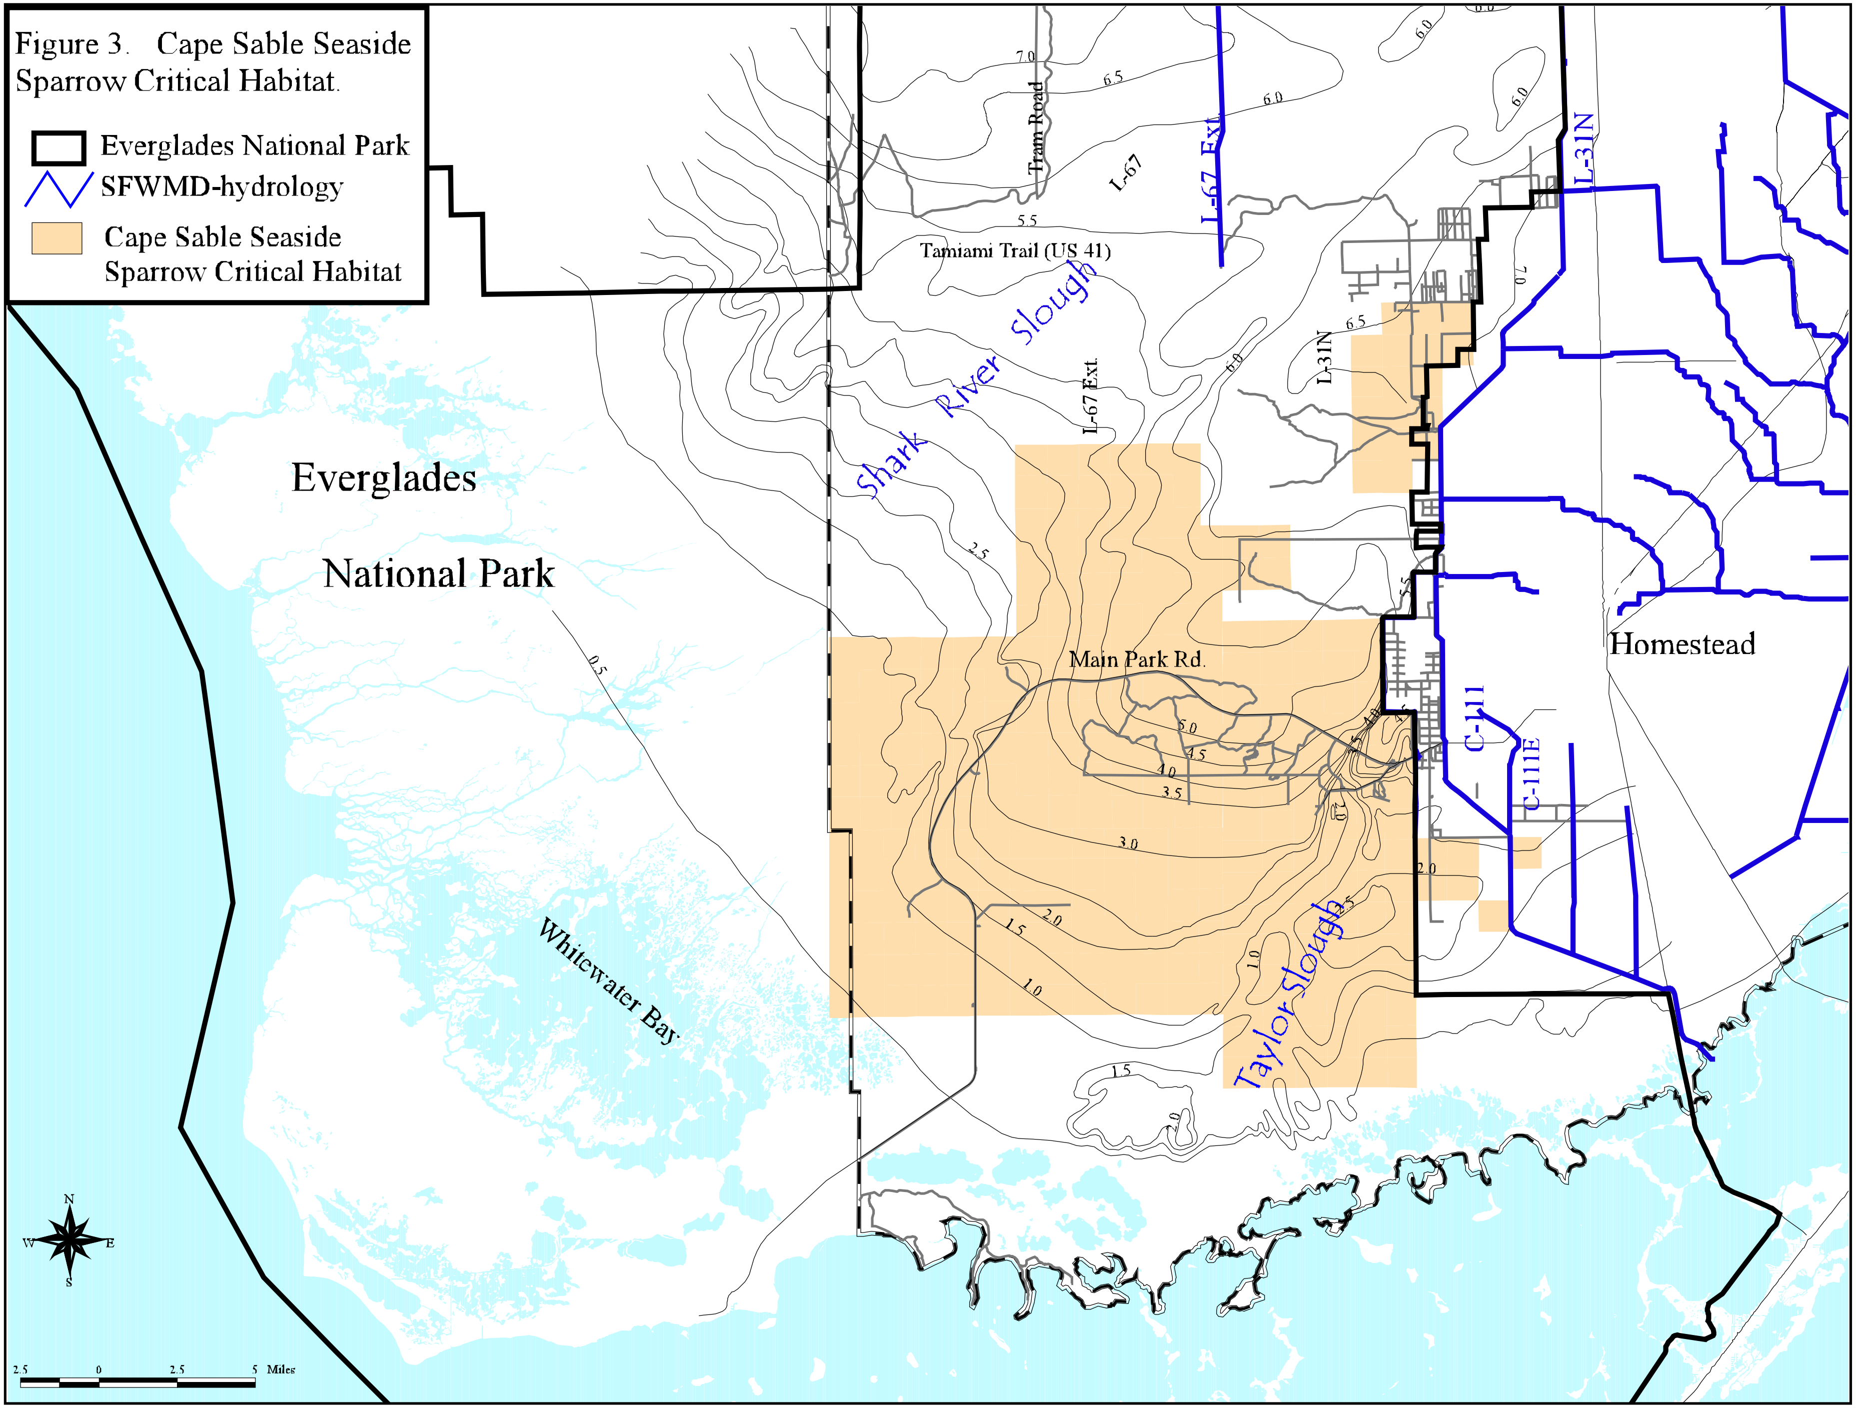

Figure 3. Cape Sable Seaside Sparrow Critical Habitat.

Timing of Implementation: Another important aspect of the proposed action is its expected timing. Currently, the planning process for the C&SF Restudy is in its earliest stage, and several years of additional planning will be necessary before any part of the proposed action can be implemented. Detailed timelines for implementation of project features have not yet been developed. The best information on timing of implementation that is currently available indicates that the initial components of the proposed action may be implemented no sooner than 10-15 years from now, and that full implementation of all components would not be expected any sooner than the year 2050.

Action Area: The action area for this consultation includes all areas within the boundaries of the SFWMD's Water Management Model. This includes Lake Okeechobee, the Everglades Agricultural Area, the Water Conservation Areas, the majority of Everglades National Park, Coastal Estuaries, Florida Bay, the majority of Big Cypress National Preserve and urban and agricultural areas along Florida's east coast south of the St. Lucie Canal.

STATUS OF THE SPECIES/CRITICAL HABITAT

Detailed biological information for listed species that may be affected by the C&SF Restudy is available in the Multi-species Recovery Plan for the Threatened and Endangered Species of South Florida, Volume I - Technical/Agency Draft (USFWS 1998).

Analysis of the species/critical habitat likely to be affected

In letters dated February 20, 1997, and April 8, 1998, the FWS initially determined that the 18 threatened and endangered species and four designated critical habitats listed on page 1 of this document may be affected by the C&SF Restudy. After review and analysis of the additional information on the proposed project and its expected impacts on these 18 threatened and endangered species and their habitats presented in the COE's June 22, 1998, Initial Draft Plan, the FWS concludes that the C&SF Restudy will not affect the Florida panther, Florida grasshopper sparrow, red-cockaded woodpecker, crenulate lead-plant, deltoid spurge, Small's milkpea, tiny polygala and Garber's spurge because the preferred habitats of these species will not be impacted by structural or hydrological changes expected to result from C&SF Restudy features modeled by the WMM. Therefore, these eight species will not be further addressed in this biological opinion.

However, as stated above, this biological opinion does not consider effects to these or other species that may result from the Other Project Elements, Critical Projects and other Feasibility Studies that are part of the C&SF Restudy, but were not modeled by the WMM. Effects to these and other listed species that may result from the Other Project Elements, Critical Projects and other Feasibility Studies will be addressed through separate informal and, if necessary, formal section 7 consultations. Additionally, if future, additional information indicates that C&SF Restudy features modeled by the WMM may affect these or other listed species in a manner or to an extent not considered in this preliminary programmatic biological opinion, the COE may need to reinitiate this section 7 consultation.

ENVIRONMENTAL BASELINE

For most section 7 consultations, the environmental baseline includes the effects of past and ongoing human and natural factors leading to the current status of the species and their habitats. For an action such as the C&SF Restudy, which is scheduled for implementation many years in the future, determination of the environmental baseline is less intuitive, and requires some assumptions regarding the expected status of the species and their habitats in the future when the proposed action will be implemented. The best information on timing of implementation that is currently available indicates that the initial components of the proposed action may be implemented no sooner than 10-15 years from now and that full implementation of all components would not be expected any sooner than the year 2050. An additional complicating factor is the need to include in the environmental baseline several other large, conceptual, projects that are planned for this area and that have already undergone section 7 consultation.

Status of the species within the action area and factors affecting species environment within the action area

Information on the current status of the species and the factors leading to their current status within the action area appears in Volume I of the Multi-Species Recovery Plan for the Threatened and Endangered Species of South Florida, Technical/Agency Draft. Light and Dineen (1994) provide an excellent discussion of factors affecting species environment within the action area up to and including current conditions.

During the C&SF Restudy alternatives development process, the COE and SFWMD anticipated the need to compare the alternatives to expected future conditions without the proposed action, and used the WMM to develop a characterization of expected future conditions without implementation of the C&SF Restudy called the 2050 Base Condition (2050 Base). A detailed technical description of all the features and assumptions included in the 2050 Base is available on the C&SF Restudy web site and will be included in the DPEIS for the C&SF Restudy. In general, the 2050 Base characterizes expected hydrological conditions in the action area taking into account implementation of the COE-sponsored Modified Water Deliveries to Everglades National Park, Canal C-111, Headwater Lakes Revitalization Project, Kissimmee River Restoration and Lower East Coast Regional Water Supply Plan projects as well as increased water supply demands resulting from projected growth in South Florida's human population.

The FWS recognizes that there is a large amount of uncertainty and difference of opinion regarding what factors were and were not included in the 2050 Base and regarding the details of how the included features were characterized. In addition, the FWS recognizes that the 2050 Base is likely to change almost continuously over the life of the proposed action due to new information resulting from ongoing planning and monitoring efforts associated with many of its features. However, the FWS has determined that the 2050 Base reasonably represents the best scientific and commercial information currently available and that it is the best currently available characterization of the expected status of species' habitats in the future when the proposed action will be implemented. Therefore, this biological opinion will use the 2050 Base as the environmental baseline.

Because the 2050 Base provides only the expected future hydrological conditions in the action area, the expected status of the species themselves in the future must be derived from this hydrological information. A sophisticated biological modeling effort for the C&SF Restudy and other restoration projects, called Across Tropic Level System Simulation (ATLSS), has been begun and provides information on the expected future status of some of the species (Institute for Environmental Modeling and USGS-BRD 1998a). The descriptions of known responses of listed species to various hydrological conditions in Volume I of the Multi-Species Recovery Plan for the Threatened and Endangered Species of South Florida, Technical/Agency Draft provides additional information on the expected future status of listed species within the action area.

EFFECTS OF THE ACTION

This section includes an analysis of the direct and indirect effects of the proposed action on the species and critical habitats and its interrelated and interdependent activities. To determine whether the proposed action is likely to jeopardize the continued existence of threatened or endangered species in the action area, the FWS focuses on consequences of the proposed action that effect rates of birth, death, immigration, and emigration, because the probability of extinction in plant and animal populations is most sensitive to changes in these rates.

Possible effects have been divided into three categories - hydrological effects, construction effects and sequencing effects. Hydrological effects are those caused by changes in the timing, volume and distribution of water flows resulting from proposed structural and operational changes in the water management system. Construction effects are those caused by construction activities necessary to install new structures or to modify or remove existing structures. Sequencing effects are those temporary effects resulting from the order in which components are constructed and put into operation. A final section summarizes expected effects on each listed species that will be affected.

1. Hydrological Effects

A. Hydrological changes in the natural system

The proposed action will alter many features of the timing, volume and distribution of water flows through the remaining Everglades system including Lake Okeechobee, the Water Conservation Areas, Everglades National Park including Florida Bay, and the eastern portion of Big Cypress

National Preserve. These alterations will be described generally here by first describing the general hydrological features of the 2050 Base (environmental baseline conditions) and then describing how the proposed action will change those features. Detailed descriptions and documentation of hydrological changes expected to result from the proposed action are available in the C&SF Restudy DPEIS.

Under 2050 Base conditions, several features of the water management system limit the system's ability to provide natural timing, volume and placement of water flows as defined by the SFWMD's Natural Systems Model (NSM), as follows: 1) the overall volume of water available to the remaining Everglades system falls far short of volumes expected under NSM conditions in most years, causing reduced depths and shorter hydroperiods over large parts of the project area. This reduced volume is due in large part to the release of excess water to the ocean during high water periods in order to avoid flooding; 2) the effects of a reduced volume of water are exacerbated by the system of canals and levees that provides unobstructed flow paths that allow much of the available water to flow quickly from Lake Okeechobee, through the WCAs and into ENP, reducing hydroperiods. Under natural conditions, water flowed much more slowly through unbroken stretches of marsh so that water was retained within the Everglades system for longer periods, increasing hydroperiods in many areas; 3) the levee system also provides barriers to natural flow paths, creating unnaturally deep and long-lasting pools of water upstream (north) of the levees separating the WCAs; and, 4) the historical flow path of Shark River Slough, the main path of drainage through the remaining Everglades system, has been re-routed from east to west in order to protect eastern urban and agricultural areas from flooding and a significant portion of the historical flow path has been permanently eliminated due to urbanization. Under natural conditions, the majority of water passing into what is now ENP entered to the east of today's L-67E levee. Under 2050 Base conditions, most water enters ENP to the west of this levee, producing unnaturally increased hydroperiods to the west and unnaturally reduced hydroperiods to the east.

The proposed action will make significant progress towards removing each of these limits to natural hydropatterns: 1) several very large Water Storage Areas and numerous Aquifer Storage and Recovery wells would capture and store much of the excess water available during wet periods. This makes more water available to the remaining Everglades system when it is needed to provide natural flow volumes, reduces damaging freshwater releases to estuaries, and reduces damage to Lake Okeechobee littoral zone habitats though attenuation of extreme high and low lake levels; 2) the rate of water flow through the remaining Everglades system is reduced through backfilling of canals including much of the Miami Canal and parts of the L-67 A and C canals, and removal of parts of the L-67 A and C levees, allowing water to travel through additional marsh areas; 3) the unnaturally deep pool of water in the southern part of WCA 3A is reduced through removal of parts of several levees, allowing water to flow more freely through this area; and, 4) the historical flow path of Shark River Slough is partially restored through removal of part of several levees, allowing large volumes of water to pass through WCA 3B and into northeast

Shark River Slough. This reduces unnaturally long hydroperiods in the area of northwestern ENP and southeastern Big Cypress National Preserve, and increases unnaturally short hydroperiods in northeastern Shark River Slough.

These more natural hydropatterns expected to result from the proposed action will have beneficial effects on several listed species. The overall increased volume of water flow though the remaining Everglades system provides greater volumes of freshwater flow into Florida Bay and Shark River Slough estuaries, reducing salinities in these areas. Since West Indian manatees prefer habitats that include sources of freshwater, the proposed action may increase the area of habitat suitable for manatees in Florida Bay. Decreased salinities and decreased temperatures associated with increased freshwater inflows may cause a shift in seagrass composition. However, manatees eat all species of seagrasses and are not thought to be food limited in this area (USFWS 1998). Consequently, implementation of the proposed action is likely to benefit the West Indian manatee. Similarly, adult American crocodiles prefer low salinity habitats and hatchling crocodiles experience increased growth rates and decreased predation when low salinity nursery habitats are available (USFWS 1998). The proposed action would increase the number of months that salinities in crocodile habitats are low and decrease the number of months that salinities in crocodile habitats increase to poorly tolerated levels. Therefore, implementation of the proposed action should benefit the American crocodile through decreased salinities in Florida Bay and Shark River Slough estuarine habitats, including designated critical habitat (Figure 2), resulting from increased freshwater flow volumes through the remaining Everglades system.

The Okeechobee gourd is also expected to benefit as a result of the proposed action. 2050 Base conditions produce periods of extreme high water in Lake Okeechobee that would flood Okeechobee gourd habitats and would be expected to cause some Okeechobee gourd mortality and reduce surrounding vegetation necessary to support mature plants (USFWS 1998). The 2050 Base also produces extreme low lake levels that overdry Okeechobee gourd habitats, reducing seedling survival rates (USFWS 1998). The proposed action would improve habitat conditions for this species through attenuation of extreme high and extreme low water levels in Lake Okeechobee.

Snail kites use many areas of the remaining Everglades system and large parts of this area have been designated as snail kite critical habitat (Figure 1). The proposed action would provide improved habitat conditions for snail kites in several ways: 1) attenuation of extreme high water levels in Lake Okeechobee would reduce flood induced die-off of woody vegetation that provides nesting substrate for snail kites, increasing available nesting habitat; 2) attenuation of extreme low water levels in Lake Okeechobee would increase availability of suitable snail kite foraging habitat in the littoral zone, particularly during drought periods when snail kite habitat in other areas is limited; 3) reduction of the deep, impounded pool areas in southern WCA 3A would reduce losses of snail kite nesting habitat due to drowning of woody vegetation (Bennetts and Kitchens 1997) and improve foraging conditions in many years, but would slightly increase the severity of drydowns during dry years (Institute for Environmental Modeling and USGS-BRD 1998b);

and, 4) more natural depths and hydroperiods in WCA 3B and along the flanks of Shark River Slough would provide improved snail kite foraging habitat in these areas during average to wet years (Institute for Environmental Modeling and USGS-BRD 1998b). During very dry years, the FWS expects a slight shift in snail kite habitat usage from WCA 3A to Shark River Slough and other habitats outside the project areas. No significant change in habitat conditions is expected for snail kite habitats in other areas of the remaining Everglades system.

The proposed action would improve habitat conditions for wood storks through reversal of factors that are thought to have caused the historic decline of nesting wood stork numbers in the remaining Everglades system. Ogden (1994) proposes that the substantial reduction in freshwater flow into Florida Bay and Shark River Slough estuaries seen under current and 2050 Base conditions reduces the production and availability of fish suitable for wood stork consumption to the point that these areas can no longer support nesting wood stork populations. Ogden (1994) further suggests that wood storks have responded by shifting their nesting attempts to parts of the WCAs and areas outside the southern Everglades that provide appropriate concentrations of fish. However, appropriate concentrations of fish are generally available in the WCAs several months later than they would be in the estuarine areas, causing wood storks to initiate nesting later in the year and increasing wood stork nest failure rates when wet season rains disperse fish concentrations before nestlings have fledged.

The proposed action would restore suitable wood stork foraging and nesting habitats in the Shark River Slough and Florida Bay areas by providing volume and timing of freshwater flows to these areas that more closely match natural conditions. Through an analysis of expected hydroperiods and flow volumes in the Shark River Slough and Florida Bay estuarine areas, Ogden (SFWMD, personal communication 1998) estimates a significant improvement in wood stork habitat suitability under the proposed action. ATLSS modeling of expected foraging conditions for long-legged wading birds and expected fish abundance also suggests that the proposed action will improve habitat conditions for wood storks (Institute for Environmental Modeling and USGS-BRD 1998b).

Cape Sable seaside sparrow habitat conditions, including designated critical habitat (Figure 3), would also be improved through reversal of factors that are thought to have caused the historic declines of this species. As described above, current delivery of the majority of water entering ENP to the west of the L-67E levee has resulted in artificially increased water levels west of Shark River Slough and artificially reduced water levels east of Shark River Slough. Nott *et al.* (1998) and Curnutt *et al.* (1998) documented the detrimental effects of current water management practices that flood Cape Sable seaside sparrow habitat west of Shark River Slough (Figure 3, ENP border area), through analysis of the various sources of water in this area and their correlation with observed Cape Sable seaside sparrow population declines and detrimental alteration of Cape Sable seaside sparrow habitat. Nott *et al.* (1998) and Curnutt *et al.* (1998) also document declines in the eastern Cape Sable seaside sparrow subpopulations (Figure 3, northern and eastern critical habitat areas) and detrimental alteration of eastern Cape Sable seaside sparrow habitats under current conditions, which they attribute to overdrainage and resultant increased fire frequencies in these areas. ATLSS modeling results indicate that 2050 Base conditions would not significantly reduce flooding in the sparrow's western population habitat, and would increase damaging overdrainage in the sparrow's eastern habitat as compared to current conditions (Institute for Environmental Modeling and USGS-BRD 1998c).

ATLSS hydroperiod modeling suggests that the proposed action will make significant progress toward reversing hydrological factors causing declines in Cape Sable seaside sparrow populations (Institute for Environmental Modeling and USGS-BRD 1998b). Increased water levels and hydroperiods in eastern marl prairie habitats utilized by the sparrow should improve habitat conditions through a reduction in woody vegetation encroachment and a reduction in fire return frequencies (Curnutt *et al*. 1998, Nott *et al*. 1998). Decreased water levels in the western marl prairie habitats would reduce the number of years in which successful sparrow breeding is reduced or precluded by flooding. ATLSS individual-based sparrow modeling and population viability analyses for the western sparrow sub-population provide further evidence that productivity and probability of persistence of this population would be improved (Institute for Environmental Modeling and USGS-BRD 1998b).

Although the proposed action would improve both western and eastern Cape Sable seaside sparrow habitats overall, some small adverse effects are also likely to result. Part of the sparrow's eastern habitat lies along the eastern flank of Shark River Slough at a lower elevation than other eastern habitat areas (Figure 3). With expected increases in water depths in Shark River Slough under the proposed action, part of this sparrow habitat would be likely to experience hydroperiods long enough to cause a shift in vegetative composition. Such a shift would increase densities of water tolerant vegetation, rendering part of the existing habitat unsuitable for Cape Sable seaside sparrows (S. Pimm, University of Tennessee and S. Bass, Everglades National Park, personal communications 1998). The FWS expects that the effect of this small loss of habitat would be minor given the overall beneficial effects in other habitat areas. However, the sequence in which components of the proposed action are implemented may influence the effect of this habitat shift on the overall sparrow population. This concern is discussed further below.

B. Hydrological changes in the new water storage and treatment areas

The proposed action includes approximately 125,000 acres of new Water Storage Areas, 60,000 acres of Water Preserve Areas and approximately 10,000 acres of new Stormwater Treatment Areas. This represents a large and significant part of South Florida's remaining natural habitats, including upland habitats, that will be hydrologically altered by the C&SF Restudy. Although the exact locations of the new Water Storage Areas and Stormwater Treatment Areas have not been determined, the COE has provided some preliminary information on possible locations. An analysis of wildlife habitats occurring in these possible locations is provided in the accompanying Draft Fish and Wildlife Coordination Act Report for the C&SF Restudy (FWCA Report).

The FWCA Report analysis reveals that habitats of several listed species occur in the possible storage and treatment area locations. The Everglades Agricultural Area storage area and Water Preserve Area locations include areas used for foraging by the wood stork, particularly during high water periods. Both possible locations for the storage area north of Lake Okeechobee include current and past bald eagle nesting sites, and the Audubon's crested caracara is present within and around both sites. Caracaras and active Florida scrub jay territories are present in the Caloosahatchee storage area site, and although there are currently no records of bald eagle nesting in this area, bald eagle nesting patterns shift over time and this species may be present in the Caloosahatchee site at the time of construction. Possible storage area locations in the St. Lucie drainage do not contain habitats of particular significance to listed species. However, records of caracara use exist for one of the areas and a wood stork nesting site occurs just outside one of the proposed areas. The COE has not provided possible sites for the storage and treatment sites in the Taylor Creek/Nubbin Slough area. However, FWS files indicate that caracaras use this general area and the COE is encouraged to avoid caracara habitats as much as possible during the siting process. Although detailed records of eastern indigo snake occurrences are not available for the proposed storage and treatment area locations, the FWS believes that eastern indigo snakes are very likely to occur in all of these areas.

It is difficult to predict what vegetative communities will be present in the new water storage areas due to the unusual hydrologic patterns they will experience. These areas will act primarily as "surge tanks", storing large amounts of excess water during wet periods and drying out completely during dry times. These alternating wet and dry conditions may last only a few days or may last for many months to more than a year, and water depths will vary widely, from as deep as 10 feet to only a few inches, depending on rainfall conditions and operational demands. These irregular hydrological patterns will certainly cause profound and widespread changes in wildlife habitats existing in these areas at the time of construction. Long periods of flooding would be expected to kill trees used as nesting sites by bald eagles, caracaras and many other species, eventually destroying the nests and reducing available nesting substrates.

Under some conditions, large areas of habitat suitable for foraging wood storks, snail kites, bald eagles, and Audubon's crested caracaras may be created and may provide some benefits to these and other wildlife species. However, the FWS is concerned that these areas would become "attractive nuisances" when temporary favorable conditions are created, drawing in opportunistic wildlife species. Temporary favorable conditions could induce species such as wood storks, snail kites, bald eagles and others to nest nearby with nesting success dependent on continued favorable foraging conditions, and could produce artificially inflated populations of some species. When storage area operations then cause a rapid change in conditions, widespread nesting failures and direct mortality of adult individuals due to loss of foraging resources could result. In addition, the rapid filling of storage areas that have been dry for extended periods would likely result in direct mortality due to drowning of less mobile species such as the eastern indigo snake.

Clearly, xeric habitats within the new water storage areas, such as oak scrub habitat used by Florida scrub jays, would be destroyed by periodic flooding. Florida scrub jays are habitat limited and the FWS expects that any scrub jay individuals residing in habitats that are subsequently destroyed by flooding would die due to starvation or predation while searching for new, unoccupied habitat unless new suitable scrub habitat is created nearby (USFWS 1998).

Expected vegetative patterns in the new Stormwater Treatment Areas are more predictable since water levels would be more stable and there are several currently operating Stormwater Treatment Areas that provide examples of expected conditions. However, uncertainty still exists because even when water levels are suitable for wildlife habitats, the high nutrient levels in the incoming water and soils tend to produce large numbers of cattails and other nutrient tolerant species that provide poor habitat for snail kites, wood storks and many other wildlife species. Stormwater Treatment Areas with water levels less than 4 feet deep, and that are not in a stage in their maintenance when high densities of cattails are present, would be expected to provide some foraging habitat for snail kites, wood storks and other wildlife species.

Detailed surveys of all proposed storage and treatment area locations will be necessary during future detailed siting and planning in order to provide up to date information on expected impacts to wildlife habitats at the time of construction. If these surveys suggest that listed species may be affected in a manner, or to an extent not analyzed above, the COE will need to reinitiate consultation on these components.

2. Construction Effects

Information on the precise location, seasonal timing and duration of C&SF Restudy construction activities will be developed during future detailed planning and design phases of the project. Therefore, analyses of the precise effects of construction activities on listed species will be conducted in the future as detailed designs and scheduling are completed. However, the general information now available suggests that these construction activities will have adverse effects on some listed species and their habitats, although the exact extent and magnitude of these adverse effects can not be determined at this time.

Construction of five very large Water Storage Areas and several smaller storage, Water Preserve Areas and Stormwater Treatment Areas may adversely affect several listed species. These water storage and treatment areas total more than 100,000 acres as currently designed. Impacts to wildlife resulting from construction of perimeter levees and control structures would include disturbance due to prolonged use of heavy construction equipment and disruptive construction techniques such as blasting. In addition, although exact design specifications have not yet been developed, the area of habitat destroyed within the footprint of these new structures could be significant. The COE has provided some preliminary data on possible locations for these water storage and treatment areas and an analysis of wildlife habitats occurring in these locations is provided in the accompanying FWCA report. Based on this analysis, the FWS concludes that construction locations are likely to include habitats of the bald eagle, Audubon's crested caracara, wood stork, eastern indigo snake and Florida scrub jay. An analysis of the nature and extent of any adverse effects to these species resulting from construction of these water storage and treatment areas will not be possible until exact siting and construction schedule information is available. The COE will need to reinitiate consultation on these components when such information has been developed. The FWS encourages the COE to carefully consider impacts to wildlife habitats during the siting process in order to avoid and minimize possible adverse effects. Thorough surveys of these areas will need to be conducted during the siting process in order to provide timely information on species locations at the time of construction.

Removal/redesign of several existing C&SF project features is likely to adversely affect several listed species. Removal of portions of the L-28 and Tamiami Trail levees and their associated canals, backfilling part of the Miami Canal and removal/redesign of the L-67 A and C levees will require prolonged use of heavy construction equipment and may require potentially disruptive construction techniques such as blasting. Several known snail kite and wood stork nesting areas occur immediately adjacent to portions of these levees slated for removal (Bennetts *et al*. 1994, Bennetts and Kitchens 1997, Ogden 1994) and the FWS believes that wood stork and snail kite individuals could be harassed and could abandon nesting activities as a result of physical disturbance and/or noise disturbance resulting from these construction activities if they occur during the breeding season and birds are actively engaged in breeding activities nearby. Such harassment could cause nesting individuals to flush from their nests, increasing the likelihood that eggs or nestlings would be lost to predation. In addition, eastern indigo snakes are known to occur along canal banks in South Florida, where they use crab holes in lieu of gopher tortoise burrows (Lawler 1977). Therefore, removal of large portions of these existing levees would destroy potential eastern indigo snake habitat and would likely result in death or injury of eastern indigo snake individuals present during construction.

Many other construction activities, such as new canal/levee construction for the Water Preserve Areas, construction of additional water control structures along the eastern perimeter levees, and installation of Aquifer Storage and Recovery wells, are also included in the proposed action. The FWS believes that these construction activities will generally have only discountable effects on the wood stork, snail kite, Cape Sable seaside sparrow and other listed species that may avoid using foraging and/or resting habitats immediately adjacent to construction sites during active construction due to physical and/or noise disturbance. However, if future detailed design and construction schedules for these components reveal that construction activities will occur immediately adjacent to snail kite, wood stork, Cape Sable seaside sparrow or bald eagle nesting areas during the nesting season, or that additional listed species may be affected, the COE should enter into consultation with the FWS to determine whether adverse effects to listed species are likely. All new water control structures will include devices designed to avoid trapping or otherwise injuring West Indian manatees (COE 1994); therefore, the FWS does not expect any adverse effects to manatees due to construction or operation of new water control structures.

The FWS recommends that the COE plan seasonal timing of construction activities to protect listed species whenever possible. This reflects the ongoing responsibility of all Federal agencies to minimize adverse effects to listed species, even when the cumulative effect of their actions do not reach the level of jeopardy. For example, if disturbance of a wading bird colony containing nests of the endangered wood stork can be avoided by scheduling construction activities outside the nesting season of the word stork, such scheduling changes are justified regardless of whether the long-term effects of the project will benefit the species as a whole.

3. Sequencing Effects

The above analysis includes expected effects of construction and implementation of the full complement of components included in the proposed action. Additional and possibly quite different effects are likely to occur as a result of the sequencing of component implementation. For example, implementation of the planned removal of part of the Tamiami Trail canal and levee starting at the eastern end and proceeding west would likely have very different effects on natural habitats during implementation than would a west to east progression. The east to west progression would remove one of the major impediments to restoring water flows to the main historic channel of Shark River Slough first, quickly relieving the overdrying of Northeast Shark River Slough and the flooding of marl prairie areas west of Shark River Slough. This broadly corresponds to improvements in eastern and western Cape Sable seaside sparrow habitats. A west to east progression would prolong limitations on our ability to alleviate these problems and may exacerbate flooding of western marl prairies due to loss of control over western water flows with levee removal. This may cause additional adverse effects to Cape Sable seaside sparrows prior to realization of any expected benefits, raising serious doubts as to the species ability to survive until these benefits could be realized. In addition, an east to west progression would allow development of improved foraging habitat for snail kites along the banks of Shark River Slough before removal of the western part of the Tamiami Trail levee reduces the snail kite habitat currently provided by artificial impoundment of water in southern WCA 3A.

Another example is the timing of land acquisition activities. Lands within the action area are undergoing development for residential and industrial uses every day, making acquisition of these lands for restoration purposes increasingly difficult. As options for placement of proposed water storage and treatment facilities are limited in this way, the likelihood increases that these limitations will force siting of facilities on ecologically sensitive lands, including listed species habitats. If land acquisition is scheduled and completed early in the implementation sequence, conflicts with other land uses in acquisition areas would likely be minimized, enhancing our ability to avoid sensitive natural areas.

Countless other sequencing considerations exist, and will best be addressed in the future detailed planning and design phases of the C&SF Restudy. However, guiding principles for minimizing adverse effects to listed species due to sequencing of component implementation can be outlined at this point and incorporated into future planning. First, sequencing should attempt to provide a smooth transition for those species that will lose habitat in some areas and gain it in others. The

Tamiami Trail levee removal example above illustrates this for shifts in snail kite habitats. Second, sequencing should attempt to implement actions that will benefit a species before those that will adversely affect it. The Tamiami Trail levee example illustrates this for the Cape Sable seaside sparrow. Third, when it is necessary to choose between sequences or other options that will differentially affect listed species, priority should be given to those species that are: 1) most imperiled; 2) most limited in their distribution to areas affected by the action; and, 3) least able to adjust to proposed changes. For example, higher priority should be placed on avoiding Florida grasshopper sparrow habitat during placement of storage reservoirs than on avoiding Audubon's crested caracara habitat because the grasshopper sparrow is more imperiled, more limited in distribution and less flexible in its habitat requirements.

4. Species Summary

A. West Indian Manatee and American Crocodile

The proposed action would improve habitat conditions for the West Indian manatee and American crocodile through decreased salinities in Florida Bay and Shark River Slough estuarine habitats resulting from increased volume and improved timing of freshwater flows to these areas.

B. Okeechobee Gourd

The proposed action would improve habitat conditions for the Okeechobee gourd through attenuation of extreme high and extreme low water levels in Lake Okeechobee.

C. Florida Scrub Jay and Audubon's Crested Caracara

Construction and operation of water storage and treatment areas is likely to destroy some Florida scrub jay and Audubon's crested caracara habitat.

D. Eastern Indigo Snake

Construction and operation of water storage and treatment areas, and removal of some existing levees is likely to destroy some eastern indigo snake habitat.

E. Bald Eagle

Construction and operation of water storage and treatment areas is likely to destroy some bald eagle nesting sites. Disturbance due to nearby construction activities may cause some additional adverse effects. Additional adverse effects are possible due to water storage and treatment area operations that may create "attractive nuisance" conditions.

F. Snail Kite

Snail kite habitats in Lake Okeechobee, southern WCA 3A, WCA 3B and Shark River Slough would be improved through more natural hydrology and a shift of snail kite habitat use from WCA 3A to Shark River Slough is expected during very dry years. Disturbance due to construction activities and possible temporary reductions in available habitats due to the sequencing of component implementation are likely to cause adverse effects. Additional adverse effects are possible due to water storage and treatment area operations that may create “attractive nuisance” conditions.

G. Wood Stork

Wood stork nesting habitats in Florida Bay and Shark River Slough estuarine areas would be improved by restoring more natural hydrology. Overall increases in fish availability may provide improved foraging in many areas. Disturbance due to construction activities and loss of foraging habitats to water storage areas are likely to cause adverse effects. Additional adverse effects are possible due to water storage and treatment area operations that may create “attractive nuisance” conditions.

H. Cape Sable Seaside Sparrow

Significant improvement in breeding habitat availability is expected in eastern and western sparrow habitats due to more natural hydrology. Minor adverse effects are likely due to expected vegetative shifts in a small area sparrow of habitat on the eastern bank of Shark River Slough.

Conflicts among the needs of listed species within the action area appear to be a concern for the proposed project as a whole only in the apparent need to eliminate or otherwise adversely affect some listed species habitat associated with new water storage facilities in order to provide benefits to many other species and habitats downstream. This tradeoff should be acceptable as long as the priority guidelines described above are adopted and any adverse impacts do not reach or exceed the jeopardy threshold. The proposed overall changes in the hydrology of the remaining Everglades do not appear to contain such conflicts - they benefit all listed species that would be affected.

CUMULATIVE EFFECTS

Cumulative effects include the effects of future State, local or private actions that are reasonably certain to occur in the action area considered in this preliminary biological opinion. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to section 7 of the ESA.

All future actions that are reasonably certain to occur in the action area and would affect listed species are expected to be carried out, funded and/or permitted by the COE, NPS or FWS. Therefore, all future actions would require separate section 7 consultation and will not be included here in a cumulative effects analysis.

PRELIMINARY CONCLUSION

After reviewing the current status of the West Indian manatee *(Trichechus manatus*) and its designated critical habitat, snail kite (*Rostrhamus sociabilis plumbeus*) and its designated critical habitat, wood stork *(Mycteria americana*), Cape Sable seaside sparrow *(Ammodramus maritimus mirabilis*) and its designated critical habitat, American crocodile (*Crocodylus acutus*) and its designated critical habitat, Florida grasshopper sparrow (*Ammodramus savannarum floridanus*), Okeechobee gourd (*Cucurbita okeechobeensis),* bald eagle (*Haliaeetus leucocephalus),* Audubon's crested caracara (*Polyborus plancus),* eastern indigo snake (*Drymarchon corais couperi*), and Florida scrub jay (*Aphelocoma coerulescens*), the environmental baseline for the action area, the effects of the proposed Central and Southern Florida Project C&SF Restudy and the cumulative effects, it is the Service's preliminary biological opinion that the C&SF C&SF Restudy alternative D13R, as proposed, is:

1) not likely to adversely affect and is likely to benefit the West Indian Manatee, American crocodile and Okeechobee gourd, and is not likely to adversely modify designated West Indian Manatee or American crocodile critical habitat;

2) is likely to adversely affect, but is not likely to jeopardize and, as a whole, is likely to benefit the snail kite, wood stork and Cape Sable seaside sparrow (this determination reflects minor, localized adverse effects that are expected to occur during the implementation of actions that will provide overall benefits to the species clearly outweighing the adverse effects) and is not likely to adversely modify designated snail kite or Cape Sable seaside sparrow critical habitat; and,

3) is likely to adversely affect, but is not likely to jeopardize the bald eagle, Audubon's crested caracara, eastern indigo snake and Florida scrub jay.

INCIDENTAL TAKE STATEMENT

INTRODUCTION

Sections 4(d) and 9 of ESA, as amended, prohibit taking (harass, harm, purse, hunt, shoot, wound, kill, trap, capture of collect, or attempt to engage in any such conduct) of listed species of fish or wildlife without a special exemption. Harm is further defined to include significant habitat modification or degradation that results in death or injury to listed species b significantly impairing behavioral patterns such as breeding, feeding or sheltering. Harass is defined as actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns which include, but are not limited to, breeding, feeding or sheltering. Incidental take is any take of listed animal species that results from, but is not the purpose of, carrying out an otherwise lawful activity conducted by the Federal agency or the applicant. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered a prohibited taking provided that such taking is in compliance with the terms and conditions of this incidental take statement.

The measures described below are non-discretionary, and must be implemented by the agency, if this preliminary biological opinion is confirmed, so that they become binding conditions of any grant or permit issued to the applicant, as appropriate, in order for the exemption in section 7(o)(2) to apply. The COE has a continuing duty to regulate the activity covered by this incidental take statement. If the COE (1) fails to ensure that all implementing entities adhere to the terms and conditions of the incidental take statement through enforceable terms that are added to permit, grant or other documents, and/or (2) fails to retain oversight to ensure compliance with these terms and conditions, the protective coverage of section 7(o)(2) may lapse.

Sections 7(b)(4) and 7(o)(2) of the Act do not apply to the incidental take of listed plant species. However, protection of listed plants is provided to the extent that the Act requires a Federal permit for removal or reduction to possession of endangered plants from areas under Federal jurisdiction, or for any act that would remove, cut, dig up, or damage or destroy any such species on any State or in the course of any violation of a State criminal trespass law.

AMOUNT OR EXTENT OF TAKE ANTICIPATED

In meeting the provisions for incidental take in section 7(b)(4) of the ESA, the FWS has reviewed the biological opinion and other available information relevant to the proposed action. Based on our review, incidental take is anticipated as follows.

Audubon’s crested caracara

Incidental take of Audubon’s crested caracara individuals and habitat is likely during construction and operation of the large water storage areas that are part of the proposed action. The amount or extent of this incidental take cannot be anticipated at this time because a proposal for precise siting of these storage areas has not yet been developed. Therefore, this incidental take statement does not provide protection from liability under the taking provisions of section 9 of the ESA for take of Audubon’s crested caracaras associated with the proposed action.

Some preliminary recommendations for siting of water storage areas are provided in the accompanying FWCAR for the C&SF Restudy, and the FWS will provide detailed technical assistance during future development of siting proposals in order to minimize adverse effects to listed species. Reinitiation of formal consultation for Audubon's crested caracara will likely be necessary if final siting proposals include caracara habitat areas.

Bald eagle

Incidental take of bald eagle individuals and habitat is likely during construction activities, particularly construction of the large water storage areas, that are part of the proposed action. The amount or extent of this incidental take cannot be anticipated at this time because precise siting, engineering and construction activity schedule proposals have not yet been developed. Therefore, this incidental take statement does not provide protection from liability under the taking provisions of section 9 of the ESA for take of bald eagles associated with the proposed action.

Some preliminary recommendations for siting of water storage areas are provided in the FWS's FWCAR for the C&SF Restudy and the FWS will provide detailed technical assistance during future development detailed construction proposals in order to minimize adverse effects to listed species. The COE should refer to the FWS's Habitat Management Guidelines for the Bald Eagle in the Southeastern Region (USFWS 1987) during detailed planning. Reinitiation of formal consultation for the bald eagle will be necessary if final proposals include destruction of bald eagle nests or disruptive construction activity near bald eagle nests.

Cape Sable seaside sparrow

Incidental take of Cape Sable seaside sparrow individuals and habitat is likely during C&SF Restudy implementation, primarily through flooding and eventual loss of a small portion of habitat on the eastern bank of Shark River Slough. Current topographical and hydrological modeling information is not sufficient to determine the exact amount of this anticipated incidental take. Therefore, this incidental take statement does not provide protection from liability under the taking provisions of section 9 of the ESA for take of Cape Sable seaside sparrows associated with the proposed action.

Reinitiation of formal consultation for the Cape Sable seaside sparrow will likely be necessary when the availability of additional information allows a precise determination of anticipated incidental take.

Eastern indigo snake

Incidental take of eastern indigo snake individuals and habitat is likely during construction and operation activities, particularly construction and operation of the large water storage areas that are part of the proposed action. The amount or extent of this incidental take cannot be anticipated at this time because precise siting, engineering and construction activities and scheduling proposals have not yet been developed. Therefore, this incidental take statement does not provide protection from liability under the taking provisions of section 9 of the ESA for take of eastern indigo snakes associated with the proposed action.

Some preliminary recommendations for siting of water storage areas are provided in the FWS's FWCAR for the C&SF Restudy and the FWS will provide detailed technical assistance during future development detailed construction proposals in order to minimize adverse effects to listed species. Reinitiation of formal consultation for the eastern indigo snake will likely be necessary if final proposals include destruction and/or disturbance of eastern indigo snake habitat.

Florida scrub jay

Incidental take of Florida scrub jay individuals and habitat is likely during construction of the large water storage areas that are part of the proposed action. The amount or extent of this incidental take cannot be anticipated at this time because a proposal for precise siting of these storage areas has not yet been developed. Therefore, this incidental take statement does not provide protection from liability under the taking provisions of section 9 of the ESA for take of Florida scrub jays associated with the proposed action.

Some preliminary recommendations for siting of water storage areas are provided in the FWS's FWCAR for the C&SF Restudy and the FWS will provide detailed technical assistance during future development of siting proposals in order to minimize adverse effects to listed species. It should be possible to choose final sites that avoid all scrub jay habitat, thereby eliminating all adverse affects to this species. Reinitiation of formal consultation for the Florida scrub jay will likely be necessary if final siting proposals do include scrub jay habitat areas.

Snail kite

Incidental take of snail kite individuals and habitat is likely during construction and operation of the large water storage areas that are part of the proposed action and during other construction activities that occur near snail kite foraging and/or nesting areas while snail kites are present. The amount or extent of this incidental take cannot be anticipated at this time because proposals for precise siting and construction schedules have not yet been developed. Therefore, this incidental take statement does not provide protection from liability under the taking provisions of section 9 of the ESA for take of snail kites associated with the proposed action.

The FWS will provide detailed technical assistance during future development of siting and operations proposals in order to minimize adverse effects to listed species. Construction schedules should include provisions for surveys to determine if snail kites or other listed species are present near the construction site and measures to adjust the timing and/or location of construction activities to avoid disturbance. Reinitiation of formal consultation will be necessary if final proposals may adversely affect snail kites.

Wood stork

Incidental take of wood stork individuals and habitat is likely during construction and operation of the large water storage areas that are part of the proposed action and during other construction activities that occur near wood stork foraging and/or nesting areas while wood storks are present. The amount or extent of this incidental take cannot be anticipated at this time because proposals for precise siting and construction schedules have not yet been developed. Therefore, this incidental take statement does not provide protection from liability under the taking provisions of section 9 of the ESA for take of wood storks associated with the proposed action.

Some preliminary recommendations for siting of water storage areas are provided in the FWS's FWCAR for the C&SF Restudy and the FWS will provide detailed technical assistance during future development of siting and operations proposals in order to minimize adverse effects to listed species. Construction schedules should include provisions for surveys to determine if wood storks or other listed species are present near the construction site and measures to adjust the timing and/or location of construction activities to avoid disturbance. Reinitiation of formal consultation will be necessary if final proposals may adversely affect wood storks.

EFFECT OF THE TAKE

Based on the accompanying biological opinion, the FWS has determined that this level of anticipated incidental take is not likely to result in jeopardy to listed species or destruction or adverse modification of critical habitat.

REASONABLE AND PRUDENT MEASURES

When providing an incidental take statement the FWS is required to provide reasonable and prudent measures it considers necessary or appropriate to minimize the take along with terms and conditions that must be complied with, to implement the reasonable and prudent measures. The FWS believes the following reasonable and prudent measures are necessary and appropriate to reduce take:

1. Placement of water storage areas, water treatment areas and other impoundments should avoid listed species habitats as much as possible.

2. Construction schedules for all project features should avoid disturbance of listed species as much as possible.

3. Sequencing of component implementation should maximize benefits and minimize adverse affects to listed species as much as possible.

TERMS AND CONDITIONS

To implement the above reasonable and prudent measures, the FWS has outlined the following terms and conditions for incidental take. In accordance with the Interagency Cooperation Regulations (50 CFR 402), these terms and conditions must be complied with to implement the reasonable and prudent measures for incidental take.

1. The COE, in cooperation with FWS and other natural resources professionals, must design and implement a detailed monitoring and adaptive management program sufficient to provide information on the locations of listed species and the effects of C&SF Restudy components on listed species that can be used to maximize benefits and minimize adverse affects to listed species during detailed planning and implementation.

2. The COE must solicit advice from FWS and other natural resources professionals on options for siting of water storage areas, water treatment areas and other impoundments that minimize adverse effects to listed species during the detailed planning and implementation phases of the C&SF Restudy. Such advice must be implemented to the maximum extent possible within the basic scope of the C&SF Restudy.

3. The COE must solicit advice from FWS and other natural resources professionals on options for construction methods and schedules that maximize benefits and minimize adverse effects to listed species during the detailed planning and implementation phases of the C&SF Restudy. Such advice must be implemented to the maximum extent possible within the basic scope of the C&SF Restudy.

4. The COE must solicit advice from FWS and other natural resources professionals on options for sequencing of component implementation that maximize benefits and minimize adverse effects to listed species during the detailed planning and implementation phases of the C&SF Restudy. Such advice must be implemented to the maximum extent possible within the basic scope of the C&SF Restudy.

CONSERVATION RECOMMENDATIONS

In a February 24, 1998, letter the FWS provided the COE with an extensive list of recommendations for maximizing benefits to threatened and endangered species resulting from the C&SF Restudy in accordance with section 7(a)(1) of the ESA. This letter is incorporated herein by reference as conservation recommendations. Additional conservation recommendations are provided in the accompanying FWCAR on the C&SF Restudy.

REINITIATION - CLOSING STATEMENT

Because the proposed action is likely to have adverse effects on listed species, the FWS has included an incidental take statement pursuant to section 7(b)(4) of the ESA. However, because this is an early consultation on the initial draft plan, this incidental take statement does not eliminate the COE's liability under the taking prohibitions of section 9 of the ESA.

Instead, this statement provides your agency with foreknowledge of the terms and conditions that will be required if C&SF Restudy alternative D13R is formally submitted for Congressional authorization. These reasonable and prudent measures and implementing terms and conditions become effective only after the FWS confirms this preliminary biological opinion as a final biological opinion on the prospective action.

This concludes early consultation for actions modeled by the South Florida Water Management Model as part of C&SF Restudy alternative D13R. You may ask the FWS to confirm this preliminary biological opinion as a final biological opinion when the prospective action is ready for formal submission for Congressional authorization. The request must be in writing and the FWS is allowed 45 days from receipt of the written request to provide its response. If the FWS reviews the proposed action and finds that there are no significant changes in the action as planned or in the information used during the early consultation, it will confirm this preliminary biological opinion as a final biological opinion on the project and no further section 7 consultation will be necessary, except when one of the following criteria for Reinitiation is met: (1) the amount or extent of incidental take is exceeded; (2) new information reveals effects of the agency action that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; (3) the agency action is subsequently modified in a manner that causes an effect on listed species or critical habitat that was not considered in this opinion; or (4) a new species is listed or critical habitat designated that may be affected by the action. When the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation. If the FWS does not confirm this preliminary biological opinion as a final biological opinion on the prospective action, the COE is required to reinitiate formal consultation with the FWS.

Thank you for the opportunity to comment on this project. If you have any questions, feel free to contact me at 561/778-0896.

Sincerely,

Stephen W. Forsythe
State Supervisor

ANNEX C

PROGRAMMATIC
SECTION 404(b)(1) EVALUATION

ANNEX C

PROGRAMMATIC
SECTION 404(b)(1) EVALUATION

CENTRAL AND SOUTHERN FLORIDA PROJECT
COMPREHENSIVE RESTUDY

PREFACE This document is a programmatic Section 404(b)(1) Evaluation. As such it addresses, at a general level, the potential environmental effects of the wetland and aquatic ecosystem alterations expected from the construction of the structural components of the recommended comprehensive plan. Subsequent site-specific Section 404(b)(1) Evaluations will be done for individual project components, or groups thereof, in sufficient detail for final decision making and for full compliance with the Section 404(b)(1) Guidelines and National Environmental Policy Act requirements.

PROJECT DESCRIPTION

A. Location. The Central and Southern Florida (C&SF) Project area encompasses approximately 18,000 square miles from Orlando to Florida Bay with at least 11 major physiographic provinces: Everglades, Big Cypress, Lake Okeechobee, Florida Bay, Biscayne Bay, Florida Reef Tract, nearshore coastal waters, Atlantic Coastal Ridge, Florida Keys, Immokalee Rise, and the Kissimmee River Valley. The Kissimmee River, Lake Okeechobee and the Everglades are the dominant watersheds that connect a mosaic of wetlands, uplands, coastal areas, and marine areas.

B. General Description. The existing C&SF Project, which was first authorized by Congress in 1948, is a multi-purpose project that provides flood control; water supply for municipal, industrial, and agricultural uses; prevention of saltwater intrusion; water supply for Everglades National Park; and protection of fish and wildlife resources. The primary system includes about 1,000 miles each of levees and canals, 150 water control structures, and 16 major pump stations. The recommended Comprehensive Plan is the initial draft plan, alternative D-13R, along with Other Project Elements (OPEs). The plan consists of construction components, real estate requirements, a monitoring program, and operation and maintenance of the completed project. In addition, several feasibility studies are recommended to investigate additional improvements needed to support restoration, protection, and preservation of the South Florida ecosystem. A large number of components have been identified in the recommended Comprehensive

Plan. These components have been evaluated on a regional scale using the South Florida Water Management Model, an effective tool for analyzing regional hydrologic effects of the combined components. However, due to the scale of the model (four-square-mile grid cells), more site-specific analyses of components will be needed. Detailed planning and design will be necessary to determine the optimum size, depth and configuration, and management of various facilities which are proposed for construction. This will include collecting necessary physical data, finalizing performance targets, performing water quality evaluations, conducting refined modeling and pilot projects, and resolving regulatory issues. Upon resolution of outstanding issues, detailed design of the components and projects will occur. In a number of cases, water storage facilities have not been sited in the comprehensive plan, a cooperative effort with landowners in the areas where storage facilities are proposed will be used to identify suitable sites with willing sellers to the greatest degree possible.

C. Authority and Purpose. This study is authorized by Section 309(l) of the Water Resources Development Act of 1992 (P.L.102-580) which states:

> *"(1) CENTRAL AND SOUTHERN FLORIDA. -- The Chief of Engineers shall review the report of the Chief of Engineers on central and southern Florida, published as House document 643; 80th Congress, 2nd Session, and other pertinent reports, with a view to determining whether modifications to the existing project are advisable at the present time due to significantly changed physical, biological, demographic, or economic conditions, with particular reference to modifying the project or its operation for improving the quality of the environment, improving protection of the aquifer, and improving the integrity, capability, and conservation of urban water supplies affected by the project or its operation."*

This study is also authorized by two resolutions of the Committee on Public Works and Transportation, United States House of Representatives, dated September 24, 1992. The first resolution states:

> *"Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Board of Engineers for Rivers and Harbors, is requested to review the report of the Chief of Engineers on Central and Southern Florida, published as House Document 643, Eightieth Congress, Second Session, and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at the present time, in the interest of environmental quality, water supply and other purposes."*

The second resolution states:

"Resolved by the Committee on Public Works and Transportation of the United States House of Representatives, That the Board of Engineers for Rivers and Harbors, is requested to review the report of the Chief of Engineers on Central and Southern Florida, published as House Document 643, Eightieth Congress, Second Session, and other pertinent reports, to determine whether modifications of the recommendations contained therein are advisable at the present time, in the interest of environmental quality, water supply and other purposes for Florida Bay, including a comprehensive, coordinated ecosystem study with hydrodynamic modeling of Florida Bay and its connections to the Everglades, the Gulf of Mexico, and the Florida Keys Coral Reef ecosystem."

The Water Resources Development Act of 1996 was enacted on October 12, 1996. Section 528 of the Act entitled "Everglades and South Florida Ecosystem Restoration authorizes a number of ecosystem restoration activities and also provides specific direction and guidance for the Restudy. The specific provisions of Section 528 concerning the Restudy are:

"(b) RESTORATION ACTIVITIES-

(1) COMPREHENSIVE PLAN-

(A) DEVELOPMENT-

(i) PURPOSE- The Secretary shall develop, as expeditiously as practicable, a proposed comprehensive plan for the purpose of restoring, preserving, and protecting the South Florida ecosystem. The comprehensive plan shall provide for the protection of water quality in, and the reduction of the loss of fresh water from, the Everglades. The comprehensive plan shall include such features as are necessary to provide for the water-related needs of the region, including flood control, the enhancement of water supplies, and other objectives served by the Central and Southern Florida Project.

(ii) CONSIDERATIONS- The comprehensive plan shall--

(I) be developed by the Secretary in cooperation with the non-Federal project sponsor and in consultation with the Task Force; and

(II) consider the conceptual framework specified in the report entitled "Conceptual Plan for the Central and Southern Florida Project Restudy", published by the Commission and approved by the Governor.

(B) SUBMISSION- Not later than July 1, 1999, the secretary shall--

(i) complete the feasibility phase of the Central and Southern Florida Project comprehensive review study as authorized by section 309(l) of the Water Resources Development Act of 1992 (106 Stat. 4844), and by 2 resolutions of the Committee on Public Works and Transportation of the House of Representatives, dated September 24, 1992; and

(ii) submit to Congress the plan developed under subparagraph (A)(i) consisting of a feasibility report and a programmatic environmental impact statement covering the proposed Federal action set forth in the plan.

(C) ADDITIONAL STUDIES AND ANALYSES- Notwithstanding the completion of the feasibility report under subparagraph(B), the Secretary shall continue to conduct such studies and analyses as are necessary, consistent with subparagraph (A)(i).

(2) USE OF EXISTING AUTHORITY FOR UNCONSTRUCTED PROJECT FEATURES- The Secretary shall design and construct any features of the Central and Southern Florida Project that are authorized on the date of the enactment of this Act or that may be implemented in accordance with the Secretary's authority to modify an authorized project, including features authorized under sections 315 and 316, with funds that are otherwise available, if the Secretary determines that the design and construction--

(A) will accelerate the restoration, preservation, and protection of the South Florida ecosystem;

(B) will be generally consistent with the conceptual framework described in paragraph (1)(A)(ii)(II); and

(C) will be compatible with the overall authorized purposes of the Central and Southern Florida Project.

(3) CRITICAL RESTORATION PROJECTS-

(A) IN GENERAL- In addition to the activities described in paragraphs (1) and (2), if the Secretary, in cooperation with the non-Federal project sponsor and the Task Force, determines that a restoration project for the South Florida ecosystem will produce independent, immediate, and substantial restoration, preservation, and protection benefits, and will be generally consistent with the conceptual framework described in paragraph (1)(A)(ii)(II), the Secretary shall proceed expeditiously with the implementation of the restoration project.

(B) INITIATION OF PROJECTS- After September 30, 1999, no new projects may be initiated under subparagraph (A).

(C) AUTHORIZATION OF APPROPRIATIONS-

(i) IN GENERAL- There is authorized to be appropriated to the Department of the Army to pay the Federal share of the cost of carrying out projects under subparagraph (A) $75,000,000 for the period consisting of fiscal years 1997 through 1999.

(ii) FEDERAL SHARE- The Federal share of the cost of carrying out any 1 project under subparagraph (A) shall be not more than $25,000,000.

(4) GENERAL PROVISIONS-

(A) WATER QUALITY- In carrying out activities described in this subsection and sections 315 and 316, the Secretary--

(i) shall take into account the protection of water quality by considering applicable State water quality standards; and

(ii) may include in projects such features as are necessary to provide water to restore, preserve, and protect the South Florida ecosystem.

(B) COMPLIANCE WITH APPLICABLE LAW- In carrying out the activities described in this subsection and subsection (c), the Secretary shall comply with any applicable Federal law, including the National Environmental Policy Act of 1969 (42 U.S.C. 4321 et seq.) and the Endangered Species Act of 1973 (16 U.S.C. 1531 et seq.).

(C) PUBLIC PARTICIPATION- In developing the comprehensive plan under paragraph (1) and carrying out the activities described in this subsection and subsection (c), the Secretary shall provide for public review and comment on the activities in accordance with applicable Federal law.

(c) INTEGRATION OF OTHER ACTIVITIES-

(1) IN GENERAL- In carrying out activities described in subsection (b), the Secretary shall integrate such activities with ongoing Federal and State projects and activities, including--

(A) the project for the ecosystem restoration of the Kissimmee River, Florida, authorized by section 101 of the Water Resources Development Act of 1992 (106 Stat. 4802);

(B) the project for modifications to improve water deliveries into Everglades National Park authorized by section 104 of the Everglades National Park Protection and Expansion Act of 1989 (16 U.S.C. 410r-8);

(C) activities under the Florida Keys National Marine Sanctuary and Protection Act (16 U.S.C. 1433 note; 104 Stat. 3089); and

(D) the Everglades Construction Project of the State of Florida.

(2) STATUTORY CONSTRUCTION-

(A) EXISTING AUTHORITY- Except as otherwise expressly provided in this section, nothing in this section affects any authority in effect on the date of the enactment of this Act, or any requirement of the authority, relating to participation in restoration activities in the South Florida ecosystem, including the projects and activities specified in paragraph (1), by--

(i) the Department of the Interior;

(ii) the Department of Commerce;

(iii) the Department of the Army;

(iv) the Environmental Protection Agency;

(v) the Department of Agriculture;
(vi) the State of Florida; and
(vii) the South Florida Water Management District.

(B) NEW AUTHORITY- Nothing in this section confers any new regulatory authority on any Federal or non-Federal entity that carries out any activity authorized by this section.

(d) JUSTIFICATION-

(1) IN GENERAL- Notwithstanding section 209 of the Flood Control Act of 1970 (42 U.S.C. 1962-2) or any other provision of law, in carrying out the activities to restore, preserve, and protect the South Florida ecosystem described in subsection (b), the Secretary may determine that the activities--

(A) are justified by the environmental benefits derived by the South Florida ecosystem in general and the everglades and Florida Bay in particular; and

(B) shall not need further economic justification if the Secretary determines that the activities are cost-effective.

(2) APPLICABILITY- Paragraph (1) shall not apply to any separable element intended to produce benefits that are predominantly unrelated to the restoration, preservation, and protection of the South Florida ecosystem.

(e) COST SHARING-

(1) IN GENERAL- Except as provided in sections 315 and 316 and paragraph (2), the non-Federal share of the cost of activities described in subsection (b) shall be 50 percent.

(2) WATER QUALITY FEATURES-

(A) IN GENERAL- Except as provided in subparagraph (B), the non-Federal share of the cost of project features to improve water quality described in subsection (b) shall be 100 percent.

(B) EXCEPTION-

(i) IN GENERAL- Subject to clause (ii), if the Secretary determines that a project feature to improve water quality is essential to Everglades restoration, the non-Federal share of the cost of the feature shall be 50 percent.

(ii) APPLICABILITY- Clause (I) shall not apply to any feature of the Everglades Construction Project of the State of Florida.

(3) OPERATION AND MAINTENANCE- The operation and maintenance of projects carried out under this section shall be a non-Federal responsibility.

(4) CREDIT- Regardless of the date of acquisition, the value of lands or interests in land acquired by non-Federal interests for any activity described in subsection (b) shall be included in the total cost of the activity and credited against the non-Federal share of the cost of the activity. Such value shall be determined by the Secretary."

D. General Description of Dredged or Fill Material. Many of the project components are expected to involve the discharge of dredged or fill material into wetlands or other aquatic resources. However, specific information is unknown at this time. The (1) **general characteristics**, (2) **quantities**, and (3) **sources** of dredged or fill material will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

E. Description of the Proposed Discharge Site. The (1) **locations** of many of the components are unknown at this time and therefore the associated discharge sites can not be described herein. The estimated cumulative (2) **size** of water storage areas and stormwater treatment areas in the recommended Comprehensive Plan is approximately 216,800 acres. This is not an estimate of the total wetland and aquatic area to be filled; rather it is the estimated acreage of the land needed for these components. Notwithstanding the current uncertainty regarding component locations, an analysis was conducted to determine the approximate extent of wetlands that could be encountered. Estimates of the wetland acreage to be affected by each of the water storage and treatment areas were made. For the known sites, the acreage estimates were based on available information, such as existing studies, aerial photography and other physiographic data. For those sites where only the conceptual location is known, estimates were made of the percent of wetland area expected to be encountered in the region. The total area of wetlands and that could be affected by these types of components is conservatively estimated to be approximately 34,000 acres. In addition to the estimates of wetland acreage that could be affected, habitat quality estimates were made for both the existing and with plan conditions. These habitat quality estimates were made using a scale of zero to one, with 0.0 representing very poor habitat quality and 1.0 representing optimum habitat quality. For the existing condition estimates, habitat quality was based on available data for project features with known locations and best professional judgement was used for project features with conceptual locations. To estimate the habitat quality for the with-project condition, operational details of the feature are needed. For example, the hydrologic operation and vegetative management of the Water Preserve Areas will dictate the effect on habitat quality as either beneficial or detrimental. Again, a conservative approach was taken and all features were assumed to produce an adverse impact. The total estimate of the potential adverse impacts of the Recommended Comprehensive Plan is a loss of approximately 10,000 “wetland habitat units”. These units were derived by multiplying the estimated area of affected wetlands by the difference between the existing and with plan habitat quality estimates. The (3) **types of sites**, (4) **types of habitats**, and (5) **timing and duration of the discharges** for many of the components are also unknown at this time. The pertinent information will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

F. Description of Disposal Method. Specific information is unknown at this time. The disposal method(s) for dredged or fill material will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

FACTUAL DETERMINATION

A. Physical Substrate Determination. Specific information is unknown at this time. The (1) **substrate elevation and slope**, (2) **sediment type**, (3) **dredge/fill material movement**, and (4) **physical effects on benthos** at the disposal sites for dredged or fill material will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

B. Water Circulation, Fluctuation and Salinity Determination. Specific information is unknown at this time. The (1) **water column effects**, (2) **current patterns and circulation**, and (3) **normal water level fluctuations and salinity gradients** at the disposal sites for dredged or fill material will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

C. Suspended Particulate/Turbidity Determinations.

(1) Expected Changes in Suspended Particulates and Turbidity Levels in the Vicinity of the Disposal Site. Although site-specific information is unknown at this time, temporary increases in suspended particulates and turbidity levels can be expected during the construction of some of the components. All appropriate measures to reduce and contain turbidity will be employed so State Water Quality Standards will not be violated.

(2) Effects on the Chemical and Physical Properties of the Water Column. Specific information is unknown at this time. Effects on (1) **light penetration** (2) **dissolved oxygen**, (3) **toxic metals, organics, and pathogens** and (4) **aesthetics** of the water column will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

(3) Effects on Biota. Specific information is unknown at this time. Effects on (1) **primary productivity and photosynthesis**, (2**) suspension/filter feeders**, and (3) **sight feeders** will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

D. Contaminant Determinations. Specific information is unknown at this time. The presence of contaminants will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

E. Aquatic Ecosystem and Organism Determinations.

(1) Endangered and Threatened Species. It is the Biological Opinion of the U.S. fish and Wildlife Service that implementation of this project will either benefit, or not adversely affect, the continued existence of any endangered and/or threatened species which occur in the project area (see Annex B).

(2) Hardbottom Habitat. Currently, there are no project components proposed in marine ecosystems with known hardbottom habitat.

F. Proposed Disposal Site Determinations.

(1) Mixing Zone Determination. Specific information is unknown at this time. The mixing zone will be determined during planning and design activities for each component. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

(2) Determination of Compliance with Applicable Water Quality Standards. Although specific information is unknown at this time, the construction and operation of the project components will comply with State water quality standards.

(3) Potential Effects on Human Use Characteristics.

(a) Municipal and Private Water Supplies. In addition to the primary goal of restoring the greater Everglades ecosystem, the project includes components that will improve urban and agricultural water supplies.

(b) Recreational and Commercial Fisheries. The project will benefit recreational and commercial fisheries.

(c) Water Related Recreation. Although specific information is unknown at this time, water related recreation may be reduced by some components and improved by others. Accordingly, this information will be addressed in subsequent Section 404(b)(1) Evaluations.

(**d)** **Aesthetics**. Although specific information is unknown at this time, it is expected that the components will be in keeping with general characteristics of the area.

(e) Parks, **National and Historic Monuments, National Seashores, Wilderness Areas, Research Sites, and Similar Preserves.** The project will enhance environmental conditions at these types of sites within the project area.

G. **Determination of Cumulative Effects on the Aquatic Ecosystem.** The restoration of hydrology to the greater Everglades ecosystem and the increase in spatial extent of protected wetland acreage in the study area will produce extensive cumulative beneficial effects. These beneficial effects are expected to substantially outweigh the cumulative adverse effects produced by the aquatic ecosystem alterations that may be necessary to construct some of the project components.

3. FINDINGS OF COMPLIANCE OR NON-COMPLIANCE WITH THE RESTRICTIONS ON DISCHARGE

a. No significant adaptations of the guidelines were made relative to this evaluation.

b. No practicable alternative exists which meets the study objectives that does not involve discharge of fill into waters of the United States.

c. The discharges of fill materials will not cause or contribute to, after consideration of disposal site dilution and dispersion, violations of any applicable State water quality standards for Class III waters. The discharge operations will not violate the Toxic Effluent Standards of Section 307 of the Clean Water Act.

d. The placement of fill materials in the project area will not jeopardize the continued existence of any species listed as threatened or endangered or result in the likelihood of destruction or adverse modification of any critical habitat as specified by the Endangered Species Act of 1973, as amended (See Annex B).

e. The placement of fill materials will not result in significant adverse effects on human health and welfare, including municipal and private water supplies, recreational and commercial fishing, plankton, fish, shellfish, wildlife, and special aquatic sites. The life stages of aquatic species and other wildlife will not be adversely affected. Significant adverse effects on aquatic ecosystem diversity, productivity and stability, and recreational, aesthetic, and economic values will not occur.

f. Subsequent application of the Section 404(b) (1) Guidelines during planning and design activities for each component of the recommended Comprehensive Plan will ensure that the proposed disposal sites for the discharge of dredged material will comply with the requirements of these Guidelines.

ANNEX D

PROGRAMMATIC
FLORIDA COASTAL ZONE MANAGEMENT PROGRAM
FEDERAL CONSISTENCY EVALUATION PROCEDURES

ANNEX D

PROGRAMMATIC
FLORIDA COASTAL ZONE MANAGEMENT PROGRAM
FEDERAL CONSISTENCY EVALUATION PROCEDURES

CENTRAL AND SOUTHERN FLORIDA PROJECT
COMPREHENSIVE RESTUDY

PREFACE: This document is a programmatic evaluation of the overall project's consistency with the Florida Coastal Zone Management Program. As such it addresses, at a general level, the potential environmental effects expected from implementation of the recommended Comprehensive Plan. Subsequent site-specific evaluations will be done for individual project components, or groups thereof, in sufficient detail for final decision making and for full compliance with the Florida Coastal Zone Program and National Environmental Policy Act requirements.

1. Chapter 161, Beach and Shore Preservation.

The intent of the coastal construction permit program established by this chapter is to regulate construction projects located seaward of the line of mean high water and which might have an effect on natural shoreline processes.

Response: No work is proposed seaward of the line of mean high water in beach areas. The Florida Keys Tidal Restoration project included in the recommended Comprehensive Plan involves retrofitting several areas of the Overseas Highway (U.S. Highway 1) in the Florida Keys. This project will have beneficial effects on natural shoreline processes.

2. Chapters 186 and 187, State and Regional Planning.

These chapters establish the State Comprehensive Plan which sets goals that articulate a strategic vision of the State's future. It's purpose is to define in a broad sense, goals and policies that provide decision-makers directions for the future and provide long-range guidance for an orderly social, economic and physical growth.

Response: The proposed project will achieve the goals of this chapter by developing a long range master plan for South Florida's water resources which, will support the continued orderly social, economic and physical growth of the region.

3. Chapter 252, Disaster Preparation, Response and Mitigation.

This chapter creates a state emergency management agency, with the authority to provide for the common defense; to protect the public peace, health and safety; and to preserve the lives and property of the people of Florida.

Response: This statute is not applicable to this project.

4. Chapter 253, State Lands.

This chapter governs the management of submerged state lands and resources within state lands. This includes archeological and historical resources; water resources; fish and wildlife resources; beaches and dunes; submerged grass beds and other benthic communities; swamps, marshes and other wetlands; mineral resources; unique natural features; spoil islands; and artificial reefs.

Response: The proposed project contributes positively to the preservation of cultural, water, fish and wildlife, wetland and estuarine resources. The Everglades is a unique natural resource.

5. Chapters 253, 259, 260, and 375, Land Acquisition.

This chapter authorizes the state to acquire land to protect environmentally sensitive areas.

Response: The project has many components that require the acquisition of many types of land by the State. No encumbrance of the State's rights under this chapter is established under this project.

6. Chapter 258, State Parks and Aquatic Preserves.

This chapter authorizes the state to manage state parks and preserves. Consistency with this statute would include consideration of projects that would directly or indirectly adversely impact park property, natural resources, park programs, management or operations.

Response: The project will enhance environmental conditions at State parks or aquatic preserves within the project area.

7. Chapter 267, Historic Preservation.

This chapter establishes the procedures for implementing the Florida Historic Resources Act responsibilities.

Response: This project has been coordinated with the State Historic Preservation Officer (SHPO). Historic preservation compliance will be completed to meet all responsibilities under Chapter 267.

8. Chapter 288, Economic Development and Tourism.

This chapter directs the state to provide guidance and promotion of beneficial development through encouraging economic diversification and promoting tourism.

Response: The proposed project will achieve the goals of this chapter by developing a long range master plan for South Florida's water resources which, will support economic diversification and tourism.

9. Chapters 334 and 339, Public Transportation.

This chapter authorizes the planning and development of a safe, balanced and efficient transportation system.

Response: The proposed project will not adversely impact the existing public transportation systems in the long-term. Proposed modifications to existing major transportation infrastructure will include temporary bypasses during construction.

10. Chapter 370, Saltwater Living Resources.

This chapter directs the state to preserve, manage and protect the marine, crustacean, shell and anadromous fishery resources in state waters; to protect and enhance the marine and estuarine environment; to regulate fisherman and vessels of the state engaged in the taking of such resources within or without state waters; to issue licenses for the taking and processing products of fisheries; to secure and maintain statistical records of the catch of each such species; and, to conduct scientific, economic, and other studies and research.

Response: In addition to the primary goal of restoring the greater Everglades ecosystem, the project includes components expressly designed to improve ecological conditions in the downstream estuaries.

11. Chapter 372, Living Land and Freshwater Resources.

This chapter establishes the Game and Freshwater Fish Commission and directs it to manage freshwater aquatic life and wild animal life and their habitat to perpetuate a diversity of species with densities and distributions that provide sustained ecological, recreational, scientific, educational, aesthetic, and economic benefits.

Response: The project has been coordinated with the U.S. Fish and Wildlife Service for compliance with Section 7 of the Endangered Species Act. No threatened or endangered species will be adversely affected. The proposed action will not adversely impact any resource under the management of the Game and Freshwater Fish Commission.

12. Chapter 373, Water Resources.

This chapter provides the authority to regulate the withdrawal, diversion, storage, and consumption of water.

Response: The project sponsor is the South Florida Water Management District, the State agency responsible for implementing this statute in the project area. Coordinated planning has been done with this agency to ensure compatibility with established policies.

13. Chapter 376, Pollutant Spill Prevention and Control.

This chapter regulates the transfer, storage, and transportation of pollutants and the cleanup of pollutant discharges.

Response: This project does not involve the transportation or discharging of pollutants. Environmental protection measures will be enforced during construction to avoid inadvertent spills or other sources of pollution.

14. Chapter 377, Oil and Gas Exploration and Production.

This chapter authorizes the regulation of all phases of exploration, drilling, and production of oil, gas, and other petroleum products.

Response: This project does not involve the exploration, drilling or production of gas, oil or petroleum products.

15. Chapter 380, Environmental Land and Water Management.

This chapter establishes criteria and procedures to assure that local land development decisions consider the regional impact nature of proposed large-scale development.

Response: The proposed project will achieve the goals of this chapter by developing a long range master plan for South Florida's water resources which, will support the continued orderly social, economic and physical growth of the region.

16. Chapter 388, Arthropod Control.

This chapter provides for a comprehensive approach for abatement or suppression of mosquitoes and other pest arthropods within the state.

Response: The project will not further the propagation of mosquitoes or other pest arthropods, and will foster high populations of insectivorous fishes.

17. Chapter 403, Environmental Control.

This chapter authorizes the regulation of pollution of the air and waters of the state of the Florida.

Response: An environmental assessment of project impacts has been prepared and will be reviewed by the appropriate resource agencies including the Department of Environmental Protection.

18. Chapter 582, Soil and Water Conservation.

This chapter establishes policy for the conservation of the state soil and water through the Department of Agriculture and Consumer Services. Land use policies will be evaluated in terms of their tendency to cause or contribute to soil erosion or to conserve, develop, and utilize soil and water resources both onsite or in adjoining properties affected by the project. Particular attention will be given to projects on or near agricultural lands.

Response: The proposed project is expected to impact agricultural land. The exact extent of agricultural land to be affected is unknown at this time. The project has been coordinated under the Farmland Protection Policy Act with the U.S. Department of Agriculture, Natural Resources Conservation Service. Project implementation will include appropriate erosion control plans and measures to ensure compliance.

APPENDIX A

PLAN FORMULATION

APPENDIX A
PLAN FORMULATION

This Appendix is a compilation of plan formulation documents. Below is a brief summary of each of these documents.

A1 PLAN FORMULATION DOCUMENT

The Plan Formulation Document was prepared during the component screening phase of the study. The document presents a range of components (ideas) that were screened during the initial phases of plan formulation. In the preliminary screening phase, information gained through a cost effectiveness analysis (Appendix A2) was joined with information from hydrologic modeling and information gained through previous studies to support best professional judgement in the selection of specific project components. This screening phase aimed to identify which components (from the initial list of potential project components) would be carried forward in the development of alternative comprehensive plans.

A2 COST EFFECTIVENESS SCREENING ANALYSIS

The Restudy Team used a cost effectiveness analysis as a tool in the preliminary screening phase. The results of this analysis are presented in this Appendix.

A3 SUMMARY DESCRIPTION OF ALTERNATIVES A-D

The Restudy Team evaluated a number of Alternatives. The description of the final array of alternatives is presented in the Appendix.

A4 DESCRIPTION OF ALTERNATIVE D13-R

Alternative D13-R is the plan selected by the Restudy Team as the Initial Draft Plan. This plan is comprised of forty-nine operational and structural features that the are referred to as components. Together, these forty-nine components make the Initial Draft Plan that addresses many of the water resources problems of south Florida. This Section of the Plan Formulation Appendix includes a description of each of the components that make up the Initial Draft Plan. At the end of this Section is a series of figures and maps to aid the reader in understanding the conceptual features of the Initial Draft Plan. However, not all components have been mapped due to uncertainty in site location.

A5 CRITICAL PROJECTS

Section 528 of the Water Resources Development Act (WRDA) of 1996 authorizes the Secretary of the Army to expeditiously implement restoration projects that are deemed critical to the restoration of the south Florida ecosystem. These projects are referred to as Critical Projects. This authority allows the Corps of Engineers to implement projects that are needed for restoration in advance of completion of the Comprehensive Plan. Thirty-five candidate Critical Projects were identified and prioritized by the Working Group of the South Florida Ecosystem Restoration Task Force through a process that utilized input from the Governor's Commission for a Sustainable South, project proponents, and the public. However, the cumulative cost estimate for all 35 candidate Critical Projects exceeds the current legislatively mandated funding limit. Therefore, it is anticipated that only the top priority candidates will be implemented under this authority. The Restudy addresses all of the Critical Projects nominated by the Working Group to ensure they will be implemented. This appendix briefly explains the Critical Project program, provides narrative summaries of each project and its expected benefits, and explains how each project is addressed in the Restudy.

A6 DESCRIPTION OF OTHER PROJECT ELEMENTS

The recommended comprehensive plan is comprised of the Initial Draft Plan (Alternative D-13R) and a select group of components that could not be evaluated during the iterative alternative plan formulation process. This group of components has been termed Other Project Elements (OPEs). An initial list of potential OPEs was developed by the Restudy Team from the Critical Projects list; the Governor's Commission Conceptual Plan, the Restudy Plan Formulation document, and nominations Restudy Team members. The list was screened against certain criteria and an interdisciplinary team evaluated the remaining OPEs. This Appendix describes the OPE screening and evaluation processes, the resulting conclusions, and the OPEs themselves.

APPENDIX A1
PLAN FORMULATION DOCUMENT

A1.1 INTRODUCTION

Plan formulation is an iterative planning process that identifies alternative plans to achieve a set of planning objectives and allows those plans to be modified as more information becomes available. Each iteration of this process provides an opportunity to refine and sharpen the planning focus. The reconnaissance phase of the Comprehensive Review Study (Restudy) and the South Florida Water Management District's Lower East Coast Regional Water Supply Planning process provides a foundation from which to begin reducing and refining the many ideas that have been proposed to a manageable set of ideas that deserve further evaluation during the ensuing feasibility study. This feasibility study will culminate in the selection of a Comprehensive Plan for the C&SF Project.

In February 1996, the Restudy Team began considering a vast array of ideas (components or options) that could be included in a comprehensive plan. These components were generated from a number of sources including the Restudy reconnaissance report and the Lower East Coast Regional Water Supply planning documents. The components were then used by the Governor's Commission for a Sustainable South Florida (GCSSF) to create their *Conceptual Plan for the Restudy*. This Conceptual Plan contains 13 Thematic Concepts that will be used during the Restudy as an organizing framework for developing and evaluating alternative components and generating the comprehensive plan that will be recommended to Congress by July 1999.

The 13 Thematic Concepts include:

1. Regional Storage Within the Everglades Headwaters and Adjacent Areas
2. Lake Okeechobee Operational Plan
3. Everglades Agricultural Area Storage
4. Water Preserve Areas
5. Natural Areas Continuity
6. Water Supply and Flood Protection for Urban and Agricultural Areas
7. Adequate Water Quality for Ecosystem Functioning
8. Spatial Extent and Quality of Other Wetlands
9. Invasive Plant Control
10. Aquifer Storage and Recovery
11. Protection and Restoration of Coastal, Estuarine, and Marine Ecosystems
12. Conservation of Soil
13. Operation and Management of the C&SF Project and Related Lands

The purpose of this paper is to present a refined set of alternative components to be considered and evaluated during the feasibility phase of the Restudy. This paper guides the reader from problem identification, development of goals and objectives, and the development of components through an initial screening of alternative ideas. After the initial screening of these components, alternative plans will be created and evaluated -- after which the final comprehensive plan will be selected and documented in a draft Feasibility Report and integrated Programmatic Environmental Impact Statement.

A1.2 PROBLEM IDENTIFICATION

The south Florida ecosystem encompasses more than 18,000 square miles from Orlando to Florida Bay and the Keys. Historically, the area sustained a mosaic of ecologic communities ranging from the uplands of the coastal ridge to the marshes of the Everglades to the near shore coastal waters of the Atlantic Ocean, Florida Bay, and the Gulf of Mexico. This complex system of inter-related communities was supported by distinct hydrologic characteristics.

Rain that fell on the northern reaches of this vast system collected in the lakes north of the Kissimmee River. This water would flow slowly south through meandering rivers and sheetflow through the prairies and floodplains to Lake Okeechobee. In its natural state, Lake Okeechobee was much larger and had no well-defined outlets. During the extremely wet years, Lake Okeechobee would over-top its southern rim, which was lined with huge pond-apple trees, where it would become the River of Grass and its water would mingle with the tremendous amount of standing rain water. The River of Grass, defined by the expansive spatial scale and dynamic patterns of storage and sheetflow, formed south of Lake Okeechobee, flowed slowly southward and escaped eastward through a few small rivers which flowed through the east-coast barrier ridge, or passed eventually to Florida Bay through marshes and tangled mangrove thickets. The dynamic hydrologic patterns combined with the mosaic of landscapes throughout the region organized and concentrated a sufficient biomass to support abundant animal populations, established relatively low salinity gradients in the estuaries, and created an extensive network of dry-season refugia for many species.

With the expansion of human activity within south Florida, the aerial expanse of the natural system has become significantly reduced and much of the remaining natural system has degraded. Drainage of the wetland systems within south Florida and the development of uplands have resulted in significant loss of natural values and brings into question whether south Florida can sustain continued social and economic growth. The Governor’s Commission for a Sustainable South Florida in their October 1995 *Initial Report* stated that “south Florida is not sustainable on its present course.”

To this end, the C&SF Project Comprehensive Review Study provides an opportunity to investigate and recommend short- and long-term solutions to address the system's hydrologic problems. Solutions to these hydrologic problems are not a panacea for all the problems hindering sustainability of the region. Other social, cultural, and economic issues must be resolved also.

The altered hydrologic characteristics of the region are now apportioned among often competing sub-regions. These sub-regions include: Kissimmee River Valley; Upper East Coast, consisting of Martin and St. Lucie Counties; Caloosahatchee River and estuary; Lake Okeechobee; Everglades Agricultural Area; Lower East Coast urban area (coastal metropolitan and agricultural areas of North Palm Beach, Palm Beach, Broward, Miami-Dade, and Southern Miami-Dade Counties); Holey Land Wildlife Management Area; Rotenberger Wildlife Management Area; Water Conservation Areas 1, 2A, 2B, 3A, and 3B; Big Cypress National Preserve; Everglades National Park; and coastal areas of Florida Bay, Biscayne Bay, Florida Keys and the Florida Reef Tract.

A1.3 HISTORIC AND PRESENT OBJECTIVES OF THE C&SF PROJECT

In the late 1800s and early 1900s, draining the Everglades was clearly the objective of the people of Florida. South Florida had tremendous natural resources that were subject to long periods of inundation, and the people of south Florida wanted to harness these resources in order to realize their economic potential. As a result, major drainage projects sponsored by the State of Florida were initiated in the late 1800s and continued into the 1920s. There were problems associated with many of these projects and following a series of hurricanes and significant loss of life, the State of Florida initiated a partnership with the Federal government, through the Corps of Engineers, to address the flooding and the other problems created by these drainage projects.

As this partnership embarked to control the hydrologic conditions that were hampering economic development, the project planners recognized a need to strike a balance among competing economic needs. However, the emphasis on economic goals clearly focused the design of the C&SF Project towards the economic development of the region with little understanding of the consequences for the natural system.

In 1948, a comprehensive plan was presented in a report to Congress to meet a set of objectives to promote economic development of the region. These objectives included: reducing flood damages and enhancing land use throughout the region; controlling ground water levels for healthy agriculture; storing excess flood-water for beneficial use; reducing salt water intrusion into coastal wellfields; preserving fish and wildlife; enhancing navigation through a cross-Florida waterway; and providing recreational opportunities. While the project has met and surpassed many of these objectives, it has also had unintended adverse environmental consequences. It is these consequences that have driven the need for the Restudy.

Table 1
HISTORICAL C&SF PROJECT OBJECTIVES (PURPOSES)

•Reduce flood damages and enhance land use throughout the region
•Control ground water levels for agriculture
•Store excess flood-water for beneficial use
•Reduce salt water intrusion into coastal wellfields
•Preserve fish and wildlife
•Enhance navigation
•Provide recreational opportunities

To meet these historical project objectives, the C&SF Project converted a significant portion of the natural system to other uses. The Kissimmee River was channelized. Lake Okeechobee was diked to prevent uncontrolled discharges from the lake. The Everglades Agricultural Area was drained and ground water levels managed to reduce flood damages. The flooding risk was also reduced in the Lower East Coast to allow for urban and suburban development and intensified agriculture. Central portions of the Everglades were diked to create areas in which water could be stored for human needs in the Lower East Coast and for deliveries to Everglades National Park. While some fish and wildlife value was expected to remain in the Water Conservation Areas, the only natural area intended to be preserved in pristine condition was Everglades National Park.

A1.4 RESTUDY GOALS AND OBJECTIVES

The purpose of the Restudy is to review how well the C&SF Project is functioning and determine what modifications may be needed to achieve a new set of objectives. The precursor to the feasibility phase of the study -- the reconnaissance study -- identified a set of regional-scale planning objectives. The Governor's Commission for a Sustainable South Florida also developed a set of regional-scale objectives for the Restudy. A synthesis of these has resulted in an inclusive set of objectives to achieve two general goals for south Florida's ecosystem: enhance ecologic values and enhance economic values and social well being.

Table 2
GOALS AND OBJECTIVES FOR THE C&SF RESTUDY

Goal: Enhance Ecologic Values
• Increase the total spatial extent of natural areas • Improve habitat and functional quality • Improve native plant and animal species abundance and diversity
Goal: Enhance Economic Values And Social Well Being
• Increase availability of fresh water (agricultural/municipal & industrial) • Reduce flood damages (agricultural/urban) • Provide recreational and navigation opportunities • Protect cultural and archeological resources and values

The Restudy planning objectives were developed as the result of public participation and scientific knowledge of south Florida. Through workshops conducted during the reconnaissance phase of the Restudy and subsequent technical evaluations, it is evident that the C&SF Project must continue to provide valuable services to developed areas as originally intended. Therefore, many of the economic and social objectives are similar to those of the original C&SF Project. However, unlike the original set of objectives for the C&SF Project, the Restudy includes objectives that recognize the importance of the natural system in achieving sustainability of the region.

A1.4.1 ENHANCE ECOLOGIC VALUES

Healthy natural systems are integral to the sustainability of south Florida. These systems provide numerous functions, such as plant and animal habitat, recreation and educational opportunities (photography, fishing, hunting, bird watching, etc.), water quality filtration including removal of nutrients and silt, ground water recharge, soil formation, hydrologic linkages, ground water quality protection, interception of airborne pollutants, shoreline stabilization, and protection against erosion. Wetlands, in particular, retard floodwater and provide surface water storage. Mangroves and estuarine areas provide critical breeding habitat for finfish and shellfish, including several of commercial interest. Upland natural systems function as noise buffers, urban green space, habitat for plants and animals (such as tree snails, deer, hundreds of species of birds, and the endangered panther and indigo snake), and travel corridors for these same animals. Thus, plant and animal habitat, although perhaps the most obvious benefit or function, is just one of many functions that natural systems provide. Collectively, these systems benefit the natural ecology and support agricultural, urban, and other human interests as well.

Two recent documents are particularly important in framing the Restudy's goal for enhancing *ecological* values. These documents, which were prepared by many of the leading experts on Everglades ecology, are *The Science Sub-Group Report, Federal Objectives for the South Florida Restoration* (Science Sub-Group, 1993), and *Everglades, the Ecosystem and Its Restoration* (Davis and Ogden, 1994). Another earlier publication, *Ecosystems of Florida* (Myers and Ewel, 1990) also contributed substantial input into the Restudy.

A1.4.1.3 Spatial Extent

Scientists have identified the large spatial extent of the south Florida wetlands as one of the defining physical characteristics of the pre-drainage ecosystem. The size of the south Florida wetlands, in combination with the complex mosaic of habitats, enabled multiple populations of plants and animals to persist over time. The size of the pre-drainage area made it possible for the natural ecosystem to: 1) support genetically viable numbers and sub-populations of species with large feeding ranges and/or narrow habitat requirements; 2) provide the aquatic production to support large numbers of higher vertebrate animals in a naturally nutrient-poor environment; and 3) sustain habitat diversity despite natural disturbances. The ability of populations to recover from disturbances decreases as the available habitat area decreases since habitat diversity, the amount of seasonal refugia, and the number of dispersal options also decrease.

Roughly 50 percent of the pre-drainage wetland area and 90 percent of pinelands have been lost to development. The resulting loss of these natural areas has caused wading bird, snail kite, and panther populations, for example, to be stressed. Assuring adequate spatial extent for natural systems, necessary to support the mosaic of habitats characteristic of the pre-drainage ecosystem, will provide for genetically viable numbers and populations of native species and habitat diversity.

The health of south Florida's ecosystem, and particularly the Everglades, is of important concern to the public. Most people recognize that the spatial extent of the ecosystem has been reduced in the wake of human development. Many people have also stated that they do not believe that the "natural" area of the ecosystem should be enlarged at the expense of communities, jobs, and businesses.

A1.4.1.4 Habitat and Functional Quality

The public has noted the adverse changes in natural habitats, such as sawgrass, mangroves, sea grass beds, and other native wetland habitats, as well as in many native fish and wildlife species, such as wading birds, alligators, shrimp, and lobsters, that depend on the native habitats for survival. The adverse effects of invasive non-native species, such as melaleuca, Brazilian pepper and Australian pine, are also of concern to many. The specific functions that a wetland or upland performs are closely associated with its condition or quality. A reduction in the quality of these areas results in the loss of many or all of the functions that these areas historically performed. Improving the functional quality of the remaining natural areas is important to system-wide restoration given the loss of spatial extent and, thus, function of the historic wetlands and uplands.

South Florida natural habitats have been physically and hydrologically altered and manipulated. Consequently, the south Florida ecosystem is now substantially less productive and diverse than the historic system. For example, although many of the historic short hydroperiod wetlands no longer exist, wetlands that were historically much wetter now have short hydroperiods. Another example is the alteration of wetlands in the Water Conservation Areas. These areas are managed as separate entities that are hydrologically different from historic conditions resulting in changed hydropatterns and quality of the wetlands. Aquatic productivity has been reduced or highly altered throughout the marshes of the central Everglades and the estuaries. Additionally, changes within interior and coastal wetlands have adversely influenced downstream commercial fish and other species in coastal ecosystems such as Florida Bay.

Invasive plant and animal species have also impacted the quality of the south Florida landscape. Invasive species include both native (i.e. cattails) and non-native species (e.g. melaleuca, Brazilian pepper, and Australian pine). The increasing dominance of any community by a single species ultimately reduces the habitat variability necessary to sustain a healthy community of both plants and animals. Water management has encouraged the spread of these invasive species by creating conditions under which they can out-compete the native habitat that existed under pre-drainage conditions. For example, high phosphorus loads and increased hydroperiods have contributed to cattails out-competing sawgrass; altered hydrologic regimes have increased the spread of melaleuca and Brazilian pepper; and the construction of levees has contributed to the spread of Australian pine and Brazilian pepper. Eliminating the invasive and exotic species and the conditions that favor these species will contribute to restoration of native plants and animal species and a more natural ecosystem hydrology and function.

A1.4.1.5 Species Abundance and Diversity

The changes that have taken place in the natural system have led to decreases in native animal and plant populations. One of the most obvious indicators that the Everglades has experienced an ecologically significant reduction in productivity is the decline in wading bird populations. Several species are now so reduced in numbers that their long-term existence is jeopardized unless measures are taken to ensure their sustainability. Other species have a naturally restricted range; these species are also vulnerable to extinction if their specialized habitats are altered. In addition to considering these species, it is important to recognize that maintaining balanced communities of the more abundant species is also essential to a sustainable ecosystem. It is also important to recognize that a balanced community is dynamic; population levels fluctuate widely from year to year as natural conditions fluctuate. Unnaturally small, isolated populations can be quickly extinguished by natural conditions.

Increasing spatial extent and improving habitat quality can provide a base for improving species abundance and diversity. However, compartmentalization caused by construction of physical barriers such as canals, levees, and roads, or even hydrologic barriers (such as the Water Conservation Areas) has fragmented the system by creating a series of poorly connected natural areas. These barriers have restricted the movement of many fish and consequently reduced their range. Fragmented communities are more likely to lose species because the number of individuals in each fragment may be too small to persist. The smaller the fragment, the higher is the likelihood of losing species, or favoring an imbalance in the species that do inhabit the areas. Moreover, fragmentation itself alters the landscape by breaking connections between the various habitat types that were distributed historically across the landscape. Therefore, improving the connectivity of habitats will improve the range of many animals and their prey-base and provide for a more natural balance of species within the system.

Many people have expressed concern about the ability of the south Florida ecosystem to maintain healthy populations of endangered species, including the Florida panther, the tree cactus, the manatee, the wood stork, and the snail kite, to name just a few. There is ample scientific evidence to support such concern; over 65 species in Florida have been listed as endangered or threatened under the Endangered Species Act of 1973, as amended. The State has also identified an additional 50 species of special concern (e.g. little blue heron, snowy egret). In addition to public and scientific concern, the Act directs Federal agencies to carry out programs to conserve endangered and threatened species, in consultation with the Secretary of the Interior (or the Secretary of Commerce in appropriate situations), and to protect the habitat of such species.

A1.4.2 ENHANCE ECONOMIC VALUES AND SOCIAL WELL BEING

The C&SF Project provides economic benefits through regional water supply, flood damage reduction, navigation, and recreation. While most people recognize the need for a healthy ecosystem to support the region's economy and jobs, there are others who are concerned that potential restoration projects will displace farms and other businesses, limit development, and reduce job opportunities. By contrast, continued degradation of the south Florida environment will inevitably adversely affect the tourism and recreational industry that are important to the regional economy.

Many people recognize the beneficial services provided by the C&SF Project. Public concerns about water supply and flood control generally center on preservation of the existing protection from relatively frequent flooding, and delivering water for aquifer recharge, as provided by the C&SF Project.

A1.4.2.3 Water Supply

Public comment and technical analysis both support the need for additional water supply for south Florida. Drainage has reduced the available water supply by sending stormwater to tide, while agricultural and urban development has greatly increased water demand. The 1990 base case developed by South Florida Water Management District planning studies indicates a limited number of water supply shortfalls. If no further action is taken, by the year 2010, the supply shortages will be quite severe and unacceptable to the public.

Drainage, water supply, and flood protection afforded by the C&SF Project have provided for the growth of south Florida's population, which by 1990 was 5.2 million. Local governments in south Florida are predicting that total population will reach 8 million by the year 2010 and will range from 12-15 million people by the year 2050. Approximately 88 percent of the region's current population are concentrated in the coastal urban counties of Miami-Dade, Broward, Palm Beach, Lee, and Collier; this distribution pattern is projected to continue. Urban water supply demands could increase from approximately 1 billion gallons of water per day (BGD) today to 3 BGD by 2050. The growing demand for dependable water for agriculture, industry, and a burgeoning population at a reasonable cost could rapidly exceed the limits of readily accessible sources. If the needs of the region's natural systems are factored in, conflicts for water among users will become even more severe.

In the study area, surficial aquifers supply the majority of water for urban use. These aquifers are vulnerable to salinity intrusion. In the Lower East Coast area, salinity intrusion has resulted from two major events. The first is the lowering of the ground water table in the area due to drainage and reduced recharge as well as the increased withdrawal of water by pumping. The second reason, which has had a more direct impact, is the construction of numerous drainage and navigation canals from inland areas to the coastal waters.

In order to prevent saltwater from entering the local surficial aquifer and contaminating nearby well fields, the water table in coastal areas should be maintained at the level needed to prevent the fresh and saltwater boundary from moving inland. Existing criteria to protect against saltwater intrusion requires maintenance of a one-foot mound of fresh water between the withdrawal point and the saline interface. This is accomplished by maintaining canal levels high enough so that the hydraulic interconnection of the canals and the aquifer maintains a fresh water gradient that is adequate to prevent intrusion of saltwater into the fresh surficial aquifer.

A1.4.2.4 Flood Protection

The C&SF Project was conceived and authorized to provide regional flood protection for all of central and south Florida. The system of canals, levees, water control structures and pump stations conveys and confines flood waters to regional storage facilities, such as Lake Okeechobee and the Water Conservation Areas, or to tidal receiving waters. Further, additional protection is afforded by the local systems operated by special districts, private property owners, and local governments. Public concerns about flood control generally center on preservation of existing flood protection provided by the C&SF Project and increased flood protection in specific areas of need.

The existing investment in flood protection infrastructure was never intended to totally eliminate flooding in developed areas and flooding does occur periodically. In addition, natural areas have also suffered damage as a result of operating the flood control system to benefit the developed areas. Florida's high vulnerability to flooding demands responses to protect the public health, safety, and welfare, the social and economic impacts of which can be staggering.

Flood protection needs have increased since the original flood control project was constructed. As agricultural and urban development continues, the volume, duration, and frequency of floodwaters may increase; the actual level of flood protection may have declined in some areas. There is an opportunity to further reduce the extent of damages from flooding through operational and structural changes to the C&SF Project.

A1.4.2.5 Recreation and Navigation

Public use has been an important consideration of the C&SF Project since it was first developed. The C&SF Project provides opportunities for a wide range of outdoor activities, including: fresh water and estuarine fishing, boating, hunting, camping, picnicking, nature watching, and photography. It also provides the public with access to areas where they can simply "get away from it all." The opportunity to pursue these activities is very important to the economy of south Florida and to the people who make use of these opportunities, including residents, visitors, eco-tourists, and the Native American Tribes. Restoration and protection of the remaining Everglades system, the Keys, south Florida estuaries (including Florida Bay), and reef tracts are essential to the economic base provided by these recreational and traditional uses.

A1.4.2.6 Social and Cultural

The developers of the C&SF Project recognized that a comprehensive plan could not be a panacea for all problems inherent in the development of the region. Management of local and regional growth issues, including changes in population and development, is the responsibility of state, county, city, and other local interests. Although, in this study, alternative plans will not be formulated to address public concerns about growth, the possible effects of alternative restoration plans on population, development, and other growth issues must be evaluated and displayed in the assessment of restoration plans' effects.

Societal sustainability requires the preservation of the rich cultural diversity of the region, such as the Native American communities and the multi-generational culture of the agricultural communities. The rapidly growing population of south Florida is decreasingly dependent directly on the environment for its sustenance, with the exception of water needs. Yet that population is increasingly dependent indirectly on a restored and sustainable environment, such as for support for the economic base of tourism as well as the heightened awareness of the environmental ethic to preserve and sustain this unique natural environment for the future generations to experience and value.

A1.5 PLAN FORMULATION STRATEGY

Alternative plans must be formulated for the Restudy such that they can be evaluated to reveal important effects, including effects that reflect progress toward meeting the objectives, as well as effects that are of interest for other reasons. Usually, plans are developed based on a particular strategy. A strategy defines the approach to a problem in terms of the means and the results that are sought. It is a process of translating the objectives to means to achieve them.

Numerous studies support the theory that the remaining natural system can be changed in the direction of its pre-drainage wetland character through modifications to the hydrologic features. The issue that remains is how to accomplish the ecologic restoration objectives while allowing the system to serve the economic and social needs of the region. The hydrologic characteristics that form this strategy, while not in themselves objectives, provide a basis to formulate alternative components as well as measure and evaluate how they will effect both ecologic and economic goals. They include:

- Regain lost storage capacity
- Restore more natural hydropatterns
- Improve timing and quantities of fresh water deliveries to estuaries
- Restore water quality conditions

A1.5.1 REGAIN LOST STORAGE CAPACITY

Historically, functioning of the natural system depended more on large storage capacity and slow rate of water flow than on the immediate effects of rainfall. Due to the storage and the slow rate of water flow throughout the natural system, wet season rainfall kept the wetlands flooded and maintained fresh water flow to the estuaries well into the dry season. The carry-over effect of the enormous storage capacity of the natural system was so great that a year of high rainfall maintained surface water in wetlands and fresh water flow to estuaries even into one or more subsequent drought years. Further, ground water seepage driven by hydraulic gradients provided the base flow of creeks, rivers, and possibly even surface runoff across the mangrove zone.

Human modifications to the Everglades ecosystem have resulted in the loss of roughly 6 million acre-feet of storage. In southeast Florida, approximately 2 million acre-feet is diverted to the sea on an average annual basis due to seepage from the Water Conservation Areas and drainage in the lower east coast. Increasing storage capacity in the system will provide sufficient quantities of water necessary to meet the needs of the Everglades, Florida Bay, urban, and agricultural areas, while reducing the adverse stormwater impacts to coastal estuaries.

Lake Okeechobee provides considerable storage capacity today and it could be managed in such a way as to maximize storage capability within the existing levee design while at the same time protecting the littoral zone. However, this increase is inadequate to provide for all the regional system demands; therefore, additional sources of water need to be developed with specific users in mind. Flood releases from Lake Okeechobee could be used to fill regional storage facilities prior to allowing discharges to the Caloosahatchee and St. Lucie Estuaries. Storage facilities could also be used to capture water prior to entering Lake Okeechobee.

Operational and structural modifications to existing project features, along with new reservoirs, Water Preserve Areas, seepage barriers, and aquifer storage and recovery (ASR) could enhance stormwater storage for environmental, urban, and agricultural uses. Increased water levels and stormwater storage adjacent to the Water Conservation Areas in Miami-Dade and Broward Counties could prevent excessive seepage from the Everglades and provide increased flows to both Shark River Slough and Florida Bay. Taking advantage of the seasonal nature of water availability from the regional system and greater use of local sources for meeting the demands of urban water supply could provide greater use of the regional water supply system for enhancing the ecologic health of the Everglades and Florida Bay.

A1.5.2 RESTORE MORE NATURAL HYDROPATTERNS

Water supply releases and flood releases involved in the management of stage levels in Lake Okeechobee, the Water Conservation Areas, and the East Everglades, have decoupled water flows from rainfall. Peak flows are higher following major rain events and flow rates decline more abruptly following the end of the wet season than in the natural system. Flows to the Everglades from Lake Okeechobee have shifted from primarily wet season flows in response to rainfall to controlled dry season deliveries in response to urban and agricultural water demands. Channelization and impoundment have disrupted the annual pattern of rising and falling water depths in the remaining wetlands of south Florida. In a few areas, such as the southern parts of the Water Conservation Areas, channelization, coupled with impoundment, has increased depth and hydroperiod. Regulatory water releases from the Water Conservation Areas have flooded alligator nesting sites in Everglades National Park causing nest failure. In addition, these releases have disrupted wading bird nesting, which depends upon lower seasonal water levels that concentrate food supplies.

The importance of hydrology to almost every aspect of Everglades ecosystem function, both in annual and pulse of wet and dry cycles and in stochastic deviations as they relate to disturbances, suggests that water delivery plans should be based on antecedent rainfall and natural system modeling for all major remnant Everglades marshland, including the Water Conservation Areas. The rainfall-based plan for water delivery to Everglades National Park is a first attempt to restore a natural hydrology pattern in the Everglades. Application of this approach to other undeveloped areas of marsh may represent the best strategy for ecosystem restoration. The Everglades system could be operated with rainfall driven targets triggering deliveries to the Water Conservation Areas and Everglades National Park with special attention to protecting tree islands from high water levels. These environmental deliveries could be made first from regional storage facilities if water is available, then from Lake Okeechobee as needed. However, Water Conservation Areas-2B and 3B could continue to function in a multi-purpose role as identified in the original federal authorization. Water storage areas are needed to recover some of the system flexibility originally considered in the C&SF Project (e.g. areas to receive backpumped storm water, sources of water for urban and agricultural consumption, wildlife conservation, etc.). These areas should be designed to reduce excessive seepage from the Everglades system into the coastal basin over and above the amounts desired to maintain a seaward groundwater flow gradient to prevent saltwater intrusion and provide appropriate fresh water flows to the estuaries along the Lower East Coast.

A1.5.3 IMPROVE TIMING AND QUANTITY OF FRESH WATER FLOWS TO ESTUARIES

Water management has altered the natural timing, quantity, and quality of fresh water flow into the coastal ecosystems in south Florida. Water management has resulted in increased short duration, high volume water flow to the St. Lucie and Caloosahatchee Estuaries and less life-sustaining base flows to these estuaries. Flood releases needed to control lake and ground water levels, causing large pulses of fresh water to enter the St. Lucie and Caloosahatchee Estuaries which have caused rapid, drastic decreases in salinity that stressed estuarine organisms. In addition, water flows have been diverted from one receiving basin to another that changed the long-term salinity regimes in both systems.

Areas that have experienced detrimental changes due to alterations in fresh water flows are: Florida Bay (impacted by reduced and untimely fresh water inflows), Manatee Bay (impacted by large fresh water discharges), Caloosahatchee Estuary (impacted by episodic large fresh water discharges and reduced minimum flows during dry seasons), St. Lucie Estuary (same as the Caloosahatchee), Lake Worth Lagoon (impacted by large flood discharges and water quality degradation), and Biscayne Bay (impacted by untimely fresh water inflows). Improving quality, quantity, and timing of fresh water flows to downstream waterbodies should improve the salinity, nutrients, turbidity, and other characteristics that impact the bays, estuaries and reef ecosystems offshore.

A1.5.4 RESTORE WATER QUALITY CONDITIONS

Human activities in south Florida have changed water quality parameters by altering flow characteristics and introducing urban and agricultural pollutants into storm water. The public has expressed particular concerns for six major areas: eutrophication of Lake Okeechobee, flood releases from Lake Okeechobee to the St. Lucie and Caloosahatchee Estuaries, flow into the Water Conservation Areas particularly from the Everglades Agricultural Area, salinity in Florida Bay, urban water quality, and system-wide mercury pollution. These public concerns are complex and varied but can be grouped into three categories: salinity changes, eutrophication, and contaminants.

Changes in salinity characteristics of estuaries have resulted from the alteration of flow throughout the study area. Flood releases from Lake Okeechobee as well as local basin runoff have been routed to the St. Lucie and Caloosahatchee Estuaries and result in short periods of too much fresh water. Similar effects have occurred in Barnes Sound as a result of C-111. Other areas, such as Florida Bay (via Taylor Slough) and the Ten Thousand Islands (via Shark River Slough), have received less fresh water than under historical conditions, which results in periods of hyper-saline conditions. In all cases, natural communities have suffered. Modifications in the timing and quantity of fresh water inflow to Florida Bay have had substantial impact including: more saline bay waters in more locations and for longer periods of time than under pre-managed conditions; reduced recruitment of pink shrimp, snook, and redfish; lowered reproductive success of ospreys and great white herons; shifts in distributions of West Indian manatees and American crocodiles; reduction in wading birds; and contribution to a complex series of factors in the mass mortality of sea grasses that have occurred in the bay since 1987.

Eutrophication, caused by watershed activities that have produced too many nutrients, caused dramatic changes in algal growth within Lake Okeechobee and resulted in shifts of plant communities within the Everglades from sawgrass to cattails. These changes have resulted in further degradation of natural conditions. Contamination problems are characterized by pesticide/herbicide residues and mobilization of mercury within the system. The cause of mercury contamination remains uncertain because not enough is known about the potential sources or the catalyst for mobilization.

Water quality treatment must be incorporated into the facilities that support hydrologic modifications. To date, uptake relationships in the Water Conservation Areas have focused on a rapid flow-through marsh system as a means to achieve an increment of water quality treatment (50 ppb of total phosphorus). But if detention time is as important as literature suggests, then some degree of water quality improvement can be expected from the components that regain lost storage capacity. Captured seepage from storage areas may prove to be a means through which water quality may also be significantly improved.

Different water quality standards apply to different uses, jurisdictional responsibilities, and criteria established by various regulatory agencies. For example, drinking water standards are much higher than water quality standards for agriculture. Furthermore, allowable phosphorus loadings vary among regions of the natural system. Water quality improvement features must specify the potential use of the treated water. The delivery of water for urban use occurs primarily through ground water recharge and subsequent well pumping. Due to the nature of aquifers, contamination would pose long term problems because clean up may be impractical. Any redistribution of water in the C&SF Project must account for movements of existing contaminants so that ground water sources are protected. In addition, the Water Preserve Areas could be designed to provide water quality treatment of captured stormwater prior to release into the Water Conservation Areas or to help meet Lower East Coast area demands.

A1.6 COMPONENTS

The Comprehensive Plan for the C&SF Project will consist of structural and operational changes to the C&SF Project. Individual project features have been termed components. Components have been developed by sub-regions and will be optimized at the sub-regional level, then grouped with other components to form a preliminary Comprehensive Plan. This plan will then be evaluated and trade-offs determined using the system-wide objectives stated previously. This evaluation will provide the Restudy critical data to determine what refinements to the plan are needed.

The components described below were developed based on knowledge gained from considerable public comment, research and analytical studies. However, further evaluation of a range of components is needed to test and verify our knowledge of the system before a comprehensive plan can be selected. Further, some components listed below have been proposed for the sake of gaining greater knowledge of how the system might respond to certain management actions. These components are not intended to be all inclusive of the options available to the Restudy. Public involvement activities and further design and optimization of these and other components will impact the final array of project features.

The components and general issues in ***Table 3*** are organized by sub-region. The left-hand column lists the Governor's Commission for a Sustainable South Florida (GCSSF) Thematic Concept(s) as they relate to the individual components.

Table 3
Initial List of Components

I. KISSIMMEE RIVER AREA

Issues/Problems

- Excess flood discharge to Lake Okeechobee.
- Water quality of inflows into Lake Okeechobee.
- Reduced spatial extent of natural areas and loss of habitat.

Concept		Components
1	1.	Storage reservoirs to reduce high Lake Okeechobee stages. These reservoirs will be designed for flood attenuation and water supply benefits.
1,7	2.	Wetland detention areas for tributaries along the Kissimmee River to improve timing of flows and reduce nutrient impacts to Lake Okeechobee.
1	3.	Additional storage in the Kissimmee Chain of Lakes (above Cypress Lake) through modification in regulation schedules and improved outlet capacities that would protect lake littoral zones while providing proper timing and volume to Kissimmee River and not worsen flood damages.
8	4.	Restore wetlands and aquatic habitat at Pool A along Kissimmee River.
8	5.	Restore wetlands and aquatic habitat at Pool E along Kissimmee River.
8	6.	Restore wetlands and aquatic habitat at Paradise Run along Kissimmee River.
1, 7	7.	Creation of a wetland detention area or stormwater treatment area at Taylor Creek/Nubin Slough to reduce

Phosphorus loading to Lake Okeechobee.

II. UPPER EAST COAST/ST. LUCIE AND MARTIN COUNTIES

Issues/Problems

- Excess local and Lake Okeechobee flood releases to estuary.
- Water quality of fresh water discharges to estuary.
- Base flow needed to maintain healthy estuary.
- Limited agricultural water supply sources.
- Increased dissolved organics and sediment entering the estuary.
- Degraded wetland values within remnant sloughs.
- Reduction of spatial extent of agricultural land due to urban development pressures or planned project modifications.

Concept		Components
1	1.	Storage reservoirs to capture runoff from C-44 and releases from Lake Okeechobee. These reservoirs will be designed for flood attenuation, water supply benefits, and water quality benefits to reduce nutrient impacts of runoff that is allowed to backflow to Lake Okeechobee or to the estuary.
1,7	2.	On-site detention facility to attenuate basin runoff to C-44 and provide water supply. Facilities will also reduce water quality impacts to the St. Lucie Estuary, Indian River Lagoon, and Lake Okeechobee through backpumping.
8	3.	Wetland restoration of remnant sloughs in western St. Lucie and Martin Counties to regain a portion of the habitat lost due to drainage. This is similar to the impoundments recently constructed in the Upper St. John's River Basin and could provide attenuation benefits.
1	4.	Conveyance feature (C-131) to Lake Okeechobee from C-23, 24, 25 to reduce quantity and quality impacts to the St. Lucie Estuary and Indian River Lagoon while providing an additional source of water for Everglades restoration. The quality of water and the stages of Lake Okeechobee must not be adversely effected by the backpumped water.
7	5.	Water quality treatment of existing flows from C-44 to Lake Okeechobee. A portion of the stormwater runoff that is presently discharged to C-44 from basins adjacent to the canal will be backpumped through a stormwater treatment facility and then backpumped to Lake Okeechobee.
2	6.	Backpumping and water quality treatment of additional flows from C-44 to Lake Okeechobee. This component is intended to capture local drainage within the C-44 Basin and

backpump through a stormwater treatment facility to Lake Okeechobee.

6,10	7.	Regional Aquifer Storage & Recovery for water supply.
8	8.	Flowway feature to divert excess treated water south through the J. W. Corbett Wildlife Management Area to the proposed Everglades Construction Project Divide Structure S-316 that is intended to divert flow to Water Conservation Area-1. The J. W. Corbett Wildlife Management Area must not be adversely effected by the backpumped water, necessitating a treatment facility to improve water quality before backpumping. Flowway will reduce quantity and quality impacts to the St. Lucie Estuary and Indian River Lagoon while providing an additional source of water for Everglades restoration.

III. CALOOSAHATCHEE

Issues/Problems

- Excess local and Lake Okeechobee discharges to estuary.
- Water quality of fresh water discharges to estuary.
- Maximum and minimum flow needed to maintain healthy estuary.
- Limited agricultural water supply sources.
- Reduction of spatial extent of agricultural land due to urban development pressures or planned project modifications.

<u>Concept</u>		Components
1, 7, 11	1.	Storage reservoirs to capture basin runoff and releases from Lake Okeechobee. These reservoirs will be designed for flood attenuation, water supply benefits, and water quality benefits to reduce nutrient impacts of runoff that is allowed to backflow to Lake Okeechobee or to the estuary.
1,7, 11	2.	On-site detention facility to attenuate basin runoff to C-43 and provide water supply. Facilities will also reduce water quality impacts to the St. Lucie Estuary, Indian River Lagoon, and Lake Okeechobee through backpumping.
7	3.	Water quality treatment of existing flows from C-43 to Lake Okeechobee. A portion of the stormwater runoff that is presently discharged to C-43 from basins adjacent to the canal will be backpumped through a stormwater treatment facility and then backpumped to Lake Okeechobee.
2	4.	Backpumping and water quality treatment of additional flows from C-43 to Lake Okeechobee. This component is intended to capture local drainage within the C-43 Basin and

backpump through a stormwater treatment facility to Lake Okeechobee.

6,10	5.	Regional Aquifer Storage & Recovery for water supply.
8	6.	Lake Hicpochee restoration as an environmental feature and potential attenuation of local runoff for water supply. The reservoir will provide water quality improvements through detention that will reduce nutrient impacts of runoff that is allowed to backflow to Lake Okeechobee or to the estuary.
1, 7, 11	7.	Additional storage in C-43 adjacent to Moore Haven. Will provide water supply and water quality benefits.
5, 11	8.	Restore natural flows under San Carlos Bay/Sanibel Island causeway. (Raise roadway, add culverts, etc.)

IV. LAKE OKEECHOBEE

Issues/Problems

- Prolonged high water levels impact littoral zone.
- Low lake levels for extended periods impact littoral zone.
- Quality of water flowing into Lake Okeechobee.
- High water supply demands on Lake Okeechobee.
- Unnaturally large fluctuations in lake stages.
- Navigation and public water supply intake problems with lower lake levels.
- Sedimentation of Lake Okeechobee and release waters.

Concept		Components
2	1.	New operating criteria for Lake Okeechobee that includes flood control, water supply and Everglades demand driven releases to the Water Conservation Areas to meet estimated natural system needs. This new criteria would need to be derived from an optimization based on rainfall and antecedent conditions. The regulation schedule would include:

- Additional storage capacity that would not result in long term impacts to the littoral zone (i.e. temporary higher stages that serves to avoid continuous periods of marsh inundation greater than two to three years).
- Operation for lake habitat and water quality improvement (lower stages during certain times of the year) and provide more natural fluctuations for the existing littoral zone.
- Maintain a minimum water level in the Lake for ecosystem health.
- Aquifer Storage & Recovery zone in schedule for withdrawal

of lake water for injection into Aquifer Storage & Recovery facilities.

- Regulatory (flood) discharges would be prioritized as follows;

Priority 1: Sends regulatory discharges to downstream storage facilities if capacity is available (Everglades Agricultural Area & Caloosahatchee storage, Water Preserve Areas, etc.)

Priority 2: Releases to Water Conservation Areas up to estimated natural system limits

Priority 3: Pulse releases to Caloosahatchee and St. Lucie Estuaries

Priority 4: Major releases to Caloosahatchee and St. Lucie Estuaries.

2,6,10 2. Lake Okeechobee regional Aquifer Storage & Recovery to reduce peak water stages for flood protection and water supply.

8 3. Restoration of Kreamer, Torry and Ritta Islands dependent on new operating criteria for Lake Okeechobee.

V. EVERGLADES AGRICULTURAL AREA

Issues/Problems

- Water quality of runoff degrading downstream ecosystem.
- High water demands and limited agricultural water supply sources.
- Limitations on conveyance through the basin.
- Continuing subsidence of organic soils.
- Reduction of spatial extent of agricultural land due to urban development pressures or planned project modifications.

<u>Concept</u> Components

3 1. Storage areas (reservoirs) to reduce flood releases to the Water Conservation Areas, to improve timing of environmental deliveries to the Water Conservation Areas and to meet agricultural water supply demands and flood protection within the Everglades Agricultural Area.

- Capture local runoff and Lake Okeechobee regulatory (flood) releases.
- Canal conveyance improvements as required to convey flood waters to storage and treatment areas.
- Modifications to Stormwater Treatment Areas as necessary for Everglades water deliveries to meet the appropriate water quality.

3,6,10 2. Regional Aquifer Storage & Recovery for storage of local stormwater and Lake Okeechobee water for water supply.

7 3. Water quality treatment facility (Stormwater Treatment

Area) within the northern reaches of the Everglades Agricultural Area to capture and treat water that is presently backpumped to Lake Okeechobee.

2, 3, 7 4. Backpumping additional water from the Everglades Agricultural Area to Lake Okeechobee with a water quality feature. The quality of water and the stages of Lake Okeechobee must not be adversely effected by this backpumping.

LOWER EAST COAST URBAN

VI. North Palm Beach County

Issues/Problems

- Limited surficial aquifer capacity for growing public water supply demand.
- Improved quantity and timing of fresh water flows to the Loxahatchee River and Slough, and West Palm Beach's Water Catchment Area.
- Improved continuity of natural areas needed including areas of Pal Mar, Corbett, West Palm Beach's Water Catchment Area, and Loxahatchee River and Slough.
- Urban flood protection needed in Indian Trail Water Control District, South Indian River Water Control District, and the C-18 Basin.
- Reduction of spatial extent of agricultural land due to urban development pressures or planned project modifications.
- Salt water intrusion.
- Lowering of groundwater table.

Concept		Components
4,6,8	1.	Southern L-8 Project, which will take local basin runoff, and if needed provide additional water quality treatment and store flood waters (reservoirs, e.g. western C-18 reservoir) for flood protection and for enhancing water supply to Loxahatchee River and Slough along with enhanced urban water supply for the City of West Palm Beach via the Water Catchment Area, and improved recharge to the Seacoast and Jupiter wellfields.
6	2.	Further expansion and utilization of reuse of reclaimed water and water conservation.
6	3.	Further expansion and utilization of the Floridan Aquifer as a water source.
6, 10	4.	Further expansion and utilization of utility Aquifer Storage & Recovery.

6,10	5.	Regional Aquifer Storage & Recovery for water supply.
4	6.	Link Lake Okeechobee with Water Preserve Areas and reservoirs by improving Lake Okeechobee outlet at the L-8 with enlarged canal to marshes and storage areas. L-10 / L-12 / L-8 / S-5A(E) conveyance improvement for improved water supply deliveries to the C-51 Basin (Lake Worth Drainage District) from Lake Okeechobee.
8	7.	Protect and enhance existing wetland systems including Pal Mar, Corbett, and Loxahatchee Sloughs by restoring hydropatterns. Some flood attenuation benefits may be achieved.
6	8.	Improved operation of secondary and primary canal systems in 298 Districts to enhance stormwater diversion while increasing ground water recharge.

VII. Palm Beach County

Issues/Problems

- Growing public water supply demand increasing potential for saltwater intrusion and demand on regional system.
- Drainage of area causing large flood discharges and water quality degradation in Lake Worth Lagoon.
- Wetlands east of Water Conservation Area-1 require hydropattern restoration.
- Quality of stormwater runoff.
- Limited availability of land with sufficient size to serve as water storage areas.
- Potential decrease in water supply available due to minimum flows and levels.

Concept		Components
6	1.	Further expansion and utilization of reuse of reclaimed water and water conservation.
6	2.	Further expansion and utilization of the Floridan Aquifer as a water source.
6, 10	3.	Further expansion and utilization of utility Aquifer Storage & Recovery.
6	4.	Further expansion and relocation of existing wellfields.
6, 10	5.	Regional ground water Aquifer Storage & Recovery adjacent to primary canal system.

VIII. Broward County

Issues/Problems

- Growing public water supply demand increasing potential for

saltwater intrusion and demand on regional system.
- Drainage of area causes large flood discharges to Intracoastal Waterway which previously flowed west to the Everglades.
- Limited spatial area for project features to control and manage the significant amount of seepage from the Everglades to the developed areas.

Concept		Components
6	1.	Further expansion and utilization of reuse of reclaimed water and water conservation.
6	2.	Further expansion and utilization of the Floridan Aquifer as a water source.
6, 10	3.	Further expansion and utilization of utility Aquifer Storage & Recovery.
6	4.	Further expansion and relocation of existing wellfields.
6,10	5.	Regional ground water Aquifer Storage & Recovery adjacent to primary canal system.
6	6.	Improved operation of secondary and primary canal systems in 298 Districts to enhance stormwater diversion while increasing ground water recharge and maximizing system storage.

IX. Miami-Dade County

Issues/Problems
- Growing public water supply demand increasing potential for saltwater intrusion and demand on regional system.
- Drainage of area causing large flood discharges to intracoastal waterway.
- Significant amount of seepage from the Everglades to the developed areas.
- Base flows needed for Biscayne Bay.
- Conversion or degradation of remaining natural areas.
- Excess discharge to Biscayne Bay

Concept		Components
6	1.	Further expansion and utilization of reuse of reclaimed water and water conservation.
6	2.	Further expansion and utilization of the Floridan Aquifer as a water source.
6, 10	3.	Further expansion and utilization of utility Aquifer Storage & Recovery.
6	4.	Further expansion and relocation of existing wellfields.
6,10	5.	Regional ground water Aquifer Storage & Recovery adjacent to primary canal system.

X. South Miami-Dade County and Biscayne Bay

Issues/Problems

- Significant amount of seepage from the Everglades to the developed areas.
- Altered hydropatterns causing negative impacts on Model Lands and East Everglades.
- Conversion or degradation of remaining natural areas.
- Water quality issue with south Miami-Dade County agriculture and in eastern portions (L-31E, Military Canal, etc.).
- Reduction of spatial extent of agricultural land due to urban development pressures or planned project modifications.

Concept		Components
11	1.	Environmental deliveries to Biscayne Bay.
4, 8,11	2.	Create additional water preserve areas in south Miami-Dade County by the addition of eastern Model Lands and Biscayne Bay Coastal wetlands. Preservation and/or restoration will increase the spatial extent of wetlands in southern Miami-Dade County.
6	3.	Create additional water preserve areas for urban/agricultural water supply storage. Water Preserve Areas can be used to capture wet season runoff for use in early dry season.
7	4.	Water quality treatment facilities.
5	5.	Backfill C-111 to increase hydropattern restoration and produce sheetflow across the Southern Glades; used in conjunction with other measures to provide flood control.

XI. HOLEY LAND WILDLIFE MANAGEMENT AREA

Issues/Problems

- Altered hydropatterns causing negative impacts to the ecosystem.
- Quality of water entering the area causing changes to the ecosystem.
- Nutrients in sediment may cause cattail proliferation even if water entering the area is clean.

		Components
5	1.	Rainfall driven schedule consistent with Florida Game and Fresh Water Fish Commission's management schedule recommendations.

8 2. Once the water entering the area is clean and the sediment is stabilized, structurally reconnect the area with the Water Conservation Areas to provide for more natural water flow.

XII. ROTENBERGER WILDLIFE MANAGEMENT AREA

Issues/Problems

- Altered hydropatterns causing negative impacts to the ecosystem.
- Quality of water entering the area causing negative impacts to the ecosystem.
- Water supply to the tribal lands.
- Antecedent soil conditions and topography.

Components

5 1. Rainfall driven schedule consistent with Florida Game and Fresh Water Fish Commission's Everglades Construction Project recommendations.

8 2. Once the water entering the area is clean and the sediment is stabilized, structurally reconnect the area with the Water Conservation Areas to provide for more natural water flow.

XIII. WATER CONSERVATION AREAS

Issues/Problems

- Altered hydropatterns causing negative impacts to the ecosystem.
- Quality of water entering the Water Conservation Areas causing negative impacts to the ecosystem.
- Water quality regulation of urban runoff.
- Large amounts of seepage from Water Conservation Areas to eastern developed areas.
- Must consider water supply impacts if seepage is reduced.
- Invasive plant and animal species causing negative impacts to the ecosystem.
- Reduced spatial extent and habitat loss.
- Antecedent soil conditions and topography.
- Connectivity between Water Conservation Areas.
- High water levels causing impacts to tree islands.

Concept Component

5 1. Rainfall driven schedule with NSM levels triggering deliveries with consideration to tree island impacts and minimum floor levels consistent with SFWMD's proposed minimum levels criteria. This type of operation would be contingent upon improved seepage management adjacent to developed areas, and may require a step down levee system consistent with Water Preserve Area components or seepage barriers. This schedule would be multi-objective and attempt to balance environmental, water supply, flood control, and water quality objectives. Coordinate rainfall-driven schedules between all the Water Conservation Areas.

6 2. Cross-Water Conservation Area aqueduct(s) that would convey water across the Water Conservation Areas (Everglades Agricultural Area to Lower East Coast and Lower East Coast to Everglades Agricultural Area) depending on locations of supplies and demands. The aqueduct would be designed to minimize impacts on the ability to restore desired overland flow and hydroperiods within the water conservation areas.

5 3. Decompartmentalization of natural areas through the removal of levees, in a phased approach, within and between all Water Conservation Areas.

5 4. Berms or low levees within the Water Conservation Areas to slow water flow and redirect it toward overland flow. These levees should be adjustable and removable and the process of constructing them should not cause major impacts. This should be viewed as an experimental project and should employ adaptive management strategies.

XIII(1). LOXAHATCHEE NWR (Water Conservation Area 1-Service Area 1)

5 1. Rainfall driven schedule with NSM levels triggering deliveries with consideration to tree island impacts and minimum floor levels consistent with SFWMD's proposed minimum levels criteria. This type of operation would be contingent upon improved seepage management adjacent to developed areas, and may require a step down levee system consistent with Water Preserve Area components or seepage barriers. This schedule would be multi-objective and attempt to balance environmental, water supply, flood control, and water quality objectives. Coordinate rainfall-driven schedules between all the Water Conservation Areas.

4, 8 2. Creation of Water Preserve Areas for wetland restoration and/or preservation. These areas would be outside the Refuge and would increase the spatial extent of wetlands in Palm Beach County.

6 3. Creation of Water Preserve Areas for water supply storage for urban, agricultural and environmental uses. Wet season runoff from western C-15 and C-16, eastern C-51 and Hillsboro Basins will be diverted to storage to serve as water supplies during the early dry season.

7 4. Creation of Water Preserve Areas for use as water quality treatment facilities. Wet season runoff from western C-15 and C-16, eastern C-51, and Hillsboro Basins will be treated and released to Water Conservation Area-1, Water Conservation Area-2, or adjacent wetlands for use in hydropattern restoration.

4 5. A seepage barrier or impervious underground barrier will be constructed along the eastern edge of the Refuge to prevent losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

6 6. A seepage collection system will be constructed along the eastern edge of the Refuge to recover losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

XIII(2A/2B). WATER CONSERVATION AREA 2A/2B (Service Area 2)

5 1. Rainfall driven schedule with NSM levels triggering deliveries with consideration to tree island impacts and minimum floor levels consistent with SFWMD's proposed minimum levels criteria. This type of operation would be contingent upon improved seepage management adjacent to developed areas, and may require a step down levee system consistent with Water Preserve Area components or seepage barriers. This schedule would be multi-objective and attempt to balance environmental, water supply, flood control, and water quality objectives. Coordinate rainfall-driven schedules between all the Water Conservation Areas.

5 2. New schedule for flood attenuation into 3A.

4 3. A seepage barrier or impervious underground barrier will be constructed along the eastern edge of the Water Conservation Area to prevent losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

6 4. A seepage collection system will be constructed along the eastern edge of the Water Conservation Area to recover losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

4 5. A step down levee system inside Water Conservation Area-2B to reduce seepage flows. Water reserved in the regional system will be used to achieve hydropattern restoration and regional water supply deliveries to the Lower East Coast.

XIII(3A/3B). WATER CONSERVATION AREA 3A/3B (Service Area 2)

5 1. Rainfall driven schedule with NSM levels triggering deliveries with consideration to tree island impacts and minimum floor levels consistent with SFWMD's proposed minimum levels criteria. This type of operation would be contingent upon improved seepage management adjacent to developed areas, and may require a step down levee system consistent with WPA components or seepage barriers. This schedule would be multi-objective and attempt to balance environmental, water supply, flood control, and water quality objectives. Coordinate rainfall-driven schedules between all the Water Conservation Areas.

4, 8 2. Sheetflow distribution system for flows into Water Conservation Area-3A.

4, 8 3. Creation of Water Preserve Areas for wetland restoration and/or preservation. These areas would be outside the Water Conservation Area and would increase the spatial extent of wetlands in Broward County.

6 4. Creation of Water Preserve Areas for water supply storage for urban, agricultural and environmental uses. Wet season runoff from western North New River and C-11 Basins will be diverted to storage to serve as water supplies during the early dry season.

7 5. Creation of Water Preserve Areas for use as water quality treatment facilities. Wet season runoff from western North New River and C-11 Basins will be treated and released to Water Conservation Areas-3A/3B or adjacent wetlands for use in hydropattern restoration.

4 6. A seepage barrier or impervious underground barrier will be constructed along the eastern edge of the Water Conservation Area to prevent losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

6 7. A seepage collection system will be constructed along the eastern edge of the Water Conservation Area to recover losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

XIII(3B). WATER CONSERVATION AREA 3B (Service Area 3 – Lake Belt Area)

4, 8 1. Creation of Water Preserve Areas for wetland restoration and/or preservation. These areas would be outside the Water Conservation Area and would increase the spatial extent of wetlands in Northwest Dade County.

6 2. Creation of Water Preserve Areas for water supply storage for urban, agricultural and environmental uses. Wet season runoff from western Miami Canal, C-4, C-9, and L-31N Basins will be diverted to storage to serve as water supplies during the early dry season.

7 3. Creation of Water Preserve Areas for use as water quality treatment facilities. Wet season runoff from western Miami Canal, C-4, C-9, and L-31N Basins will be treated and released to Water Conservation Area-3B or adjacent wetlands for use in hydropattern restoration.

4 4. A seepage barrier or impervious underground barrier will be constructed along the eastern edge of the Pennsuco Wetlands to prevent losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

6 5. A seepage collection system will be constructed along the eastern edge of the Pennsuco Wetlands to recover losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

4, 6 6. Creation of Water Preserve Areas or bathtub reservoirs in part of the excavated Lake Belt.

4, 8 7. Additional structures in western C-4 and C-6 Canals.

XIV. BIG CYPRESS NATIONAL PRESERVE

Issues/Problems

- Altered hydropatterns may cause negative impacts to the ecosystem over the long term.
- Hydrologic and physical barriers from roads/airport/levees/canals.
- Agricultural development north of the Preserve and potential effects from the loss of headwaters on the Mullet Slough watershed.
- Impacts from all terrain vehicles.

Concept		Components
5	1.	Rainfall driven deliveries triggered by gages with environmental deliveries consistent with NSM.
5	2.	Gap southern levee of L-28 interceptor to restore sheet flow within the Preserve in conjunction with a water quality feature north of tribal lands.
5	3.	Enhance sheetflow within Preserve (Loop Road and Tamiami Trail modifications).
1	4.	Reservoir off the Caloosahatchee to supply headwater to Mullet Slough.
8	5.	Restoration of Golden Gate Estates.
8	6.	Restoration of Belle Meade and Fakahatchee Strand

XV. TRIBAL LANDS

Issues/Problems

- Quality of water entering the area causing negative impacts to the ecosystem.
- High water levels inhibiting tribal land development.

Concept		Components
6	1.	Flood control improvements adjacent to I-75 between L-28 and L-28 interceptor.
7	2.	Water quality feature north of tribal lands (Feeder Canal).
6,7	3.	Seminole Water Conservation Project which will improve water quality of runoff into the Everglades and detain flows during high water events.

XVI. EVERGLADES NATIONAL PARK

Issues/Problems

- Altered hydropatterns causing negative impacts to the ecosystem.
- Large amounts of seepage from Everglades National Park to eastern developed areas.
- Unnatural distribution of flows entering the park.
- Physical and hydrologic barriers within Everglades National Park (roadways).
- Efforts must be linked to the 8.5 Square Mile Area and Southern Everglades Restoration Alliance (SERA).

Concept		Components
5	1.	Rainfall-driven deliveries with NSM levels triggering environmental deliveries.

5 2. Enhance distribution (east-west) of flows into the Park by operating 3B as a flow-through system; would favor Northeast Shark River Slough. Modified / additional structures in L-67 levees to "control" releases into Water Conservation Area-3B dependent on real-time ability to mitigate seepage losses and meeting water quality concerns.

5 3. Improve flow into and through the Park by elevating low sections Tamiami Trail (below 3B) and Flamingo Road with bridges.

5 4. Gap or remove L-67 extension (remove the function).

8 5. Creation of Water Preserve Areas for wetland preservation and/or restoration. Will increase spatial extent of wetlands in Miami-Dade County.

6 6. Storage reservoirs or water conveyance improvements to provide water supply capacity for use in hydropattern restoration within Everglades National Park and to augment urban/agricultural supplies. Excess water from northern Water Preserve Area facilities could be diverted south as an additional water supply source for the Everglades or to manage seepage losses from Everglades National Park. Wet season runoff from L-31N and C-11 Basins will be diverted to storage to augment urban and agricultural supplies during early dry season.

7 7. Water quality treatment facilities and water conveyance improvements to provide wet season water supply capacity for use in hydropattern restoration within Everglades National Park. Surplus wet season runoff from L-31N and C-11 Basins will be treated through water quality treatment facilities and released through a dedicated conveyance system to either the Park, Model Lands, or Biscayne Bay or adjacent wetlands for use in hydropattern restoration of the remnant Everglades to augment urban/agricultural supplies.

4 8. Divert Everglades National Park seepage losses at 8.5 Square Mile Area into Northeast Shark River Slough through development of an isolated seepage recovery plan, separate from the residential runoff treatment scheme.(see South Dade).

4 9. A seepage barrier or impervious underground barrier will be constructed along the eastern edge of the Park to prevent losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

6 10. A seepage collection system will be constructed along the eastern edge of Everglades National Park to recover losses due to seepage to the east coast. Additional water retained in the regional system will be used to restore hydropatterns and for water supply to the Lower East Coast.

XVII. FLORIDA BAY and FLORIDA KEYS

Issues/Problems

- Altered timing and distributions of flows to the bay may be negatively impacting the ecosystem.
- Reduced conveyance through the Keys (U.S. 1 and railroad).
- Persistent water quality contaminant problems.

Concept		Components
5,11	1.	Restoration of more natural flows to Taylor and Shark River Sloughs is expected to have beneficial affect on flows to Florida Bay. Further study of the Buttonwood embankment is needed.
5,7,11	2.	Restore sheet flow in Taylor Slough (C-111) and Northeast Shark River Slough by removal of causeways.
5, 11	3.	Restore natural flow into Florida Bay by removal of causeway at Adams Waterway, mile marker 103, Florida Keys.

A1.7 SCREENING

The purpose of the screening analysis is to create a range of components to be used by the Restudy Team in developing alternative comprehensive plans. The Restudy defines components as conceptual project features (or options) intended to achieve a particular planning objective or set of planning objectives. During the next phase of the Restudy, the team will develop alternative comprehensive plans, each consisting of different combinations of these components.

Presently, the Restudy Team is considering more than 100 components. Different alternative restoration plans could be developed by making different combinations of these components. To put this into perspective, if the team were to evaluate all the possible combinations of these components, the number of possible comprehensive plans would be approximately $6.72x10^{30}$. Therefore, the Restudy Team needs a process to allow the Team to select a smaller number of plans for the evaluation phase. Because screening is limited and the nature of assumptions made during the screening process are generalized, components are not being eliminated from further consideration at this point. Rather, the screening process organizes and prioritizes the components for consideration in alternative plans. Clearly, more detailed evaluations are necessary before the Restudy can recommend any particular component be included in, or excluded from, the Comprehensive Plan.

This screening process involves: (1) optimizing component design (such as size and configuration) based on hydrologic criteria, (2) comparing similar components in terms of costs and magnitude of output, and (3) applying best professional judgment to reduce the inordinate number of plans.

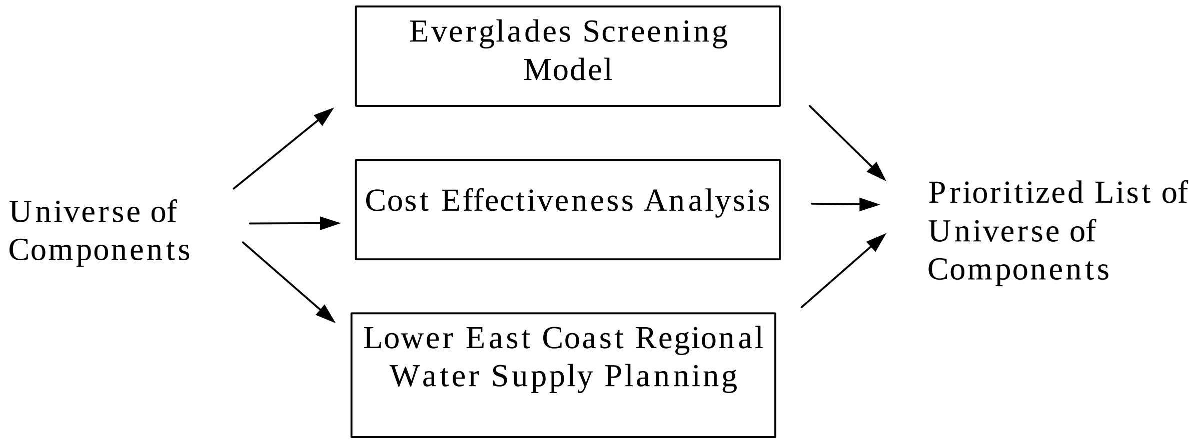
A1.7.1 COMPONENT SCREENING

Screening is a process for comparing alternative components or plan features against certain criteria. The screening process at this stage of the study provides a basis for identifying relative differences between components. The information gathered during the screening process will be used to combine components into alternative comprehensive plans. The alternatives will then undergo a more rigorous evaluation utilizing a system-wide hydrologic model and a suite of ecologic and water quality models.

The screening process involves three sets of screening criteria, including: hydrologic modeling using the Everglades Screening Model, a cost effectiveness analysis, and findings from the South Florida Water Management District's Lower East Coast Regional Water Supply Planning process, which utilized the South Florida Water Management Model for system-wide evaluations. Best professional judgment and findings from other studies such as the L-28 Feasibility Study and the Water Preserve Area Land Suitability Analysis also provide a basis from which screening conclusions can be drawn.

The component screening involves comparing the components against the three sets of screening criteria, not to eliminate components, but rather to identify which ones appear to be better than others in terms of their performance and financial investment.

Figure 1
Screening Criteria



A1.7.2 EVERGLADES SCREENING MODEL (ESM)

The Everglades Screening Model allows the Restudy Team an opportunity to evaluate and optimize particular hydrologic components at a broad level of detail relatively quickly. This hydrologic model is similar to the model used during the Reconnaissance Study to evaluate alternative plans. The model can be easily modified to compare system responses to changes in infrastructure or operations, such as adding a reservoir or comparing different sized reservoirs. This hydrologic model lets the Restudy Team look at a number of different component configurations in a short period of time.

As part of the screening phase, a number of components were investigated using this tool, including: storage reservoirs in the Everglades Agricultural Area, the Kissimmee River Basin, the Caloosahatchee Basin, and the St. Lucie Basin; Lake Okeechobee operation schedules; Lake Okeechobee aquifer storage and recovery systems; Water Preserve Area reservoirs and wetlands; seepage barriers; and seepage recycling.

The Everglades Screening Model helped identify optimal component designs based on hydrologic criteria such as evaporation-transpiration, seepage, and water demand. Findings from the Everglades Screening Model will guide the design of components that will be modeled and evaluated during the next phase of plan evaluation.

A1.7.3 COST EFFECTIVENESS ANALYSIS (CEA)

Cost effectiveness analysis is an evaluation tool that can be used to facilitate informed decision making. Cost effectiveness analysis is typically done near the end of a study to compare complete alternative plans. However, the analysis can also be used earlier to compare similar components to assist in the formulation of cost effective alternative plans. For screening, the cost effectiveness analysis was used to identify the least-cost component at each level of output, as well as to examine how cost varies as output levels increase. To do this, the components were first arranged into "functions." These functions are displayed in ***Table 4***.

Of the 112 components being considered by the Restudy, 47 of them had sufficient known detail to be grouped in the above categories and analyzed using the cost effectiveness analysis. In this way, only components with similar output were compared to identify cost effective features. The other 65 components were screened using findings from the Lower East Coast Regional Water Supply Plan, other studies, or best professional judgment.

The cost effectiveness analysis is conducted by first designing each of the components. The general nature of the description of each of the Restudy components provided the Restudy Team an opportunity to look at different designs for each component, resulting in nearly 175 designs which are referred to as *management measures*. For example, a component such as a storage reservoir could have a near infinite number of designs to achieve its desired effect. Based on previous system knowledge, a limited range of designs for this component was developed. In the case of Kissimmee River Storage Reservoirs, nine designs were developed ranging from 10,000 to 30,000 acres at 4, 8 and 12 foot depths.

For each management measure, cost estimates were developed for construction, real estate, and operation and maintenance. Outputs were also estimated for each design. The outputs were derived from a number of sources. Outputs for components designed to improve the quality of Lake Okeechobee inflows were obtained by applying the same design equations used for the Stormwater Treatment Areas for the Everglades Construction Project. The output for components designed to manage Lake Okeechobee water levels and provide additional water supply capability within Lake Okeechobee were calculated from the South Florida Water Management Model. The Everglades Screening Model was used to calculate outputs for the components designed to: (1) provide additional regional water sources within the Lower East Coast; (2) manage Everglades Protection Area inflows from the Everglades Agricultural Area; and (3) retain additional water in the regional system. Finally, spatial extent was measured by estimating the acreage of wetlands to be restored.

Table 4
Output Measurement Units

Function	Desired Effect (unit of measure)
Improve quality of Lake Okeechobee inflows	Reduction in Phosphorus load to Lake Okeechobee (tons)
Improve management of Lake Okeechobee water levels	Reduction in regulatory releases (acre-feet)
Additional Lake Okeechobee water supply capability (water otherwise lost to tide)	Increase in net inflows to Lake Okeechobee (acre-feet)
Additional regional water source (Lower East Coast)	Reduction in demand on existing regional system (acre-feet)
Increase spatial extent of wetlands	Restored or Preserved Wetlands (acres)
Improved management of Everglades Protection Area inflows from Everglades Agricultural Area	Increase in storage capacity within the Everglades Agricultural Area (acre-feet)
Additional water retained in the regional system	Increase in water retained in the Everglades Protection Area (acre-feet)

The cost effectiveness analysis provides the Restudy Team organized information about different levels of output and their associated cost which is useful both for making selections as to project scale and in describing the rationale for that selection.

A1.7.4 LOWER EAST COAST REGIONAL WATER SUPPLY PLAN

The South Florida Water Management District's Lower East Coast Regional Water Supply planning process modeled and evaluated five alternative plans. The South Florida Water Management Model (SFWMM) was used to help identify water supply problems in the Lower East Coast Region and to assist staff in the evaluation of the five plans.

The SFWMM is an integrated surface water – ground water model that simulated the hydrology and the existing and proposed water supply conditions in the region based on 26 years of historical climatic data (1965-1990) (Note: The model has now been updated to include a 31-year period of record from 1965 to 1995). The model encompasses: Lake Okeechobee, the Everglades Agricultural Area, the Water Conservation Areas, Everglades National Park, the Lower East Coast urban areas and parts of the Big Cypress National Preserve. The model also includes flows from the Kissimmee River, and Lake Okeechobee outflows to the Caloosahatchee and St. Lucie Estuaries. The model simulates the major components of the hydrologic cycle, which includes surface water flow, ground water flow, rainfall, and evaporation. The model also simulates the operation of the regional water management system, including pump stations, water control structures and canals.

A wide range of options (components) were modeled and evaluated in the five alternatives. These options can be divided into nine general categories:

- Facilities or operating procedures to modify storage in Lake Okeechobee
- Facilities to capture and use runoff from the Caloosahatchee Basin
- Facilities to capture and use runoff from the Everglades Agricultural Area
- Facilities and operational procedures to improve the timing and distribution of water released into the Everglades and move between locations in the Everglades
- Facilities to manage losses of water from the Everglades
- Facilities to protect and make better use of water resources in the coastal basins
- Facilities to capture and use excess water in the coastal basins
- Facilities and procedures to create and restore wetlands outside the Everglades
- Operational procedures to improve the timing and location of releases to tide

A number of options, which were considered in the first four alternatives, were found to be quite effective in meeting the planning objectives. However, it became apparent that the plans were not implementable within the year 2010 planning horizon and should be deferred to the Restudy for further evaluation.

Because of the use of the SFWMM and options considered in each alternative, important insight can be gained regarding the system-wide affects and interactions of a variety of water management options and strategies.

A1.7.5 SCREENING CONCLUSIONS

Screening conclusions for each component can be drawn from the Everglades Screening Model, cost effectiveness analysis, and/or the Lower East Coast Regional Water Supply Planning process. For the components that were analyzed with the Everglades Screening Model, the model provided an optimum component design based on hydrologic criteria. This optimum level, when applied to the cost effectiveness analysis, was used to determine if a cost effective component could achieve the same level of output as determined by Everglades Screening Model screening or if other or additional components should be considered.

The cost effectiveness analysis, when used by itself, provides a range of cost effective components with varying output levels. Without a target or optimal design from the Everglades Screening Model, the screening conclusion is limited to identification of the most cost-efficient component. That is, the component with the lowest cost per unit of output desired. If an output target is available, and the most cost-efficient component fails to meet its target, the analysis can be used to identify the next most cost-efficient component or group of components. This will give the Restudy Team a hierarchy for selecting components during the development of alternative comprehensive plans.

Finally, the Lower East Coast Regional Water Supply planning process provides a system-wide perspective on outputs that is lacking from the other analyses. The screening conclusions for each of the components is displayed in the attached matrix. The matrix displays each of the 112 components, the screening evaluation tool applied, and a brief summary of the findings. A summary of the major conclusions from screening is shown in ***Table 5***.

A1.7.6 APPLICATION OF FINDINGS

The screening analysis gives the Restudy team information to guide the order in which components are added together. The findings from the screening analysis allow the Restudy team to categorize the components based on hydrologic output and cost effectiveness. These findings are listed in ***Table 6***. The conclusions from screening will be used to create the first alternative comprehensive plan; but the power of this information extends well beyond the first alternative.

Consider this analogy: through screening, the components have been stocked and organized in a warehouse based on hydrologic output and cost effectiveness. Through the screening process, the components have, in a sense, gone through a “quality control” check. These components are available to the Restudy team to meet targets set forth during the next phase of plan evaluation. In developing alternatives, the team will be able to “order” an appropriate component from the warehouse with some certainty as to the effectiveness and efficiency of the component.

Each time the team must select a new component to achieve a desired effect, they will have the data from the screening analysis to help them choose from the warehouse. For instance, if a least cost alternative plan results in too many regulatory releases to the estuaries, then the team will have a basis to select (request from the warehouse) a component that may not be the least cost feature but is more effective (has greater output) at managing Lake Okeechobee water levels without impacting the estuaries.

Table 5

Restudy Components Screening Conclusions

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
I	KISSIMMEE RIVER AREA				
1	Storage Reservoirs	10,000 - 20,000 acre reservoir @ 10' optimum	20,000 acre reservoir @ 12' is cost effective Lake Okeechobee operation criteria more cost effective		
2	Wetland Detention Areas		Taylor Creek/Nubbin Slough most cost effective water quality treatment		
3	Additional Storage in the Kissimmee River Chain of Lakes				No conclusive findings - extensive lake-side development may preclude rise in Lake levels
4	Pool A Restoration		Not as cost effective as Paradise Run – would consider as next increment (quality not evaluated)		
5	Pool E Restoration		Not as cost effective as Pool A Restoration (quality not evaluated)		
6	Paradise Run		Most cost effective measure in sub-region to increase spatial extent (quality not evaluated)		
7	Taylor Creek/Nubin Slough		Most cost effective measure to reduce Phosphorus loading to Lake Okeechobee		
II	UPPER EAST COAST/ST. LUCIE AND MARTIN COUNTIES				
1	Storage Reservoirs (C-44)	10,000 acre reservoir @ 4' optimum	2,500 or 5,000 acre reservoir @ 8' (however, Backpumping C-44 to Lake (6) more cost effective)		
2	On-site Detention Facility (C-44)		Not cost effective compared to other components		

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
3	Wetland Restoration in western portion of counties		10,000 acres are most cost effective for sub-region (quality not evaluated)		Numerous opportunities to increase spatial extent in this sub-region
4	Backpump C-23, 24, 25 to Lake Okeechobee		C-44 Backpump (6) is more cost effective (Potential impact to littoral zone and estuaries)		
5	Water quality Treatment of existing flows from C-44 to Lake Okeechobee		Kissimmee water treatment options are more cost effective		
6	Backpump C-44 to Lake Okeechobee (additional flows)		Most cost effective in increasing water in Lake Okeechobee (Potential impact to littoral zone and estuaries not evaluated)		
7	Regional ASR		8 wells with 2,500 acre reservoir most cost effective storage option for this region		
8	Corbett WMA Flowway from C-44 to L-8				Impact to high quality wetlands - results in further fragmentation
III.	CALOOSAHATCHEE				
1	Storage Reservoirs	20,000 acres @ 8' optimum	Lake Hicpochee reservoir most cost effective – additional storage site needed to achieve target	20,000 acres provides water supply to meet a portion of demands in that basin	
2	On-site Detention		Not cost effective - may require site specific analysis		
3	Water quality treatment of existing flows from C-43 to Lake Okeechobee		Kissimmee water treatment options are more cost effective		
4	Backpump C-43 to Lake Okeechobee (additional flow)		Most Cost effective in increasing water to Lake Okeechobee (Potential impact to littoral zone and estuaries not evaluated)		

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
5	Regional ASR		Not as cost effective as storage or backpumping but should consider as the next increment		
6	Lake Hicpochee Reservoir	See Storage Reservoirs (1)	Most cost effective reservoir option for this sub-region - see Storage Reservoir (1)	See Storage Reservoirs (1)	
7	Additional Storage in C-43 adjacent to Moore Haven		Not cost effective		
8	Restore natural flows under San Carlos Bay/Sanibel Island causeway. (Raise roadway, add culverts, etc.)				No Conclusive findings - Bay circulation model needed to access impacts
IV	LAKE OKEECHOBEE				
1	New operating criteria	Limited opportunities for additional storage	Increasing Lake levels is most cost effective storage option (Potential impact to littoral zone and estuaries not evaluated)	Limited opportunities for additional storage	
2	Lake Okeechobee regional ASR	Limited benefits to Lake level management	Not cost effective compared to other Lake level management options		
3	Restoration of Kreamer, Torry and Ritta Islands		Middle of the road compared to increasing spatial extent in other sub-regions (quality not evaluated)		Possible HTRW contamination
V	EVERGLADES AGRICULTURAL AREA				
1	Storage Reservoirs	40,000 - 60,000 acres @ 6' optimum	20,000 acres @ 10 feet may give similar benefit as 40,000 @6' (However, Backpumping (4) more cost effective)	20,000 acres @ 8' modeled, storage option improves timing of flows to the Everglades and provided water supply benefits	

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
2	Regional ASR			Reservoir required to achieve benefit, technology at the scale proposed remains to be proven	
3	Water quality treatment facility to Lake Okeechobee (existing flows)		Kissimmee water treatment options more cost effective		
4	Backpump/treat additional EAA water to Lake Okeechobee		More cost effective than reservoir (Potential impact to littoral zone and estuaries not evaluated)		
VI	NORTH PALM BEACH COUNTY				
1	Southern L-8 Project			Effective in delivering water to North Palm Beach County and Loxahatchee Slough	
2	Re-use (M&I)				Should be considered with other local water utility options
3	Floridan Aquifer Blending (M&I)				Should be considered with other local water utility options
4	Utility ASR (M&I)			Maybe effective in meeting local needs but did not appear to have significant regional impact	
5	Regional ASR			Very effective in Palm Beach County on C-51 and Hillsboro (not evaluated North of C-51)	
6	New Lake Okeechobee Outlet and L-8 Improvements				Benefits uncertain - requires more detailed modeling
7	Wetland Enhancement of Pal Mar and Corbett				Pal Mar and Corbett are existing high quality wetlands that contribute to spatial extent

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
8	Improved operation of secondary and primary canal systems in 298 Districts			Requires site specific design	
9	C-17 Modifications				Project not defined - should improve water quality in Lake Worth Lagoon
VII	Palm Beach County				
1	Re-use (M&I)				Should be considered with other local water utility options
2	Floridan Aquifer Blending				Should be considered with other local water utility options
3	Utility ASR			Maybe effective in meeting local needs but did not appear to have significant regional impact	Very effective in Palm Beach County on C-51 and Hillsboro (not evaluated North of C-51)
4	Wellfield Expansion and Relocation			Very effective for coastal utilities with well fields at risk from salt water intrusion	
5	Regional ASR				
VIII	Broward County				
1	Re-use (M&I)				Should be considered with other local water utility options
2	Floridan Aquifer Blending				Should be considered with other local water utility options
3	Utility ASR			Maybe effective in meeting local needs but did not appear to have significant regional impact	
4	Wellfield Expansion and Relocation			Effective for coastal utilities with well fields at risk from salt water intrusion	

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
5	Regional ASR			North New River facility captures significant volume of water however, substantially exceeded basin demand	
6	Improved operation of secondary and primary canal systems in 298 Districts			Very effective in recharging aquifer near eastern wellfields in north and central Broward	
IX	Miami-Dade County				
1	Re-use (M&I)				Should be considered with other local water utility options
2	Floridan Aquifer Blending				Should be considered with other local water utility options
3	Utility ASR			Effective with large regional wellfields	
4	Wellfield Expansion and Relocation				May be needed to meet future demand
5	Regional ASR			L-31E facility effective but limited quantities of water to capture, should consider other basins (C-6)	
X	South Miami-Dade County and Biscayne Bay				
1	Environmental Deliveries to Biscayne Bay				No conclusive findings - more detailed analysis necessary
2	WPA - Model Lands and Biscayne Bay Coastal Wetland Preservation/ Restoration		Model Lands and Biscayne Bay coastal wetlands are most cost effective at increasing spatial extent (quality not evaluated)	Some benefit to south Dade utilities and overland flow to Biscayne Bay/Barnes Sound	Portions of Area K and M have high intrinsic value
3	WPA - Water Supply Storage				Potential impact to surrounding areas - need has not been identified

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
4	WPA - Water Quality Treatment Facilities				Must consider water quality treatment if runoff is used for restoration
5	Backfill C-111				Potential urban and agricultural flood impact - being revisited by SERA
XI	HOLEY LAND WILDLIFE MANAGEMENT AREA				
1	Rainfall driven schedule				No conclusive findings - more detailed analysis necessary
2	Reconnect with the WCAs				Must be evaluated with system-wide modeling
XI	ROTENBERGER WILDLIFE MANAGEMENT AREA				
1	Rainfall Driven Schedule				No conclusive findings - more detailed analysis necessary
2	Reconnect with the WCAs				Future "Without" project condition - Everglades Construction Project
XIII	WATER CONSERVATION AREA (General)				
1	Rainfall Driven Schedule			Very effective method to restoring more natural hydroperiod	
2	Cross-WCA aqueduct(s) (EAA to LEC and LEC to EAA)				No conclusive findings
3	Removal of Levees between WCAs				Must be evaluated with more detailed modeling
4	Overland Flow Berms (adjustable/ removable) within the WCAs				Must be evaluated with more detailed modeling
XIII(1)	LOXAHATCHEE NWR (Water Conservation Area 1 - Service Area 1)				
1	Rainfall Driven Schedule			Very effective method to restoring more natural hydroperiod	

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
2	WPA - Wetland Preservation/ Restoration	Retains water by reducing seepage from WCA	Not cost effective for spatial extent as compared to wetlands in other regions (quality not evaluated)		Area B has high intrinsic value, cypress dome (NAS)
3	WPA - Water Supply Storage	1639 acres @ 6' in Hillsboro Basin very effective – consider additional 900 acres in C-18 Basin (ASR could reduce acreage)	Area E most cost effective for sub-region – Area E and C may be needed to reach target	Significant amount of water could be captured and backpumped to Site 1 Reservoir	
4	WPA - Water Quality Treatment Facilities				Must consider water quality treatment if backpumping to WCAs or adjacent wetlands
5	Seepage Barrier	Effective at retaining water in WCA – potential impact to coastal wellfields & estuaries not evaluated	Not cost effective compared to seepage collection		
6	Seepage Collection		Cost effective at retaining water in regional system		
XIII (2A/2B)	WATER CONSERVATION AREA 2A/2B (Service Area 2)				
1	Rainfall Driven Schedule			Very effective method to restoring more natural hydroperiod	
2	New schedule for flood attenuation into 3A.				Unacceptable environmental impact - should be considered as a last increment
3	Seepage Barrier	Effective at retaining water in WCA – potential impact to coastal wellfields & estuaries not evaluated	Not cost effective compared to seepage collection		
4	Seepage Collection		Cost effective at retaining water in regional system		
5	Step-down levee system inside WCA 2B		Not as cost effective as seepage collection		

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
XIII (3A/3B)	WATER CONSERVATION AREA 3A/3B (Service Area 2)				
1	Rainfall Driven Schedule			Very effective method to restoring more natural hydroperiod	
2	Sheet Flow Distribution System for flows into WCA-3A			ECP addressing flows from EAA - flows from 2A require more detailed modeling	
3	WPA - Wetland Preservation/ Restoration	Retains water by reducing seepage from WCA	Area A most cost effective in sub-region – however, other spatial extent options are more cost effective (quality not evaluated)	Sites retain water by reducing seepage from WCA	Portions of A, B, C, H have high intrinsic value
4	WPA - Water Supply Storage	2,900 acres @ 4' in C-11 Basin effective	Area A most cost effective in sub-region – impact to high quality wetlands - Area D, H, I the next potential storage sites that would avoid impact		
5	WPA - Water Quality Treatment Facilities				Water quality treatment must be addressed in this sub-region - S-9 Critical Project under study
6	Seepage Barrier	Effective at retaining water in WCA – potential impact to coastal wellfields & estuaries not evaluated	Not cost effective compared to seepage collection	Effective at retaining water in WCA - impact to coastal wellfields & estuaries	
7	Seepage Collection	Effective at retaining water in WCA	Cost effective at retaining water in regional system		
XIII(3B)	WATER CONSERVATION AREA 3B (Service Area 3 - Lake Belt Area)				
1	WPA - Wetland Preservation/ Restoration		Area B (Pennsuco) most cost effective for sub-region – also cost effective compared to other regions (quality not evaluated)	Increasing hydroperiods in Pennsuco retains waters in WCA 3B	Portions of A, B and C have high intrinsic value

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
2	WPA - Water Supply Storage	2,900 acres @4' in C-6/C-4 Basin effective	Area B most cost effective (however, impact to wetlands) - A portion of Area A would be next most cost effective	Bath-tub concept in Lake Belt effective storage mechanism	
3	WPA - Water Quality Treatment Facilities				Must consider water quality treatment if backpumping to WCAs or adjacent wetlands
4	Seepage Barrier	Effective at retaining water in WCA – potential impact to coastal wellfields & estuaries not evaluated	Not cost effective	Effective at retaining water in WCA - impact to coastal wellfields & estuaries	
5	Seepage Collection	Effective at retaining water in WCA	Cost effective at retaining water in regional system		
6	WPA - Bathtub reservoirs in part of excavated Lake Belt.				May be only means of achieving storage in this sub-region
7	Additional structures in western C-4 and C-6 canals			Should be first increment to reduce seepage from Pennsuco and improving flows to ENP	
XIV	BIG CYPRESS				
1	Rainfall driven deliveries			Very effective method to restoring more natural hydroperiod	
2	Gap southern levee of L-28 interceptor				Water quality concerns - treatment needed for this drainage basin (see Tribal Lands)
3	Enhance sheetflow within Preserve (Loop Road and Tamiami Trail modifications)				Presently under study
4	Reservoir off the Caloosahatchee to supply headwater to Mullet Slough				No conclusive findings - project not defined

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
5	Restoration of Southern Golden Gate Estates		Most cost effective at increasing spatial extent (quality not evaluated)		High ecological values
6	Restoration of Belle Meade and Fakahatchee Strand				No conclusive findings - project not defined
XV	TRIBAL LANDS Adjacent to WCAs				
1	Flood control improvements adjacent to I-75 between L-28 and L-28 interceptor				Adverse impact on surrounding wetlands - area could be used as an STA for L-28 interceptor water
2	Water quality feature north of tribal lands (Feeder Canal)				Project needs to address high nutrient levels entering WCA 3
3	Seminole Water Conservation Project				Conceptual project needs further study
XVI	EVERGLADES NATIONAL PARK				
1	Rainfall-driven deliveries			Very effective method to restoring more natural hydroperiod	
2	Enhance distribution (east-west) of flows into ENP			Future "Without" Project condition - Mod Water Deliveries	
3	Elevate low sections Tamiami Trail (below 3B) and Flamingo Road (bridges)				Detailed modeling required to evaluate
4	Gap or remove L-67 extension (function)			Future "Without" Project condition - Mod Water Deliveries	
5	WPA - Wetland Preservation/ Restoration		Area E (Bird Drive Basin) most cost effective for this sub-region (quality not evaluated)		Portions of Areas F and G have high intrinsic value

	Geographic Area/ Components	Everglades Screening Model	Cost Effectiveness Analysis	Lower East Coast Regional Water Supply Plan	Other Analysis or Best Professional Judgment
6	WPA - Water Supply Storage and Conveyance Improvements	Conveyance and seepage management critical	Area G and F most cost effective		
7	WPA - Water Quality Treatment Facilities				Must consider water quality treatment if backpumping to ENP
8	WPA - Isolated Seepage Recovery Plan 8.5 Square Mile Area				Detailed evaluation underway
9	Seepage Barriers		As cost effective as seepage collection	Effective at retaining water in N.E. Shark River Slough - impact to coastal wellfields & estuaries	
10	Seepage Collection	As cost effective as seepage barriers			
XVII	FLORIDA BAY and FLORIDA KEYS				
1	Buttonwood Embankment modifications				No conclusive findings - insufficient data
2	Removal of causeways between Keys				No conclusive findings - need Florida Bay circulation model

Table 6
SCREENING FINDINGS

KISSIMMEE RIVER BASIN
• Storage reservoirs effective for Lake level management
• Water quality treatment very cost effective for improving Lake Okeechobee
• Paradise Run most cost effective way to increase spatial extent of wetlands in this basin
UPPER EAST COAST
• Storage reservoirs for C-44 Basin effective to improve estuary conditions
• Increased backpumping of treated water to Lake Okeechobee cost effective; however, impacts to Lake's littoral zone were not evaluated
• Adding Aquifer Storage & Recovery to storage reservoirs should be considered
• Opportunities to increase spatial extent of wetlands in this basin
• C-23, C-24, and C-25 Basins being considered in detail as part of Indian River Lagoon Study
CALOOSAHATCHEE RIVER BASIN
• Storage reservoirs effective.
• Lake Hicpochee should be considered as first increment for storage
• Increased backpumping of treated water to Lake Okeechobee cost effective; however, impacts to Lake's littoral zone were not evaluated
• Adding Aquifer Storage & Recovery to storage reservoirs should be considered
LAKE OKEECHOBEE
• Increases to Lake levels cost effective; however, impacts to Lake's littoral zone were not evaluated
• Regional Aquifer Storage & Recovery not cost effective in this area for lake level management
EVERGLADES AGRICULTURAL AREA
• Storage reservoirs effective
• Increased backpumping of treated water to Lake Okeechobee cost effective; however, impacts to Lake's littoral zone were not evaluated
WATER CONSERVATION AREAS
• Detailed modeling required to evaluate components to reconnect habitats
• Rainfall driven delivery schedules are needed to achieve hydropattern restoration
LOWER EAST COAST
• Southern L-8 project effective in delivering water to North Palm Beach County and Loxahatchee Slough
• Urban Water Supply: (depending on location) wellfield relocation/expansion, utility Aquifer Storage & Recovery, and secondary canal operations are effective
• Regional Aquifer Storage & Recovery is very effective on C-51 and Hillsboro canals
• Opportunities to increase spatial extent of wetlands in Northern Palm Beach County, Model Lands, and Biscayne Bay coastal areas
BIG CYPRESS
• Restoration of southern Golden Gate Estates very cost effective to increase spatial extent of wetlands
WATER PRESERVE AREAS
• Storage reservoirs adjacent to Water Conservation Areas effective in a number of basins
• Aquifer Storage & Recovery should be considered to reduce size of storage reservoirs
• Seepage collection and backpumping generally most cost effective seepage management component
• Water quality treatment needed if drainage water is backpumped to natural areas
• Opportunities to increase spatial extent of wetlands

APPENDIX A2
COST EFFECTIVENESS SCREENING ANANLYSIS

A2.1 INTRODUCTION

The Restudy defines “components” as conceptual project features (or options) intended to achieve particular planning objectives. The plan formulation phase of the Restudy would look at combining these components into alternative comprehensive plans. At the Restudy’s start, the initial list of potential components numbered 112. If the Restudy were to develop every possible combination of these initial components, the number of possible alternative comprehensive plans would number approximately 5.19×10^{33}. Because it was impossible to look at that many plans, the preliminary screening phase was designed to provide information to support decisions regarding which components to include in a more discrete range of comprehensive plans.

Cost effectiveness analysis was used in the Restudy as a tool in the preliminary screening phase. In the preliminary screening phase, information gained through the cost effectiveness analysis was joined with information from hydrologic optimization modeling and information gained through previous studies to support best professional judgement in the selection of specific project components. This screening phase aimed to identify which components (from the initial list of potential project components) would be carried forward in the development of alternative comprehensive plans.

A2.2 DEVELOPMENT OF COMPONENTS AND MANAGEMENT MEASURES

The development of the initial list of components began in January 1996, when the Restudy Team met to review and discuss a broad range of ideas from the Reconnaissance Study and other related efforts such as the South Florida Water Management District’s Lower East Coast Regional Water Supply Plan. These ideas or “components” were listed, described, and linked to Restudy planning objectives. The list of potential components was then considered and refined by the Governor’s Commission for a Sustainable South Florida when they developed their Conceptual Plan for the Restudy. The Restudy Team met again in November 1996 to design a formulation and evaluation strategy for comprehensive plans. Subsequently, a draft document entitled *Restudy Plan Formulation* was produced, outlining the Restudy goals and planning objectives and listing the components to be evaluated with a brief description of each. The Restudy Plan Formulation document was reviewed by the Restudy Team and was the basis of a series of stakeholder focus group meetings. These meetings helped to ensure that most stakeholders were satisfied with the components to be considered and the strategy for formulating and evaluating the different comprehensive plans.

Of the 112 components in the initial list, 47 had sufficient known detail to compile cost and output estimates for cost effectiveness analysis. The other 65 components were screened using findings from other studies or best professional judgement. Considering different sizes and scales of the 47 components, 58 specific management measures were designed and modeled, providing the necessary data for their examination through cost effectiveness analysis.

Where the Restudy defined a "component" as a *conceptual* project feature intended to achieve a particular planning objective, a "management measure" was defined as a *specific* action, project feature or project modification intended to achieve a particular planning objective. Multiple management measures might address a single component. For example, the initial list of components included the component "Wetland Detention Areas"; specific management measures addressing this component included a "Detention Area at Yates Marsh", and a "Detention Area at Maple River Marsh". Management measures were further broken down into "scales", defined as ranges of specific designs for a management measure. For example, the management measure "Lake Okeechobee Regional ASR" included the scales "25 wells," "50 wells," "75 wells," and "100 wells." Components, management measures, and scales are summarized in ***Table 1***.

Table 1: Terminology

TERM	MEANING	EXAMPLE
Components	Conceptual Project Features	Water Storage Area
Management Measures	Specific Project Features	Storage Reservoir in the Everglades Agricultural Area
Scales	Specific Designs of Management Measure	20,000 acres at 6 and 10 feet 40,000 acres at 6 and 10 feet 60,000 acres at 6 and 10 feet

For the Cost Effectiveness Analysis, components of the Water Preserve Areas were identified by an alpha-numeric designation due to the sheer number of options and the range of possible sites. Refer to the site maps that follow on pages A2-4 through A2-7. This 5 digit designation is broken down as follows:

Example – SA1AC
The first three digits (SA1) represents a geographic region known as the Lower East Coast service areas. In this instance SA1 represents Service Area 1. The fourth digit (A) represents a specific site within the service area, as depicted on Figures 1-4. The fifth digit is the functional use of the site (A- wetland preservation/restoration, B- deep water storage, C- shallow water storage). Occasionally, partial areas were considered. These sub-areas were

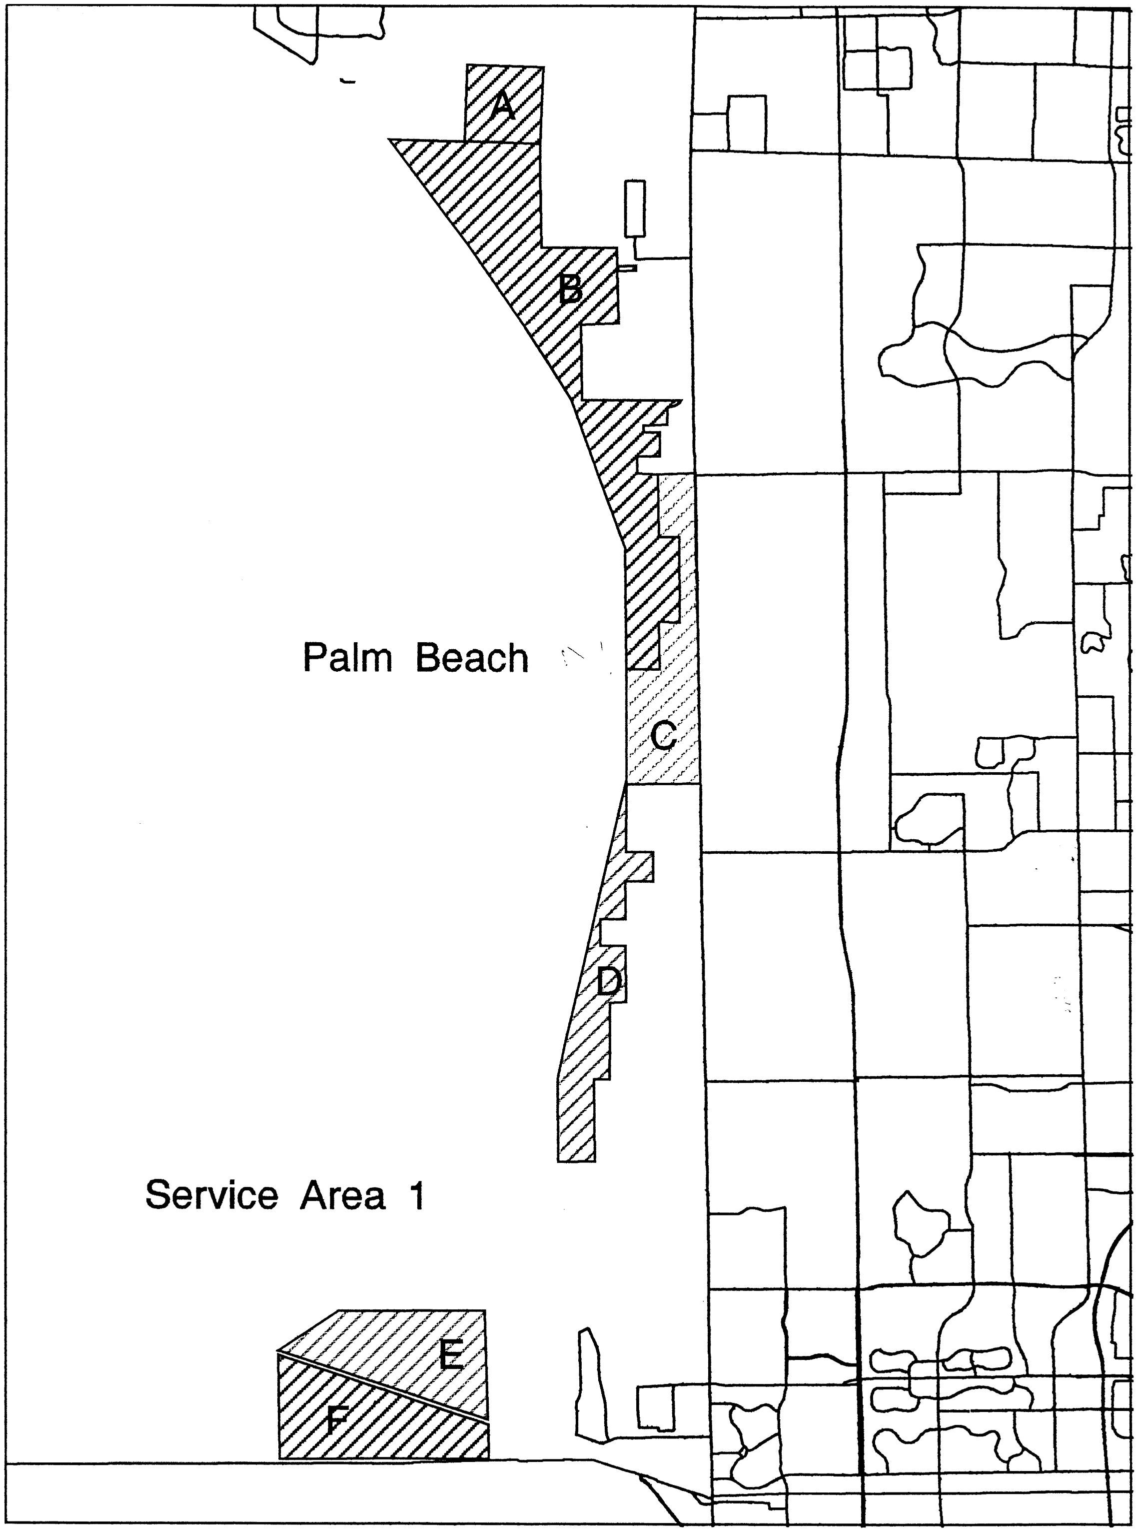
designated by an additional digit of .0 – .3; depending on the number of sub-areas considered.

Cost effectiveness analysis was chosen to compare and prioritize the management measures based upon both the cost and the output of each measure; and to look at the variations in cost and output across combinations of management measures. The Restudy examined 58 different management measures (with a total of 174 scales) through cost effectiveness analysis. All possible combinations of these measures numbered 6.2 $X10^{27}$. Because it was impossible to look at this many combinations in the screening phase, all measures were grouped into functional categories and cost effectiveness analyses were conducted for each functional category. Each functional category had a different objective or "desired effect". The seven functional categories and their respective desired effects are listed in ***Table 2.***

A2.3 INFORMATION FOR DECISION MAKING

Grouping the management measures into functional categories allowed the cost effectiveness screening to compare "apples to apples". For example, Table 1 shows that in "Function A – Improve Quality of Lake Okeechobee Inflows" the desired effect is "reduced phosphorous loading" which is measured in the unit "tons of phosphorous". By passing all measures aimed at reducing phosphorous loading into Lake Okeechobee through a common cost effectiveness analysis, information was identified to support selecting, or not selecting, particular Function A measures for inclusion in the development of comprehensive (multi-functional area) plans. The information gained through the analysis identified the relative efficiency and effectiveness of different measures (and combinations of measures) aimed at reducing phosphorus loading.

A similar analysis was applied in each remaining functional category. The results of these analyses provided information to support the selection of individual measures (and combinations of measures) for further evaluation, helping to assure the development of alternative comprehensive plans that are good financial investments.



Water Preserve Areas

Site Maps

Service Area 3 (South Miami-Dade County)

Table 2: Output Measurement Units for Each Functional Category

FUNCTIONAL CATEGORY	DESIRED EFFECT (unit of measure)
Function A – Improve Quality of Lake Okeechobee Inflows	Reduced Phosphorous Loading (tons)
Function B – Manage Lake Okeechobee Water Levels	Reduced Regulatory Releases (acre-feet)
Function C – Provide Additional Water Storage Capability within Lake Okeechobee	Increased Net Inflows to Lake (acre-feet)
Function D – Increase Regional Water Supply in Lower East Coast Area	Reduced Demand on Existing System (acre-feet)
Function E – Increase Spatial Extent Of Wetlands	Restored or Preserved Wetlands (acres)
Function F – Increase Everglades Protection Area Inflows from Everglades Agricultural Area	Increased Storage Capacity in EAA (acre-feet)
Function G – Reduce Seepage	Increased Water Retained in EPA (acre-feet)

Two different levels of cost effectiveness information were derived for each functional area. The first level of information concerned the relative production efficiency of all individual scales of measures within each functional category. The second level of information concerned the relative production efficiency across all possible combinations of management measures within each category. The two types of information supported different types of decisions.

The information related to the production efficiency of individual measures was used in the preliminary screening to identify what measures were better investments than others at producing a given type of output. This information was used to support best professional judgement regarding what measures made it into subsequent iterations of comprehensive plan formulation.

A2.4 COST EFFECTIVENESS ANALYSIS DATA REQUIREMENTS

The cost effectiveness analyses required cost and benefit (or “output”) estimates for each management measure. Monetary cost estimates were developed for construction, real estate, and operation and maintenance costs and are displayed in ***Table 3*** in average annual equivalent terms. The nonmonetary output estimates for different functional areas were derived through a variety of models (described below) and are displayed in average annual terms.

Table 3 Preliminary Cost And Output for Components

	Management Function and Measures	IWR-Plan Designation	Unit of Measure (Average Annual)	Construction Cost ($)	Real Estate Cost ($)	Total Capital Cost ($)	Annual O&M ($1,000)	Annual Cost ($1,000)
A	**Improve quality of Lake Okeechobee inflows**		**Phosphorus (tons)**					
	KISSIMMEE RIVER AREA							
	Wetland Detention Areas							
	Maple River Marsh	A1	5.7	$1,408,000	$4,900,000	$6,308,000	$2	$481

The no-action options for each measure show zero cost and zero output – this does not mean that there is no change in the future, but rather that by not implementing a measure, the future condition will not change. All cost and output estimates used in these analyses reflect the difference between the future condition with no action and the future condition with implementing the respective management measure - "with and without" analysis.

The output estimates for management measures designed to improve the quality of Lake Okeechobee inflows (*Function A*) were obtained by using the same design equations used for the Stormwater Treatment Areas for the Everglades Construction Project (Burns and McDonnell, 1994). The output estimates for measures designed to manage Lake Okeechobee water levels (*Function B*) and to provide additional water storage capability within Lake Okeechobee (*Function C*) were calculated from the South Florida Water Management Model (see Appendix B for a description of this model). The Everglades Screening Model (Appendix B) was used to estimate outputs for management measures designed to:

(1) provide additional regional water sources within the Lower East Coast (*Function D*),
(2) manage Everglades Protection Area inflows from the Everglades Agricultural Area (*Function F*), and
(3) retain additional water in the regional system (*Function G*).

Finally spatial extent of wetlands (*Function E*) was calculated by estimating the acreage of wetlands to be restored, protected, or enhanced.

A2.5 COST EFFECTIVENESS ANALYSIS APPROACH

The cost analyses were generally conducted in three stages and utilized the following tools: ECO-EASY: Cost Effectiveness and Incremental Cost Analyses Software, Beta Version 2.6; IWR-PLAN Decision Support Software, Alpha Version 1.5; and Microsoft Excel '97. Management measures for each functional category were entered into the ECO-EASY software with their cost and output estimates. ECO-EASY was used to derive all combinations and conduct the cost effectiveness and incremental cost analyses. Input data and results from each category were then imported into Microsoft Excel from the ECO-EASY output files. Excel was used to sort input data by average cost, and to format the tables and graphs included in this summary. When IWR-PLAN became available, it was used to verify the results of the analyses.

The first stage of the analyses calculated the average cost of all measures within each functional area and sorted them by increasing average cost. The result of this step was an ordered list of management measures, ordered by decreasing efficiency in producing that function's output. That is, the first measure in the list would be the most efficient, producing output at the lowest cost per unit of output, and the last measure in the list would be the least efficient, having the highest cost per unit.

The second stage of the analyses looked at all possible combinations of management measures within each functional category, comparing the different costs and output of each combination. Combinations were identified as "non-cost effective" if any other combination provided the same level of output for less cost, or if any other combination provided more output for the same or less cost. This analysis identified which combinations of measures "dominate" other combinations. The goal was not to delete non-cost effective solutions from further consideration, but rather to explicitly identify where combinations exist that appear to be better financial investments for providing output.

In the third stage of the analyses, an incremental cost analysis was performed on the cost effective set of combinations from each functional category to identify the most efficient combinations for producing output. The resultant subset of combinations, called the "best buys", comprise the most efficient production schedule for the output in each functional category based upon the management measures considered and their cost and output estimates. Just as cost-effective solutions were "better" investments than non-cost effective solutions; best buy combinations are the subset of the cost effective set that can be thought of as "superior" investments. The best buys provide the greatest increase in output for the least increase in cost – or in other words, "the biggest restoration bang for the buck".

A2.6 REPORT ORGANIZATION

The remainder of this Cost Effectiveness Screening Summary provides the results of the cost effectiveness analyses conducted for each of the functional categories. The results of each function's results include discussions of the *Cost Effectiveness Analysis Approach*, the *Management Measures and Data*, and the *Results of Analyses*.

The *Cost Effectiveness Analysis Approach* section describes the approach taken for conducting the analyses within that functional area. The *Management Measures and Data* section lists the management measures examined in each functional area with cost, output, and average cost; and describes which measures were combinable with others. The *Results of Analyses* section provides a discussion of the results of each stage of the analyses with tables showing: management measures sorted by average cost, cost effective combinations of management measures, and best buy combinations of management measures. Graphs accompany the tables for cost effective combinations of management measures, and best buy combinations of management measures. The information for decision making section describes how the results of the analyses were used in the Restudy.

A2.7 ANALYSIS RESULTS: FUNCTION A, IMPROVE QUALITY OF LAKE OKEECHOBEE INFLOWS

A2.7.1 Cost Effectiveness Analysis Approach.

For Function A, six management measures were examined through cost effectiveness and incremental cost analyses. Three of these management measures included multiple scales. The approach for Function A was to (1) calculate the average cost for each management measure and sort measures by increasing average cost, (2) formulate all possible combinations of these measures and identify the cost effective set, and (3) conduct an incremental cost analysis to identify the most efficient production schedule, or set of "best-buys".

A2.7.2 Management Measures and Data.

Function A's six management measures (with cost, output and average cost) are included in ***Table A1***. The management measures are grouped by geographic area. The entry in the "Code" column will be referenced when showing all possible combinations of Function A measures. Each measure has its own code letter. The no-action option, or "scale" for any measure gets a "0" following its code letter. Each scale of a measure has a different number following its code letter. For example, measure D has three scales: D0, D1, and D2. All Function A management measures

Table A1 – Function A Management Measures

were combinable with one another; scales of the same measure were not combinable.

A2.7.3 Results of Analyses.

The first step in the analyses was to display the management measures sorted by increasing average cost. This display is included in ***Table A2***. This table shows the relative production efficiency of the management measures being considered in Function A. The measure with the lowest average cost is the most efficient measure (from a financial investment perspective) for reducing phosphorous loading into Lake Okeechobee. Each successive measure is less efficient at reducing tons of phosphorous from the Lake.

Table A2 – Function A Management Measures Sorted by Average Cost

CODE	DESCRIPTION	COST ($1,000)	OUTPUT (tons phosphorous)	AVG. COST ($1,000/ton)
C1	TAYLOR CREEK TREATMENT CENTER	236	9.0	26.2222
A1	MAPLE RIVER WETLAND DETENTION CENTER	481	5.7	84.3860
B1	YATES MARSH WETLAND DETENTION CENTER	608	5.1	119.2157

F1	EAA TREATMENT FACILITY(50% INFLUENT)	909	1.9	478.4211
D1	C-44 BACKPUMP (50% INFLUENT)	3,961	5.9	671.3559
D2	C-44 BACKPUMP (100% INFLUENT)	8,049	11.1	725.1351
E2	BACKPUMP C-43 TO LAKE OKEECHOBEE	4,260	5.6	760.7143
E1	BACKPUMP C-43 TO LAKE OKEECHOBEE	3,739	2.8	1,335.3571

The second step of the analyses was to formulate all possible combinations of the Function A management measures and identify the cost effective set. Of the full 216 combinations of Function A management measures, 18 were cost effective. The 18 cost effective combinations can be found in ***Table A3***. The value in the "Count" column simply counts the number of cost effective plans. The entries in the "Code" columns correspond to the Codes from Tables A1 and A2 and show what measures are included in each combination. A graph of cost vs. output for cost effective combinations of Function A measures is plotted in ***Figure A3***.

Table A3 – Cost Effective Combinations of Management Measures for Function A

COUNT	CODE						COST ($1,000)	OUTPUT (tons)	AVG. COST ($1,000/ton)

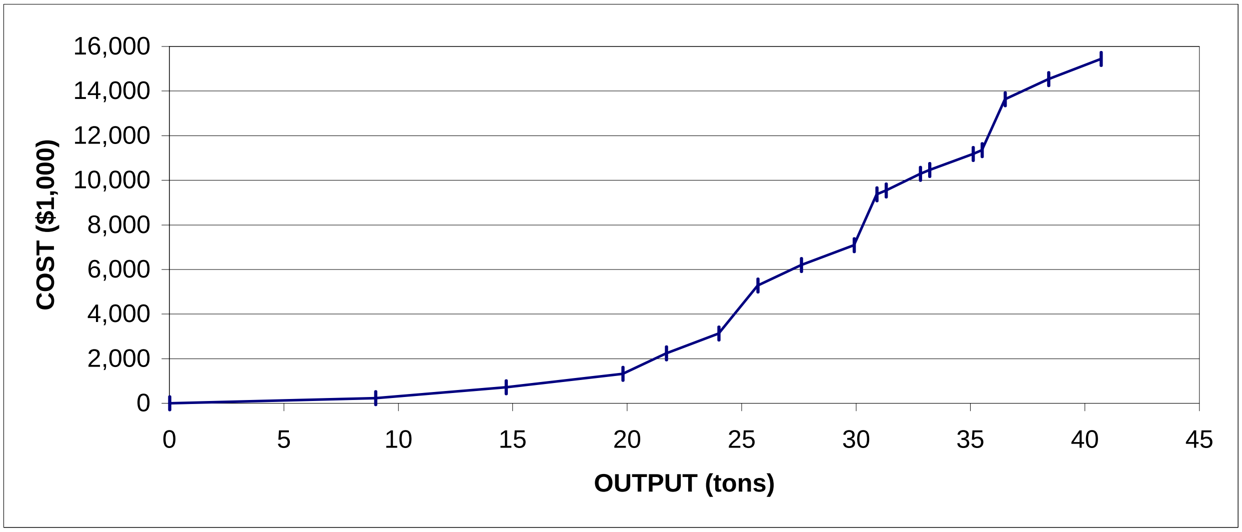
Figure A3 – Cost and Output of Cost Effective Combinations (Function A)



The third step of the cost analyses for Function A was to identify the subset of the cost-effective combinations that were most efficient at reducing phosphorous loading into Lake Okeechobee. The eight "best-buy" plans are listed in ***Table A4***.

Table A4 – Best Buy Combinations of Management Measures for Function A

COUNT	CODE						COST ($1,000)	OUTPUT (tons)	AVG. COST ($1,000/ton)	INC. COST	INC. OUTPUT	INC. COST PER UNIT ($1,00/ton)
1	A0	B0	D0	E0	F0	C0	0	0.0	not applicable	not applicable	not applicable	not applicable
2	A0	B0	D0	E0	F0	C1	236	9.0	26.2222	236.00	9.0	26.2222

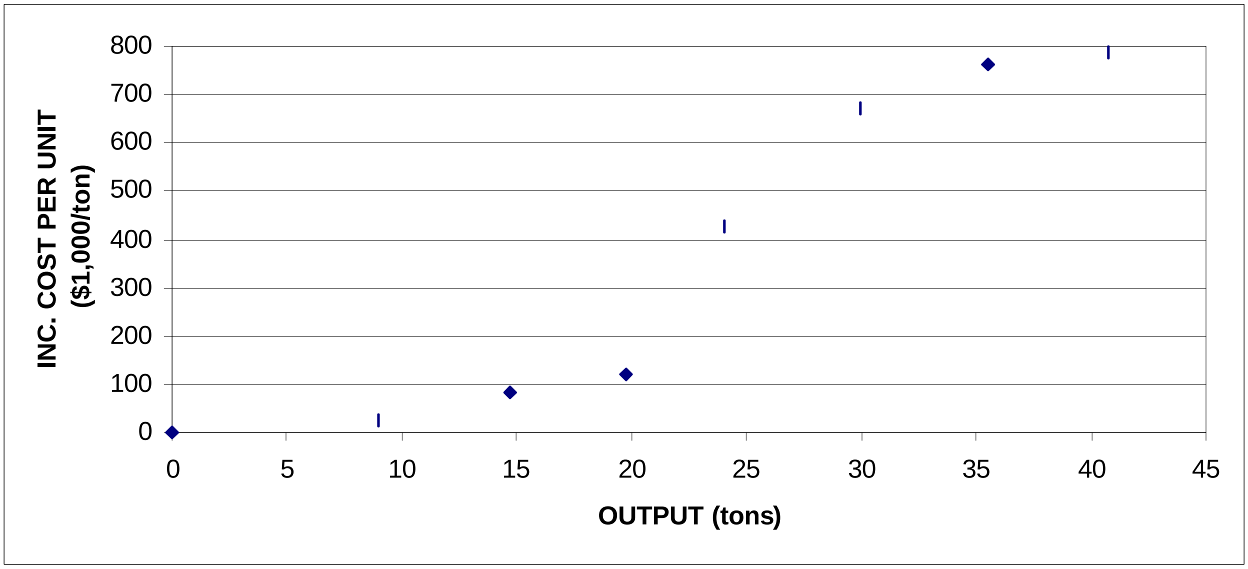
The values in the "Count" column simply count the number of best buys. The entries in the "Code" columns identify the management measures in each combination and correspond to the measure codes found in Tables A1 and A2. The values in the "Average Cost" column were calculated by dividing cost by output for each combination. The values in the "Incremental Cost" column show the change in cost from one combination to the next and were calculated by subtracting the cost of the next-smaller (in terms of output) combination from each combination. The values in the "Incremental Output" column show the change in output from one combination to the next and were calculated by subtracting the output of the next-smaller (in terms of output) combination from each combination. The last column

"Incremental Cost Per Unit" shows the cost per unit of the incremental output for each combination. A plot of output vs. incremental cost per unit for the Function A Best Buys is included in ***Figure A4***.

Figure A4 – Incremental Cost per Unit and Output of Best Buy Combinations (Function A)



A2.8 ANALYSIS RESULTS: FUNCTION B, MANAGE LAKE OKEECHOBEE WATER LEVELS

A2.8.1 Cost Effectiveness Analysis Approach.

For Function B, three management measures were examined through cost effectiveness analysis, all of which included multiple scales. The cost analysis approach for Function B was to: (1) calculate the average cost for each management measure and sort measures by increasing average cost; (2) formulate all possible combinations of these measures and identify the cost effective set; and (3) conduct an incremental cost analysis to identify the most efficient production schedule, or set of "best-buys".

A2.8.2 Management Measures and Data

Function B's three management measures (with cost, output and average cost) are included in ***Table B1***. The measures are grouped by geographic area. The entry in the "Code" column will be referenced when showing all possible combinations of Function B measures. Each measure has its own code letter. The no-action option, or "scale" for any measure gets a "0" following its code letter. Each scale of a measure has a different number following its code letter. For example, measure C has four scales: C0, C1, C2, C3, C4, and C5. In Function B, all measures were combinable with one another; scales of the same measure were not combinable.

A2.8.3 Results of Analyses.

The first step in the analyses was to display the management measures sorted by increasing average cost. This display is included in ***Table B2***. This table shows the relative production efficiency of the management measures being considered in Function B. The measure with the lowest average cost is the most efficient measure for reducing regulatory releases from Lake Okeechobee. Each successive measure is less efficient at reducing releases from the Lake.

Table B2 – Function B Management Measures Sorted by Average Cost

CODE	DESCRIPTION	COST ($1,000)	OUTPUT (acre-feet)	AVG. COST ($1,000/acre-foot)
B1	.5 FOOT RISE IN EXISTING SCHEDULE	0	35,080	0.0000

The second step of the analyses was to formulate all possible combinations of the Function B management measures and identify the cost effective set. Of the full 200 combinations of Function B management measures, 24 were cost effective. The 24 cost effective combinations can be found in ***Table B3***. The value in the "Count" column simply counts the number of cost effective plans. The entries in the "Code" columns correspond to the Codes from Tables B1 and B2 and show what measures are included in each combination. A graph of cost vs. output for the Function B cost effective plans is plotted in ***Figure B3***.

Table B3 – Cost Effective Combinations of Management Measures for Function B

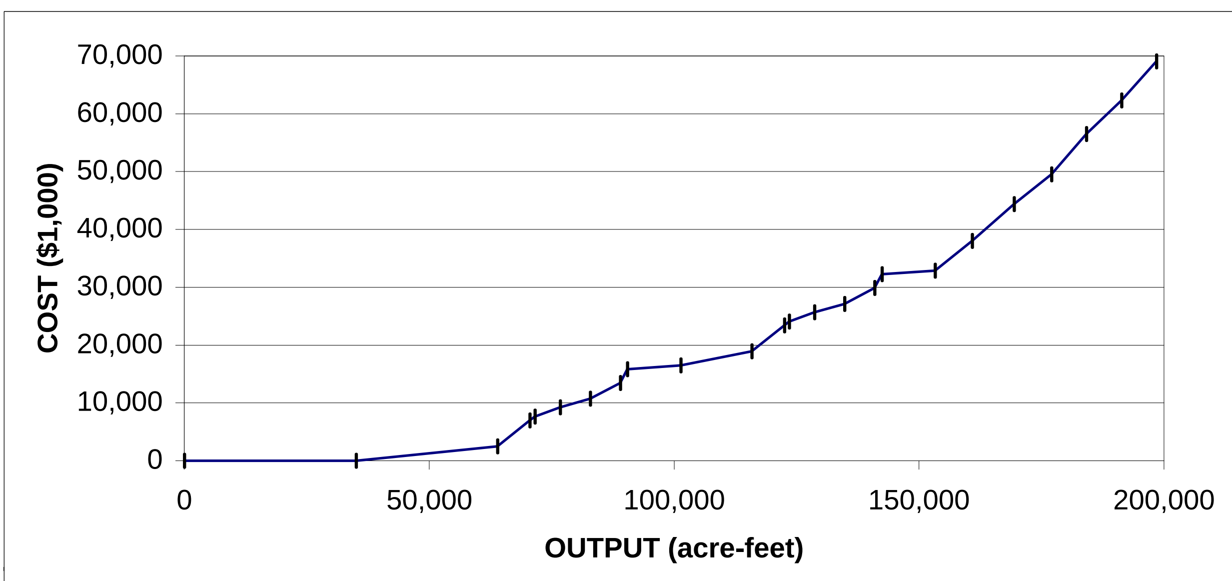
Figure B3 – Cost and Output of Cost Effective Combinations (Function B)



The third step of the cost analyses for Function B was to identify the subset of the cost-effective combinations that were most efficient at reducing regulatory releases from Lake Okeechobee. These nine "best-buy" plans are listed in ***Table B4***. The values in the "Count" column simply count the number of best buys. The entries in the "Code" columns identify the management measures in each combination and correspond to the measure codes found in Tables B1 and B2. The values in the "Average Cost" column were calculated by dividing cost by output for each combination. The values in the "Incremental Cost" column show the change in cost from one combination to the next and were calculated by subtracting the cost of the next-smaller (in terms of output) combination from each combination. The values in the "Incremental Output" column show the change in output from one combination to the next and were calculated by subtracting the output of the next-smaller (in terms of output) combination from each combination. The last column "Incremental Cost Per Unit" shows the cost per unit of the incremental output for each combination. A plot of output vs. incremental cost per unit for the Function B Best Buys is included in ***Figure B4***.

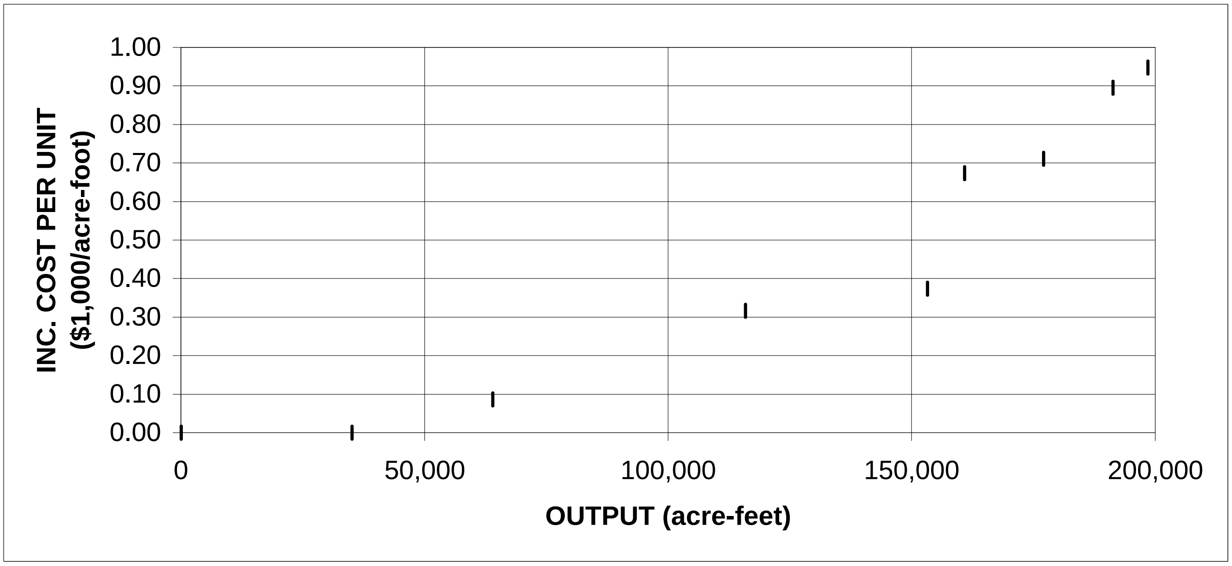
Figure B4 – Incremental Cost per Unit and Output of Best Buy Combinations Function B



A2.9 ANALYSIS RESULTS: FUNCTION C, PROVIDE ADDITIONAL LAKE OKEECHOBEE WATER SUPPLY FROM EAST AND WEST BASINS

A2.9.1 Cost Effectiveness Analysis Approach.

For Function C, six management measures were examined through cost effectiveness analysis, three of which included multiple scales. The cost analysis approach for Function C was to: (1) calculate the average cost for each management measure and sort measures by increasing average cost; (2) formulate all possible combinations of these measures and identify the cost effective set; and (3) conduct an incremental cost analysis to identify the most efficient production schedule, or set of "best-buys".

A2.9.2 Management Measures and Data.

Function C's twelve management measures (with cost, output and average cost) are included in ***Table C1***. The measures are grouped by geographic area. The entry in the "Code" column will be referenced when showing combinations of Function C measures. Each measure has its own code letter. The no-action option for any measure gets a "0" following its code letter. Each scale of a measure has a different number following its code letter. For example, measure B has two scales:

B0 and B1. In Function C, measure A was not combinable with measures E and X; measure F was not combinable with measures I or J; and measure I was not combinable with measures F or Z. In all cases, scales of the same measure were not combinable.

A2.9.3 Results of Analyses.

The first step in the analyses was to display the management measures sorted by increasing average cost. This display is included in ***Table C2***. This table shows the relative production efficiency of the management measures being considered in Function C. The measure with the lowest average cost is the most efficient measure for increasing net inflows into Lake Okeechobee. Each successive measure is less efficient at increasing net inflows.

The second step of the analyses was to formulate all possible combinations of the Function C management measures and identify the cost effective set. Of the full 698,386 combinations of Function C management measures, 294 were cost effective. The 294 cost-effective combinations can be found in ***Table C3***. The value in the "Count" column simply counts the number of cost effective plans. The entries in the "Code" columns correspond to the Codes from Tables C1 and C2 and show what measures are included in each combination. A graph of cost vs. output for Function C's cost effective combinations of management measures is plotted in Figure C3.

Table C3 – Cost Effective Combinations of Management Measures for Function C

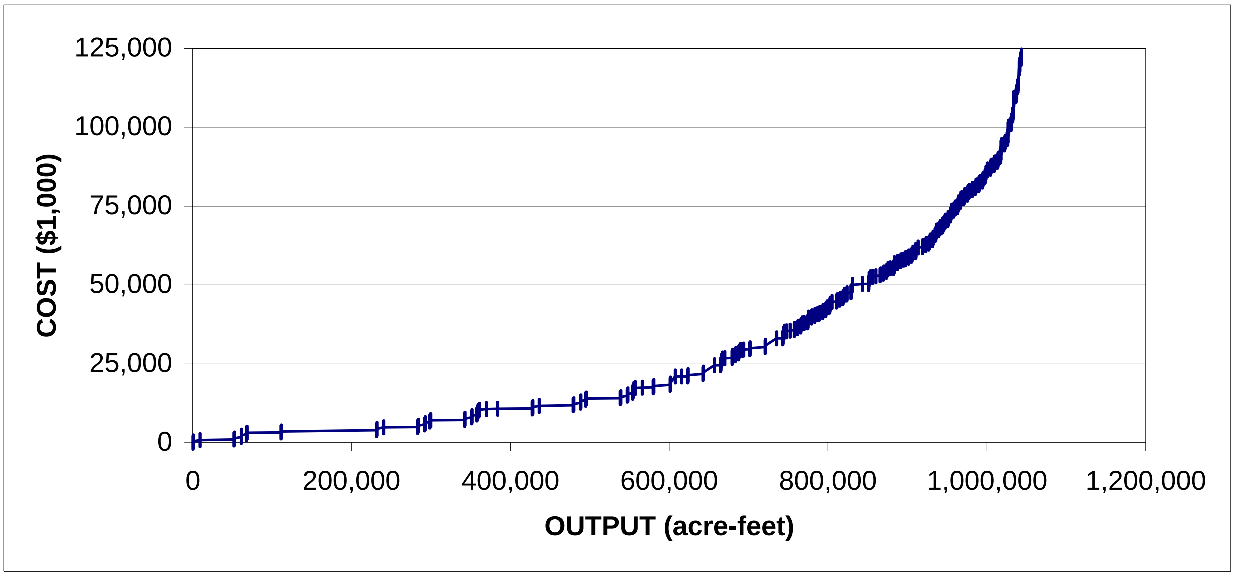
Figure C3 – Cost and Output of Cost Effective Combinations (Function C)



The third step of the cost analyses for Function C was to identify the subset of the cost effective combinations that were most efficient at providing additional water supply to Lake Okeechobee from the east and west basins. The 24 "best-buy" combinations are listed in ***Table C4***.

The values in the "Count" column simply count the number of best buys. The entries in the "Code" columns identify the management measures in each combination and correspond to the measure codes found in Tables C1 and C2. The values in the "Average Cost" column were calculated by dividing cost by output for each combination. The values in the "Incremental Cost" column show the change in cost from one combination to the next and were calculated by subtracting the cost of the next-smaller (in terms of output) combination from each combination. The values in the "Incremental Output" column show the change in output from one combination to the next and were calculated by subtracting the output of the next-smaller (in terms of output) combination from each combination. The last column "Incremental Cost Per Unit" shows the cost per unit of the incremental output for each combination. A plot of output vs. incremental cost per unit for the Function C best buys is included in ***Figure C4***.

Table A4 – Best Buy Combinations of Management Measures for Function C

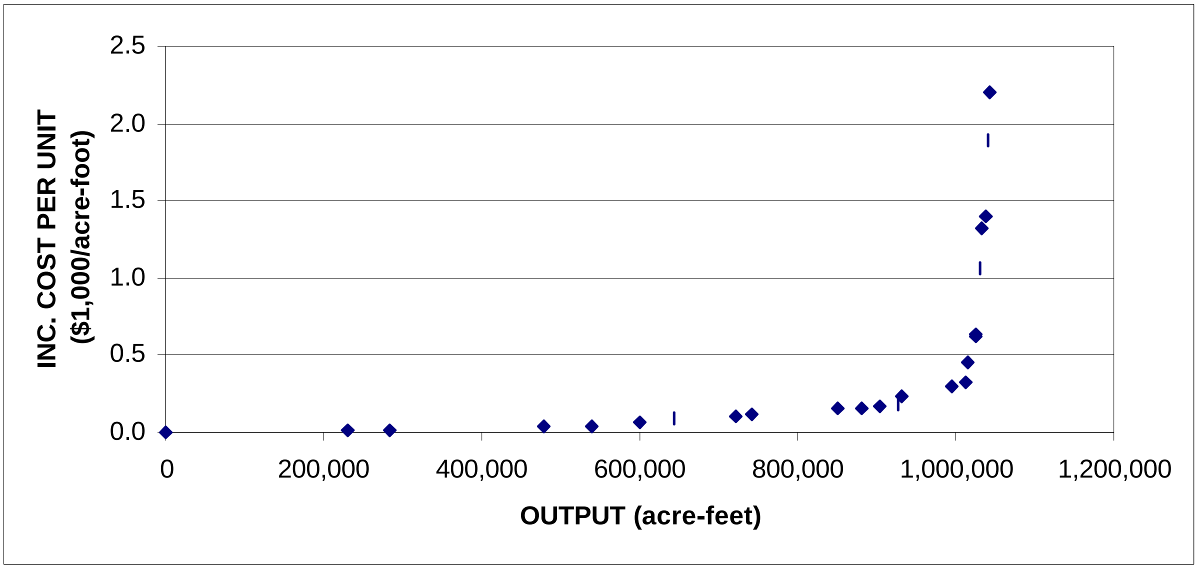
Figure C4 – Incremental Cost per Unit and Output of Best Buy Combinations (Function C)



A2.10 ANALYSIS RESULTS: FUNCTION D, INCREASE REGIONAL WATER SUPPLY IN LOWER EAST COAST AREA

A2.10.1 Cost Effectiveness Analysis Approach.

For Function D, eight management measures were examined through cost effectiveness analysis, all of which included multiple scales. The cost analysis approach for Function D was to (1) calculate the average cost for each management measure and sort measures by increasing average cost, (2) formulate all possible combinations of these measures and identify the cost effective set, and (3) conduct an incremental cost analysis to identify the most efficient production schedule, or set of "best-buys".

A2.10.2 Management Measures and Data.

Function D's eight management measures (with cost, output and average cost) are included in ***Table D1***. The measures are grouped by geographic area. The entry in the "Code" column will be referenced when showing all possible combinations of Function D measures. Each measure has its own code letter. The no-action option for any measure gets a "0" following its code letter. Each scale of a measure has a different number following its code letter. In Function D, measure C was not combinable with measure X, measure D was not combinable with measure Y, and measure E was not combinable with measure Z.

A2.10.3 Results of Analyses.

The first step in the analyses was to display the management measures sorted by increasing average cost. This display is included in ***Table D2***. This table shows the relative production efficiency of the management measures being considered in Function D. The measure with the lowest average cost is the most efficient measure for reducing demands on the existing system. Each successive measure is less efficient at reducing demands.

Table D2 – Function D Management Measures Sorted by Average Cost

The second step of the analyses was to formulate all possible combinations of the Function D management measures and identify the cost effective set. Of the full 15,915 combinations of Function D management measures, 67 were cost effective. The 67 cost effective combinations can be found in ***Table D3***. The value in the “Count” column simply counts the number of cost effective plans. The entries in the “Code” columns correspond to the Codes from Tables D1 and D2 and show what measures are included in each combination. A graph of cost vs. output for Function D’s cost effective combinations is plotted in ***Figure D3***.

Table D3 – Cost Effective Combinations of Management Measures for Function D

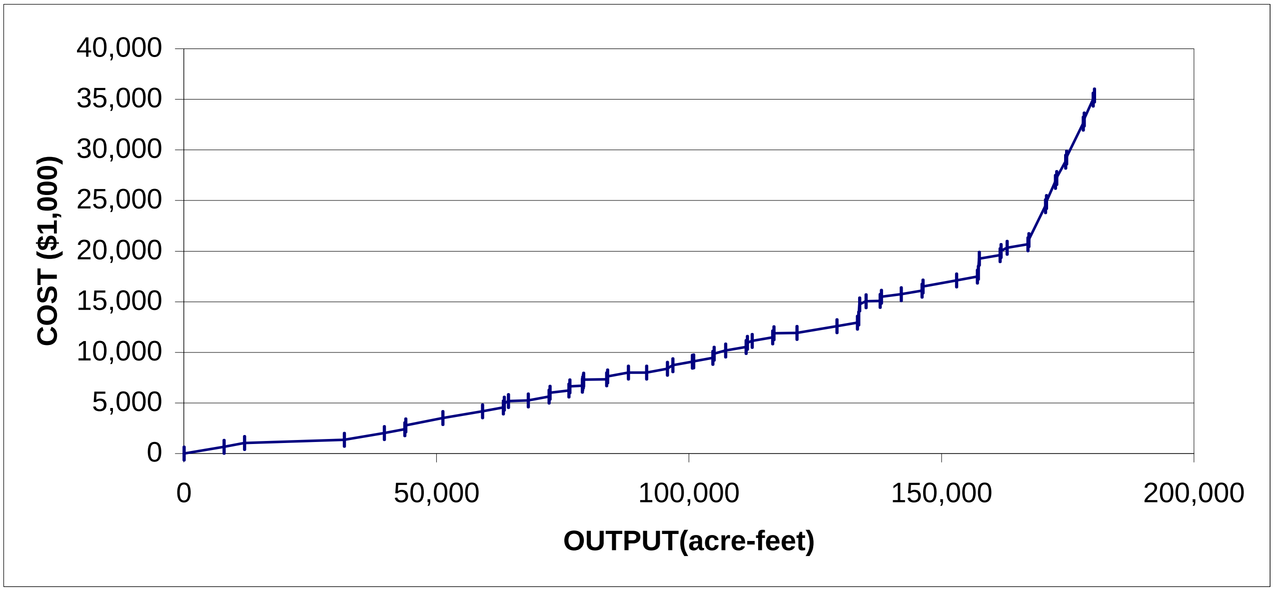
Figure D3 – Cost and Output of Cost Effective Combinations (Function D)



The third step of the cost analyses for Function D was to identify the subset of the cost-effective combinations that were most efficient at reducing demand on the existing system. These 14 "best-buy" plans are listed in ***Table D4***.

The values in the "Count" column simply count the number of best buys. The entries in the "Code" columns identify the management measures in each combination and correspond to the measure codes found in Tables D1 and D2. The values in the "Average Cost" column were calculated by dividing cost by output for each combination. The values in the "Incremental Cost" column show the change in cost from one combination to the next and were calculated by subtracting the cost of the next-smaller (in terms of output) combination from each combination. The values in the "Incremental Output" column show the change in output from one combination to the next and were calculated by subtracting the output of the next-smaller (in terms of output) combination from each combination. The last column "Incremental Cost Per Unit" shows the cost per unit of the incremental output for each combination. A plot of output vs. incremental cost per unit for the Function D best buys is included in ***Figure D4***.

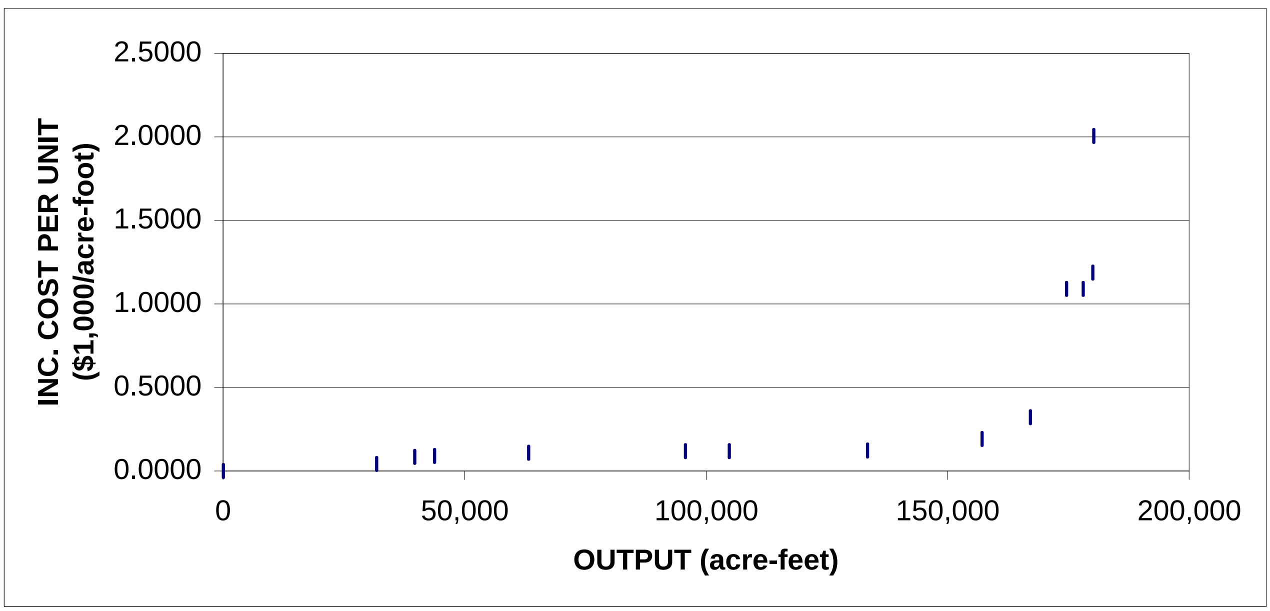
Figure D4 – Incremental Cost per Unit and Output of Best Buy Combinations (Function D)



A2.11 ANALYSIS RESULTS: FUNCTION E, INCREASE SPATIAL EXTENT OF WETLANDS

A2.11.1 Cost Effectiveness Analysis Approach.

The cost analysis for Function E involved a different approach than was carried out for other functional areas. In Function E, cost effectiveness analyses were conducted individually for each of nine geographic areas: Kissimmee River Area, Upper East Coast/ St. Lucie and Martin Counties, Lake Okeechobee, South Miami-Dade County/Biscayne Bay, Loxahatchee National Wildlife Refuge, Water Conservation Area 3A/3B (Service Area 2), Water Conservation Area 3B (Service Area 3 – Lake Belt Area), Big Cypress, and Everglades National Park.

It was chosen not to look at all combinations of Function E measures after determining that there were 1,274,019,840 possible combinations. Instead, the best-buy combinations, identified through each of the individual (geographic) cost effectiveness and incremental cost analyses runs were combined. To examine the relative cost effectiveness of all Function E management measures (across all geographic areas within Function E) measures were sorted by increasing average cost.

A2.11.2 All Function E Management Measures and Data.

Function E included 26 management measures, many of which had multiple scales. The Function E measures (with cost, output and average cost) are included in ***Table E1***. Measures are grouped by geographic area. Each measure has its own code letter. The no-action option for any measure gets a "0" following its code letter. Each scale of a measure has a different number following its code letter. For example, measure A has two scales: A0 and A1. In Function E, all measures were combinable with one another; scales of the same measure were not combinable.

A2.11.3 Results of Analyses.

The first step in the analyses was to display all the Function E management measures sorted by increasing average cost. This display is included in ***Table E2***. This table shows the relative production efficiency of the management measures being considered in Function E. The measure with the lowest average cost is the most efficient measure for increasing spatial extent of wetlands. Each successive measure is less efficient at preserving or restoring wetlands.

Table E2 – All Function E Management Measures Sorted by Average Cost

The second phase of the analyses for Function E involved conducting an individual cost effectiveness and incremental cost analysis for each geographic area within the Function E category. For each geographic area, the approach was to: (1) calculate the average cost for each management measure and sort measures by increasing average cost: (2) formulate all possible combinations of these measures and identify the cost effective set: and (3) conduct an incremental cost analysis to identify the most efficient production schedule, or set of "best-buys". The results of the analyses for each geographic area are summarized sequentially below.

A2.11.13 Combinations of Best Buys from all Geographical Areas.

After the cost effective and best buy plans were identified for each geographic area within Function E, the best buys from each were combined to identify the best set of investments looking at the entire Function E category. To enter the best buys into the cost effectiveness analysis software, a new code letter had to be assigned to each. Each geographic area was treated as a "management measure" with each best buy combination from that area treated as a "scale" of that measure. Table E3 lists these new management measure codes – and for each, the code description from the previous cost analysis run (runs E_A-E_J) and the description from Table E1 that describes what measures make up each best buy combination. ***Table E4*** lists the same measures as ***Table E3*** with cost, output, and average cost. The entries in the "New Code" column will correspond to the codes for the cost effective and best buy combinations in ***Tables E5*** and ***E6***, respectively.

Table E3 – Best Buys from Each Geographic Category with Description

NEW CODE	CODE FROM COST ANALYSIS RUNS E_A-E_J	DESCRIPTION FROM TABLE E1
Best Buys from Function E_A – Kissimmee River Area		
A0	*No Action – Function E_A*	
A1	C1	Paradise Run Restoration
A2	C1 A1	Paradise Run Restoration + Pool A Restoration
A3	C1 A1 B1	Paradise Run Restoration + Pool A Restoration + Pool E Restoration
Best Buys from Function E_B – Upper East Coast/St. Lucie and Martin Islands		
B0	*No Action – Function E_B*	
B1	D3	UEC WETLAND RESTORATION (10,000 ACRES)
B2	D4	UEC WETLAND RESTORATION (20,000 ACRES)
Best Buys from Function E_C – Lake Okeechobee		
C0	*No Action – Function E_C*	
C1	E1	RESTORE KREAMER, TORRY AND RITA ISLANDS
Best Buys from Function E_E – South Miami-Dade County and Biscayne Bay		
E0	*No Action – Function E_E*	
E1	J1	SA3MA
E2	J1I1	SA3MA + SA3LA.0

All possible combinations of Function E management measures were derived to identify the cost effective set. Of the full 115,200 possible combinations, 233 were cost effective. The 233 cost effective combinations can be found in Table E3. The value in the "Count" column simply counts the number of cost effective plans. The entries in the "Code" columns correspond to the Codes from Tables E3 and E4 and show what best buys are included in each combination. A graph of cost vs. output for Function E's cost effective combinations of best buys from each geographic area is plotted in ***Figure E5***.

Table E5 – Cost Effective Combinations of Best Buys from all Function E Geographic Categories

COUNT	CODE									COST ($1,000)	OUTPUT (acres)	AVG. COST ($1,000/acre)

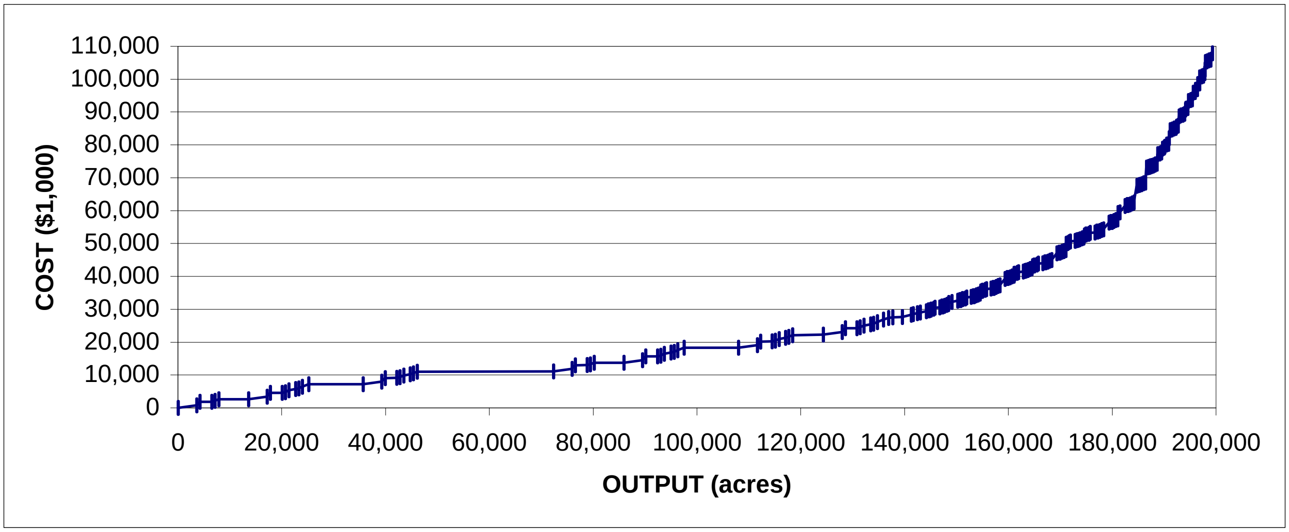
Figure E5 – Cost and Output of Cost Effective Combinations of Function E Best Buys from all Geographic Areas



The third step of the cost analyses for Function E was to identify the subset of the cost effective combinations that were most efficient at protecting or restoring wetlands. These 28 best-buy plans are listed in ***Table E6***.

The values in the "Count" column simply count the number of best buys. The entries in the "Code" columns identify the management measures in each combination and correspond to the measure codes found in Tables E3 and E4. The values in the "Average Cost" column were calculated by dividing cost by output for each combination. The values in the "Incremental Cost" column show the change in cost from one combination to the next and were calculated by subtracting the cost of the next-smaller (in terms of output) combination from each combination. The values in the "Incremental Output" column show the change in output from one combination to the next and were calculated by subtracting the output of the next-smaller (in terms of output) combination from each combination. The last column "Incremental Cost Per Unit" shows the cost per unit of the incremental output for each combination. A plot of output vs. incremental cost per unit for the Function E best buys is included in ***Figure A6***.

Table E6 – Best Buy Combinations of Best Buys from all Function E Geographic Categories

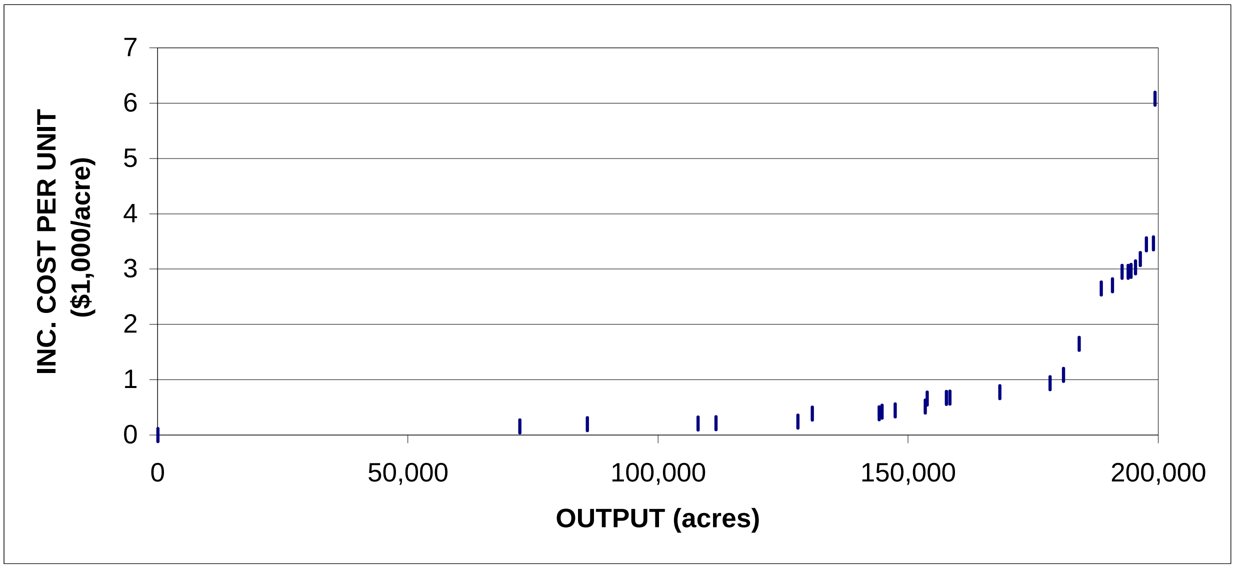
Figure E6 – Incremental Cost per Unit and Output of Best Buy Combinations of Best Buys from Each Function E Geographical Area



A2.12 ANALYSIS RESULTS: FUNCTION F, MANAGE EVERGLADES PROTECTION AREA INFLOWS

A2.12.1 Cost Effectiveness Analysis Approach.

For Function F, two management measures were examined through cost effectiveness analysis, both of which included multiple scales. The cost analysis approach for Function F was to: (1) calculate the average cost for each management measure and sort measures by increasing average cost; (2) formulate all possible combinations of these measures and identify the cost effective set; and (3) conduct an incremental cost analysis to identify the most efficient production schedule, or set of "best-buys".

A2.12.2 Management Measures and Data.

Function F's two management measures (with cost, output and average cost) are included in ***Table F1***. The measures are grouped by geographical area. The entry in the "Code" column will be referenced when showing all possible combinations of Function F measures. Each measure has its own code letter. The no-action option for any measure gets a "0" following its code letter. Each scale of a measure has a different number following its code letter. For example, measure B has three scales: B0, B1, and B2. In Function F, both measures were combinable; scales of the same measure were not combinable.

Table F1 – Function F Management Measures

CODE	DESCRIPTION	COST ($1,000)	OUTPUT (acre-feet)	AVG. COST ($1,000/acre-foot)
Everglades Agricultural Area				
A0	*No Action - EAA Storage Reservoirs*	0	0	0.0000
A1	EAA STORAGE RESEVOIRS (20,000 ACRES/6 FEET)	14,345	118,234	0.1213
A2	EAA STORAGE RESEVOIRS (20,000 ACRES/10 FEET)	16,388	178,419	0.0919
A3	EAA STORAGE RESEVOIRS (40,000 ACRES/6 FEET)	26,519	179,686	0.1476
A4	EAA STORAGE RESEVOIRS (40,000 ACRES/10 FEET)	29,745	236,652	0.1257
A5	EAA STORAGE RESEVOIRS (60,000 ACRES/6 FEET)	38,601	212,568	0.1816
A6	EAA STORAGE RESEVOIRS (60,000 ACRES/10 FEET)	43,776	265,332	0.1650
B0	*No Action - Treat/Backpump EAA Water to Lake Okeechobee*	0	0	0.0000
B1	TREAT BACKPUMP EAA WATER TO LAKE OKEECHOBEE (2,500 ACRE STATION)	4,899	167,100	0.0293
B2	TREAT BACKPUMP EAA WATER TO LAKE OKEECHOBEE (5,000 ACRE STATION)	8,636	285,000	0.0303
B3	TREAT BACKPUMP EAA WATER TO LAKE OKEECHOBEE (7,500 ACRE STATION)	17,811	441,500	0.0403

A2.12.3 Results of Analyses.

The first step in the analyses was to display the management measures sorted by increasing average cost. This display is included in ***Table F2***. This table shows the relative production efficiency of the management measures being considered in Function F. The measure with the lowest average cost is the most efficient measure for providing increased storage capacity in the Everglades Agricultural Area to manage inflows into the Everglades Protection Area. Each successive measure is less efficient at holding this water for the EPA.

Table F2 – Function A Management Measures Sorted by Average Cost

CODE	DESCRIPTION	COST ($1,000)	OUTPUT (acre-feet)	AVG. COST ($1,000/acre-foot)
B1	BACKPUMP EAA WATER TO LAKE OKEECHOBEE (2,500 ACRE STATION)	4,899	167,100	0.0293
B2	BACKPUMP EAA WATER TO LAKE OKEECHOBEE (5,000 ACRE STATION)	8,636	285,000	0.0303
B3	BACKPUMP EAA WATER TO LAKE OKEECHOBEE (7,500 ACRE STATION)	17,811	441,500	0.0403
A2	EAA STORAGE RESEVOIRS (20,000 ACRES/10 FEET)	16,388	178,419	0.0919
A1	EAA STORAGE RESEVOIRS (20,000 ACRES/6 FEET)	14,345	118,234	0.1213
A4	EAA STORAGE RESEVOIRS (40,000 ACRES/10 FEET)	29,745	236,652	0.1257

CODE	DESCRIPTION	COST ($1,000)	OUTPUT (acre-feet)	AVG. COST ($1,000/acre-foot)
A3	EAA STORAGE RESEVOIRS (40,000 ACRES/6 FEET)	26,519	179,686	0.1476
A6	EAA STORAGE RESEVOIRS (60,000 ACRES/10 FEET)	43,776	265,332	0.1650
A5	EAA STORAGE RESEVOIRS (60,000 ACRES/6 FEET)	38,601	212,568	0.1816

The second step of the analyses was to formulate all possible combinations of the Function F management measures and identify the cost effective set. Of the 28 possible combinations of Function F measures, 10 were cost effective. The cost-effective combinations can be found in ***Table F3***. The value in the "Count" column simply counts the number of cost effective plans. The entries in the "Code" columns correspond to the Codes from Tables F1 and F2 and show what measures are included in each combination. A graph of cost vs. output for cost effective combinations of Function F's management measures is plotted in Figure F3.

Table F3 – Cost Effective Combinations of Management Measures for Function F

COUNT	CODE		COST ($1,000)	OUTPUT (acre-feet)	AVG. COST ($1,000/acre-foot)
1	A0	B0	0	0	0.0000
2	A0	B1	4,899	167,100	0.0293
3	A0	B2	8,636	285,000	0.0303
4	A0	B3	17,811	441,500	0.0403
5	A2	B2	25,024	463,419	0.0540

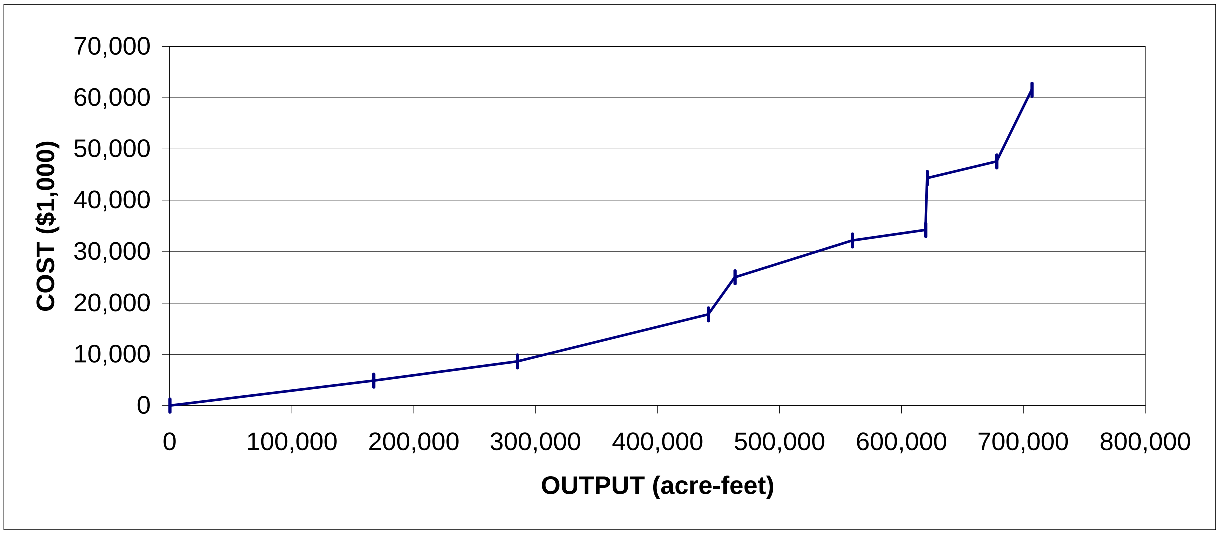
7	A2	B3	34,199	619,919	0.0552
8	A3	B3	44,330	621,186	0.0714
9	A4	B3	47,556	678,152	0.0701
10	A6	B3	61,587	706,832	0.0871

Figure F3 – Cost and Output of Cost Effective Combinations (Function F)



The third step of the cost analyses for Function F was to identify the subset of the cost-effective combinations that were most efficient at storing water for the EPA. These seven best-buy plans are listed in ***Table F4***.

The values in the "Count" column simply count the number of best buys. The entries in the "Code" columns identify the management measures in each combination and correspond to the measure codes found in Tables F1 and F2. The values in the "Average Cost" column were calculated by dividing cost by output for each combination. The values in the "Incremental Cost" column show the change in cost from one combination to the next and were calculated by subtracting the cost of the next-smaller (in terms of output) combination from each combination. The values in the "Incremental Output" column show the change in output from one combination to the next and were calculated by subtracting the output of the next-smaller (in terms of output) combination from each combination. The last column "Incremental Cost Per Unit" shows the cost per unit of the incremental output for each combination. A plot of output vs. incremental cost per unit for the Function F best buys is included in ***Figure F4***.

Table F4 – Best Buy Combinations of Management Measures for Function F

COUNT	CODE		COST ($1,000)	OUTPUT (acre-feet)	AVG. COST ($1,000/acre-foot)	INC. COST ($1,000)	INC. OUTPUT (acre-feet)	INC. COST PER UNIT ($1,000 per acre-foot)
1	A0	B0	0	0	0.0000	0	0	0.0000
2	A0	B1	4,899	167,100	0.0293	4,899	167,100	0.0293

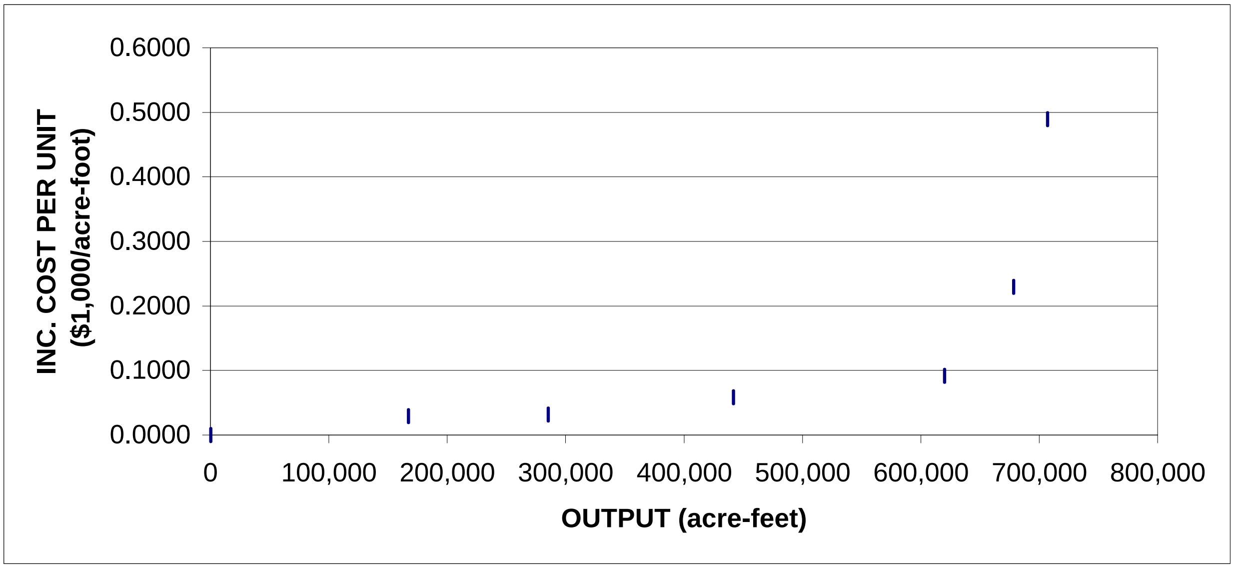
Figure F4 – Incremental Cost per Unit and Output of Best Buy Combinations (Function F)



A2.13 ANALYSIS RESULTS: FUNCTION G, REDUCE SEEPAGE FOR EVERGLADE PROTECTION AREA

A2.13.1 Cost Effectiveness Analysis Approach.

For Function G, five management measures were examined through cost effectiveness analysis, all of which included multiple scales. The cost analysis approach for Function G was to (1) calculate the average cost for each management measure and sort measures by increasing average cost, (2) formulate all possible combinations of these measures and identify the cost effective set, and (3) conduct an incremental cost analysis to identify the most efficient production schedule, or set of "best-buys".

A2.13.2 Management Measures and Data.

Function G's five management measures (with cost, output and average cost) are included in ***Table G1***. The measures are grouped by geographical area. The entry in the "Code" column will be referenced when showing all possible combinations of Function G measures. Each measure has its own code letter. The no-action option for any measure gets a "0" following its code letter. Each scale of a measure has a different number following its code letter. For example, measure A has three scales: A0, A1, and A2. In Function G, all measures were combinable with one another; scales of the same measure were not combinable.

Table G1 – Function G Management Measures

A2.13.3 Results of Analyses.

The first step in the analyses was to display the management measures sorted by increasing average cost. This display is included in ***Table G2***. This table shows the relative production efficiency of the management measures being considered in Function G. The measure with the lowest average cost is the most efficient measure for reducing seepage of water from the EPA. Each successive measure is less efficient at reducing seepage.

Table G2 – Function G Management Measures Sorted by Average Cost

CODE	DESCRIPTION	COST ($1,000)	OUTPUT (acre-feet)	AVG. COST ($1,000/acre -foot)
B2	WCA 2A/2B (SEEPAGE RECYCLE)	1,159	77,357	0.0150
A2	LNWR (SEEPAGE RECYCLE)	1,457	73,370	0.0199
C2	WCA 3A/3B (SEEPAGE RECYCLE)	956	45,144	0.0212
B3	WCA 2A/2B (SEEPAGE RECYCLE)	700	32,623	0.0215

A1	LNWR (SEEPAGE BARRIER)	70,234	73,370	0.9573

The second step of the analyses was to formulate all possible combinations of the Function G management measures and identify the cost effective set. Of the full 324 combinations of Function G management measures, 22 were cost effective. The 22 cost effective combinations can be found in ***Table G3***. The value in the "Count" column simply counts the number of cost effective plans. The entries in the "Code" columns correspond to the Codes from Tables G1 and G2 and show what measures are included in each combination. A graph of this data is plotted in ***Figure G3.***

Table G3 – Cost Effective Combinations of Management Measures for Function G

APPENDIX A3
SUMMARY DESCRIPTIONS OF ALTERNATIVES A - D

A3.1 ALTERNATIVE A

Alternative A is the first of four alternatives (Alternatives A – D) which was evaluated and compared by the Alternative Evaluation Team in the selection of the technically preferred alternative. The components contained in Alternative A were derived from components which were developed in earlier Alternatives. Some components have been modified from their original design to allow the comparison of the four alternatives on an equal basis.

A3.1.1 Summary of Alternative A by Geographic Regions

The following is a summary of the components, which have been included in Alternative A, grouped by region.

A3.1.1.3 Lake Okeechobee

- Storage reservoirs have been proposed north, east and west of the Lake to provide flood flow attenuation to the St. Lucie River and Caloosahatchee River estuaries and lands adjacent to the Lake. The storage reservoirs will also provide water supply benefits, water quality benefits and benefits to the Lake littoral zone.

- Aquifer Storage and Recovery has been proposed around the Lake and in conjunction with reservoirs to provide additional storage for use during dry times to meet regional water supply demands and enhance flood protection.

- The desired estuary target discharges at S-79 and S-80 for the Caloosahatchee (C-43) and St. Lucie (C-44) basins were revised to support the desired estuary environmental values and also to reduce the volume of discharges required from the basin storage reservoirs and Lake Okeechobee.

- Operational changes to the Lake Okeechobee regulation schedule are proposed to eliminate all but emergency discharges to the estuaries.

A3.1.1.4 Everglades Agricultural Area

- Storage reservoirs have been proposed in the Everglades Agricultural Area to provide flood flow attenuation, water supply benefits and water quality benefits to the Everglades Agricultural Area and to increase regional water resources.

- Conveyance in the Miami and North New River Canals from Lake Okeechobee and the Everglades Agricultural Area storage area was increased to convey additional Lake Okeechobee regulatory releases which would have been discharged to the estuaries.

A3.1.1.5 Water Conservation Areas And Everglades National Park

- The timing and location of water depths in the Holey Land and Rotenberger Wildlife Management Areas and Loxahatchee National Wildlife Refuge were improved.

- The timing and location of water depths in the Water Conservation Areas and Everglades National Park were improved by modifying the rain-driven operations.

- Conveyance was improved between Water Conservation Area 3B and Everglades National Park.

- Levee seepage for Water Conservation Area 2B along L-35A and a portion of L-36 was managed only during the wet season.

- Levee seepage was reduced for Water Conservation Areas 3A and 3B by allowing higher water levels and longer inundation in the marsh areas located east of the Water Conservation Areas and west of US Highway 27 while maintaining flood protection. Wet season levee seepage was further reduced by L-31N Levee improvements along Everglades National Park.

- Operational changes to the S-343 A & B Structures were proposed to reduce potential adverse impacts on the nesting season of the Cape Sable Seaside Sparrow.

- The S-345 structures, allowing flow through the L-67 Levee were relocated south to relieve high water conditions in northern Water Conservation Area 3B.

- Deliveries were improved to Northeast Shark River Slough in Everglades National Park and seepage was reduced to Lower East Coast Service Area 3.

- Hydropattern restoration and water availability was increased in northwest corner of Water Conservation Area 3A.

A3.1.1.6 Lower East Coast

- The L-8 Project was modified to capture additional excess water from the southern L-8, C-51 and C-17 basins and route this water to the West Palm

Beach water Catchment Area in order to increase regional water supplies, improve hydropatterns in the Loxahatchee Slough and increase base flows to the Northwest Fork of the Loxahatchee River.

- In the lower east coast urban areas, wellfield pumpages were shifted inland to reduce the impact of saltwater intrusion for Riviera Beach, Dania, Miramar, Broward County 3A, Lake Worth, Lantana, Manalapan, Boca Raton, Hollywood (including water supply to Broward 3B and 3C), Hallandale and Florida City.

- The Broward County Secondary Canal System was enhanced by the increase of pump capacities and construction of canal improvements and pump facilities to provide recharge to the groundwater and wellfields and stabilize the saltwater interface in southeastern and southern coastal Broward County.

- The Dade-Broward Levee was improved to reduce seepage to the east from the Pennsuco wetlands and southern Water Conservation Area 3B, enhance hydroperiods in the Pennsuco, and enhance recharge to the Miami-Dade County's NW wellfield.

- An additional control structure was added in the C-4 Canal to increase recharge to coastal wellfields and reduce demand on Lake Okeechobee and the Water Conservation Areas.

A3.1.1.7 Water Preserve Areas

- Water Preserve Area components for Site 1, C-9 and C-11 Stormwater Treatment Area/Impoundments, Central Lake Belt In-ground Storage Area and the Bird Drive Recharge Area were included to provide storage for flood flow attenuation, water quality treatment, groundwater and wellfield recharge, seepage control, dry season flows to meet environmental and urban water supply demands and to reduce the impact of saltwater intrusion.

- Regional groundwater Aquifer Storage and Recovery facilities were used to capture and store excess water which would have been lost to tide in the C-51 and Hillsboro Canal basins.

- The Water Preserve Area components for backpumping from the C-51 and C-17 Canals were modified to enhance the performance of the stormwater treatment areas.

A3.1.2 List of Components in Alternative A

The following is a list of each component included in Alternative A along with a brief summary.

Component A6. A Storage Reservoir (20,000 acres at 10 ft. maximum depth) north of Lake Okeechobee. Purpose: incorporate climate-based inflow forecasting to increase the utilization of the reservoir to provide additional flood protection, water supply and environmental enhancement. Operation revised from Alternative 5.

Component B2. A Storage Reservoir (10,000 acres at 4 ft. maximum depth) in the St. Lucie basin. Purpose: capture local runoff from C-44 for flood attenuation, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary.

Component C6. Environmental Water Supply Deliveries to the St. Lucie Estuary. Purpose: provide freshwater flow to the St. Lucie Estuary to protect and restore more natural estuarine conditions. The time series of estuary target flows was revised from Alternative 5.

Component D5. A Storage Reservoir (20,000 acres at 8 ft. maximum depth) with Aquifer Storage and Recovery (44, 5-MGD wells) in the Caloosahatchee basin. Purpose: capture basin runoff and regulatory releases from Lake Okeechobee to provide water supply benefits, some flood attenuation and environmental water supply deliveries to the Caloosahatchee estuary. Operated in conjunction with DDD5.

Component E5. Environmental Water Supply Deliveries to the Caloosahatchee Estuary (operational change only). Purpose: provide freshwater deliveries to the Caloosahatchee Estuary to establish desirable salinity at locations of key estuarine biota. Operational target flow at S-79 revised in Alternative 5.

Component F3. Current Lake Okeechobee Regulation Schedule (elimination of all except Zone A [emergency] regulatory releases to the St. Lucie and Caloosahatchee Estuaries). Purpose: implement operating criteria for Lake Okeechobee that includes flood control, water supply (including releases to the Water Conservation Areas to meet estimated natural system needs) as well as Lake littoral zone and estuary protection.

Component G3. A Storage Reservoir (one 20,000 acre compartment at 6 ft. maximum depth for supplying EAA irrigation demands and one 40,000 acre compartment at 6 ft. maximum depth for supplying environmental demands) in the Everglades Agricultural Area with increased conveyance from Lake Okeechobee to the reservoir. Purpose: improve timing of environmental deliveries to the Water Conservation Areas including reducing damaging flood releases from the EAA to the Water Conservation Areas, reduce Lake Okeechobee regulatory releases to estuaries, meet supplemental agricultural irrigation demands and increase flood protection within the Everglades Agricultural Area. Conveyance capacity of the Miami and North New River Canals between Lake Okeechobee and the Storage Reservoirs are increased to convey additional Lake Okeechobee regulatory releases that would have otherwise been discharged to the Caloosahatchee and St. Lucie Estuaries.

Component H3. Everglades Rain-Driven Operations. Purpose: improve the timing and location of water depths in the Water Conservation Areas and Everglades National Park.

Component I3. Improved Conveyance between Water Conservation Area 3B and Everglades National Park. Purpose: improve water deliveries to Everglades National Park from Water Conservation Area 3B by increasing conveyance capacity through L-29 and US Highway 41 (Tamiami Trail).

Component J. Plug L-67A borrow canal (between S-151 and Modified Water Delivery Structures S-345s). Not included in this Alternative.

Component K2. Water Preserve Areas / L-8 Project Phase II in northern Palm Beach County – modified from Alternative 1 to capture additional water and improve stages in the West Palm Beach Water Catchment Area. Purpose: reduce water supply restrictions in the Northern Palm Beach County Service Area by capturing more of the annual discharges from portions of the southern L-8, C-51 and C-17 basins and route this water to the West Palm Beach Water Catchment Area. Intent is to increase water supply availability and provide pass through flow to enhance hydroperiods in Loxahatchee Slough and increase base flows to the Northwest Fork of the Loxahatchee River.

Component L3. Change Coastal Wellfields Operations in the Lower East Coast Service Area. Purpose: shift demands from eastern wellfields inland to western facilities away from the saltwater interface to reduce impact of salt water intrusion.

Component M4. Water Preserve Areas / Site 1 Impoundment (1660 acres at 6 ft. maximum depth) with Aquifer Storage and Recovery wells increased to 15, 5-MGD wells in Palm Beach County. Purpose: increase regional water resources and supplement water deliveries to the Hillsboro Canal during the dry-season.

Component N2. Water Conservation Area 2B Levee Seepage Management in Broward County to manage only wet season seepage. Purpose: implement seasonal seepage management along the eastern edge of Water Conservation Area 2B to reduce losses due to levee seepage to the Lower East Coast.

Component O1. Water Conservation Area 3A and 3B Levee Seepage Management in Broward County. Purpose: reduce seepage from Water Conservation Areas 3A and 3B, to improve hydropatterns within the Conservation Areas by utilizing the marsh areas that are located east of the Water Conservation Areas and west of U.S. Highway 27 and to allow higher water levels and longer inundation durations within those marshes. Seepage from the marshes will be collected and returned to the Water Conservation Areas to maintain flood protection. Serves to separate Water Conservation Area 3A seepage water from urban runoff originating in the C-11 Basin.

Component P2. Water Preserve Areas / North New River Diversion Canal and Treatment Facility (1600 acres at 4 ft. maximum depth north of C-11) in Broward County with increased pump and structure capacities and seasonal S-141 operations. Purpose: capture excess North New River and Water Conservation Area 2B water, store and treat it in western C-11 and backpump it to Water Conservation Area 3A. This will (1) restore a portion of water deliveries to Water Conservation Area 3A that are eliminated by segregating the C-11 runoff from levee seepage, (2) reduce stages above NSM in Water Conservation 2B and (3) divert water through Water Conservation Area Nos. 3A and 3B to North East Shark River Slough. Untreated, western C-11 runoff that is presently backpumped through the S-9 pump station into Water Conservation Area 3A will be redirected into the new canal and diverted to the Central Lake Belt Storage Area (refer to Component Q1).

Component Q1. Water Preserve Areas / Western C-11 Diversion Canal (to Central Lake Belt Storage) in Broward County. Purpose: divert untreated runoff from western C-11 (presently discharged into Water Conservation Area 3A) and excess flows from the North New River and C-9 Canals to the Central Lake Belt Reservoir.

Component R3. Water Preserve Areas / C-9 Stormwater Treatment Area/Impoundment (2500 acres at 4 ft. maximum depth) in Broward County. Purpose: capture runoff from western C-9 basin by backpumping into the impoundment area to provide flood peak attenuation within the basin, groundwater recharge and seepage control.

Component S3. Central Lake Belt In-ground Storage Area (4000 acres) in Miami-Dade County. Purpose: capture a portion of runoff from western North New River, C-11, C-9, C-6 and C-7 basins in an in-ground reservoir which will allow storage of untreated runoff without concerns of ground water contamination. The stored water will be used to maintain stages during the dry season in the C-9, C-6, Northwest wellfield protection canal, C-4, C-2 and the South Dade Conveyance System Canals.

Component T6. C-4 Structures (2) in Miami-Dade County. Purpose: maintain higher water levels in the C-4 Canal to reduce seepage losses from the Pennsuco Wetlands and areas west of the Dade-Broward Levee and reduce deliveries from Lake Okeechobee and the Water Conservation Areas by diverting dry season stormwater flows into the C-2 Canal to increase recharge to several nearby coastal wellfields.

Component U3. Water Preserve Areas / Bird Drive Recharge Area (2877 acres at 4 ft. maximum depth) in Miami-Dade County with operational rules for the C-4 downstream diversion structure. Purpose: capture runoff from western C-4 basin and induce seepage collection/treatment of Bird Drive water by pumping seepage collection canal to L-31N. The facility will provide C-4 flood peak attenuation within the basin, provide water to L-31N available to be pumped west through the proposed S-356 A and B pumps (see Component FF3) and enhance groundwater recharge.

Component V2. L-31N Levee Improvements for Seepage Management in Miami-Dade County with additional reduction of seepage in the wet season. Purpose: manage levee seepage along the eastern edge (L-31N) of Everglades National Park to eliminate losses to the East Coast. An additional feature has been added to reduce all wet-season seepage/ground water flows to the east to help restore hydropatterns in Everglades National Park.

Component W2. Taylor Creek / Nubbin Slough Storage and Treatment Area (5000-acre storage area at 10 ft. maximum depth and 5000-acre stormwater treatment area at 4 ft. maximum depth) in Okeechobee and St. Lucie Counties. Purpose: provide flood protection, water quality treatment, estuary protection and water supply benefits.

Component X6. Water Preserve Areas / C-17 Backpumping in North Palm Beach Service Area (550-acre stormwater treatment area at 4 ft. maximum depth). Purpose: increase regional water resources to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-17 basin (which would otherwise be sent to tide) to the West Palm Beach Water Catchment Area and enhance hydroperiods in the Loxahatchee Slough. Delivery route to the stormwater treatment area revised and operational changes made from Alternative 5.

Component Y6. Water Preserve Areas / C-51 Backpumping to Water Catchment Area in Palm Beach County (600-acre stormwater treatment area at 4 ft. maximum depth). Purpose: increase regional water resources to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-51 West basin (which would otherwise be sent to tide) to the West Palm Beach Water Catchment Area and enhance hydroperiods in Loxahatchee Slough. Operational changes made to the stormwater treatment area as compared to Alternative 5.

Component AA3. Additional S-345 Structures in L-67A in Water Conservation Area 3B. Purpose: improve conveyance to Water Conservation Area (WCA) 3B through the L-67 levee system to help in re-establishing NSM-like hydroperiods and hydropatterns in WCA 3B and Northeast Shark River Slough.

Component BB4. Dade-Broward Levee / Pennsuco Wetlands in Miami-Dade County. Purpose: reduce seepage to the east from the Pennsuco wetlands and southern Water Conservation Area 3B, enhance hydroperiods in the Pennsuco and enhance recharge to Miami-Dade County's NW wellfield.

Component CC6. Broward County Secondary Canal System. Purpose: increase pump capacity of existing facilities (from the 2050 Base Case) and construct additional canal improvements and pump facilities for the Broward County Secondary Canal System to provide additional recharge to wellfields located in central and southern coastal Broward County, stabilize the salt water interface and reduce discharges to tide. The groundwater table and recharge to the aquifer were improved from Alternative 5 by modifying secondary canals in the C-10 and C-12 basins.

Component DD5. Revised Holey Land Operation Plan (based on rain-driven operations) in Palm Beach County. Purpose: improve timing and location of water depths within the Holey Land Wildlife Management Area based on rain-driven operations. Operational change only for Alternative 5.

Component EE5. Modified Rotenberger Operation Plan (based on rain-driven operations) in Palm Beach County. Purpose: improve timing and location of water depths within the Rotenberger Wildlife Management Area based on rain-driven operations. Operational change only for Alternative 5.

Component FF3. Construction of S-356 A & B Structures (L-31N along east side of Northeast Shark River Slough) in Miami-Dade County. Purpose: improve deliveries to Northeast Shark River Slough in Everglades National Park and reduce seepage to Lower East Coast Service Area 3.

Component GG4. Lake Okeechobee Aquifer Storage and Recovery (200, 5-MGD wells) along the lake peripheral levee. Purpose: utilize climate based operational rules for the aquifer storage and recovery wells to provide additional regional storage while reducing both evapotranspiration losses and the amount of land removed from current land use (e.g. agriculture) that would normally be associated with construction and operation of above-ground storage facilities (reservoirs); increase the Lake's water storage capability to better meet regional water supply demands for agriculture, Lower East Coast urban areas, and the Everglades; manage a portion of regulatory releases from the Lake primarily to improve Everglades hydropatterns, meet environmental targets within the Water Conservation Areas (WCAs), and meet supplemental water supply demands of the Lower East Coast; reduce harmful regulatory discharges to the St. Lucie and Caloosahatchee estuaries; and maintain existing level of flood protection.

Component HH3. Operation Change of S-343 A and B (closed during the January to June time period) in Miami-Dade County. Purpose: reduce the potential adverse effects on the nesting season of the Cape Sable Seaside Sparrow due to high water levels, the S-343 A and B structures will be closed during the January to June time period.

Component II3. Pump Station G-404 Modification in Palm Beach County. Purpose: increase the capacity of proposed Everglades Construction Project pump station G-404 from 1000 cfs to 2000 cfs to improve the hydropattern restoration in the northwest corner of Water Conservation Area (WCA) 3A and increase the amount of water available in the west-central region of WCA 3A to reduce dry out periods.

Component JJ. Loxahatchee National Wildlife Refuge Rainfall-Driven Operations in Palm Beach County. Not included in this Alternative.

Component KK4. Loxahatchee National Wildlife Refuge Internal Canal Structures. Purpose: improve timing and location of water depths in the Refuge by keeping the borrow canal structures closed except to pass Stormwater Treatment Areas 1 East and 1 West outflow and water supply deliveries.

Component LL3. C-51 Regional Groundwater Aquifer Storage and Recovery (34 well clusters) in Palm Beach County. Purpose: capture and store excess water during wet periods, then recover the water for utilization during dry periods to increase regional water resources.

Component MM4. Hillsboro Canal Basin Regional Groundwater Aquifer Storage and Recovery (22 well clusters, total injection and recovery capacity is 110 MGD) in Broward and Palm Beach Counties. Purpose: increase regional water resources by capturing and storing excess water during wet periods and recover the water for utilization during dry periods.

Component NN. North New River Regional Groundwater Aquifer Storage and Recovery. Not included in this Alternative.

Component OO4. Modification to South Dade Conveyance System in Southern Portion of L-31N and C-111. Purpose: modify C-111 Canal operations to improve deliveries to Everglades National Park and decrease potential flood risk in the lower east coast service area.

Component PP3. Backpumping of the C-7 Basin to the Central Lake Belt In-ground Storage Reservoir via the C-6 Canal in Miami-Dade County. Purpose: backpump a portion of excess runoff from the C-7 basin, previously lost to tide, to the Central

Lake Belt Storage Reservoir to be used for water supply and decrease flooding problems in the C-7 basin.

Component QQ. Decompartmentalization of Water Conservation Area 3. Not included in this Alternative.

Component RR. Flow to Central Water Conservation Area 3A. Not included in this Alternative.

Component SS. Reroute Miami-Dade County Water Supply Deliveries. Not included in this Alternative.

Component TT. Decompartmentalization of Water Conservation Area 2. Not included in this Alternative.

Component UU6. Storage Reservoirs (20,200 acres at 8 ft. maximum depth and 15,000 acres at 2 ft. maximum depth) in Martin and St. Lucie Counties. Purpose: capture local runoff from the C-23, 24, and Northfork and Southfork Basins of the St. Lucie River Estuary for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. The reservoirs were increased in size and reconfigured from the design presented in Alternative 5.

Component VV. Palm Beach County Agricultural Reserve Reservoir. Not included in this Alternative.

Component WW. C-111N Spreader Canal in Miami-Dade County. Not included in this Alternative.

Component XX. North Lake Belt Storage Area in Miami-Dade County. Not included in this Alternative.

Component YY. Divert Water Conservation Area 2 flows to Central Lake Belt Storage in Broward County. Not included in this Alternative.

Component ZZ. Divert Water Conservation Area 3A and 3B flows to Central Lake Belt Storage Area. Not included in this Alternative.

Component AAA. Lower East Coast Utility Water Conservation. Not included in this Alternative.

Component BBB. South Miami-Dade County Reuse (South District Reclaimed Water Treatment Plant). Not included in this Alternative.

Component CCC. Big Cypress/ L-28 Interceptor Modifications. Not included in this Alternative.

Component DDD5. Caloosahatchee Backpumping with Stormwater Treatment Area. Purpose: increase the regional water resources by capturing excess C-43 basin runoff and diverting it into Lake Okeechobee after treatment through a stormwater treatment area when storage is available in the Lake.

Component EEE. Flows to Eastern Water Conservation Area 3B from Central Lake Belt Storage Area. Not included in this Alternative.

Component FFF. Biscayne Bay Coastal Canals. Not included in this Alternative.

Component GGG. C-51 and Southern L-8 Reservoir. Not included in this Alternative.

Component HHH. West Miami-Dade Reuse. Not included in this Alternative.

A3.2 ALTERNATIVE B

Alternative B is second of four alternatives (Alternatives A – D) which were evaluated and compared by the Alternative Evaluation Team in the selection of the technically preferred alternative. Alternative B enhances the performance of Alternative A by modifying or adding features that are considered to have the potential to solve system-wide problems identified by the Alternative Evaluation Team. Many of the components developed for Alternative A have not been modified and are included as part of Alternative B.

A3.2.1 Summary of Alternative B by Geographic Regions

The following is a summary of the components which have either changed from Alternative A or been added in Alternative B, grouped by region.

A3.2.1.3 Lake Okeechobee

(No changes in this area as compared to Alternative A.)

A3.2.1.4 Everglades Agricultural Area

(No changes in this area as compared to Alternative A.)

A3.2.1.5 Water Conservation Areas And Everglades National Park

- The timing and location of water depths in the Water Conservation Areas and Everglades National Park were further improved by modifying the rain-driven operations and relocating pumps and increasing capacities.

- Levee seepage from the eastern boundaries of Water Conservation Areas 2 and 3 was modified to send all seepage south to Northeast Shark River Slough or the Central Lake Belt In-ground Storage Area enhance hydroperiods within the Water Conservation Areas and Pennsuco Wetlands and keep it separate from runoff from the eastern basins.

- Water supply deliveries to Northeast Shark River Slough were improved and seepage losses from L-31N were reduced by relocating and increasing the capacities of the S-356 pumps and relocating the L-31N levee east of buffer area.

- Water Conservation Area 3 was decompartmentalized to re-establish historic sheetflow and the ecologic and hydrologic connections between the Water Conservation Area and Northeast Shark River Slough (removal of the L-28 and L-28 Tieback levees, the L-29, L-67A, L-67-C and L-68A levees and backfilling of the Miami Canal).

- The S-140 pump station capacity was increased and relocated to increase water depths and extend hydroperiods in central Water Conservation Area 3A.

- The Miami Canal water supply deliveries to Miami-Dade County were re-routed through the North New River Canal as a result of the decompartmentalization of Water Conservation Area 3.

- The additional S-345 structures in L-67A were eliminated and the S-343 A and B structure operations were returned to normal as a result of decompartmentalization of Water Conservation Area 3.

A3.2.1.6 Lower East Coast

- The L-8 Project was modified to include the addition of 25 MGD Aquifer Storage and Recovery (ASR) well clusters at Lake Mangonia.

- The capacity of the ASR system along the C-51 Canal was increased by 100 MGD.

- The backpumping of the C-7 basin to the Central Lake Belt Storage Area was eliminated.

- Water supply deliveries to the Model Lands and Southern Glades were improved by pumping water from C-111 to C-111E through a Stormwater Treatment Area to C-111N.

A3.2.1.7 Water Preserve Areas

- The Water Preserve Area components for the C-9 and C-11 Stormwater Treatment Area/Impoundments, the Central Lake Belt In-ground Storage Area and the Bird Drive Recharge Area were modified to further increase the regional water resources, improve wellfield and groundwater recharge, provide seepage control, flood peak attenuation and reduce discharge of fresh water to tide.

- The Water Preserve Area components for the North Lake Belt Storage Area and the Palm Beach County Agricultural Reserve Reservoir were added to increase the regional water resources.

A3.2.2 List of Components in Alternative B

The following is a list of each component included in Alternative B along with a brief summary.

Component A6. A Storage Reservoir (20,000 acres at 10 ft. maximum depth) north of Lake Okeechobee. Purpose: incorporate climate-based inflow forecasting to increase the utilization of the reservoir to provide additional flood protection, water supply and environmental enhancement. Operation revised from Alternative 5.

Component B2. A Storage Reservoir (10,000 acres at 4 ft. maximum depth) in the St. Lucie basin. Purpose: capture local runoff from C-44 for flood attenuation, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary.

Component C6. Environmental Water Supply Deliveries to the St. Lucie Estuary. Purpose: provide freshwater flow to the St. Lucie Estuary to protect and restore more natural estuarine conditions. The time series of estuary target flows was revised from Alternative 5.

Component D5. A Storage Reservoir (20,000 acres at 8 ft. maximum depth) with Aquifer Storage and Recovery (44, 5-MGD wells) in the Caloosahatchee basin. Purpose: capture basin runoff and regulatory releases from Lake Okeechobee to provide water supply benefits, some flood attenuation and environmental water supply deliveries to the Caloosahatchee estuary. Operated in conjunction with DDD5.

Component E5. Environmental Water Supply Deliveries to the Caloosahatchee Estuary (operational change only). Purpose: provide freshwater deliveries to the Caloosahatchee Estuary to establish desirable salinity at locations of key estuarine biota. Operational target flow at S-79 revised in Alternative 5.

Component F3. Current Lake Okeechobee Regulation Schedule (elimination of all except Zone A [emergency] regulatory releases to the St. Lucie and Caloosahatchee Estuaries). Purpose: implement operating criteria for Lake Okeechobee that includes flood control, water supply (including releases to the Water Conservation Areas to meet estimated natural system needs) as well as Lake littoral zone and estuary protection.

Component G3. A Storage Reservoir (one 20,000 acre compartment at 6 ft. maximum depth for supplying EAA irrigation demands and one 40,000 acre compartment at 6 ft. maximum depth for supplying environmental demands) in the Everglades Agricultural Area with increased conveyance from Lake Okeechobee to the reservoir. Purpose: improve timing of environmental deliveries to the Water Conservation Areas including reducing damaging flood releases from the EAA to the Water Conservation Areas, reduce Lake Okeechobee regulatory releases to estuaries, meet supplemental agricultural irrigation demands and increase flood protection within the Everglades Agricultural Area. Conveyance capacity of the Miami and North New River Canals between Lake Okeechobee and the Storage Reservoirs are increased to convey additional Lake Okeechobee regulatory releases that would have otherwise been discharged to the Caloosahatchee and St. Lucie Estuaries.

Component H4. Everglades Rain-Driven Operations. Purpose: improve the timing and location of water depths in the Water Conservation Areas and Everglades National Park. Operational change from Alternative A.

Component I. Improved Conveyance between Water conservation Area 3B and Everglades National Park. Not included in this Alternative.

Component J. Plug L-67A borrow canal (between S-151 and Modified Water Delivery Structures S-345s). Not included in this Alternative.

Component K4. Water Preserve Areas / L-8 Project. Purpose: further reduce water supply restrictions in the Northern Palm Beach County Service Area by capturing more of the annual discharges from portions of the southern L-8, C-51 and C-17 basins in local Aquifer Storage and Recovery facilities (25 MGD well clusters at Lake Mangonia) and route this water to the West Palm Beach Water Catchment Area. Intent is to increase regional water supply availability, provide pass through flow to enhance hydroperiods in Loxahatchee Slough and increase base flows to the Northwest Fork of the Loxahatchee River.

Component L3. Change Coastal Wellfields Operations in the Lower East Coast Service Area. Purpose: shift demands from eastern wellfields inland to western facilities away from the saltwater interface to reduce impact of salt water intrusion.

Component M4. Water Preserve Areas / Site 1 Impoundment (1660 acres at 6 ft. maximum depth) with Aquifer Storage and Recovery wells increased to 15, 5-MGD wells in Palm Beach County. Purpose: increase regional water resources and supplement water deliveries to the Hillsboro Canal during the dry-season.

Component N. Water Conservation Area 2B Levee Seepage Management in Broward County to manage only wet season seepage. Not included in this Alternative.

Component O4. Water Conservation Area (WCA) 3A and 3B Levee Seepage Management. Purpose: reduce seepage from WCAs 3A and 3B and to improve hydropatterns within the Conservation Areas by allowing higher water levels in the borrow canals and longer inundation durations within the marsh areas that are located east of the WCAs and west of US Highway 27. Seepage from the WCAs and marshes will be collected and directed south into the Central Lake Belt Storage Area. This will maintain flood protection and the separation of seepage water from urban runoff originating in the C-11 Basin and separation of Lake Okeechobee water supply deliveries.

Component P2. Water Preserve Areas / North New River Diversion Canal and Treatment Facility. Not included in this Alternative.

Component Q4. Water Preserve Areas / Western C-11 Diversion Impoundment and Canal (1600 acres of stormwater treatment area / impoundment and 2500 cfs diversion canal) in Broward County. Purpose: divert untreated runoff from western C-11 that is presently discharged into Water Conservation Area 3A through the C-11 Stormwater Treatment Area / Impoundment and then into the North Lake Belt Storage Area.

Component R4. Water Preserve Areas / C-9 Stormwater Treatment Area / Impoundment (2500 acres at 4 ft. maximum depth) in Broward County. Purpose: provide treatment of water supply deliveries from the North Lake Belt Storage Area prior to deliveries to the C-9, C-6/C-7 and C-2/C-4 Canals, groundwater recharge within the basin and seepage control of Water Conservation Area 3 and buffer areas to the west.

Component S5. Central Lake Belt Storage Area (5200 acres with subterranean seepage barrier around the perimeter) in Miami-Dade County. Purpose: receive and store excess water from Water Conservation Area (WCA) 2B, 3A and 3B without groundwater seepage losses in this highly transmissive region. The stored water will be provided based on priority to 1) Northeast Shark River Slough, 2) Water Conservation Area 3B, 3) to supply flows to Biscayne Bay and 4) when available to meet Snapper Creek demands and to maintain Dade-Broward levee borrow canal at elevation 5.0 feet NGVD.

Component T6. C-4 Structures (2) in Miami-Dade County. Purpose: maintain higher water levels in the C-4 Canal to reduce seepage losses from the Pennsuco Wetlands and areas west of the Dade-Broward Levee and reduce deliveries from Lake Okeechobee and the Water Conservation Areas by diverting dry season stormwater flows into the C-2 Canal to increase recharge to several nearby coastal wellfields.

Component U4. Water Preserve Areas / Bird Drive Recharge Area (2877 acres at 4 ft. maximum depth) in Miami-Dade County. Purpose: provide flood peak attenuation by capturing runoff from western C-4 basin and pumping it to the Bird Drive Recharge Area, reduce seepage from the Everglades National Park buffer areas by increasing water table elevations east of Krome Ave. and enhance groundwater recharge.

Component V4. L-31N Levee Improvements for Seepage Management in Miami-Dade County with additional reduction of seepage in the wet season. Purpose: manage levee seepage along the eastern edge (L-31N) of Everglades National Park to eliminate losses to the East Coast. In Alternative 4, an additional feature was added to reduce all wet-season seepage/ground water flows to the east to help restore hydropatterns in Everglades National Park. (refer to Component FF4)

Component W2. Taylor Creek / Nubbin Slough Storage and Treatment Area (5000-acre storage area at 10 ft. maximum depth and 5000-acre stormwater treatment area at 4 ft. maximum depth) in Okeechobee and St. Lucie Counties. Purpose: provide flood protection, water quality treatment, estuary protection and water supply benefits.

Component X6. Water Preserve Areas / C-17 Backpumping in North Palm Beach Service Area (550-acre stormwater treatment area at 4 ft. maximum depth). Purpose: increase regional water resources to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-17 basin (which would otherwise be sent to tide) to the West Palm Beach Water Catchment Area and enhance hydroperiods in the Loxahatchee Slough. Delivery route to the stormwater treatment area revised and operational changes made from Alternative 5.

Component Y6. Water Preserve Areas / C-51 Backpumping to Water Catchment Area in Palm Beach County (600-acre stormwater treatment area at 4 ft. maximum depth). Purpose: increase regional water resources to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-51 West basin (which would otherwise be sent to tide) to the West Palm Beach Water Catchment Area and enhance hydroperiods in Loxahatchee Slough. Operational changes made to the stormwater treatment area as compared to Alternative 5.

Component AA3. Additional S-345 Structures in L-67A in Water Conservation Area 3B. Not included in this Alternative.

Component BB4. Dade-Broward Levee / Pennsuco Wetlands in Miami-Dade County. Purpose: to reduce seepage to the east from the Pennsuco wetlands and southern Water Conservation Area 3B, enhance hydroperiods in the Pennsuco and enhance recharge to Miami-Dade County's NW wellfield.

Component CC6. Broward County Secondary Canal System. Purpose: increase pump capacity of existing facilities (from the 2050 Base Case) and construct additional canal improvements and pump facilities for the Broward County Secondary Canal System to provide additional recharge to wellfields located in central and southern coastal Broward County, stabilize the salt water interface and reduce discharges to tide. The groundwater table and recharge to the aquifer were improved from Alternative 5 by modifying secondary canals in the C-10 and C-12 basins.

Component DD5. Revised Holey Land Operation Plan (based on rain-driven operations) in Palm Beach County. Purpose: improve timing and location of water depths within the Holey Land Wildlife Management Area based on rain-driven operations. Operational change only for Alternative 5.

Component EE5. Modified Rotenberger Operation Plan (based on rain-driven operations) in Palm Beach County. Purpose: improve timing and location of water depths within the Rotenberger Wildlife Management Area based on rain-driven operations. Operational change only for Alternative 5.

Component FF4. Construction of S-356 A & B Structures and relocation of a portion of L-31N in Miami-Dade County. Purpose: improve deliveries to Northeast Shark River Slough in Everglades National Park and reduce seepage to Lower East Coast Service Area 3.

Component GG4. Lake Okeechobee Aquifer Storage and Recovery (200, 5-MGD wells) along the lake peripheral levee. Purpose: utilize climate based operational rules for the aquifer storage and recovery wells to provide additional regional storage while reducing both evapotranspiration losses and the amount of land removed from current land use (e.g. agriculture) that would normally be associated with construction and operation of above-ground storage facilities (reservoirs);

increase the Lake's water storage capability to better meet regional water supply demands for agriculture, Lower East Coast urban areas, and the Everglades; manage a portion of regulatory releases from the Lake primarily to improve Everglades hydropatterns, meet environmental targets within the Water Conservation Areas (WCAs), and meet supplemental water supply demands of the Lower East Coast; reduce harmful regulatory discharges to the St. Lucie and Caloosahatchee estuaries; and maintain existing level of flood protection.

<u>Component HH3</u>. Operation Change of S-343 A and B. Not included in this Alternative.

<u>Component II3</u>. Pump Station G-404 Modification in Palm Beach County. Purpose: increase the capacity of proposed Everglades Construction Project pump station G-404 from 1000 cfs to 2000 cfs to improve the hydropattern restoration in the northwest corner of Water Conservation Area (WCA) 3A and increase the amount of water available in the west-central region of WCA 3A to reduce dry out periods.

<u>Component JJ</u>. Loxahatchee National Wildlife Refuge Rainfall-Driven Operations. Not included in this Alternative.

<u>Component KK4</u>. Loxahatchee National Wildlife Refuge Internal Canal Structures. Purpose: improve timing and location of water depths in the Refuge by keeping the borrow canal structures closed except to pass Stormwater Treatment Areas 1 East and 1 West outflow and water supply deliveries.

<u>Component LL4</u>. C-51 Regional Groundwater Aquifer Storage and Recovery (54 well clusters, total injection and recovery capacity is 170 MGD) in Palm Beach County. Purpose: increase regional water resources by capturing and storing excess water during wet periods and recover the water for utilization during dry periods.

<u>Component MM4</u>. Hillsboro Canal Basin Regional Groundwater Aquifer Storage and Recovery (22 well clusters, total injection and recovery capacity is 110 MGD) in Broward and Palm Beach Counties. Purpose: increase regional water resources by capturing and storing excess water during wet periods and recover the water for utilization during dry periods.

<u>Component NN</u>. North New River Regional Groundwater Aquifer Storage and Recovery. Not included in this Alternative.

<u>Component OO4</u>. Modification to South Dade Conveyance System in Southern Portion of L-31N and C-111. Purpose: modify C-111 Canal operations to improve deliveries to Everglades National Park and decrease potential flood risk in the lower east coast service area.

Component PP. Backpumping of the C-7 Basin to the Central Lake Belt Storage System via the C-6 Canal. Not included in this Alternative.

Component QQ4. Decompartmentalization of Water Conservation Area 3. Purpose: remove flow obstructions to achieve uncontrolled flow between Water Conservation Areas 3A and 3B and Northeast Shark River Slough and re-establish the ecologic and hydrologic connection between these areas.

Component RR4. Flow to Central Water Conservation Area 3A. Purpose: increase depths and extend hydroperiods in central Water Conservation Area 3A by relocating the S-140 pump station approximately 8 miles south and increasing the capacity to 2000 cfs.

Component SS4. Reroute Miami-Dade County Water Supply Deliveries. Purpose: reroute water supply deliveries made to Miami-Dade County from the Miami and Tamiami Canals and Water Conservation Area 3 (WCA 3) to the North New River Canal due to the backfilling of the Miami Canal as part of the decompartmentalization of WCA 3.

Component TT. Decompartmentalization of Water Conservation Area 2. Not included in this Alternative.

Component UU6. Storage Reservoirs (20,200 acres at 8 ft. maximum depth and 15,000 acres at 2 ft. maximum depth) in Martin and St. Lucie Counties. Purpose: capture local runoff from the C-23, 24, and Northfork and Southfork Basins of the St. Lucie River Estuary for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. The reservoirs were increased in size and reconfigured from the design presented in Alternative 5.

Component VV4. Palm Beach County Agricultural Reserve Reservoir (1660 acres at 6 ft. maximum depth). Purpose: increase regional water resources in central and southern Palm Beach County by capturing and storing water currently discharged to tide to be used to maintain canal stages during the dry season.

Component WW4. C-111N Spreader Canal in Miami-Dade County. Purpose: reduce wet season flows in C-111, improve deliveries to Model Lands and Southern Glades and decrease potential flood risk in the lower south Miami-Dade area.

Component XX4. North Lake Belt Storage Area (3500 acres with subterranean seepage barrier around the perimeter) in Miami-Dade County. Purpose: increase regional water resources by capturing a portion of runoff from western C-6, western C-11 and C-9 basins without seepage losses in this very transmissive groundwater region and without concerns of ground water contamination from untreated runoff. The stored water will be used to maintain stages during the dry season in the C-9, C-6, C-7, C-4 and C-2 Canals.

Component YY4. Divert Water Conservation Area 2 flows to Northeast Shark River Slough or Central Lake Belt Storage in Broward County. Purpose: capture excess water in Water Conservation Area 2B (WCA 2B) to reduce stages above targets and to divert water through improved L-37 and L-33 borrow canals to meet the following prioritized demands 1) Northeast Shark River Slough (NESRS), or 2) Central Lake Belt Area for future delivery to NESRS, 3) to Snapper Creek and 4) to maintain Dade-Broward levee borrow canal at elevation 5.0 feet NGVD.

Component ZZ. Divert Water Conservation Area 3A and 3B flows to Central Lake Belt Storage Area. Not included in this Alternative.

Component AAA. Lower East Coast Utility Water Conservation. Not included in this Alternative.

Component BBB. South Miami-Dade County Reuse (South District Reclaimed Water Treatment Plant). Not included in this Alternative.

Component CCC. Big Cypress/ L-28 Interceptor Modifications. Not included in this Alternative.

Component DDD5. Caloosahatchee Backpumping with Stormwater Treatment Area. Purpose: increase the regional water resources by capturing excess C-43 basin runoff and diverting it into Lake Okeechobee after treatment through a stormwater treatment area when storage is available in the Lake.

Component EEE. Flows to Eastern Water Conservation Area 3B from Central Lake Belt Storage Area. Not included in this Alternative.

Component FFF. Biscayne Bay Coastal Canals. Not included in this Alternative.

Component GGG. C-51 and Southern L-8 Reservoir. Not included in this Alternative.

Component HHH. West Miami-Dade Reuse. Not included in this Alternative.

A3.3 ALTERNATIVE C

Alternative C is the third of four alternatives (Alternatives A – D) that was evaluated and compared by the Alternative Evaluation Team for the technically preferred alternative. Alternative C enhances the performance of Alternative B by modifying or adding features that are considered to have the potential to solve system-wide problems which have been identified by the Alternative Evaluation Team. Many of the components developed for Alternatives A or B have not been modified and are included as part of Alternative C.

A3.3.1 Summary of Alternative C by Geographic Regions

The following is a summary of the components which have either changed from Alternative B or been added in Alternative C, grouped by region.

A3.3.1.3 Lake Okeechobee

(No changes in this area as compared to Alternative B.)

A3.3.1.4 Everglades Agricultural Area

- The Everglades Agricultural Area reservoir includes two compartments, compartment 1 – 20,000 acres and compartment 2 – 40,000 acres. Compartment 1 remains unchanged. Compartment 2 ("the surge tank") was modified to operate as a dry storage area with withdrawals being made down to 18" below ground level. It has also been subdivided into two 20,000-acre compartments to allow for more efficient use of the reservoir and for alternative uses of the compartments during dry times (eg. agriculture).

A3.3.1.5 Water Conservation Areas And Everglades National Park

- Further refinements were made to the Everglades Rain-Driven Operations to improve timing and location of water depths in the Water Conservation Areas and Everglades National Park.

- Decompartmentalization of Water Conservation Area 3 was modified from Alternative B by maintaining the L-28 and L-29 Levees while degrading L-29 south of WCA 3B. The function of the L-67 A and C levees has been replaced by a passive weir structure to facilitate high flow sheetflow from Water Conservation Area 3A to 3B.

- The S-345 structures, allowing flow through the L-67 Levee, were replaced (same as in Alternative A) in the passive weir structure as part of the decompartmentalization of Water Conservation Area 3 to relieve high water conditions in northern Water Conservation Area 3B.

- The operational changes to the S-343 A and B structures were re-implemented from Alternative A to reduce potential adverse impacts on the nesting season of the Cape Sable Seaside Sparrow as a result of the modification to the decompartmentalization of Water Conservation Area 3.

- Excess Water Conservation Area 3A & B flows were diverted to the Central Lake Belt In-ground Storage Area, and deliveries made to eastern WCA 3B from Central Lake Belt Storage Area when needed during dryouts.

A3.3.1.6 Other Natural Systems

- The West Feeder Canal and structure S-190 of the L-28 Interceptor Canal (north) were modified to allow for compliance with the Seminole Tribe's Conceptual Water Conservation System master plan,

A3.3.1.7 Lower East Coast

- The operation of the Western C-11 Canal was modified to improve groundwater elevations in the Eastern C-11 basin.

- The Dade-Broward Levee component was modified in Alternative C to use the regional system as a source of recharge.

- The C-111N Spreader Canal component was modified to extend the C-111N east of Card Sound Road.

- Utility Water Conservation was modified to reduce the public water supply demands through the full implementation of the SFWMD's current mandatory water conservation program. This results in a reduction of public water supply demands of approximately 5 percent.

- The South Biscayne Bay and Coastal Wetlands Enhancement component was introduced to maintain higher canal stages during the dry season in the C-100, C-102 and C-103 Canals with water provided from local basin runoff and from a wastewater treatment facility (South District Reclaimed Water Treatment Plant).

A3.3.1.8 Water Preserve Areas

- The Palm Beach County Agricultural Reserve Reservoir was modified to include Aquifer Storage and Recovery, increasing the regional water resources,

- The North Lake Belt Storage Area was modified to capture additional runoff from the C-6, C-11 and C-9 basins.

A3.3.2 List of Components in Alternative C

The following is a list of each component included in Alternative C along with a brief summary.

Component A6. A Storage Reservoir (20,000 acres at 10 ft. maximum depth) north of Lake Okeechobee. Purpose: incorporate climate-based inflow forecasting to increase the utilization of the reservoir to provide additional flood protection, water supply and environmental enhancement. Operation revised from Alternative 5.

Component B2. A Storage Reservoir (10,000 acres at 4 ft. maximum depth) in the St. Lucie basin. Purpose: capture local runoff from C-44 for flood attenuation, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary.

Component C6. Environmental Water Supply Deliveries to the St. Lucie Estuary. Purpose: provide freshwater flow to the St. Lucie Estuary to protect and restore more natural estuarine conditions. The time series of estuary target flows was revised from Alternative 5.

Component D5. A Storage Reservoir (20,000 acres at 8 ft. maximum depth) with Aquifer Storage and Recovery (44, 5-MGD wells) in the Caloosahatchee basin. Purpose: capture basin runoff and regulatory releases from Lake Okeechobee to provide water supply benefits, some flood attenuation and environmental water supply deliveries to the Caloosahatchee estuary. Operated in conjunction with DDD5.

Component E5. Environmental Water Supply Deliveries to the Caloosahatchee Estuary (operational change only). Purpose: provide freshwater deliveries to the Caloosahatchee Estuary to establish desirable salinity at locations of key estuarine biota. Operational target flow at S-79 revised in Alternative 5.

Component F3. Current Lake Okeechobee Regulation Schedule (elimination of all except Zone A [emergency] regulatory releases to the St. Lucie and Caloosahatchee Estuaries). Purpose: implement operating criteria for Lake Okeechobee that includes flood control, water supply (including releases to the Water Conservation Areas to meet estimated natural system needs) as well as Lake littoral zone and estuary protection.

Component G5. A Storage Reservoir (one 20,000 acre compartment at 6 ft. maximum depth for supplying EAA irrigation demands and one 40,000 acre compartment at 6 ft. maximum depth for supplying environmental demands) in the

Everglades Agricultural Area with increased conveyance from Lake Okeechobee to the reservoir. Purpose: improve timing of environmental deliveries to the Water Conservation Areas including reducing damaging flood releases from the EAA to the Water Conservation Areas, reduce Lake Okeechobee regulatory releases to estuaries, meet supplemental agricultural irrigation demands and increase flood protection within the Everglades Agricultural Area. Conveyance capacity of the Miami and North New River Canals between Lake Okeechobee and the Storage Reservoirs are increased to convey additional Lake Okeechobee regulatory releases that would have otherwise been discharged to the Caloosahatchee and St. Lucie Estuaries. In Alternative 5, the reservoir was modified to operate compartment 2 as a dry storage area with withdrawals being made down to 18" below ground level. It was also been subdivided into two 20,000-acre compartments to allow for more efficient use of the reservoir and for alternative uses of the compartments during dry times (ie. agriculture).

<u>Component H6</u>. Everglades Rain-Driven Operations. Purpose: improve timing and location of water depths in the Water Conservation Areas and Everglades National Park. Operational change from Alternative 5.

<u>Component I</u>. Improved Conveyance between Water conservation Area 3B and Everglades National Park. Not included in this Alternative.

<u>Component J</u>. Plug L-67A borrow canal (between S-151 and Modified Water Delivery Structures S-345s). Not included in this Alternative.

<u>Component K4</u>. Water Preserve Areas / L-8 Project. Purpose: further reduce water supply restrictions in the Northern Palm Beach County Service Area by capturing more of the annual discharges from portions of the southern L-8, C-51 and C-17 basins in local Aquifer Storage and Recovery facilities (25 MGD well clusters at Lake Mangonia) and route this water to the West Palm Beach Water Catchment Area. Intent is to increase regional water supply availability, provide pass through flow to enhance hydroperiods in Loxahatchee Slough and increase base flows to the Northwest Fork of the Loxahatchee River.

<u>Component L3</u>. Change Coastal Wellfields Operations in the Lower East Coast Service Area. Purpose: shift demands from eastern wellfields inland to western facilities away from the saltwater interface to reduce impact of salt water intrusion.

<u>Component M4</u>. Water Preserve Areas / Site 1 Impoundment (1660 acres at 6 ft. maximum depth) with Aquifer Storage and Recovery wells increased to 15, 5-MGD wells in Palm Beach County. Purpose: increase regional water resources and supplement water deliveries to the Hillsboro Canal during the dry-season.

Component N. Water Conservation Area 2B Levee Seepage Management in Broward County to manage only wet season seepage. Not included in this Alternative.

Component O4. Water Conservation Area (WCA) 3A and 3B Levee Seepage Management. Purpose: reduce seepage from WCAs 3A and 3B and to improve hydropatterns within the Conservation Areas by allowing higher water levels in the borrow canals and longer inundation durations within the marsh areas that are located east of the WCAs and west of US Highway 27. Seepage from the WCAs and marshes will be collected and directed south into the Central Lake Belt Storage Area. This will maintain flood protection and the separation of seepage water from urban runoff originating in the C-11 Basin and separation of Lake Okeechobee water supply deliveries.

Component P2. Water Preserve Areas / North New River Diversion Canal and Treatment Facility. Not included in this Alternative.

Component Q5. Water Preserve Areas / Western C-11 Diversion Impoundment and Canal (1600 acres of stormwater treatment area / impoundment and 2500 cfs diversion canal) in Broward County. Purpose: divert untreated runoff from western C-11 that is presently discharged into Water Conservation Area 3A through the C-11 Stormwater Treatment Area / Impoundment and then into the North Lake Belt Storage Area. Alternative 5 maintains the western C-11 Canal at elevation 3.0 feet NGVD in order to improve groundwater conditions in the eastern C-11 basin.

Component R4. Water Preserve Areas / C-9 Stormwater Treatment Area / Impoundment (2500 acres at 4 ft. maximum depth) in Broward County. Purpose: provide treatment of water supply deliveries from the North Lake Belt Storage Area prior to deliveries to the C-9, C-6/C-7 and C-2/C-4 Canals, groundwater recharge within the basin and seepage control of Water Conservation Area 3 and buffer areas to the west.

Component S5. Central Lake Belt Storage Area (5200 acres with subterranean seepage barrier around the perimeter) in Miami-Dade County. Purpose: receive and store excess water from Water Conservation Area (WCA) 2B, 3A and 3B without groundwater seepage losses in this highly transmissive region. The stored water will be provided based on priority to 1) Northeast Shark River Slough, 2) Water Conservation Area 3B, 3) to supply flows to Biscayne Bay and 4) when available to meet Snapper Creek demands and to maintain Dade-Broward levee borrow canal at elevation 5.0 feet NGVD.

Component T6. C-4 Structures (2) in Miami-Dade County. Purpose: maintain higher water levels in the C-4 Canal to reduce seepage losses from the Pennsuco

Wetlands and areas west of the Dade-Broward Levee and reduce deliveries from Lake Okeechobee and the Water Conservation Areas by diverting dry season stormwater flows into the C-2 Canal to increase recharge to several nearby coastal wellfields.

Component U4. Water Preserve Areas / Bird Drive Recharge Area (2877 acres at 4 ft. maximum depth) in Miami-Dade County. Purpose: provide flood peak attenuation by capturing runoff from western C-4 basin and pumping it to the Bird Drive Recharge Area, reduce seepage from the Everglades National Park buffer areas by increasing water table elevations east of Krome Ave. and enhance groundwater recharge.

Component V4. L-31N Levee Improvements for Seepage Management in Miami-Dade County with additional reduction of seepage in the wet season. Purpose: manage levee seepage along the eastern edge (L-31N) of Everglades National Park to eliminate losses to the East Coast. In Alternative 4, an additional feature was added to reduce all wet-season seepage/ground water flows to the east to help restore hydropatterns in Everglades National Park. (refer to Component FF4)

Component W2. Taylor Creek / Nubbin Slough Storage and Treatment Area (5000-acre storage area at 10 ft. maximum depth and 5000-acre stormwater treatment area at 4 ft. maximum depth) in Okeechobee and St. Lucie Counties. Purpose: provide flood protection, water quality treatment, estuary protection and water supply benefits.

Component X6. Water Preserve Areas / C-17 Backpumping in North Palm Beach Service Area (550-acre stormwater treatment area at 4 ft. maximum depth). Purpose: increase regional water resources to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-17 basin (which would otherwise be sent to tide) to the West Palm Beach Water Catchment Area and enhance hydroperiods in the Loxahatchee Slough. Delivery route to the stormwater treatment area revised and operational changes made from Alternative 5.

Component Y6. Water Preserve Areas / C-51 Backpumping to Water Catchment Area in Palm Beach County (600-acre stormwater treatment area at 4 ft. maximum depth). Purpose: increase regional water resources to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-51 West basin (which would otherwise be sent to tide) to the West Palm Beach Water Catchment Area and enhance hydroperiods in Loxahatchee Slough. Operational changes made to the stormwater treatment area as compared to Alternative 5.

Component AA3. Additional S-345 Structures in L-67A in Water Conservation Area 3B. Purpose: improve conveyance to Water Conservation Area (WCA) 3B through the L-67 levee system to help in re-establishing NSM-like hydroperiods and hydropatterns in WCA 3B and Northeast Shark River Slough.

Component BB5. Dade-Broward Levee / Pennsuco Wetlands in Miami-Dade County. Purpose: reduce seepage to the east from the Pennsuco wetlands and southern Water Conservation Area 3B, enhance hydroperiods in the Pennsuco and enhance recharge to Miami-Dade County's NW wellfield. Alternative 5 recharged the Dade-Broward Levee canal with deliveries from Lake Okeechobee and the Water Conservation Areas.

Component CC6. Broward County Secondary Canal System. Purpose: increase pump capacity of existing facilities (from the 2050 Base Case) and construct additional canal improvements and pump facilities for the Broward County Secondary Canal System to provide additional recharge to wellfields located in central and southern coastal Broward County, stabilize the salt water interface and reduce discharges to tide. The groundwater table and recharge to the aquifer were improved from Alternative 5 by modifying secondary canals in the C-10 and C-12 basins.

Component DD5. Revised Holey Land Operation Plan (based on rain-driven operations) in Palm Beach County. Purpose: improve timing and location of water depths within the Holey Land Wildlife Management Area based on rain-driven operations. Operational change only for Alternative 5.

Component EE5. Modified Rotenberger Operation Plan (based on rain-driven operations) in Palm Beach County. Purpose: improve timing and location of water depths within the Rotenberger Wildlife Management Area based on rain-driven operations. Operational change only for Alternative 5.

Component FF4. Construction of S-356 A & B Structures and relocation of a portion of L-31N in Miami-Dade County. Purpose: improve deliveries to Northeast Shark River Slough in Everglades National Park and reduce seepage to Lower East Coast Service Area 3.

Component GG4. Lake Okeechobee Aquifer Storage and Recovery (200, 5-MGD wells) along the lake peripheral levee. Purpose: utilize climate based operational rules for the aquifer storage and recovery wells to provide additional regional storage while reducing both evapotranspiration losses and the amount of land removed from current land use (e.g. agriculture) that would normally be associated with construction and operation of above-ground storage facilities (reservoirs); increase the Lake's water storage capability to better meet regional water supply demands for agriculture, Lower East Coast urban areas, and the Everglades; manage a portion of regulatory releases from the Lake primarily to improve

Everglades hydropatterns, meet environmental targets within the Water Conservation Areas (WCAs), and meet supplemental water supply demands of the Lower East Coast; reduce harmful regulatory discharges to the St. Lucie and Caloosahatchee estuaries; and maintain existing level of flood protection.

Component HH3. Operation Change of S-343 A and B (closed during the January to June time period) in Miami-Dade County. Purpose: reduce the potential adverse effects on the nesting season of the Cape Sable Seaside Sparrow due to high water levels, the S-343 A and B structures will be closed during the January to June time period.

Component II3. Pump Station G-404 Modification in Palm Beach County. Purpose: increase the capacity of proposed Everglades Construction Project pump station G-404 from 1000 cfs to 2000 cfs to improve the hydropattern restoration in the northwest corner of Water Conservation Area (WCA) 3A and increase the amount of water available in the west-central region of WCA 3A to reduce dry out periods.

Component JJ. Loxahatchee National Wildlife Refuge Rainfall-Driven Operations. Not included in this Alternative.

Component KK4. Loxahatchee National Wildlife Refuge Internal Canal Structures. Purpose: improve timing and location of water depths in the Refuge by keeping the borrow canal structures closed except to pass Stormwater Treatment Areas 1 East and 1 West outflow and water supply deliveries.

Component LL4. C-51 Regional Groundwater Aquifer Storage and Recovery (54 well clusters, total injection and recovery capacity is 170 MGD) in Palm Beach County. Purpose: increase regional water resources by capturing and storing excess water during wet periods and recover the water for utilization during dry periods.

Component MM4. Hillsboro Canal Basin Regional Groundwater Aquifer Storage and Recovery (22 well clusters, total injection and recovery capacity is 110 MGD) in Broward and Palm Beach Counties. Purpose: increase regional water resources by capturing and storing excess water during wet periods and recover the water for utilization during dry periods.

Component NN. North New River Regional Groundwater Aquifer Storage and Recovery. Not included in this Alternative.

Component OO4. Modification to South Dade Conveyance System in Southern Portion of L-31N and C-111. Purpose: modify C-111 Canal operations to improve deliveries to Everglades National Park and decrease potential flood risk in the lower east coast service area.

Component PP. Backpumping of the C-7 Basin to the Central Lake Belt Storage System via the C-6 Canal. Not included in this Alternative.

Component QQ5. Decompartmentalization of Water Conservation Area 3. Purpose: remove most flow obstructions to achieve unconstrained or passive flow between Water Conservation Areas 3A and 3B and Northeast Shark River Slough and re-establish the ecologic and hydrologic connection between these areas.

Component RR4. Flow to Central Water Conservation Area 3A. Purpose: increase depths and extend hydroperiods in central Water Conservation Area 3A by relocating the S-140 pump station approximately 8 miles south and increasing the capacity to 2000 cfs.

Component SS4. Reroute Miami-Dade County Water Supply Deliveries. Purpose: reroute water supply deliveries made to Miami-Dade County from the Miami and Tamiami Canals and Water Conservation Area 3 (WCA 3) to the North New River Canal due to the backfilling of the Miami Canal as part of the decompartmentalization of WCA 3.

Component TT. Decompartmentalization of Water Conservation Area 2. Not included in this Alternative.

Component UU6. Storage Reservoirs (20,200 acres at 8 ft. maximum depth and 15,000 acres at 2 ft. maximum depth) in Martin and St. Lucie Counties. Purpose: capture local runoff from the C-23, 24, and Northfork and Southfork Basins of the St. Lucie River Estuary for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. The reservoirs were increased in size and reconfigured from the design presented in Alternative 5.

Component VV5. Palm Beach County Agricultural Reserve Reservoir (1660 acres at 6 ft. maximum depth) with Aquifer Storage and Recovery wells, 15, 5-MGD wells. Purpose: increase regional water resources in central and southern Palm Beach County by capturing and storing water currently discharged to tide to be used to maintain canal stages during the dry season.

Component WW5. C-111N Spreader Canal in Miami-Dade County. Purpose: reduce wet season flows in C-111, improve deliveries to Model Lands and Southern Glades and decrease potential flood risk in the lower south Miami-Dade area. C-111N was extended east of Card Sound Road.

Component XX5. C-111N Spreader Canal in Miami-Dade County. Purpose: reduce wet season flows in C-111, improve deliveries to Model Lands and Southern Glades and decrease potential flood risk in the lower south Miami-Dade area. C-111N was extended east of Card Sound Road.

Component YY4. Divert Water Conservation Area 2 flows to Northeast Shark River Slough or Central Lake Belt Storage in Broward County. Purpose: capture excess water in Water Conservation Area 2B (WCA 2B) to reduce stages above targets and to divert water through improved L-37 and L-33 borrow canals to meet the following prioritized demands 1) Northeast Shark River Slough (NESRS), or 2) Central Lake Belt Area for future delivery to NESRS, 3) to Snapper Creek and 4) to maintain Dade-Broward levee borrow canal at elevation 5.0 feet NGVD.

Component ZZ5. Divert Water Conservation Area 3A and 3B flows to Central Lake Belt Storage Area. Purpose: capture excess water above target stages in Water Conservation Area 3A and 3B and divert it through modified structures at S-9 and S-31 to the Central Lake Belt Storage Area via the L-33 borrow canal.

Component AAA6. Lower East Coast Utility Water Conservation. Purpose: reduce the public water supply demands through the full implementation of the SFWMD's current mandatory water conservation program.

Component BBB6. South Miami-Dade County Reuse (South District Reclaimed Water Treatment Plant). Purpose: augment water supply to the South Biscayne Bay and Coastal Wetlands Enhancement Project to restore overland flow in the coastal area, recharge groundwater to enhance groundwater discharge to Biscayne Bay and provide saltwater intrusion benefits to the southern part of Miami-Dade County through the use of superiorly treated reclaimed water from the South District Wastewater Treatment Plant. Modified from Alternative 5 to send flows northward in L-31E and L-31E extension towards C-100.

Component CCC6. Big Cypress/ L-28 Interceptor Modifications. Purpose: alleviate over-drainage in Northeast Big Cypress, Kissimmee Billy and Mullet Slough area, ensure applicable water quality treatment and restore sheetflow to wetland areas in northeast Big Cypress Addition. Modified from Alternative 5 to allow for compliance with the Seminole Tribe's Conceptual Water Conservation System master plan.

Component DDD5. Caloosahatchee Backpumping with Stormwater Treatment Area. Purpose: increase the regional water resources by capturing excess C-43 basin runoff and diverting it into Lake Okeechobee after treatment through a stormwater treatment area when storage is available in the Lake.

Component EEE5. Flows to Eastern Water Conservation Area 3B from Central Lake Belt Storage Area. Purpose: capture excess surface water and seepage from

Water Conservation Areas (WCA) 2B, 3A and 3B, store them in the Central Lake Belt Storage Area and deliver them to eastern WCA 3B during dryouts.

Component FFF5. Biscayne Bay Coastal Canals. Purpose: maintain higher stages in the C-102 and C-103 Canals for urban and environmental water supply. A proposed borrow canal will interconnect the downstream reaches of the C-102 and C-103 Canals.

Component GGG. C-51 and Southern L-8 Reservoir. Not included in this Alternative.

Component HHH. West Miami-Dade Reuse. Not included in this Alternative.

A3.4 ALTERNATIVE D

Alternative D is the fourth of four alternatives (Alternatives A – D) that were evaluated and compared by the Alternative Evaluation Team for the technically preferred alternative. Alternative D enhances the performance of Alternative C by modifying or adding features that are considered to have the potential to solve system-wide problems identified by the Alternative Evaluation Team. Many of the components developed for Alternatives A, B or C have not been modified and are included as part of Alternative D.

A3.4.1 Summary of Alternative A by Geographic Regions

The following is a summary of the components which have either changed from Alternative C or been added in Alternative D, grouped by region.

A3.4.1.3 Lake Okeechobee

(No changes in this area as compared to Alternative C.)

A3.4.1.4 Everglades Agricultural Area

(No changes in this area as compared to Alternative C.)

A3.4.1.5 Water Conservation Areas And Everglades National Park

- Decompartmentalization of Water Conservation Area 3 was increased over Alternative C with the removal of the L-28 Tieback Levee.

A3.4.1.6 Other Natural Systems

(No changes in this area as compared to Alternative C.)

A3.4.1.7 Lower East Coast

- The C-51 Regional Groundwater Aquifer Storage and Recovery capacity was reduced from Alternative C and the Hillsboro Canal Basin Regional Aquifer Storage and Recovery capacity was relocated to the Site 1 Impoundment.

- The L-8 Project was modified to include a storage reservoir and increase the ASR capacity to improve hydropatterns in the Loxahatchee Slough, increase base flows to the Northwest Fork of the Loxahatchee River, provide flood peak attenuation to the C-51 and southern L-8 basins and increase regional water supplies.

A3.4.1.8 Water Preserve Areas

- The Site 1 Impoundment was increased in size and additional ASR capacity was added to store additional fresh water which would have been lost to tide; thereby increasing regional water resources.

- The Bird Drive Recharge Area was modified to include the introduction of the West Dade Reuse water and the outflows were re-prioritized.

- The North Lake Belt Storage Area outflows were re-prioritized.

- The Central Lake Belt Storage Area and the Palm Beach County Agricultural Reserve Reservoir were modified to store additional excess water which would have been lost to tide thereby increasing the regional water resources.

- Storage in the southern L-8 basin was increased by 1,200 acres to provide estuarine benefits to the Lake Worth Lagoon, water supply benefits and to attenuate peak flood flows.

A3.4.2 List of Components in Alternative D

The following is a list of each component included in Alternative D along with a brief summary.

Component A6. A Storage Reservoir (20,000 acres at 10 ft. maximum depth) north of Lake Okeechobee. Purpose: incorporate climate-based inflow forecasting to increase the utilization of the reservoir to provide additional flood protection, water supply and environmental enhancement. Operation revised from Alternative 5.

Component B2. A Storage Reservoir (10,000 acres at 4 ft. maximum depth) in the St. Lucie basin. Purpose: capture local runoff from C-44 for flood attenuation, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary.

Component C6. Environmental Water Supply Deliveries to the St. Lucie Estuary. Purpose: provide freshwater flow to the St. Lucie Estuary to protect and restore more natural estuarine conditions. The time series of estuary target flows was revised from Alternative 5.

Component D5. A Storage Reservoir (20,000 acres at 8 ft. maximum depth) with Aquifer Storage and Recovery (44, 5-MGD wells) in the Caloosahatchee basin. Purpose: capture basin runoff and regulatory releases from Lake Okeechobee to provide water supply benefits, some flood attenuation and environmental water supply deliveries to the Caloosahatchee estuary. Operated in conjunction with DDD5.

Component E5. Environmental Water Supply Deliveries to the Caloosahatchee Estuary (operational change only). Purpose: provide freshwater deliveries to the Caloosahatchee Estuary to establish desirable salinity at locations of key estuarine biota. Operational target flow at S-79 revised in Alternative 5.

Component F3. Current Lake Okeechobee Regulation Schedule (elimination of all except Zone A [emergency] regulatory releases to the St. Lucie and Caloosahatchee Estuaries). Purpose: implement operating criteria for Lake Okeechobee that includes flood control, water supply (including releases to the Water Conservation Areas to meet estimated natural system needs) as well as Lake littoral zone and estuary protection.

Component G5. A Storage Reservoir (one 20,000 acre compartment at 6 ft. maximum depth for supplying EAA irrigation demands and two 20,000 acre compartments at 6 ft. maximum depth for supplying environmental demands) in the Everglades Agricultural Area with increased conveyance from Lake Okeechobee to the reservoir. Purpose: improve timing of environmental deliveries to the Water Conservation Areas including reducing damaging flood releases from the EAA to the Water Conservation Areas, reduce Lake Okeechobee regulatory releases to estuaries, meet supplemental agricultural irrigation demands and increase flood protection within the Everglades Agricultural Area. Conveyance capacity of the Miami and North New River Canals between Lake Okeechobee and the Storage Reservoirs are increased to convey additional Lake Okeechobee regulatory releases that would have otherwise been discharged to the Caloosahatchee and St. Lucie Estuaries. In Alternative 5, the two compartments were modified to operate as a dry storage areas with withdrawals being made down to 18” below ground level. It was also been subdivided into two 20,000-acre compartments to allow for more efficient use of the reservoir and for alternative uses of the compartments during dry times (ie. agriculture).

Component H6. Everglades Rain-Driven Operations. Purpose: improve timing and location of water depths in the Water Conservation Areas and Everglades National Park. Operational change from Alternative 5.

Component I. Improved Conveyance between Water Conservation Area 3B and Everglades National Park. Not included in this Alternative since L-29 is removed.

Component J. Plug L-67A borrow canal (between S-151 and Modified Water Delivery Structures S-345s). Not included in this Alternative.

Component K6. Water Preserve Areas / L-8 Project. Purpose: further reduce water supply restrictions in the Northern Palm Beach County Service Area by capturing more of the discharges from portions of the southern L-8, C-51 and C-17 basins in a western reservoir located north of the C-51 Canal, west of the L-8 borrow canal, and in increased local Aquifer Storage and Recovery facilities (50 MGD capacity). This water will be routed to the West Palm Beach Water Catchment Area. Intent is to increase regional water supply availability, provide pass through flow to enhance hydroperiods in Loxahatchee Slough, increase base flows to the Northwest Fork of the Loxahatchee River and provide some peak flood flow attenuation. Operated in conjunction with GGG6.

Component L3. Change Coastal Wellfields Operations in the Lower East Coast Service Area. Purpose: shift demands from eastern wellfields inland to western facilities away from the saltwater interface to reduce impact of salt water intrusion.

Component M6. Water Preserve Areas / Site 1 Impoundment (increased to 2460 acres at 6 ft. maximum depth) with Aquifer Storage and Recovery wells (increased to 30, 5-MGD wells) in Palm Beach County. Purpose: increase regional water resources and supplement water deliveries to the Hillsboro Canal during the dry-season.

Component N. Water Conservation Area 2B Levee Seepage Management. Not included in this Alternative.

Component O4. Water Conservation Area (WCA) 3A and 3B Levee Seepage Management. Purpose: reduce seepage from WCAs 3A and 3B and to improve hydropatterns within the Conservation Areas by allowing higher water levels in the borrow canals and longer inundation durations within the marsh areas that are located east of the WCAs and west of US Highway 27. Seepage from the WCAs and marshes will be collected and directed south into the Central Lake Belt Storage Area. This will maintain flood protection and the separation of seepage water from urban runoff originating in the C-11 Basin and separation of Lake Okeechobee water supply deliveries.

Component P. North New River Diversion Canal and Treatment Facility. Not included in this Alternative.

Component Q5. Water Preserve Areas / Western C-11 Diversion Impoundment and Canal (1600 acres of stormwater treatment area / impoundment and 2500 cfs diversion canal) in Broward County. Purpose: divert untreated runoff from western C-11 that is presently discharged into Water Conservation Area 3A through the C-11 Stormwater Treatment Area / Impoundment and then into the North Lake Belt Storage Area. Alternative 5 maintains the western C-11 Canal at elevation 3.0 ft. NGVD in order to improve groundwater conditions in the eastern C-11 basin.

Component R4. Water Preserve Areas / C-9 Stormwater Treatment Area / Impoundment (2500 acres at 4 ft. maximum depth) in Broward County. Purpose: provide treatment of water supply deliveries from the North Lake Belt Storage Area prior to deliveries to the C-9, C-6/C-7 and C-2/C-4 Canals, groundwater recharge within the basin and seepage control of Water Conservation Area 3 and buffer areas to the west.

Component S6. Central Lake Belt Storage Area (5200 acres with subterranean seepage barrier around the perimeter) in Miami-Dade County. Purpose: receive and store excess water from Water Conservation Area (WCA) 2B, 3A and 3B without groundwater seepage losses in this highly transmissive region. The stored water will be provided based on priority to 1) Northeast Shark River Slough, 2) Water Conservation Area 3B and 3) to supply flows to Biscayne Bay when available. Changes from Alternative 5 include increasing the above ground storage height to 16 ft. and reprioritizing outflows.

Component T6. C-4 Structures (2) in Miami-Dade County. Purpose: maintain higher water levels in the C-4 Canal to reduce seepage losses from the Pennsuco Wetlands and areas west of the Dade-Broward Levee and reduce deliveries from Lake Okeechobee and the Water Conservation Areas by diverting dry season stormwater flows into the C-2 Canal to increase recharge to several nearby coastal wellfields.

Component U6. Water Preserve Areas / Bird Drive Recharge Area (2877 acres at 4 ft. maximum depth) in Miami-Dade County. Purpose: provide flood peak attenuation by capturing runoff from western C-4 basin and pumping it to the Bird Drive Recharge Area, enhance groundwater recharge and reduce seepage from the Everglades National Park buffer areas by increasing water table elevations east of Krome Ave. with the introduction of inflows from the West Miami-Dade Wastewater

Treatment Plant (new from Alternative 5). The facility will also provide water supply deliveries to the South Dade Conveyance System and potentially to Northeast Shark River Slough.

Component V4. L-31N Levee Improvements for Seepage Management in Miami-Dade County with additional reduction of seepage in the wet season. Purpose: manage levee seepage along the eastern edge (L-31N) of Everglades National Park to eliminate losses to the East Coast. In Alternative 4, an additional feature was added to reduce all wet-season seepage/ground water flows to the east to help restore hydropatterns in Everglades National Park. (refer to Component FF4)

Component W2. Taylor Creek / Nubbin Slough Storage and Treatment Area (5000-acre storage area at 10 ft. maximum depth and 5000 acre stormwater treatment area at 4 ft. maximum depth) in Okeechobee and St. Lucie Counties. Purpose: provide flood protection, water quality treatment, estuary protection and water supply benefits.

Component X6. Water Preserve Areas / C-17 Backpumping in North Palm Beach Service Area (550-acre stormwater treatment area at 4 ft. maximum depth). Purpose: increase regional water resources to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-17 basin (which would otherwise be sent to tide) to the West Palm Beach Water Catchment Area and enhance hydroperiods in the Loxahatchee Slough. Delivery route to the stormwater treatment area revised and operational changes made from Alternative 5.

Component Y6. Water Preserve Areas / C-51 Backpumping to Water Catchment Area in Palm Beach County (600-acre stormwater treatment area at 4 ft. maximum depth). Purpose: increase regional water resources to reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-51 West basin (which would otherwise be sent to tide) to the West Palm Beach Water Catchment Area and enhance hydroperiods in Loxahatchee Slough. Operational changes made to the stormwater treatment area as compared to Alternative 5.

Component AA3. Additional S-345 Structures in L-67A in Water Conservation Area 3B. Purpose: improve conveyance to Water Conservation Area (WCA) 3B through the L-67 levee system to help in re-establishing NSM-like hydroperiods and hydropatterns in WCA 3B and Northeast Shark River Slough.

Component BB5. Dade-Broward Levee / Pennsuco Wetlands in Miami-Dade County. Purpose: reduce seepage to the east from the Pennsuco wetlands and southern Water Conservation Area 3B, enhance hydroperiods in the Pennsuco and enhance recharge to Miami-Dade County's NW wellfield. Alternative 5 recharged the Dade-Broward Levee canal with deliveries from Lake Okeechobee and the Water Conservation Areas.

Component CC6. Broward County Secondary Canal System. Purpose: increase pump capacity of existing facilities (from the 2050 Base Case) and construct additional canal improvements and pump facilities for the Broward County Secondary Canal System to provide additional recharge to wellfields located in central and southern coastal Broward County, stabilize the salt water interface and reduce discharges to tide. The groundwater table and recharge to the aquifer were improved from Alternative 5 by modifying secondary canals in the C-10 and C-12 basins.

Component DD5. Revised Holey Land Operation Plan (based on rain-driven operations) in Palm Beach County. Purpose: improve timing and location of water depths within the Holey Land Wildlife Management Area based on rain-driven operations. Operational change only for Alternative 5.

Component EE5. Modified Rotenberger Operation Plan (based on rain-driven operations) in Palm Beach County. Purpose: improve timing and location of water depths within the Rotenberger Wildlife Management Area based on rain-driven operations. Operational change only for Alternative 5.

Component FF4. Construction of S-356 A & B Structures and relocation of a portion of L-31N in Miami-Dade County. Purpose: improve deliveries to Northeast Shark River Slough in Everglades National Park and reduce seepage to Lower East Coast Service Area 3.

Component GG4. Lake Okeechobee Aquifer Storage and Recovery (200,5-MGD wells) along the lake peripheral levee. Purpose: utilize climate-based operational rules for the aquifer storage and recovery wells to provide additional regional storage while reducing both evapotranspiration losses and the amount of land removed from current land use (e.g. agriculture) that would normally be associated with construction and operation of above-ground storage facilities (reservoirs); increase the Lake's water storage capability to better meet regional water supply demands for agriculture, Lower East Coast urban areas, and the Everglades; manage a portion of regulatory releases from the Lake primarily to improve Everglades hydropatterns, meet environmental targets within the Water Conservation Areas (WCAs), and meet supplemental water supply demands of the Lower East Coast; reduce harmful regulatory discharges to the St. Lucie and Caloosahatchee estuaries; and maintain existing level of flood protection.

Component HH3. Operation Change of S-343 A and B (closed during the January to June time period) in Miami-Dade County. Purpose: reduce the potential adverse effects on the nesting season of the Cape Sable Seaside Sparrow due to high water levels, the S-343 A and B structures will be closed during the January to June time period.

Component II3. Pump Station G-404 Modification in Palm Beach County. Purpose: increase the capacity of proposed Everglades Construction Project pump station G-404 from 1000 cfs to 2000 cfs to improve the hydropattern restoration in the northwest corner of Water Conservation Area (WCA) 3A and increase the amount of water available in the west-central region of WCA 3A to reduce dry out periods.

Component JJ. Loxahatchee National Wildlife Refuge Rainfall-driven Operations. Not included in this Alternative.

Component KK4. Loxahatchee National Wildlife Refuge Internal Canal Structures. Purpose: improve timing and location of water depths in the Refuge by keeping the borrow canal structures closed except to pass Stormwater Treatment Areas 1 East and 1 West outflow and water supply deliveries.

Component LL6. C-51 Regional Groundwater Aquifer Storage and Recovery (34 well clusters, total injection and recovery capacity is 170 MGD) in Palm Beach County. Purpose: increase regional water resources by capturing and storing excess water during wet periods and recover the water for utilization during dry periods. ASR capacity reduced from 54 well clusters in Alternative 5 to 34 well clusters.

Component MM. Hillsboro Canal Basin Regional Groundwater Aquifer Storage and Recovery. Not included in this Alternative.

Component NN. North New River Regional Groundwater Aquifer Storage and Recovery. Not included in this Alternative.

Component OO4. Modification to South Dade Conveyance System in Southern Portion of L-31N and C-111. Purpose: modify C-111 Canal operations to improve deliveries to Everglades National Park and decrease potential flood risk in the lower east coast service area.

Component PP. Backpumping of the C-7 Basin to the Central Lake Belt Storage System via the C-6 Canal. Not included in this Alternative.

Component QQ6. Decompartmentalization of Water Conservation Area 3. Purpose: remove most flow obstructions to achieve unconstrained or passive flow between Water Conservation Areas 3A and 3B and Northeast Shark River Slough and reestablish the ecologic and hydrologic connection between these areas. Alternative D adds the removal of the L-28 Tieback Levee.

Component RR4. Flow to Central Water Conservation Area 3A. Purpose: increase depths and extend hydroperiods in central Water Conservation Area 3A by relocating the S-140 pump discharge approximately 8 miles south and increasing the capacity to 2000 cfs.

Component SS4. Reroute Miami-Dade County Water Supply Deliveries. Purpose: reroute water supply deliveries made to Miami-Dade County from the Miami and Tamiami Canals and Water Conservation Area 3 (WCA 3) to the North New River Canal due to the backfilling of the Miami Canal as part of the decompartmentalization of WCA 3.

Component TT. Decompartmentalization of Water Conservation Area 2. Not included in this Alternative.

Component UU6. Storage Reservoirs (20,200 acres at 8 ft. maximum depth and 15,000 acres at 2 ft. maximum depth) in Martin and St. Lucie Counties. Purpose: capture local runoff from the C-23, 24, and Northfork and Southfork Basins of the St. Lucie River Estuary for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. The reservoirs were increased in size and reconfigured from the design presented in Alternative 5.

Component VV6. Palm Beach County Agricultural Reserve Reservoir (1660 acres at 12 ft. maximum depth) with Aquifer Storage and Recovery wells, 15, 5-MGD wells. Purpose: increase regional water resources in central and southern Palm Beach County by capturing and storing water currently discharged to tide to be used to maintain canal stages during the dry season. The reservoir depth was increased to 12 ft. in Alternative D.

Component WW5. C-111N Spreader Canal in Miami-Dade County. Purpose: reduce wet season flows in C-111, improve deliveries to Model Lands and Southern Glades and decrease potential flood risk in the lower south Miami-Dade area. C-111N was extended east of Card Sound Road.

Component XX6. North Lake Belt Storage Area (4500 acres with subterranean seepage barrier around the perimeter) in Miami-Dade County. Purpose: increase regional water resources by capturing a greater portion of runoff from western C-6, western C-11 and C-9 basins in the in-ground storage area without groundwater seepage losses in this highly transmissive region and without concerns of ground water contamination from untreated runoff. The stored water will be used to maintain stages during the dry season in the C-9, C-6, C-7, C-4 and C-2 Canals. Alternative D revises the priority of water deliveries to include Biscayne Bay.

Component YY4. Divert Water Conservation Area 2 flows to Northeast Shark River Slough or Central Lake Belt Storage in Broward County. Purpose: capture excess water in Water Conservation Area 2B (WCA 2B) to reduce stages above desired target levels and to divert water through improved L-37 and L-33 borrow canals to the following prioritized locations1) North East Shark River Slough to meet targets, or 2) Central Lake Belt Storage Area.

Component ZZ5. Divert Water Conservation Area 3A and 3B flows to Central Lake Belt Storage Area. Purpose: capture excess water above target stages in Water Conservation Area 3A and 3B and divert it through a new gravity structure at S-9 and a modified structure at S-31 to the Central Lake Belt Storage Area via the L-33 borrow canal.

Component AAA6. Lower East Coast Utility Water Conservation. Purpose: reduce the public water supply demands through the full implementation of the SFWMD's current mandatory water conservation program.

Component BBB6. South Miami-Dade County Reuse (South District Reclaimed Water Treatment Plant). Purpose: augment water supply to the South Biscayne Bay and Coastal Wetlands Enhancement Project to restore overland flow in the coastal area, recharge groundwater to enhance groundwater discharge to Biscayne Bay and provide saltwater intrusion benefits to the southern part of Miami-Dade County through the use of superiorly treated reclaimed water from the South District Wastewater Treatment Plant. Alternative D sends flows northward in L-31E and L-31E extension towards C-100.

Component CCC6. Big Cypress/ L-28 Interceptor Modifications. Purpose: alleviate over-drainage in Northeast Big Cypress, Kissimmee Billy and Mullet Slough area, ensure applicable water quality treatment and restore sheetflow to wetland areas in northeast Big Cypress Addition. Alternative D allows for compliance with the Seminole Tribe's Conceptual Water Conservation System master plan.

Component DDD5. Caloosahatchee Backpumping with Stormwater Treatment Area. Purpose: increase the regional water resources by capturing excess C-43 basin runoff and diverting it into Lake Okeechobee after treatment through a stormwater treatment area when storage capacity is available in the Lake.

Component EEE5. Flows to Eastern Water Conservation Area 3B from Central Lake Belt Storage Area. Purpose: capture excess surface water and seepage from Water Conservation Areas (WCA) 2B, 3A and 3B, store them in the Central Lake Belt Storage Area and deliver them to eastern WCA 3B, as needed, during dryouts.

Component FFF5. Biscayne Bay Coastal Canals. Purpose: better maintain dry season stages in the C-102 and C-103 Canals for urban and environmental water supply. A proposed borrow canal will interconnect the downstream reaches of the C-102 and C-103 Canals.

Component GGG6. C-51 and Southern L-8 Reservoir (1200 acres with 40 ft. of working storage depth) in Palm Beach County. Purpose: reduce the number, magnitude and volume of discharges to the Lake Worth Lagoon, provide water supply deliveries to the Northwest Fork of the Loxahatchee River, Lake Worth Drainage District and the West Palm Beach Water Catchment Area, and provide flood peak attenuation to the C-51 and southern L-8 basins.

Component HHH6. West Miami-Dade Reuse. Purpose: enhance groundwater recharge to the Bird Drive Recharge Area, and to provide water supplies to the South Dade Conveyance System and potentially to Northeast Shark River Slough.

APPENDIX A4

DESCRIPTION OF ALTERNATIVE D-13R

TABLE OF CONTENTS

DESCRIPTION OF ALTERNATIVE D-13R....................1
Component A6_D13R - North of Lake Okeechobee Storage Reservoir 1

Component NN3 - (not included in this Alternative) 32
Component OO4 - Modification to South Dade Conveyance System in Southern Portion of L-31N and C-111 32
Component PP3 - (not included in this Alternative).................... 32
Component QQ6_D13R - Decompartmentalization of Water Conservation Area 3.................... 32
Component RR4 - Flow to Central Water Conservation Area 3A (WCA 3A).................... 34
Component SS4 - Reroute Miami-Dade County Water Supply Deliveries 35
Component TT4 - (not included in this Alternative) 35
Component UU6_D13R - C-23, C-24, 25 and Northfork and Southfork Basins Storage Reservoirs 35
Component VV6 - Palm Beach County Agricultural Reserve Reservoir 36

Component WW5 - C-111N Spreader Canal 37
Component XX6 - North Lake Belt Storage Area..... 38
Component YY4 - Divert WCA2 flows to Central Lake Belt Storage..... 40
Component ZZ5 - Divert WCA 3 flows to Central Lake Belt Storage Area 41
Component AAA6 - Lower East Coast Water Conservation..... 41
Component BBB6 - South Miami-Dade County..... 42
Component CCC6 - Big Cypress/L-28 Interceptor Modifications 43
Component DDD5 - Caloosahatchee Backpumping with Stormwater Treatment Area (STA) 45
Component EEE5 - Flows to Eastern Water Conservation Area..... 46
Component FFF5 - Biscayne Bay Coastal Canals..... 47
Component GGG6 - C-51 and Southern L-8 Reservoir 47
Component HHH6 - West Miami-Dade Reuse 49

APPENDIX A4
DESCRIPTION OF ALTERNATIVE D-13R

Alternative D13-R is the plan selected by the Restudy Team as the Initial Draft Plan. This plan is comprised of forty-nine operational and structural features that the are referred to as components. Together, these forty-nine components make the Initial Draft Plan; it is a Comprehensive Plan that addresses many of the water resources problems of south Florida. This Section of the Plan Formulation Appendix includes a description of each of the components that make up the Initial Draft Plan. At the end of this Section is a series of figures and maps to aid the reader in understanding the conceptual features of the Initial Draft Plan. However, not all components have been mapped due to uncertainty in site location.

Component A6 - D13R - North of Lake Okeechobee Storage Reservoir

Study Region: Kissimmee River

Map: This component is not mapped due to uncertainty in site location

Purpose: To increase the capacity of the hydrologic system to better meet the water management objectives associated with flood protection, water supply and environmental enhancement. The additional water storage capacity in the reservoir and stormwater treatment area allows for greater detention of water during wet periods for subsequent use during dry periods. It is also anticipated that this increased storage capacity will shorten the duration and frequency of both high water levels in Lake Okeechobee that are stressful to the Lake littoral ecosystems, and large discharges from the Lake that are disruptive to the downstream estuary ecosystems.

Operation: Water from Lake Okeechobee is to be pumped into the north storage reservoir when the climate-based inflow forecast projects that the Lake water level will rise significantly above those levels that are desirable for the Lake littoral zone (14.35 feet - 14.75 feet NGVD; Figure 1). During the dry season, flows will be allowed back to the Lake from the reservoir through the stormwater treatment area when the Lake level is projected to fall to within three-quarters of a foot of the supply-side management line in the same dry season, or below 11.75 feet NGVD in the upcoming wet season. During the wet season, flow is allowed from the reservoir through the stormwater treatment area to the Lake when climate-based inflow forecast projects less than 1.5 million acre-feet of inflow during the next 6 months and the Lake water level is either currently below 11.75 feet NGVD or projected to be in supply-side management during the upcoming dry season. The reservoir is also filled with runoff from the Kissimmee River or the S-65E drainage basin when water is available.

Design:
Reservoir:
17,500 acres at 11.5 feet maximum depth
Inflow pump capacity = 4800 cfs
Outflow structure = 4800 cfs
Stormwater Treatment Area:
2,500 acres at 4.0 feet maximum depth
gravity flow outlet

Location: To be determined – Specific site not necessary for Water Management Model simulation. Counties could include Glades, Highlands, or Okeechobee.

Assumption and Related Considerations: Uncertainty in land availability.

Component B2 - Component Title: St. Lucie/C-44 Basin Storage Reservoir

Study Region: Upper East Coast

Map: This component is not mapped due to uncertainty in site location

Purpose: Storage reservoir to capture local runoff from C-44 Basin. The reservoir will be designed for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary.

Operation:
Inflows from C-44 basin runoff (and only when Lake stage is > 14.5 feet NGVD)

Design:
10,000 acres at 4 feet maximum depth
Inflow pump capacity = 1,000 cfs
Outflow structure capacity = 800 cfs

Location: To be determined – Specific site not necessary for Water Management Model simulation. Counties include Martin.

Assumption and Related Considerations:
1) Uncertainty in land availability.
2) Potential water quality benefits by reducing nutrient loading to the estuary

Component C6 - Environmental Water Supply Deliveries to St. Lucie Estuary

Study Region: St. Lucie/C-44 Basin

Map: This component is not mapped.

Purpose: To provide freshwater deliveries to the St. Lucie Estuary to protect and restore more natural estuarine conditions. The time series of estuary target flows were developed to respond to desirable estuarine conditions.

Operation: Deliver desired estuary target discharge through S-80 from the reservoir when water is available or from Lake Okeechobee when the Lake stage exceeds 11.5 feet NGVD.

Design: Operational change only

Location: C-44 and St. Lucie Estuary. Counties include: Martin and St. Lucie.

Assumption and Related Considerations: Estuary deliveries are based on maintaining salinity conditions in the estuary to support a range of aquatic vegetation seagrass, invertebrates, and fish communities.

Component D5 - Caloosahatchee Basin Storage Reservoir(s) with Aquifer Storage and Recovery

Study Region: Caloosahatchee River

Map: This component is not mapped due to uncertainty in site location

Purpose: Storage reservoir(s) with Aquifer Storage and Recovery (ASR) to capture basin runoff and releases from Lake Okeechobee. These facilities will be designed for water supply benefits, some flood attenuation, and to provide environmental water supply deliveries to the Caloosahatchee estuary.

Operation: Excess runoff from the C-43 Basin and Lake Okeechobee flood control discharges will be captured by the proposed C-43 reservoir(s). Water from the reservoir(s) will be used to provide environmental deliveries to the Caloosahatchee Estuary, to meet demands in the Caloosahatchee Basin and to inject water into the ASR wellfield for long-term (multi-season) storage. The source of water to be injected into the ASR facility is surficial ground water adjacent to the reservoir. Water from the ASR facilities will be used to meet environmental demand of the estuary and meet basin demands. Any estuarine demands not met by basin runoff, the reservoir and the ASR system will be met by Lake Okeechobee, as long as Lake

Stage is above 11.5 feet NGVD. Lake water is also used to meet the remaining basin demands subject to supply-side management.

The C-43 reservoir is operated in conjunction with Component DDD5, the Caloosahatchee Backpumping Facility, which includes an STA for water quality treatment. If the levels of water in the reservoir exceed 6.5 feet and Lake Okeechobee is below the pulse release zone (see Figure 1), then water is released and sent to the backpumping/treatment facility at 2000 cfs.

Design:
Reservoir(s) total of 20,000 acres at 8 feet maximum depth.
ASR wellfields total of 44, 5-MGD wells
Reservoir(s) Inflow pump capacity = 3,800 cfs
ASR inflow capacity = limited to 220 MGD
Reservoir(s) outflow structure capacity = 3,000 cfs
ASR outflow capacity = limited to 220 MGD

Location: To be determined -- Specific site not necessary for Water Management Model simulations. Counties include Hendry, Glades, or Lee.

Assumption and Related Considerations:
1) Uncertainty in land availability.
2) Potential water quality benefits by reducing nutrient loadings.
3) Raw water ASR injection permittable.
4) 70 percent recovery for injected ASR water.
5) Size of injection bubble not limited.
6) ASR facility sized to slightly exceed minimum flows to estuary.

Component E5 - Environmental Water Supply Deliveries to Caloosahatchee Estuary

Study Region: Caloosahatchee/C-43 Basin

Map: This component is not mapped.

Purpose: To provide freshwater deliveries to the Caloosahatchee Estuary to establish desirable salinity regimes at locations of key estuarine biota.

Operation: Deliver desired estuary target flow through S-79 in priority order, from basin runoff, from the C-43 storage reservoir, from the C-43 Basin ASR system and from Lake Okeechobee when the Lake stage exceeds 15 feet NGVD.

Design: Operational changes to assure that desirable salinity patterns will be achieved and at the same time makes some water available for capture and utilization in the regional system. The capture of the excess runoff is accomplished in by the Caloosahatchee Basin Reservoir and ASR system (Component D) and by Caloosahatchee Backpumping with Stormwater Treatment Area (Component DDD).

Location: C-43 and Caloosahatchee Estuary.

Assumption and Related Considerations: Estuary deliveries are made to maintain salinity conditions in the estuary that support a range of aquatic vegetation, seagrass, invertebrates and fish communities.

Component F3 - Lake Okeechobee Regulation Schedule

Study Region: Lake Okeechobee

Map: Refer to Figure 1

Purpose: Operating criteria for Lake Okeechobee that includes flood control, water supply (including releases to the Water Conservation Areas to meet estimated natural system needs), and Lake littoral zone and estuary protection.

Operation: Use current regulation schedule with the design modifications made in components A and GG and with the exception of eliminating all St. Lucie and Caloosahatchee regulatory discharges (except emergency releases - zone A, from Run 25).

Design: Operational changes only. Modify the regulation schedule by eliminating all but emergency discharges to both the St. Lucie and Caloosahatchee Estuaries.

Location: Within existing boundary of Lake Okeechobee
Counties: Glades, Hendry, Martin, Okeechobee and Palm Beach

Assumption and Related Considerations: It is assumed that the implementation of other project components will reduce the frequency of high Lake stage events therefore reducing the need for regulatory releases to the St. Lucie and Caloosahatchee Estuaries.

Component G6 - Everglades Agricultural Area Storage Reservoir

Study Region: Everglades Agricultural Area (EAA)

Map: This component is not mapped due to uncertainty in site location

Purpose: Storage reservoir improves timing of environmental deliveries to the Water Conservation Areas (WCA) including reducing damaging flood releases from the EAA to the Water Conservation Areas; reduces Lake Okeechobee regulatory releases to estuaries; meets supplemental agricultural irrigation demands; and increases flood protection within the Everglades Agricultural Area. Conveyance capacity of the Miami and North New River Canals between Lake Okeechobee and the storage reservoir(s) is increased to convey additional Lake Okeechobee flood control releases that would have otherwise been discharged to the Caloosahatchee and St. Lucie Estuaries. Conveyance capacity of the Bolles and Cross Canals between the Miami and Hillsboro Canals is increased to facilitate interbasin transfers for storage and flood protection.

Operation: Inflows are from Lake Okeechobee regulatory discharges and runoff from Miami and North New River and adjacent basins. The reservoir will be divided into three compartments.

Compartment 1: 20,000 acres, meets EAA irrigation demands only. The source of water is excess EAA runoff. Inlet capacities for excess runoff are 2700 and 2300 cfs, for the Miami Canal and the North New River Canal Basins, respectively. Outlet capacities for EAA demands are 3000 and 4400 cfs, for the Miami Canal and the North New River Canal Basins. Overflow to compartment 2 occurs when the depth of water approaches 6 feet maximum and Lake Okeechobee regulatory discharges are not occurring or impending. Excess EAA runoff is diverted to compartment 3 only if WCA-3A is too deep.

Compartment 2: 20,000 acres, meets environmental demands as a priority, but can supply a portion of EAA irrigation demands if environmental demands equal zero. The sources of water are overflow from compartment 1 and Lake Okeechobee regulatory releases including the weather forecasting to initiate storage usage. Compartment 2A will be operated as a dry storage reservoir and discharges made down to 18 inches below ground level.

Compartment 3: 20,000 acres, meets environmental demands as a priority. The sources of water are overflow from compartment 1 and 2A and Lake Okeechobee regulatory releases only during the extreme wet events. Compartment 3 will be operated as a dry storage reservoir and discharges made down to 18 inches below ground level.

The conveyance of the northern reaches of the Miami and North New River Canals in the EAA are tripled (200% increase) for Lake Okeechobee regulatory releases as in Alternative 3. Structures with a capacity of 4500 cfs for diversion of regulatory releases through the Miami Canal and 3000 cfs for diversion of regulatory releases through the North New River Canal are added to compartments 2 and 3. When the reservoir depth falls below 1.5 feet, Lake Okeechobee is used for meeting supplemental irrigation and environmental demands. The flows will be delivered to the Water Conservation Areas through Stormwater Treatment Area 3/4.

Design:
Compartment 1: 1-20,000 acre reservoir at 6 feet maximum depth
Inflow structure capacity: inflow pumps of 2700 cfs Miami Canal Basin and 2300 cfs North New River Canal Basin for diversion of EAA runoff

Outflow structure capacity:
To Everglades Agricultural Area: 1-3000 cfs structure to Miami Canal Basin and 1-4400 cfs structure to North New River and Hillsboro Basins (initially assumed to not constrain performance).

Compartment 2: 1-20,000-acre reservoir at 6 feet maximum depth
Inflow structure capacity: inflow pumps of 4500 cfs and 3000 cfs for diversion of Lake Okeechobee regulatory releases from the Miami Canal and the North New River Canal, respectively

Outflow structure capacity:
To Stormwater Treatment Area 3/4: 3600 cfs @ 6 feet head.
Increase in Miami, North New River and Bolles and Cross Canal capacities is 200%.
To Miami Canal: 4500 cfs
To North New River Canal: 3000 cfs

Compartment 3: 1-20,000-acre reservoir at 6 feet maximum depth
Inflow structure capacity: inflow pumps of 4500 cfs and 3000 cfs for diversion of Lake Okeechobee regulatory releases from the Miami Canal and the North New River Canal, respectively

Location: To be determined - conceptually located in Palm Beach County between Miami and North New River Canals for Water Management Model simulation purposes only.

Assumption and Related Considerations:

1) Land Availability.
2) Modifications to Stormwater Treatment Areas if needed for Everglades water deliveries to meet the appropriate water quality.

Component H6 - D13R - Everglades Rain-Driven Operations

Study Region: Water Conservation Areas and Everglades National Park

Map: This component is not mapped.

Purpose: Improve timing and location of water depths in the Water Conservation Areas (WCAs) and Everglades National Park (ENP).

The rain-driven operational concept is a basic shift from the current operational practice, which uses calendar-based regulation schedules for the WCAs. Regulation schedules, also referred to as flood-control schedules, typically specify the release rules for a WCA based on the water level at one or more key water level gages. Regulation schedules do not typically contain rules for importing water from an upstream source. The schedules also repeat every year and make no allowance for inter-annual variability. The rain-driven operational concept includes rules for importing and exporting water from the WCAs in order to mimic a desired target stage hydrograph at key locations within the Everglades system. The target stage hydrographs mimic an estimate of the more natural (pre-drainage Everglades) water level response to rainfall.

Operation: Note that for the description below, the term "trigger level" means the water level used to trigger action at an upstream or downstream structure. Trigger levels are related to the target stage hydrographs by simple offsets which typically range less than +/-1.0ft. There is usually one trigger level for the import rules; and two trigger levels associated with the exportation of water. The two export trigger levels define two release zones. The lower zone is a conditional release zone; so releases are made only if the downstream area has a "need". The upper zone is an unconditional release, or flood control, release zone; so releases are made in this zone even if the downstream area doesn't "need" the water.

WCA-1: No rain-driven operations (use 1995 interim regulation schedule)

WCA-2 Import Rules: Import water from Lake Okeechobee via STA-2 if water levels fall below trigger levels in northern WCA-2A (South Florida Water Management Model grid cell R45C28).

WCA-2 Export Rules:

a. Export water from WCA-2A to WCA-2B via S-144, S-145 & S-146, if levels at gage 2A-17 exceed trigger levels.

b. Export water from WCA-2A via the S-11's if levels at gage 2A-17 exceed triggers.

c. Export water from WCA-2B to ENP via new structures at south end of WCA-2B if levels at central WCA-2B (grid cell R36C30) exceed trigger levels.

WCA-3 Import Rules:

a. Import water from Everglades Agricultural Area (EAA) storage and/or Lake Okeechobee via STA-3/4 to:

(1) Northeast WCA-3A if levels fall below trigger levels at gage 3A-NE.

(2) Northwest WCA-3A (via L-5/L-4, S8, G404, and spreader along L-4) if levels fall below trigger levels at gage 3A-NW.

(3) Central WCA-3A, via an improved S-140 & a spreader along the southernmost ~8miles of L-28{north reach}, if levels fall below trigger levels at gage 3A-4.

b. Import water from WCA-2A via S-11's if levels fall below trigger levels at gage 3A-3 (and WCA-2 has excess water {levels at gage 2A-17 significantly exceed targets}).

WCA-3 Export Rules:

a. Export water from WCA-3A to WCA-3B via proposed L-67 weir structures if water levels upstream of weirs exceed their respective crest elevations (passive structures).

b. Export water from WCA-3A to WCA-3B via proposed S-345 and S-349 structures if water levels at grid cell R33C26 exceed trigger levels.

c. Export water from WCA-3A to Central Lakebelt storage area, via proposed gravity structure near S-9, if water levels at grid cell R26C33 exceed trigger levels.

d. Export water from WCA-3B to Central Lakebelt storage area, via S-31, if water levels at grid cell R30C27 exceed trigger levels.

ENP Import Rules:

a. Import water from WCA-3A via proposed S-345 and S-349 structures if the average of water levels at Northeast Shark River Slough (NESRS) gages, NESRS-1 and NESRS-2, falls below trigger levels.

b. Import water from Central Lakebelt storage via proposed S-356A&B structures if levels at G-1502 fall below trigger levels.

c. Import excess water from WCA-2B, via improved L-37 & L-33 canals and S-356A&B.

Design: Deliveries from upstream sources (EAA runoff, EAA storage area, and/or Lake Okeechobee) through the Stormwater Treatment Areas (STAs) prior to release into the WCAs. Distribution of STA outflow designed to improve hydropatterns. Flows to ENP from WCAs 3A and 3B are uncontrolled in this alternative since the S-355 and S-12 structures, L-29, and the L-29 borrow canal are removed to allow overland flow from WCAs 3A and 3B to ENP.

Location: Within the existing boundaries of the WCAs and ENP. Counties include: Broward, Dade, Monroe, and Palm Beach

Assumption and Related Considerations:

1) Consideration given to tree islands and minimum floor levels consistent with South Florida Water Management District's proposed minimum flows and levels for these areas.

2) Potential increases in hydropatterns in relatively overdrained areas (e.g., northern WCA-3A) and decreases in hydropatterns in deep water areas (e.g., southern WCA-3A).

Component I - (not included in this Alternative)

Component J - (not included in this Alternative)

Component K6 - L-8 Project

Study Region: Lower East Coast

Map: Refer to Component Map 1

Purpose: Reduce water supply restrictions in the Northern Palm Beach County Service Area by capturing more of the annual discharges from portions of the southern L-8, C-51 and C-17 Basins and route this water to the West Palm Beach Water Catchment Area. Intent is to increase water supply availability and provide pass through flow to enhance hydroperiods in Loxahatchee Slough and increase base flows to the Northwest Fork of the Loxahatchee River.

Operation: Capture excess L-8, C-51 and C-17 Basin water to meet urban water supply demands in the Northern Palm Beach County Service Area and enhance hydroperiods in the Loxahatchee Slough. Water would be diverted through the M-Canal to the Water Catchment Area. Stormwater treatment areas will be provided to meet all water quality standards required if necessary.

Design:
48,000 acre-feet reservoir as described in component GGG6. The reservoir covers an area of approximately 1200 acres and is located immediately west of the L-8 Canal and north of the C-51 Canal.

50 MGD Aquifer Storage and Recovery (ASR) to provide water during regionally triggered droughts and as a means of reducing withdrawals from the West Palm Beach Water Catchment Area when the water levels are substantially below the target hydrograph. The majority or all of the 50 MGD ASR well clusters will be located in the vicinity of the City of West Palm Beach Water Treatment Plant (Clear Lake). However for modeling purposes, the ASR wells were located in the West Palm Beach Water Catchment Area. During periods when the West Palm Beach Water Catchment Area is above 18.0 feet NGVD, an additional (above the flow rate required to supply the water treatment plant) 50 MGD (78 cfs) will be sent to Lake Mangonia for subsequent storage through the ASR clusters (surficial well discharging into a Floridan well). The ASR wells will provide water directly to Lake Mangonia when water levels in the West Palm Beach Water Catchment Area are within 0.2 feet of the level that triggers regional supply to the West Palm Beach Water Catchment Area.

Increase the pumping capacity from the L-8 Tieback into the M-canal to 300 cfs to increase the volume of water captured from the southern L-8 Canal and deliver it to the Water Catchment Area. This pump has dual purposes, 1) to capture L-8 Basin runoff when available and 2) to deliver regional deliveries when needed.

Assume that the Indian Trail Improvement District will adopt an operation plan which promotes water conservation by prioritizing discharge. In this operation excess storm water is first offered to the West Palm Beach Water Catchment Area through installation of 2 pumps (300 cfs and 200 cfs) and secondarily discharged through off peak releases to the C-51 Canal via the M-1 Canal. For this alternative pumping from Indian Trail Improvement District into the M-Canal for subsequent discharge into the West Palm Beach Water Catchment Area will be assumed to occur under the following conditions:

1) When the City of West Palm Beach Water Catchment Area has sufficient need for imported water as defined by being below 18.2 feet NGVD.
2) When water levels in the lower M-1 Basin exceed 14.0 feet NGVD during the wet season (June 1 through October 31) or 16.0 feet NGVD during the dry season (November 1 through May 31) the lower M-1 Basin may discharge up to 200 cfs for subsequent storage.
3) When water levels in the upper M-1 Basin exceed 15.0 feet NGVD during the wet season or 16.0 feet NGVD during the dry season) the upper M-1 Basin may discharge up to 300 cfs for subsequent storage.

Increase conveyance of the M-Canal between the pump and the West Palm Beach Water Catchment Area to accommodate the increased inflow from the L-8 Canal and the Indian Trail Improvement District.

Install a new structure in the south leg of C-18 just south of the west leg to facilitate better management of water levels and discharges from the Loxahatchee Slough. The new gravity structure would consist of a variable discharge up to 400 cfs and emergency overflow weirs.

50 cfs pump for water supply deliveries to utilities. A recharge canal may be improved to convey deliveries to utilities.

New culverts under Bee-Line Highway for up to 100 cfs deliveries to Loxahatchee Slough.

Eliminate ASR component described in the Future Without Project Condition.

Location: Southern L-8 Basin including the Indian Trail Improvement District, West Palm Beach Water Catchment Area, and the Loxahatchee Slough. Counties include Palm Beach.

Assumption and Related Considerations:
1) Should help maintain stages in the Loxahatchee Slough and reduce high discharges to the southwest fork of the Loxahatchee River.
2) Stormwater Treatment Area upstream of the Water Catchment Area may be needed to accommodate future degradation of water quality.
3) Secondary structures (recharge canals) may be needed downstream of the Water Catchment Area to provide water to achieve the desired result.

Component L3 - Change Coastal Wellfield Operations

Study Region: Lower East Coast

Map: This component is not mapped.

Purpose: Shift demands from eastern wellfields to western facilities away from the saltwater interface to reduce impact of salt water intrusion.

Operation: For coastal utilities in the Lower East Coast Service Area which are experiencing an increased threat of saltwater intrusion, demands will be shifted from the eastern facilities to the western facilities away from the saltwater interface. The volume shifted is dependent upon the degree of saltwater intrusion but is generally proportional to the increase in demands between the 1995 existing conditions and the 2050 future without project conditions unless otherwise noted.

Design: For this alternative the following utilities have a portion of their demands shifted inland and include Riviera Beach, Lake Worth, Lantana, Manalapan, Boca Raton, Hollywood (including Broward County 3B and 3C), Dania, Miramar, Broward County 3A, Hallandale and Florida City. Redistribution of demands for Lake Worth, Lantana, Manalapan, Boca Raton and Florida City are generally consistent with the Lower East Coast Water Supply Plan. For the City of Riviera Beach, demands will be shifted from the eastern facilities to the western facilities, with the western facilities absorbing the increased demand between the 1995 and 2050 conditions. For this alternative, the City of Miramar's eastern wellfield will be placed on standby and all demands will be met from the western wellfield. For the City of Hollywood, Hallandale, Dania, Broward County 3A, and Broward County 3B/3C all these wellfields will be placed on standby and the entire demand (with the exception of 4 MGD from the Floridan aquifer for Hollywood) will be met from the South Broward County Regional wellfield. Recharge to the Regional wellfield will be met through the existing canal system supplied from locally captured runoff from the C-9 Basin (Components R and S).

Location: Lower East Coast Service Area. Counties include: Broward, Miami-Dade and Palm Beach.

Assumption and Related Considerations: It is assumed that the western facilities of the individual utilities have sufficient capacity to meet the increased demands.

Component M6 - Site 1 Impoundment with Aquifer Storage and Recovery

Study Region: Lower East Coast

Map: Refer to Component Map 2

Purpose: Water supply storage reservoir to supplement water deliveries to the Hillsboro Canal during the dry-season.

Operation: The enlarged reservoir will be filled during the wet-season from excess water backpumped from the Hillsboro Canal. Water will be released back to the Hillsboro Canal to help maintain canal stages during the dry-season. If water is not available in the reservoir, existing rules for water delivery to this region will be applied. Aquifer Storage and Recovery (ASR) capacity is being increased to improve water supply during dry seasons and droughts. Fifteen (15) 5 MGD capacity ASR wells will be added for a total of thirty (30) ASR clusters for this alternative (total injection and recovery capacity is 150 MGD or about 230 cfs). Water will be injected into the ASR wells when stages in the impoundment are greater than 12.0 feet NGVD (0.5 feet of depth) The source of water to be injected is surficial ground water wells located adjacent to the reservoir. Water will be recovered from the ASR wells when stages in the Hillsboro Canal are less than 7.0 feet NGVD.

Design:
2460 acres with a maximum depth of 6 feet located north and south of the Hillsboro Canal. The portion of the canal that is located within the proposed reservoir will be incorporated into the reservoir.
Inflow pump capacity = 700 cfs and is relocated to the eastern end of the Hillsboro Canal.
Outflow structure capacity = 200 cfs @ 4 feet of head.
Emergency outflow structure = 700 cfs.
Thirty (30) – 5 MGD ASR wells (total capacity 150 MGD or about 230 cfs).

Location: The Water Preserve Area Land Suitability Analysis previously identified 2460-acre site. Counties include: Palm Beach

Assumption and Related Considerations:

1) Excess storage could be discharged to Water Conservation Area 2A if a treatment facility could be added to meet Everglades' water quality standards.

2) Based on results of the pilot project, ASR facilities maybe located along Hillsboro Canal
3) Recovery rate of 70 percent for water stored by ASR.

Component N - (not included in this Alternative)

Component O4 - Water Conservation Area 3A and 3B Levee Seepage Management

Study Region: Lower East Coast

Map: Refer to Component Map 4 and 5

Purpose: Reduce seepage from WCAs 3A and 3B to improve hydropatterns within the Conservation Areas by allowing higher water levels in the borrow canals and longer inundation durations within the marsh areas that are located east of the WCAs and west of US Highway 27. Seepage from the WCAs and marshes will be collected and directed south into the Central Lake Belt Storage Area. This will maintain flood protection and the separation of seepage water from urban runoff originating in the C-11 Basin and Lake Okeechobee water supply deliveries.

Operation: The L-37 and L-33 borrow canals will be held at higher stages as part of the WCA 3 seepage collection and conveyance system (Component YY). Seepage collected in the L-37 and L-33 borrow canals and from the marsh areas will be directed into the WCA 3 seepage collection and conveyance system and directed south into the Central Lake Belt Storage Area or directly to Northeast Shark River Slough.

Design: New levees will be constructed west of US Highway 27 from the North New River Canal to the Miami (C-6) Canal to separate seepage water from the urban runoff in the C-11 diversion canal (Component Q). The L-37 and L-33 borrow canals will be controlled at higher stages as will the marshes located east of the WCAs. A divide structure will be added to the C-11 Canal west of US Highway 27 to maintain the separation of seepage water from urban runoff. Water from C-11 west will be diverted to the North Lake Belt Storage Area.

Location: Seepage collected in borrow canals along the existing eastern protective levees adjacent to WCA 3. Divide structure located in C-11 Canal east of US Highway 27 in Broward County.

Assumption and Related Considerations: It is assumed that the seepage from the Water Conservation Areas meets the water quality standards necessary to achieve ecosystem restoration.

Component P - (not included in this Alternative)

Component Q5 - Western C-11 Diversion Impoundment and Diversion Canal

Study Region: Lower East Coast

Map: Refer to Component Map 4

Purpose: Divert untreated runoff from western C-11 that is presently discharged into Water Conservation Area 3A through the C-11 Stormwater Treatment Area / Impoundment to the North Lake Belt Storage Area.

Operation: Runoff in the western C-11 Canal that was previously backpumped into Water Conservation Area 3A will be diverted to the C-11 STA/Impoundment and then to North Lake Belt Storage Area (NLBSA). If storage capacity is not available in the impoundment or NLBSA, then the S-9 pump will be used for flood protection for the Western C-11 Basin, which pumps to WCA-3A. To improve groundwater elevations in the Eastern C-11 Basin, the S-9 seepage divide structure will be operated to maintain the Western C-11 Canal stage at elevation 3.0 feet NGVD.

Design:
2500 cfs diversion canal west of U.S. 27 between C-11 and C-9 and a 2500 cfs conveyance capacity improvements to the C-9 Canal between S-30 and the NLBSA.
Intermediate 2500 cfs pump station in the C-11 Canal to direct runoff to the C11 STA/impoundment.
1600 acre STA/Impoundment with a maximum depth of 4 feet.
Seepage collection canal and pump for C-11 STA/impoundment.
2200 cfs structure to discharge from the impoundment to C-11 west of US 27 to diversion canal.

Location: The diversion canal is located west of US-27 between C-11 and C-9 Canals. The C-11 STA/impoundment is located northeast of the intersection of US27 and C-11 Canal.
Counties: Broward, Miami-Dade

Assumption and Related Considerations:
1) Flood protection component for Florida Power and Light substation and mobile home park may be needed.
2) Telemetry systems will be required for all operable structures and pump stations.

Component R4 - C-9 Stormwater Treatment Area/Impoundment

Study Region: Lower East Coast

Map: Refer to Component Map 5

Purpose: Treatment of water supply deliveries from North Lake Belt Storage Area (NLBSA) to C-9, C-6/C-7 and C-2/C-4 Canals. NLBSA is used to capture runoff from western C-9 Basin and C-11 west by backpumping into the curtain walled reservoir area. The C-9 impoundment will provide treatment of runoff stored in North Lake Belt Storage Area, groundwater recharge within the basin and seepage control of WCA3 and buffer areas to the west.

Operation: Water supply deliveries from North Lake Belt Storage Area to C-9, C-6/C-7 and C-2/C-4 Canals will be pumped into the C-9 STA/impoundment for treatment of the stormwater runoff stored in the NLBSA. Seepage from C-9 impoundment will be collected and returned to the impoundment.

Design:
2500 acres with a maximum depth of 4 feet.
Inflow structure: 1000 cfs pump (see component XX North Lake Belt Storage Area).

Outflow structure: Gravity structure with 1000 cfs capacity at 4 foot head.
Discharge C-9 impoundment to C-9, C-6/C-7 and C-2/C-4 Canals for water supply deliveries.

Seepage Collection: 200 cfs recycled into the impoundment area.

Location: Site identified by Water Preserve Area Land Suitability Analysis
Counties: Broward

Assumption and Related Considerations:

1) Additional treatment facility needed if stored water is backpumped into Water Conservation Area 3A.
2) Telemetry systems will be required for all operable structures and pump stations

Component S6 - Central Lake Belt Storage Area

Study Region: Lower East Coast

Map: Refer to Component Map 6 and 6A

Purpose: In-ground reservoir to receive excess water from Water Conservation Areas (WCA) 2B, 3A and 3B. The Central Lake Belt Storage Area (CLBSA) is an in-ground reservoir with perimeter seepage barrier will allow storage of large quantities of water without groundwater seepage losses in this highly transmissive region. The water stored in CLBSA will be provided to:

1) Northeast Shark River Slough (NESRS),
2) Water Conservation Area 3B, and
3) to supply flows to Biscayne Bay when available.

Operation: Inflows from L-33 (see Component ZZ) is through a 1500 cfs pump. Inflow ceases when stages reach ~21.0 feet NGVD (16 feet above adjacent land elevation). Inflows from L-33 diverted to CLBSA.

Outflows for water deliveries are pumped through a polishing marsh cell prior delivery to NESRS via L-30 and a reconfigured L-31 N (see component U). Deliveries of water to NESRS to maintain inundation will occur when NESRS drys below trigger levels and target hydroperiods simulations call for NESRS to be inundated. CLBSA delivers water to WCA 3B through a polishing marsh cells via L-30 to inundate the eastern area of WCA 3B to a 6 inch depth when triggers call for deliveries. This delivery occurs when WCA 3B drys below 6 inches above ground and target hydroperiods simulations indicate inundation in WCA 3B. When available, outflows will be directed to Biscayne Bay through discharges to Snapper Creek at the Turnpike.

Supply from the reservoir can be withdrawn for stages down to –15 feet NGVD (up to 36 feet of working storage & maximum head on seepage barrier).

Design:
Reservoir: 5200 acres with subterranean seepage barrier around the perimeter to enable drawdown during dry periods and to prevent seepage losses.
STA: 640 acre Stormwater Treatment Area to serve as a polishing prior to discharging to the Everglades (if required)

Inflow Structures:

1500 cfs pump from the L-33 borrow canal.
500 cfs structure at S-9 pump station to gravity discharge from WCA 3A to L-33.
700 cfs structure (Existing S-31) for WCA 3B to CLBSA via C-6 Canal.

Outflow Structures:

800 cfs pump to polishing cell to make deliveries to NESRS and WCA 3B.
500 cfs pump off L-30 to deliver to WCA 3B.
300 cfs pump to make deliveries for Snapper Creek Canal

1100 cfs structure @ 0.5 feet head to provide regional system deliveries to Snapper Creek Canal via C-6 if CLBS is out of water.

Location: Reservoir would be located within the area proposed for rock mining by the Lake Belt Issue Team. It would be sited south of Miami Canal (C-6) and north of the Northwest Wellfield Delivery Canal to minimize impacts to the Northwest Wellfield. The feature is located in Miami-Dade County.

Assumption and Related Considerations:
1) No adverse effect of a subterranean wall on Miami-Dade County's Northwest Wellfield.
2) Treatment facility maybe needed.
3) All water quality considerations will be addressed regarding releases from the reservoir to the water supply wellfields.
4) Impacts on the cone of influence of the Northwest Wellfield and its effect on wetland mitigation around the wellfield.
5) Limestone Filter Treatment system within the Reservoir may be developed through use of compartmentalization of rockmining excavation pattern.
6) Telemetry systems will be required for all operable structures and pump stations.

Component T6 - C-4 Structures

Study Region: Lower East Coast

Map: This component is not mapped.

Purpose: Proposed structures (East and West) would provide two separate benefits. The West structure would control water levels in the C-4 Canal at higher elevation to reduce seepage losses from the Pennsuco Wetlands and areas to the west of the structure. The East structure would reduce regional system deliveries by diverting dry season stormwater flows to the C-2 Canal to increase recharge nearby in several coastal wellfields.

Operation: The West structure would maintain water levels at 6.5 feet NGVD for seepage control purposes and be capable of passing flood flows with a minimum of head loss and supplying water to the C-4 Basin to meet demands. The East structure would divert dry season stormwater flows from the western C-4 Basin to the C-2 Canal to recharge the wellfields in the eastern C-2 Basin.

Design:
East Structure- Operable lift-gate with 6.5 feet NGVD overflow and approximately 400 cfs capacity (final design specifications will be determined in detailed design and hydrologic and hydraulic modeling in the future).

Location: Just downstream of the Dade-Broward Levee in C-4 Canal in Miami-Dade County.

West Structure- Operable lift-gate with 4.5 feet NGVD overflow and approximately 600 cfs capacity (final design specifications will be determined in detailed design and hydrologic and hydraulic modeling in the future).

Location: In C-4, just downstream of the confluence of the C-2 and C-4 Canals in Miami Dade County.

Assumption and Related Considerations:
1) Benefits to WCA-3B associated with improved C-4 seepage control are directly related to the proposed G-356 pumpage (Modified Water Deliveries).
2) Head losses across the proposed structures will not inhibit passing flood releases when necessary.
3) A pump may be associated with the West structure if back pumping the C-4 basin runoff to the Bird Drive Recharge Area becomes a component of the final alternative.

Component U6 - Bird Drive Recharge Area

Study Region: Lower East Coast

Map: Refer to Component Map 7

Purpose: Captures runoff from the western C-4 Basin and accepts inflows from the West Miami-Dade Wastewater Treatment Plant (WDWTP) (see component HHH) to recharge groundwater and reduce seepage from the Everglades National Park (ENP) buffer areas by increasing water table elevations east of Krome Ave. The facility will also provide C-4 flood peak attenuation and water supply deliveries to the South Dade Conveyance System (SDCS) and Northeast Shark River Slough.

Operation: Inflows from western C-4 Basin and the WDWTP will be pumped into the proposed Recharge Area. C-4 runoff in excess of 200 cfs will be discharged eastward. Inflows from the WDWTP will be continuous when the Recharge Area depth is equal to or less than 3' above ground. WDWTP discharges will be to deep injection wells if the depth is greater than 3 feet. A seepage management system will be operated around the east and southern perimeters of the Recharge Area. Recharge Area outflows will be prioritized to meet 1) groundwater recharge demands, 2) South Dade Conveyance System demands and 3) Northeast Shark River Slough demands, when supply is available. Regional system deliveries will also be routed through the seepage collection canal system of the Bird Drive

Recharge Area to the South Dade Conveyance System, which should reduce seepage from areas west of Krome Avenue.

Design:
2877 acres with a maximum depth of 4 feet.
Inflow structure: 200 cfs pump (to be resized as needed) from C-4.

Outflow structure:
Water supply: Gravity structure with 200 cfs capacity at 2 feet of head.
Seepage Collection System: up to 500 cfs pump to control seepage collection canal at 5.0 feet NGVD. Seepage is returned to Bird Drive Recharge Area.

Delivery System: 800 cfs pump to provide regional system deliveries to SDCS.
800 cfs canal capacity, in addition to the canal required for the Bird Drive seepage collection system, to pass the regional system deliveries to the South Dade Conveyance System.
5 miles of canal with 800 cfs capacity between Bird Drive seepage collection system to C-1W just east of Krome Ave.
Relocate S-338 east of Krome Ave. and delivery canal.

Location: Northwestern 4 sections in Bird Drive Basin. This site was identified during the Water Preserve Area Land Suitability Analysis.
Counties: Miami-Dade

Assumption and Related Considerations:
1) Treatment facility needed if seepage collected does not meet Everglades standards (component HHH).
2) Telemetry systems will be required for all operable structures and pump stations.
3) Flood protection in the basin will not be removed by the introduction of the West Miami-Dade Wastewater Treatment Plant inflows.
4) Regional-scale simulation using SFWMM 2mi X 2mi resolution is rather coarse for this local-scale feature. Specific land elevations in the Bird Drive Recharge Area are not precisely mimicked due to location and scale considerations in the SFWMM.

Component V4 - L-31N Improvements for Seepage Management

Study Region: Lower East Coast

Map: See Component Map 7

Purpose: Levee seepage management along the eastern edge (L-31N) of Everglades National Park to eliminate losses due to levee seepage to the East Coast. An additional feature has been added to reduce all wet-season seepage/ground water flows to the east. Feature will help restore hydropatterns in Everglades National Park.

Operation: 100% reduction in levee seepage flow from Everglades National Park year-round (to be achieved via Component FF4). Further 100% reduction in all groundwater flows during the wet-season. Bird Drive Recharge Area and North Lake Belt Storage Area will be used to recharge aquifers to the east.

Design:
Levee Seepage: Refer to Component FF4.

Wet-Season Ground Water Seepage: Distributed ground water wells adjacent to L-31N and return flows to Everglades National Park.
If needed, aquifer recharge will occur from deliveries from Bird Drive Recharge Area and North Lake Belt Storage Area.

Location: Along the existing eastern protective levee (L-31N) adjacent to Everglades National Park.
Counties: Miami-Dade

Component W2 - Taylor Creek/Nubbin Slough Storage and Treatment Area

Study Region: Kissimmee River

Map: This component is not mapped due to uncertainty of site location.

Purpose: Storage reservoir to provide flood protection, water quality treatment, estuary protection and water supply benefits.

Operation: Local runoff from the Taylor Creek/Nubbin Slough Basin to be pumped into a 5000-acre reservoir and then into a 5000-acre stormwater treatment area. The stormwater treatment area will reduce phosphorus concentrations in the runoff from approximately 0.58 mg/l to 0.117 mg/l. Treated water will then be pumped into Lake Okeechobee when the lake stage is falling and is at least 0.5 feet below the bottom pulse release zone.

Design:

Storage Reservoir:
5000-acres at 10 feet maximum depth
Inflow pump capacity 2500 cfs
Outflow pump capacity 1000 cfs

Stormwater Treatment Area:

5000-acres at 4 feet maximum depth
Inflow pump capacity 1000 cfs (same structure as reservoir outflow)
Outflow pump capacity 1000 cfs

Location: North of Lake Okeechobee
Counties: Okeechobee, St. Lucie, Martin

Assumption and Related Considerations:
1) Uncertainty in land availability.
2) Potential increase in stage duration of Lake Okeechobee.
3) Potential decrease in maximum stages of Lake Okeechobee.
Phosphorus inflow concentrations (flow-weighted) for the Taylor Creek/Nubbin Slough (S-191) Basin obtained from 5-year rolling averages (1991-1995).
4) Average annual discharge rates determined from the period of record 1965-1990.

Component X6 - C-17 Backpumping

Study Region: Lower East Coast

Map: Refer to Component Map 8

Purpose: Reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-17 Basin to the West Palm Beach Water Catchment Area and enhance hydroperiods in the Loxahatchee Slough.

Operation: Capture excess C-17 Canal water to meet urban water supply demands in North Palm Beach Service Area. Water would be diverted through existing canals to a stormwater treatment area and ultimately to the West Palm Beach Water Catchment Area.

Design: 200 cfs pump in the existing Northern Palm Beach County Improvement District Canal at its intersection with the Turnpike Canal to pull flows west and direct them south into the east Turnpike Canal.
Culvert under 45th Street (N/S) to connect the east Turnpike Canal.
150 cfs capacity culvert and pump from the Turnpike Canal to direct flows into the proposed stormwater treatment area.
550 acre stormwater treatment area at 4 feet maximum depth.
200 cfs Culvert to connect stormwater treatment area under Florida's Turnpike to allow nonrestrictive flows.
100 cfs gravity discharge structure into West Palm Beach Water Catchment Area..

Location: 550 acres located east of the West Palm Beach Water Catchment Area in Palm Beach County.

Assumption and Related Considerations:
(1) Water quality of C-17 water similar to C-51 water quality.
(2) Location of stormwater treatment area south of existing landfill.
(3) Improve conveyance in the Northern Palm Beach County Improvement District and Turnpike canals as necessary to pass flows.

Component Y6 - C-51 Backpumping to West Palm Beach Water Catchment Area

Study Region: Lower East Coast

Map Refer to Component Map 9

Purpose: Reduce water supply restrictions in Northern Palm Beach County Service Area by providing additional flows from the C-51 West Basin to the West Palm Beach Water Catchment Area and enhance hydroperiods in Loxahatchee Slough.

Operation: Capture excess C-51 Canal water to meet urban water supply demands in the North Palm Beach County Service Area. Water would be diverted from C-51 to a water treatment area and then into the Water Catchment Area.

Design: 600 acres at 4 feet maximum depth to be used for stormwater treatment.
Relocate the S-155A structure east of the intersection of Lake Worth Drainage District's E-1 Canal and the C-51 Canal and increase the capacity of S-155A as necessary to pass the additional inflows.
Improve conveyance between C-51 and the stormwater treatment area as necessary.
450 cfs inflow pump to stormwater treatment area.
100 cfs gravity discharge structure into West Palm Beach Water Catchment Area.

Location: 600 acres located southwest of West Palm Beach Water Catchment Area in Palm Beach County.

Assumption and Related Considerations:
(1) Uncertainty in land availability.
(2) Connection of L-8 and C-51 Basins.

Component Z - (not included in this Alternative)

Component AA6_D13R - Additional S-345 structures

Study Region: Water Conservation Areas

Map: Component Map

Purpose: The compartmentalization of the Water Conservation Areas (WCAs) has contributed to the loss of historic overland flows of the central Everglades slough system. This alteration of flows has resulted in temporal changes in hydropatterns and hydroperiods in the historic deepwater, central axis of the Shark River Slough system. This component adds conveyance to WCA 3B to help in re-establishing NSM-like hydroperiods and hydropatterns in WCA 3B and Northeast Shark River Slough.

Operation: The addition of a Northeast Shark River Slough rainfall trigger well and modification of western Shark River Slough Basin rainfall triggers deliver additional flows to the basin. Modification of L-67A decreases downstream conveyance to the S-12’s required to promote surface water flows to Water Conservation Area 3B and to Northeast Shark River Slough.

Design: Triple the total discharge capacity of S-345’s to 4500 cfs and the addition of associated plugs (S-349’s).

Location: The additional structures and plugs are to be spaced evenly along the southern half of L-67A.

Assumptions and related Considerations: The emphasis is in re-establishing the historic persistent, deep-water slough that existed in Water Conservation Area 3B and Northeast Shark River Slough.

Component BB5 - Dade Broward Levee / Pennsuco Wetlands

Study Region: Lower East Coast

Map: Refer to Component Map 6

Purpose: Reduce seepage to the east from the Pennsuco Wetlands and southern Water Conservation Area (WCA) 3B and enhance hydroperiods in the Pennsuco Wetlands. Also an improved Dade Broward Levee will enhance recharge to Miami-Dade County's Northwest Wellfield.

Operation: Improvements to the Dade-Broward Levee and associated conveyance system will reduce seepage losses to the east and provide recharge to Miami-Dade County's Northwest Wellfield. Seepage reduction will enhance hydroperiods in Pennsuco Wetlands and hold stage higher along southeastern WCA 3B. Recharging the conveyance features of the Dade-Broward Levee from the regional system deliveries provides recharge to Miami-Dade County's Northwest Wellfield. Treatment areas will be provided to meet all water quality standards required, if necessary.

Design:
Improve the Dade-Broward Levee:
Construct or improve existing levee to five-foot height with 2-foot top width while creating or improving existing conveyance to a capacity of up to 300 cfs.
150 cfs bypass structure and canal from C-6 Canal to Dade-Broward Levee to provide recharge from the regional system via the improved US Highway #27 borrow canal.
150 cfs gravity structure in the Dade-Broward Levee Borrow Channels due west of the southern end of the Northwest Wellfield.
Provide recharge for the Dade-Broward Levee from the regional system when the Conveyance Channel is below 5.0 feet NGVD at the C-4 structure located at the southern end of the Dade-Broward Levee.

Location: Dade-Broward Levee, Pennsuco Wetlands, WCA-3B, the Central Lake Belt Storage Area and Miami-Dade County's Northwest Wellfield.

Assumption and Related Considerations:
1) Wellfield protection must be maintain through recharge of acceptable water quality.
2) Secondary structures within the recharge canals may be needed to provide seepage reduction and wellfield recharge desired.

Component CC6 - Broward County Secondary Canal System

Study Region: Lower East Coast

Map: Refer to Component Map 10

Purpose: Increase pump capacity of existing facilities (from the 2050 Base Case) and construct additional canal and pump facilities for the Broward Secondary Canal System to provide recharge to wellfields located in central and southern coastal Broward County, stabilize the salt water interface and reduce storm water discharges to tide.

Operation: When excess water is available in the basin, water is pumped into the coastal canal systems to maintain canal stages. When local water is not sufficient to maintain canal stages, canals are maintained first from local sources and then from Lake Okeechobee and the Water Conservation Areas. Local sources include the Site 1 Impoundment (Component M) and the North Lake Belt Storage Area (Component XX).

Secondary canals maintained are 1) Broward County's C-2 from the Hillsboro Canal, 2) north secondary canal from C-13, 3) south secondary canal from C-13, 4)

Turnpike canal south from C-12 and 5) canal north from C-9 (added in Alternative 5) at levels discussed below.

Design:
Canal Conveyance: Improve canal conveyance of secondary canal located east of the Florida Turnpike from the C-12 Canal south to the Fort Lauderdale Golf and Country Club. Alternative 5 includes routing of water eastward to recharge the aquifer and help stabilize the saltwater interface at Ft. Lauderdale. Canal conveyance improvements may also be necessary for the Old Plantation Water Control District's eastern canal and in southeastern Broward County.

Pump capacities and maintenance levels:
100 cfs pump from Hillsboro to Broward County Secondary Canal (pump #1).
100 cfs pump from C-13 north to Broward County Secondary Canal.
100 cfs pump from C-13 south to Broward County Secondary Canal (pumps #2 and #3 described in the 2050 Base Case increased from 33 cfs to 100 cfs.
100 cfs pump on the east Turnpike canal withdrawing water from the C-12 Canal.
150 cfs pump on the C-9 Canal for maintaining water in southeastern Broward County.

Canal improvements and control elevations:
Improve east and west Turnpike canals and golf course lake system between C-12 and the North New River to achieve an average top width of 200 feet.
The Turnpike canals shall be maintained at a minimum elevation of 4.0 feet NGVD.
Improve canal/ lake systems in southeastern Broward County and the Orangebrook Golf Course to have an average canal top width of 30 feet.
The southeastern Broward Canal system shall be maintained at a minimum elevation of 2.5 feet NGVD.

Location: Broward County

Assumption and Related Considerations:
1) Canal levels are maintained from local basin runoff and sources. When water in not available from local sources, water is supplied to the canal systems from the regional system.
2) Canal operations do not impact existing flood control levels.

Component DD5 - Modified Holey Land Wildlife Management Area Water Management Operations

Study Region: Water Conservation Areas

Map: This component is not mapped.

Purpose: Improve timing and location of water depths within the Holey Land Wildlife Management Area based on rain-driven operations.

Operation: Rainfall-driven modified operational rules with NSM-like hydrologic conditions triggering deliveries. Rainfall-driven inflows are driven by target water depths in cell R45C18. Outflows are based on target water depths in cell R42C20. Alternative 5 truncates the peaks 1.5' above ground level and the troughs 1.0' below ground level.

Design: Operational changes only.

Location: Southern portion of the Everglades Agricultural Area, north of Water Conservation Area 3A in Palm Beach County.

Assumption and Related Considerations: Water deliveries are made to the Holey Land through G-200A or from Stormwater Treatment Areas 3 & 4 if Rotenberger Wildlife Management Area flows are insufficient. The deliveries are assumed to be of acceptable water quality from either Rotenberger Wildlife Management Area or Lake Okeechobee through Stormwater Treatment Areas 3 & 4.

Component EE5 - Modified Rotenberger Wildlife Management Area Water Management Operations

Study Region: Water Conservation Areas

Map: This component is not mapped.

Purpose: Improve timing and location of water depths within the Rotenberger Wildlife Management Area based on rain-driven operations.

Operation: Rainfall-driven operational rules with Natural System Model-like hydrologic conditions triggering deliveries. Rainfall-driven inflows and outflows are driven by the average of target water depths in South Florida Water Management Model grid cells R46C15 and R43C16. Alternative 5 truncates the peaks 1.5 feet above ground level and the troughs 1.0 feet below ground level.

Design: Operational changes only.

Location: Southern portion of the Everglades Agricultural Area, north of Water Conservation Area 3A in Palm Beach County.

Assumption and Related Considerations: Water deliveries made to Rotenberger Wildlife Management Area from Stormwater Treatment Area 5 are assumed to be of acceptable water quality.

Component FF4 - Construction of S-356 A & B Structures

Study Region: Lower East Coast

Map: Refer to Component Map 7

Purpose: To improve deliveries to Northeast Shark River Slough in Everglades National Park and reduce seepage to Lower East Coast Service Area 3.

Operation: Redirect S-357 outfall from L-31N to the mid-point of the Modified Water Deliveries (MWD) mitigation canal northwest of the 8.5 Square Mile Area. Operate new S-356 pumps to direct seepage collection from Water Conservation Areas and water deliveries from Central Lake Belt Storage Area to Northeast Shark River Slough.

Design:
Remove MWD S-356.
Relocate MWD S-357.
Add S-356 A & B Structures (900 cfs each) at locations along modified L-31N between G-211 and Tamiami Trail.
Reroute L-31N borrow canal to east side of buffer cell.
Relocate L-31N to east side of buffer cell.
Backfill portion of L-31N where levee moved.
5 foot levee along west side of existing lakes.

Location: L-31N along east side of Northeast Shark River Slough.
Counties: Miami-Dade

Assumption and Related Considerations:
1) Water Quality is not a problem
2) No adverse impacts to areas east of L-31N

Component GG4 - Lake Okeechobee Aquifer Storage and Recovery

Study Region: Lake Okeechobee

Map: Refer to Figure 1

Purpose: Provides additional regional storage while reducing both evapotranspiration losses and the amount of land removed from current land use

(e.g. agriculture) that would normally be associated with construction and operation of above-ground storage facilities (reservoirs);
Increase the Lake's water storage capability to better meet regional water supply demands for agriculture, Lower East Coast urban areas, and the Everglades;
Manage a portion of regulatory releases from the Lake primarily to improve Everglades hydropatterns, meet environmental targets within the Water Conservation Areas (WCAs), and meet supplemental water supply demands of the Lower East Coast;
Reduce harmful regulatory discharges to the St. Lucie and Caloosahatchee Estuaries;
Maintain existing level of flood protection.

Operation: Water from Lake Okeechobee is to be pumped into the Lake Aquifer Storage and Recovery (ASR) wells when the climate-based inflow forecast projects that the Lake water level will rise significantly above those levels that are desirable for the Lake littoral zone (15.25 - 14.85 feet NGVD; Figure 1). During the dry season, flow may be made back to the Lake from the ASR wells either when the Lake water level is projected to fall to within three-quarters of a foot of the supply-side management line the same dry season, or below 11.75 feet NGVD the upcoming wet season. During the wet season, flow is allowed from the ASR wells to the Lake when climate-based inflow forecast projects less than 1.5 million acre-feet of inflow during the next 6 months, and the Lake water level is either below 11.75 feet (NGVD) during the current wet season, or is projected to be in supply-side management during the upcoming dry season.

Design: 1000 MGD total: 200, 5-MGD ASR wells and associated infrastructure

Location: Glades and Okeechobee Counties

Assumption and Related Considerations:
1) Current United States Environmental Protection Agency and Florida Department of Environmental Protection regulations require that ASR source water meet primary drinking water standards before injection.
2) ASRs will have an approximate recovery rate of 70%, i.e. 30% of water injected to the deep wells is lost due to transmission (injection and recovery) and storage (mixing with deep aquifer saline water, migration of ASR storage flume) losses.

Component HH- (not included in this Alternative)

Component II3 - Pump Station G-404 Modification

Study Region: Everglades Agricultural Area (EAA)

Map: Refer to Component Map 15

Purpose: Increase the capacity of proposed Everglades Construction Project (ECP) pump station G-404 to improve the hydropattern restoration in the northwest corner of Water Conservation Area 3A (WCA 3A) and increase the amount of water available in the west-central region of WCA 3A to reduce dry out periods.

Operation: Pump the maximum Stormwater Treatment Area (STA) 3/4 treated discharge possible across the Miami Canal from the L-5 borrow canal to the L-4 borrow canal to the northwest corner of WCA 3A. The treated discharge will sheet flow across the northern reach of WCA 3A between the Miami Canal and L-28 and flow down the L-28 Canal through structure S-140. This additional water should improve the hydropattern restoration and reduce the number of dry out periods in the central region of WCA 3A. This diversion of water from the northeast section of WCA 3A should reduce the inundation duration and extreme high water depths in this sector of the water conservation area.

Design: Increase the capacity from 1000 cfs to 2000 cfs on this proposed vertical, axial flow, low head, high capacity pump station (may be slightly resized after further hydraulic analyses).

Location: Confluence of Miami Canal, L-5 Borrow Canal and the L-4 Borrow Canal north of the S-8 Pump Station.
Counties : Palm Beach

Assumption and Related Considerations:
1) Land Availability.
2) Compatibility with proposed G-404 design.
3) Modifications to the L-4 and L-5 borrow canals if needed to increase the conveyance capacities to handle the additional conveyance.
4) Preliminary analyses indicate the pump intake elevation for G-404 and S-8 should be about 8.0 feet NGVD to facilitate water supply deliveries west through G-404 and south through S-8.

Component JJ - (not included in this Alternative)

Component KK4 - Loxahatchee National Wildlife Refuge Internal Canal Structures

Study Region: Water Conservation Areas

Map: This component is not mapped.

Purpose: Improve timing and location of water depths in the Refuge.

Operation: Structures would remain closed except to pass Stormwater Treatment Area (STA) 1 East and STA – 1 West outflow and water supply deliveries.

Design:

(1) L-7 borrow canal structure: 1500 cfs gravity structure at 0.5 foot head.
(2) L-40 borrow canal structure: 1500 cfs gravity structure at 0.5 foot head.

Location: The L-7 structure is located at cell R28C50 in the L-7 borrow canal within the Loxahatchee National Wildlife Refuge. The L-40 structure is located at cell R34C50 in the L-40 borrow canal within the refuge.
Counties: Palm Beach

Assumptions and Related Considerations: STA discharges to the Loxahatchee National Wildlife Refuge are assumed to be of acceptable water quality.

Component LL6 - C-51 Regional Groundwater Aquifer Storage and Recovery

Study Region: Lower East Coast

Map: Refer to Component Map 1

Purpose: This is a regional groundwater aquifer storage and recovery (ASR) system which will capture and store excess water during wet periods and recover the water for utilization during dry periods. The ability to use the recovered water during dry periods will increase regional water resources.

Operation: Water will be captured and stored when water is being discharged out of S-155 to tide. Water will be recovered during dry periods based on canal elevations. Recoverable water is limited to 70 % of injected water.

Design: This component consists of 34 well clusters located along the West Palm Beach Canal (C-51 Canal), each being composed of two (2) surficial aquifer wells and one Upper Floridan aquifer ASR well. The surficial aquifer wells will each have a 2.5 MGD withdrawal capacity and be located in proximity to the canal so that the water withdrawn would result in the interception of water that would otherwise go to tide in wet periods. Each upper Floridan aquifer ASR well will have a capacity of 5 MGD (the total injection and recovery capacity of the ASR system is 170 MGD or about 264 cfs.) Water will be injected when stages in the C-51 Canal are above 8.0 feet NGVD. Water will be retrieved from the ASR wells when canal stages are below 7.8 feet NGVD. Recovered water will be discharged to the C-51 Canal.

Location: Along the C-51 Canal in eastern Palm Beach County east of U.S. Route 441.

Assumption and Related Considerations: It is assumed that groundwater ASR in proximity to the C-51 Canal is permittable without treatment.

Component MM4 - (not included in this Alternative)

Component NN3 - (not included in this Alternative)

Component OO4 - Modification to South Dade Conveyance System in Southern Portion of L-31N and C-111

Study Region: Lower East Coast

Map: This component is not mapped.

Purpose: To improve deliveries to Everglades National Park and decrease potential flood risk in the Lower East Coast Service Area.

Operation: Modify C-111 Canal operations by holding lower canal water levels by increasing pumping frequency.

Design:
S-332D at 500 cfs (consistent with Experimental Program for Water Deliveries to Everglades National Park)
Remove S-332B (consistent with recent C-111 detailed project designs)
Add 100 cfs to S-332C (keep total of S-332 A-D < 1200 cfs)
Remove S-332 pump station
Remove S-332D Tieback Canal which provides flow from C-111 to S-332.

Location: South Dade Conveyance System in Miami-Dade County.

Assumption and Related Considerations:
1) Will not cause adverse impacts to ENP and South Dade Agricultural Lands.
2) This component is dependent on Component FF.

Component PP3 - (not included in this Alternative)

Component QQ6_D13R - Decompartmentalization of Water Conservation Area 3

Study Region: Water Conservation Areas and Everglades National Park

Map: Refer to Component Map 17

Purpose: Remove most flow obstructions to achieve unconstrained or passive flow between Water Conservation Areas 3A and 3B and Northeast Shark River Slough and reestablish the ecological and hydrologic connection between these areas.

Operation: Rain-driven trigger gages in Northwest Shark River Slough similar to Alternative 3. Sheetflow to Everglades National Park (refer to Component H6_D13R for Everglades Rain-Driven Operations).

Design:

Structural Changes:
-Backfill the Miami Canal in Water Conservation Area 3 from the east coast protective levee to one to two miles south of the S-8 pump station to maintain flood discharge capability. Water supply deliveries previously made through the Miami Canal will be delivered through the North New River Canal, and improved US 27 borrow canal (see Component SS).
-Remove the L-68A levees (this feature is outside SFWMM model detail).
-Degrade the L-67C levee and backfill the adjacent borrow canal.
-Backfill the L-67A Canal from Tamiami Trail approximately 7.5 miles north.
-Relocate a single S-349 structure at the downstream end of L-67A Canal (upstream of the S-345 structures).
-Remove the L-29 Levee and Canal (south of WCA-3A and 3B) to restore sheetflow into Everglades National Park.
-Remove the L-28 and L-28 Tieback levees and borrow canals from L-28 Tieback south to L-29.
- Elevate Tamiami Trail (U.S. 41) through the installation of a series of bridges between L-31N and L-28 consist with conveyance capacities determined at I-75 and any increases required due to inflows downstream of I-75 and upstream of Tamiami Trail.
-Remove the S-344, S-343A and B and S-12 structures.
-Construct 8 passive weir structures along the entire length of L-67A to promote sheetflow during high flow conditions and locate the S-345s (component AA3) just downstream of the new termination of L-67A Canal.

Operational Changes:
1) Operate WCA-2A import trigger using only 2A-N gage as the trigger rather than using average of 2A-N and 2A-17 gages.
2) The time series target at 2A-N was truncated at 1.25 ft above and 0.5 ft below land surface elevation.
3) The time series target at 3A-NE was truncated at 1.0 ft above and 0.5 ft below land surface elevation.

4) S-345 operations are now based on triggers at R33C26 and the NESRS-1 and NESRS-2 gages (the 3A-4 gage is no longer used).
5) S-349 structure operations are the same as the S-345's operations.

Location: Within the existing boundaries of the Water Conservation Areas and Everglades National Park in Broward and Miami-Dade County.

Assumption and Related Considerations:
1) Potential increases in hydropatterns in dry areas and decrease in hydropatterns in deep water areas.
2) Tradeoff between water levels and hydroperiods in central and south central Water Conservation Area 3A and Everglades National Park.
3) Additional S-345s are needed to ensure that significant dry season flows into WCA-3B and ultimately Everglades National Park can be achieved.
4) Miccosukee Tribal Lands adjacent to L-29 and Tamiami Trail will not be impacted.

Component RR4 - Flow to Central Water Conservation Area 3A (WCA 3A)

Study Region: Water Conservation Areas

Map: Refer to Component Map 15

Purpose: To increase depths and extend hydroperiods in central WCA 3A.

Operation: Relocate pump station S-140 and distribute flows into central WCA 3A. Pump operation will be driven by target stages at the 3A-4 gage.

Design: Relocate S-140 pump station approximately 8 miles south of its current location and increase the capacity from 1300 cfs to 2000 cfs. A spreader system will be needed to distribute the S-140 discharge via sheetflow.

Location: Within the existing boundaries of the Water Conservation in Broward County.

Assumption and Related Considerations:
1) Potential increases in hydropatterns in dry areas and decrease in hydropatterns in deep water areas.
2) Tradeoff between water levels in indicator regions 18 and 17 in central WCA 3A.
3) May require increased flows from Lake Okeechobee to achieve the desired hydropatterns in central WCA 3A.
4) Spreader mechanism required at the point where flows will be introduced into WCA 3.

Component SS4 - Reroute Miami-Dade County Water Supply Deliveries

Study Region: Everglades Agricultural Area and Lower East Coast

Map Refer to Component Map 11

Purpose: Reroute water supply deliveries made to Miami-Dade County from the Miami and Tamiami Canals and Water Conservation Area 3 (WCA 3) to the North New River Canal due to the backfilling of the Miami Canal as part of the decompartmentalization of WCA 3.

Operation: Send water supply deliveries from Lake Okeechobee to Miami-Dade County southeast through the North New River Canal in the Everglades Agricultural Area (EAA) (L-20, L-19, L-18) to S-150. From S-150 send deliveries into L-38W and at the southern terminus of L-38W south through a 1500 cfs pump to the borrow canal along the west side of US 27.

Design:
Double the capacity of the North New River Canal south of the proposed EAA Storage Reservoir (see Component G3) to convey additional water supply deliveries to Miami-Dade County as necessary.
Double the capacity of S-351 and S-150 to pass additional water supply deliveries to Miami-Dade County as necessary.
Improve conveyance in the borrow canal on the west side of US 27 between L-38W and the Miami Canal as necessary to pass the additional flows.
Pump intake at S-7 lowered to elevation 8.0 feet NGVD.

Location: EAA and Water Conservation Area 3 in Palm Beach, Broward, and Miami-Dade County.

Assumption and Related Considerations: Operational flexibility is reduced since there is only one delivery route to Miami-Dade County (back-up routes have been eliminated).

Component TT4 - (not included in this Alternative)

Component UU6_D13R - C-23, C-24, 25 and Northfork and Southfork Basins Storage Reservoirs

Study Region: Upper East Coast

Map: This component is not mapped due to uncertainty in site location.

Purpose: Storage reservoirs to capture local runoff from the C-23, 24, 25, and Northfork and Southfork Basins of the St. Lucie River Estuary. The reservoirs will be designed for flood flow attenuation to the estuary, water supply benefits including environmental water supply deliveries to the estuary, and water quality benefits to reduce salinity and nutrient impacts of runoff to the estuary. There is one reservoir in each basin.

Operation:
Inflows from C-23, C-24, C-25, and Northfork and Southfork of the St. Lucie River.

Design:
A total of 39,000 acres at 8 feet maximum depth distributed as follows among these basins: C-23 – 8,400 acres, C-24 – 6,000 acres, C-25 – 12,800 acres, Northfork – 11,800 acres. In the Southfork Basin storage requirements were met using 9,350 acres inundated to a depth of 4 feet.

Inflow pump capacity = 1.0 to 1.5 inches per day
Outflow structure capacity = TBD (initially assumed to not constrain performance)

Location: To be determined – Specific site not necessary for Water Management Model simulation. Conceptually located in Martin and St. Lucie Counties.

Assumption and Related Considerations:
(1) Uncertainty in land availability
(2) Potential water quality benefits by reducing nutrient and sediment loading to the estuary

Component VV6 - Palm Beach County Agricultural Reserve Reservoir

Study Region: Lower East Coast

Map: Refer to Component Map 12

Purpose: Supplement water supply deliveries to central and southern Palm Beach County by capturing and storing water currently discharge to tide. These supplemental deliveries will reduce demands on Lake Okeechobee and the Water Conservation Areas.

Operation: The reservoir will be filled during the wet-season from excess water pumped out of the western portions of the Lake Worth Drainage District (LWDD) (backpumped). Water will be released back to LWDD to maintain canal stages during the dry-season. As with the base cases and the previous alternatives, regional water will be supplied to the LWDD when water level fall below 15.8’

NGVD. Water will be back pumped into the reservoir when water levels are above 16.0 feet NGVD.

Aquifer Storage and Recovery (ASR) capacity was added in Alternative 5 to improve supply during dry seasons and droughts. Fifteen (15), 5-MGD capacity ASR wells (total injection and recovery capacity 75 MGD or about 116 cfs) were added. Water will be injected when depths in the impoundment are above 1 foot. The source of water to be injected is surficial ground water adjacent to the reservoir. Water will be supplied from the reservoir before tapping water from ASR systems. Specifically, the water supplied from the reservoir will be maximized (up to the outflow capacity) before water is supplied from ASR storage.

Design:
1660 acres with a maximum depth of 12 feet (volume of 19920 acre-feet)
Inflow pump capacity = 500 cfs (provided by two 250 cfs pumps)
Outflow structure capacity = 500 cfs @ 4 feet head
Emergency outflow structure = 300 cfs

Location: The western portion of central Palm Beach County.

Assumption and Related Considerations:
1) Excess storage could be discharged to the LWDD during off peak times.
2) Canal conveyance improvements for two secondary canals LWDD's E-1 to the E-2.
3) No operation changes in the LWDD.

Component WW5 - C-111N Spreader Canal

Study Region: Lower East Coast

Map: Refer to Component Map 13

Purpose: To reduce wet season flows in C-111, improve deliveries to Model Lands and Southern Glades and decrease potential flood risk in the lower south Miami-Dade area.

Operation: Water is pumped from C-111 and C-111E into a Stormwater Treatment Area (STA) prior to pumping through S-332E into C-111N Canal to Southern Glades and Model Lands. S-197 and S-18C are removed and C-111 is backfilled.

Design:
Increase S-332E to 500 cfs from 50 cfs (pump when available)
Relocate C-111N to SW theoretical 440th street (approximately 1 section north)
Culvert under US 1

Culvert under Card Sound Road
Canal through triangle area of Model Lands, east of Card Sound Road
Fill in C-111 Canal south of confluence with C-111N to S-197
Remove levees and access roads
Completely backfill C-110
Create STA in triangle land between C-111 and C-111E Canals to clean water prior to putting in Model Lands

Location: South Dade Conveyance System in Miami-Dade County.

Assumption and Related Considerations:
1) Will not cause adverse impacts to South Miami-Dade Agricultural and Urban Lands.
2) Assume clean water from C-111 and C-111E

Component XX6 - North Lake Belt Storage Area

Study Region: Lower East Coast

Map: Refer to Component Map 6A

Purpose: The North Lake Belt Storage Area (NLBSA) is an in-ground reservoir to capture a portion of runoff from C-6, western C-11 and C-9 Basins. The in-ground reservoir, with perimeter seepage barrier, will allow storage of untreated runoff without concerns of ground water contamination. The stored water will be used to maintain stages during the dry season in the C-9, C-6, C-7, C-4 and C-2 Canals and to provide deliveries to Biscayne Bay to aid in meeting salinity targets.

Operation: Inflows from C-6 (west of the turnpike), western C-11, and C-9 Basin runoff are pumped and gravity fed into the in-ground reservoir. Inflow ceases when stages reach ~5.0 feet NGVD (0 feet above adjacent land elevation).

Outflows for water supply are pumped to the C-9 Storm Water Treatment Area (STA)/Impoundment prior to delivery to the C-9, C-6, C-7, C-4 and C-2 Canals.

Water from the reservoir can be withdrawn down to a stage of -15 feet NGVD (up to 20 feet of working storage & maximum head on seepage barrier).

Prioritization of outflows: If water levels in NLBSA are from between +5.0 feet NGVD and 0.0 feet NGVD flows will be discharged to Biscayne Bay via the C-2 Canal. If water levels in NLBSA are from between –10 feet NGVD and 0.0 feet NGVD flows will be discharged to C-9, C-6, C-7, C-4 and C-2 Canals only to prevent salt water intrusion. If water levels in NLBSA drop to levels between –15 feet

NGVD and -10.0 feet NGVD flows will be limited to discharge to the C-9 Canals only to avoid water shortage restrictions.

The storage area is 4500 acres to capture runoff from C-6, C-9 and C-11 basins. (Note: SFWMM simulation assumes 5120 acres of surface area. To simulate equivalent working storage volumes, the simulated water levels are higher from those prescribed here.)

Design:
Reservoir: 4500 acres with subterranean seepage barrier around perimeter to enable drawdown during dry periods, prevent seepage and to prevent water quality impacts. The component also includes 1250 acres of stormwater treatment area.

Inflow Structures:
2500 cfs gravity structure @ 0.5 feet head, from C-11W
600 cfs pump from C-9
300 cfs pump from C-6 west of divide structure
Outflow Structures:1000 cfs pump to C-9 STA/Impoundment for treatment prior to deliveries to C-6, C-7, C-2, C-4 and C-9 to prevent saltwater intrusion in coastal canals. (Stormwater Treatment Area detention time requirements need to be addressed. Pretreatment in reservoir may reduce size requirements of treatment area).

Canal: 800 cfs canal capacity - Water supply discharges are routed to C-4/C-2 via a canal to be located east of the Snapper Creek Canal (Northwest wellfield protection canal system).
2-1400 cfs delivery structures, one each at the new canal's confluence with C-6 and C-4.

Location: Reservoir would be located within the area proposed for rock mining by the Lake Belt Issue Team. It would be sited north of Miami Canal (C-6) and south of the C-9 Canal to minimize impacts to the Northwest Wellfield in Miami-Dade County.

Assumption and Related Considerations:
1) No adverse effect of a subterranean wall on Miami-Dade County's Northwest Wellfield.
2) Treatment facility needed if stored water is backpumped to the Everglades.
3) All water quality considerations will be addressed regarding releases from the reservoir to the water supply wellfields.
4) Impacts on the cone of influence of the Northwest Wellfield and its effect on wetland mitigation around the wellfield.
5) Limestone Filter Treatment system within the Reservoir may be developed through use of compartmentalization of rockmining excavation pattern.

6) Telemetry systems will be required for all operable structures and pump stations.
7) Any specific water quality considerations regarding capture of C-6 Basin runoff will be addressed during the detailed design stage.

Component YY4 - Divert WCA2 flows to Central Lake Belt Storage

Study Region: Lower East Coast

Map: Refer to Component Map 11

Purpose: Capture excess in Water Conservation Area 2B (WCA 2B) to reduce stages above desired target levels in Water Conservation Area 2B and to divert water through improved L-37 and L-33 Borrow Canals to 1) Northeast Shark River Slough (NESRS) to meet targets or 2) Central Lake Belt Storage Area.

Operation: Surface water in WCA 2B above NSM will overflow through 3 structures along L-35 and L-35A to North New River Canal along with seepage from WCA 2B and pumped to L-37. North New River Canal, L-37 and L-33 Borrow Canals will be improved to accept this additional flow along with the seepage collected from WCA 3. This water will be pumped to Northeast Shark River Slough (NESRS) if the Slough is below target levels or into a lined reservoir south of the confluence of L-33 and the C-6 Canal referred to as the Central Lake Belt Storage Area (CLBSA). SEE COMPONENT S.

Design:
3- diversion structures with 120 cfs capacity @0.5 feet of head and 350 cfs capacity @4.0 feet of head along the southern perimeter of WCA 2B.
Intermediate 1500 cfs pump station to divert overflow and seepage from North New River to L-37.
Inverted siphon with 1500 cfs capacity to pass water supply deliveries from L-38 borrow canal to US 27 West borrow canal.
Improved conveyance of L-37 and L-33 to 3000 cfs to handle WCA 2B flows plus seepage from WCA 3.
Remove S-9XN and S-9XS or improve structures to accommodate increased flows.

Location: The overflow structures are located along the southern levee of WCA 2B. L-37 and L-33 borrow canal improvements are located east of the Protective levees and 0.5 miles west of US 27 between North New River Canal and the Miami Canal in Broward County.

Assumption and Related Considerations:
1) Prioritization of use of Central Lake Belt Storage Area water.
2) Telemetry systems will be required for all operable structures and pump stations

Component ZZ5 - Divert WCA 3 flows to Central Lake Belt Storage Area

Map: Refer to Component Map 6

Study Region: Lower East Coast

Purpose: Capture excess in Water Conservation Area 3A (WCA 3A) and WCA 3B to reduce stages above target stages in Water Conservation Area 3 and to divert water through modified structures at S-9 and S-31 to Central Lake Belt Storage Area via the L-33 borrow canal.

Operation: When surface water in WCA 3B exceeds target depths by 0.10 feet it will be diverted to the Central Lake Belt Storage Area via L-33. When surface water in WCA 3A near S-9 exceeds target depths by 1.0 foot, water will be diverted to the Central Lake Belt Storage Area via L-33.

Design:
Outflow Structures - 500 cfs structure @ 2.0 feet of head (new structure) at S-9 (WCA 3A).
700 cfs structure (modify existing S-31 if necessary) (WCA 3B)

Location: The eastern levees of WCA 3.
Counties: Broward and Miami-Dade

Assumption and Related Considerations:
1) Prioritization of use of Central Lake Belt Storage Area water.
2) Telemetry systems will be required for all operable structures and pump stations

Component AAA6 - Lower East Coast Water Conservation

Study Region: Lower East Coast Service Areas

Map: This component is not mapped.

Purpose: The purpose of this component is to reduce the public water supply demands through the full implementation of the South Florida Water Management District's (SFWMD) current mandatory water conservation program. The regional affect from the implementation of water conservation would include greater efficiency of the water utilized by the public water supply utilities and a year round reduction of the volume of water delivered from the regional water resource facilities to recharge coastal canals and wellfields.

Operation: On average, a six percent reduction in the projected 2050 withdrawals will be applied to each service area uniformly over each month of the simulation period. The percentage reduction will be based on the anticipated water conservation measures for each of the service areas.

Design: The current mandatory water conservation program of the SFWMD was applied throughout the service area to the public water supply demand projections using the Institute for Water Resources-Main (IWR-Main) forecasts. The percentage reduction is a result of the conversion of residential end users to ultra-low flow fixtures and daytime restrictions on lawn watering throughout the service areas, both practices are required by existing regulations. The percentage of the population using water-conserving fixtures is increased thereby reducing public water supply demands when compared to the 2050 Base. The percentage reduction is calculated from the 2050 Base that contains a moderate application of conservation techniques. The reduction applied in this component assumes full implementation of the District's water conservation program as predicted by IWR-Main.

The 2050 Base utility demands in the Lower East Coast Service Area were reduced by six percent on average in this Alternative.

Location: Lower East Coast in Palm Beach, Broward and Miami-Dade County.

Assumption and Related Considerations:
1) Water conservation measures apply to all sources of water. It is most likely that demands met by reuse water would not be affected by restrictions in irrigation.

Component BBB6 - South Miami-Dade County

Study Region: Lower East Coast

Map: Refer to Component Map 14

Purpose: The existing South District Wastewater Treatment Plant (SDRWTP) located north of the C-1 Canal will provide wastewater treatment coupled with superior treatment technology to supply reclaimed water to the South Biscayne Bay and Coastal Wetlands Enhancement (SBBCWE) Project. The water will be provided throughout the year to augment water supply to the SBBCWE upon demand. This supplemental water will restore overland flow in the coastal area and recharge groundwater to enhance groundwater discharge to Biscayne Bay. Saltwater intrusion benefits to the southern part of Miami-Dade County are anticipated.

Operation: The SDRWTP with superior treatment technology will be operated when the additional water is needed to supply the SBBCWE. When water is not needed, the SDRWTP will stop treatment beyond secondary treatment standards and will dispose of the secondary treated effluent into the existing deep injection wells.

Design: The SDRWTP will be designed to add on pretreatment and membrane treatment system to the existing secondary treatment facility. The plant will have a capacity of 131 MGD. It is anticipated that phosphorus will be the constituent of concern in the reclaimed water. Therefore, the treatment will be designed to remove total phosphorous to acceptable levels.

The SDRWTP will be located at, or in the vicinity of, the existing SDRWTP. The reclaimed water will be discharged to the C-1 Canal (Black Creek), upstream of S-21A, and then delivered southward towards the C-102 and C-103 Canals, and northward towards the C-100 Canal. The wastewater treatment facility will provide advanced treated water to L-31E. Flow southward in L-31E towards C-102 and C-103 shall be 202 acre-feet per day. Flow northward in L-31E towards C-100 shall be 200 acre-feet per day (through a canal extension). The combined inflow into L-31E shall be 402 acre-feet per day for every day of the simulation. Flows will reach C-102 and C-100 via modifications to L-31E as shown on Component Map 14. Operation of C-102 and C-103 shall be contingent upon Component FFF5.

Location: Miami-Dade County

Assumptions and other considerations:
1) The reuse facility uses advanced treatment resulting in water quality acceptable to the Bay.
2) No adverse impacts to adjacent agricultural or urban areas.
3) Discharge capacity at S-123, S-20F, S-21 and S-21A is sufficient to pass basin runoff and inflows from the reuse facility during storm events.
4) This component is dependent on Component FFF.

Component CCC6 - Big Cypress/L-28 Interceptor Modifications

Study Region: Big Cypress

Map: Refer to Component Map 15

Purpose: Alleviate over drainage in Northeast Big Cypress, Kissimmee Billy and Mullet Slough area and ensure that inflows meet applicable water quality standards.

Operation: Reroute water from West and North Feeder Canals to wetlands in Northeast Big Cypress. Allow flow along the south side of the West Feeder at designated locations and through a new S-190 Pump Station, while maintaining flood protection on Tribal lands and consistency with the Seminole Tribe's Conceptual Water Conservation System master plan. Establish sheetflow south of the West Feeder Canal across the Native Area of the Big Cypress Reservation. Establish sheetflow off the reservation in the Big Cypress National Preserve Addition. Operate pumps for approximate equalization of flows.

Design:
Degrade the levee on the SW side of the L-28 Interceptor Canal below the S-190 structure.
Backfill the L-28 Interceptor Canal at a point south of the Big Cypress Reservation boundary with Big Cypress National Preserve Addition.
Retain levee on NE side of L-28 Interceptor through the Big Cypress Seminole Reservation.
Develop sheetflow along the south side of the West Feeder Canal through three pump stations and spreader canals. The pump station locations shall be adjacent to the discharge points from Water Resource Areas (WRA) 1, 2 and 3 of the Seminole Conceptual Water Conservation System.
Pump station at WRA-1 discharge: 250 cfs
Pump station at WRA-2 discharge: 500 cfs
Pump station at WRA-3 discharge: 750 cfs
Replace S-190 gated structure (existing capacity of 2960 cfs) with a 1460 cfs pump station.
North Feeder stormwater treatment area: 1100 acres at 4-foot maximum depth.
Inflow pump station: 270 cfs
Outflow structure: 100 cfs
West Feeder stormwater treatment area: 800 acres at 4-foot maximum depth.
Inflow pump station: 430 cfs
Outflow structure: 150 cfs

Location: Western Basin, Big Cypress Seminole Reservation, Big Cypress National Preserve Addition in Hendry, Collier, and Broward Counties.

Assumption and Related Considerations:

1) Water quality treatment for runoff entering the West and North Feeder Canals is provided by stormwater treatment areas, if necessary, to meet applicable water quality standards.
2) Design shall be consistent with the Seminole Tribe's Conceptual Water Conservation System master plan.
3) Existing flood protection shall be maintained.
4) Evaluation of flow changes in the area south of the West Feeder Canal and

5) S-190 shall be accomplished by assessing impact on Seminole Tribe's passive use rights.
6) Evaluation of flow changes reflects minimal impact.
7) Component construction occurs after completion of the Seminole Conceptual Water Conservation System.

Component DDD5 - Caloosahatchee Backpumping with Stormwater Treatment Area (STA)

Study Region: Caloosahatchee River

Map: This component is not mapped due to uncertainty of site location

Purpose: Capture excess C-43 Basin runoff to augment the regional system. These facilities will be designed to backpump excess water from C-43 to Lake Okeechobee after treatment through an STA.

Operation: This component operates after estuary and Agricultural/Urban demands have been met in the C-43 Basin and when water levels in the C-43 storage reservoir (Component D5) exceed 6.5 feet. When this situation occurs, water will be released from the reservoir and delivered to the STA at the capacity of the backpumping/treatment system (2000 cfs). The STA water is then backpumped to Lake Okeechobee. An additional requirement for the backpumping to take place is that Lake Okeechobee must be considered to have available storage, i.e. when its levels are below the pulse release zone line shown on Figure 1.

Design: The key components in the design are pumps and a stormwater treatment area. For the design it has been assumed that the STA is located adjacent to Lake Okeechobee. Because it is not known where the reservoir will be located relative to the STA, it has been assumed that water to be delivered to the STA will be released from the reservoir to the Caloosahatchee River and then pumped from the River into the STA. Since no pump to bring water from the lower basin (below S-78) to the upper basin has been included in the reservoir design and since most of the basin runoff is generated in the lower basin, a pump to bring the water from the lower Caloosahatchee Basin to the upper basin has also been included. The STA has been included to meet the anticipated need to improve the quality of the water before it enters Lake Okeechobee. Finally, a pump station will be used to lift the water from the STA to Lake Okeechobee.

Pumps: 1 pump of 2000 cfs capacity to take water from the lower Caloosahatchee Basin to the upper Caloosahatchee Basin; 1 pump of 2000 cfs capacity to take water from the Caloosahatchee River into the STA; and 1 pump of 2000 cfs capacity to discharge water from the STA to Lake Okeechobee.

STA: an STA of approximately 5000 acres is proposed to achieve water quality improvements.

Location(s)TBD - Specific site not necessary for model simulations. Conceptually located in Hendry and Glades Counties.

Assumption and Related Considerations:
1) Uncertainty in land availability.
2) Water quality benefits to the Lake.
3) The Franklin Lock and Dam S-79 time series flow demand for the Caloosahatchee Estuary has been reduced. The Performance Measures were not changed.
4) The model assumes that the backpumping/treatment facility, primarily the STA, functions as a flow-through system.

Component EEE5 - Flows to Eastern Water Conservation Area

Study Region: Water Conservation Areas and Lower East Coast

Map: Refer to Component Map 6 and 11

Purpose: Captured excess surface water and seepage from Water Conservation Area 2B, 3A and 3B in Central Lake Belt Storage Area (CLBSA) delivered to eastern WCA 3B during dryouts.

Operation: Deliveries will be made to maintain 6 inch depths in WCA 3B if NSM hydroperiod indicate WCA 3B water levels should be at or above 6 inches and water is available in CLBSA. Deliveries from CLBSA will occur through a wetland treatment cell and the L-30 borrow canal to a spreader swale system in the eastern areas of WCA 3B.

Design: 500 cfs pump from L-30 to eastern portion of WCA 3B.
Spreader Swale along eastern WCA 3B to convert 500 cfs to sheetflow
Upgrade of 1500 cfs from CLBSA deliveries NESRS to 2000 cfs to accommodate additional flows to WCA 3B (also seen in component S5)

Location: The discharge point from L-30 borrow canal to WCA 3B is at the bend in the canal and is approximately 4.5 miles south of the intersection of the L-30 and the C-6 Canal in Miami-Dade County

Assumption and Related Considerations:
1) Prioritization of use of Central Lake Belt Storage Area water.
2) Telemetry systems will be required for all operable structures and pump stations.

Component FFF5 - Biscayne Bay Coastal Canals

Study Region: Lower East Coast and Biscayne Bay

Map: Refer to Component Map 14

Purpose: Maintain higher stages in C-102 and C-103 for urban and environmental water supply.

Operation: Maintain canal stages in C-102 and C-103 with water provided from local sources. Wet season operation for C-102 between S-21A and S-195 (open at 2.2 feet NGVD, close at 2.0 feet NGVD) and for C-103 between S-20F and S-179 (open at 2.2 feet NGVD, close at 2.0 feet NGVD) will remain unchanged. Dry season operation of C-102, between S-21A and S-195, and C-103 between S-20F and S-179, will both change from opening at 1.4 feet NGVD and closing at 1.2 feet NGVD to opening at 1.6 feet NGVD and closing at 1.5 feet NGVD.
A borrow canal will be constructed west of L-31E which directly connects the downstream reach of C-102 with C-103 to maintain levels in the lower reaches of C-103.

Design: 3.5 mile connection canal

Location: Biscayne Bay Coastal Canals in Miami-Dade County.

Assumption and Related Considerations:
1) Local water source tied to Component BBB5, water reuse.
2) Component simulates overland flow to Biscayne Bay. South Biscayne Bay Coastal Wetlands Components will be included as part of Other Project Elements, since their effect is not measurable with current modeling techniques. The intent of these components is to restore overland flow and groundwater seepage to Biscayne Bay while reducing the frequency of point-source discharges.

Component GGG6 - C-51 and Southern L-8 Reservoir

Study Region: Lower East Coast

Map: Refer to Component Map 16

Purpose: Storage reservoir managed for the environmental and water supply goals listed below:

- Reduce the number of events when discharges to the Lake Worth Lagoon exceed the desired daily average flow rate of 500 cfs.
- Reduce the magnitude of events exceeding the desired flow rate of 500 cfs.

- Reduce the average annual volume discharged to tide (over the S-155 structure) by detaining storm water runoff for subsequent environmental (routing from the West Palm Beach Water Catchment Area to the Northwest Fork of the Loxahatchee River) and water supply needs (providing water to the Lake Worth Drainage District and the West Palm Beach Water Catchment Area).
- Provide increased drainage to the C-51 Basin and the Southern L-8 Basin by lowering the average stages in the C-51 Canal

Operation: The reservoir will be filled, with excess water from the Southern L-8 Basin and the C-51 Basin, when flows over the S155 structure exceed 300 cfs during the wet-season from excess water in C-51 Canal and Southern L-8 (backpumped). Water will be released back to C-51 to help maintain canal stages during the dry-season.

Design:
1200 acres of usable area with a 100-foot deep, 2-foot thick slurry wall for seepage control along the approximate perimeter length of 6 miles (this depth assumes a surficial aquifer thickness of 170 feet, 20 feet of embankment and 10 feet of embedment of the slurry was into the confining layer). The reservoir will have a total storage depth of 40 feet (30 below grade and 10 above grade).
Inflow pump capacity of 1500 cfs at the reservoir.
Emergency outflow structure with a capacity of 1500 cfs when the water level exceeds the maximum operation depth of 40 feet by 2 feet.
Pumped outflow with a maximum rate of 400 cfs at 40 feet and using the discharge schedule shown below.

Depth (feet)	Discharge Rate (cfs)	Storage Volume (acre-feet)
42	1500	50400
41	415	49200
40	400	48000
30	300	36000
20	300	24000
10	300	12000
0	300	0

This component includes a 1000 cfs pump at S-155A, which will be operated when flows through S-155 exceed 300 cfs, and there is capacity in the reservoir.

Location: Immediately west of the L-8 Canal and north of the C-51 Canal in Palm Beach County.

Assumption and Related Considerations:

1) This parcel is owned by Palm Beach Aggregate and is currently an active mining operation with a nominal excavation depth of 40 feet.
2) Slurry wall surrounding perimeter to address seepage and water quality issues due to ancient or connate water with a chloride content of 500 mg/L.
3) The component will include telemetry control and monitoring.

Component HHH6 - West Miami-Dade Reuse

Study Region: Lower East Coast

Map: Refer to Component Map 7

Purpose: The future West Miami-Dade Wastewater Treatment Plant (WDWTP), will be located immediately south of the Bird Drive Recharge Area and east of the relocated L-31 North Protective Levee, will provide wastewater treatment coupled with superior treatment technology to supply reclaimed water to the Bird Drive Recharge Area. The water will be supplied year round as needed to enhance groundwater recharge. Excess water, when available, will be sent as a second priority to the South Dade Conveyance System, to Northeast Shark River Slough as a third priority and to deep injection wells when there are no demands from the three designated priorities.

Operation: The proposed reclaimed water production facility will be operated by Miami-Dade County and has the potential to discharge 100 MGD. As stated previously, the water will be provided to three prioritized demands of 1) Bird Drive Recharge Area, 2) South Dade Conveyance System and 3) Northeast Shark River Slough. When all demands have been met, the WDWTP will stop treatment beyond secondary treatment standards and will dispose of the secondary treated effluent into deep injection wells.

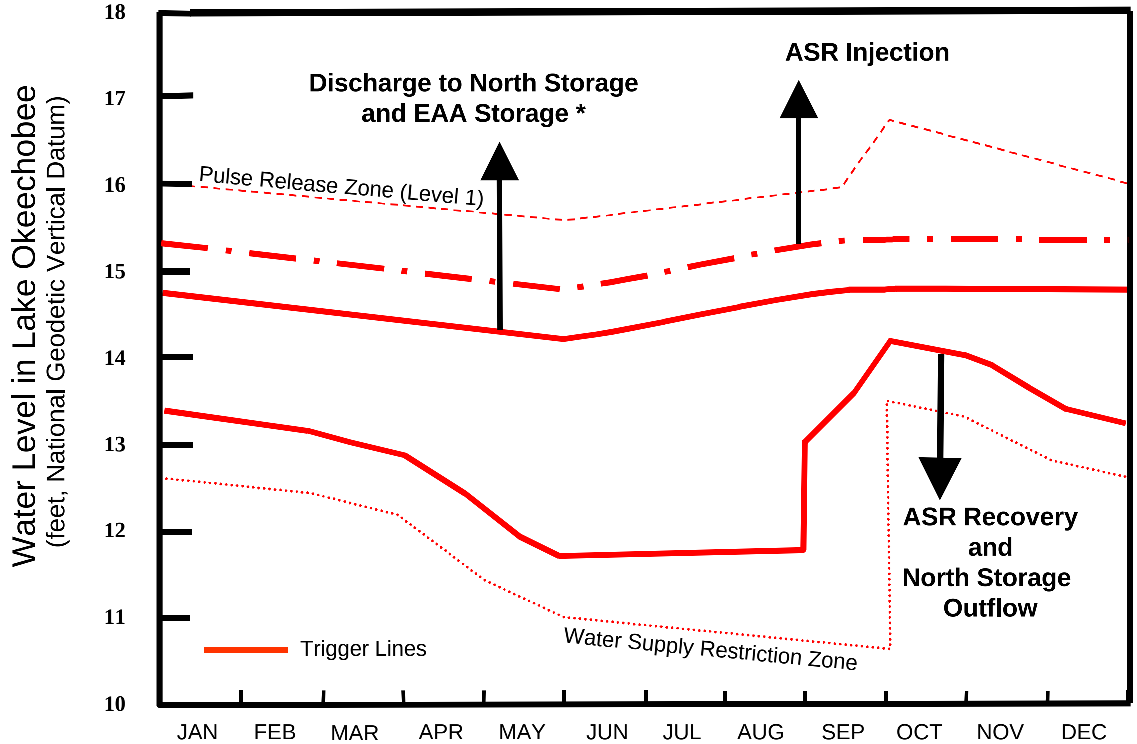
Design: Treatment will be biological nutrient-removal advanced wastewater treatment (AWT) followed by a superior treatment technology using iron salts to lower phosphorus to levels required for Everglades discharges. The iron salt coagulation system would be designed for a constant flow rate of 100 MGD.

The WDWTP will pump superior, advanced treated water to the Bird Drive Recharge Area when the elevation of the Recharge Area is equal to or below 3' above natural ground at a rate of 155 cfs (100 MGD).

Location: South of the Bird Drive Recharge Area and east of the relocated L-31 North protective levee in Miami-Dade County.

Assumption and Related Considerations: The superior treatment technology will be able to treat the AWT effluent to remove phosphorous and nitrogen to the low levels desired to meet State water quality standards and provide an acceptable water quality for the above priorities.

Figure 1. Operation Criteria for Lake Okeechobee and Surrounding Storage Components



* Discharge to North and EAA Storage if Lake Okeechobee stage is forecasted to be above “Discharge to …Storage” line, or if stage is above Pulse Release Zone (level 1) line.

APPENDIX A5
CRITICAL PROJECTS

Section 528 of the Water Resources Development Act (WRDA) of 1996 authorizes the Secretary of the Army to expeditiously implement restoration projects that are deemed critical to the restoration of the south Florida ecosystem. These projects are referred to as Critical Projects. This authority allows the Corps of Engineers (Corps) to implement projects that are needed for restoration in advance of completion of the Comprehensive Plan. Thirty-five candidate Critical Projects were identified and prioritized by the Working Group of the South Florida Ecosystem Restoration Task Force (Working Group) through a process that utilized input from the Governor's Commission for a Sustainable South Florida (Governor's Commission), project proponents, and the public. Based on the priorities recommended by the Working Group, the Corps evaluates each candidate project and submits a short letter report justifying the project to Assistant Secretary of the Army for Civil Works (ASA(CW)). Critical Projects that are approved by the ASA(CW) are implemented through the Critical Projects program. The cumulative cost estimate for all 35 candidate Critical Projects exceeds the current legislatively mandated funding limit. Therefore, it is anticipated that only the top priority candidates will be implemented under this authority. The Restudy addresses all of the Critical Projects nominated by the Working Group to ensure they will be implemented. This appendix briefly explains the Critical Project program, provides narrative summaries of each project and its expected benefits, and explains how each project is addressed in the Restudy.

A5.1 AUTHORITY

The Critical Projects program is authorized by Section 528(b)(3) of the Water Resources Development Act of 1996 (Public Law 104-303) which states:

"(b) RESTORATION ACTIVITIES-

(3) CRITICAL RESTORATION PROJECTS-

(A) IN GENERAL- In addition to the activities described in paragraphs (1) and (2), if the Secretary, in cooperation with the non-Federal project sponsor and the Task Force, determines that a restoration project for the South Florida ecosystem will produce independent, immediate, and substantial restoration, preservation, and protection benefits, and will be generally consistent with the conceptual framework described in paragraph (1)(A)(ii)(II), the Secretary shall proceed expeditiously with the implementation of the restoration project.

(B) INITIATION OF PROJECTS- After September 30, 1999, no new projects may be initiated under subparagraph (A).

(C) AUTHORIZATION OF APPROPRIATIONS-

(i) IN GENERAL- There is authorized to be appropriated to the Department of the Army to pay the Federal share of the cost of carrying out projects under subparagraph (A) $75,000,000 for the period consisting of fiscal years 1997 through 1999.

(ii) FEDERAL SHARE- The Federal share of the cost of carrying out any 1 project under subparagraph (A) shall be not more than $25,000,000."

A5.2 NOMINATION AND RANKING PROCESS

Candidate projects were identified by project proponents and prioritized by the Working Group through a process that utilized input from the Governor's Commission, the project proponents, and the public. Critical Projects were nominated through submittal of a summary sheet to the Working Group. Any agency, organization, or individual could nominate a project. Each Working Group member was requested to solicit input from his or her respective constituencies. The Working Group coordinated the list of projects with the Governor's Commission and the public. After public input, the Working Group revised and prioritized the list and then submitted the top thirty-five candidate projects to the Corps for further evaluation. This process and the results are described below in greater detail.

A5.2.1 CRITICAL PROJECTS NOMINATION AND PRIORITIZATION CRITERIA

Critical Projects must be within the Corps' general authorities for water resources projects. The Corps evaluated the nominated projects to ensure that they met all of the required criteria. The Corps' initial evaluation of the nominated projects was discussed with the Working Group before it was finalized. In order to be qualified, the project must meet all of the following criteria.

- The project produces independent, immediate, and substantial restoration, preservation, and protection benefits.
- The project must be generally consistent with the elements of the Governor's Commission's Conceptual Plan.
- It must be possible to initiate the project prior to 30 September 1999. Project initiation is defined as execution of the Project Cooperation Agreement (PCA) which is the contract between the Corps and the project sponsor.
- The total project cost estimate must be less that $50 million. If the total project cost is estimated to be more than $50 million, the sponsor must agree to provide all funding for the excess costs.

- A potential cost-sharing partner must be identified. The Corps and the sponsor will share all project costs as specified in the PCA.

- The project cannot be an authorized component of the C&SF Project. Additionally, this authority should not be used as an alternative funding source for projects for which a funding source has already been identified and a schedule is in place for accomplishing the work.

A5.2.2 DETERMINING PRIORITIES OF APPLICABLE PROJECTS

The Working Group evaluated and prioritized the list of applicable projects based on the following considerations;

- The level of benefits provided by a candidate project. This was a subjective estimate made by the Working Group.

- Time sensitivity of a candidate project. Congress' intent is to allow near-term implementation of critical, time-sensitive projects and to take advantage of unique opportunities. This authority can be used to avoid penalties that may result from using the normal processes for project implementation. In the prioritization process, consideration was given to whether the project offers a significant benefit (cost savings or ecosystem benefit) from early implementation.

- Visibility of a candidate project. It is also Congress' intent that the authority be used to implement projects that have visible results and benefits. Studies and research will be difficult to justify unless they are short-term and provide tangible, near-term ecosystem benefits.

A5.2.3 NOMINATION AND PRIORITIZATION RESULTS

Table A5-1 displayed on the next page lists the 35 Critical Projects as prioritized by the Working Group. Section A5.5 provides narrative summaries of each project.

Table A5-1
CRITICAL PROJECTS LIST

Critical Projects Nominated by the Working Group	
Rank	**Critical Project Title**
1	East Coast Canal Structures
2	Tamiami Trail Culverts
3	Melaleuca Eradication Project
4	Florida Keys Carrying Capacity Study
5	Western C-11 Water Quality Treatment
6	Seminole Tribe Big Cypress Reservation Water Conservation Plan (west)
7	Southern Golden Gates Hydrologic Restoration
8	South Miami-Dade Agricultural and Rural Land Use and Water Management Plan
9	Southern CREW Project Addition/Imperial River Flowway
10	Lake Okeechobee Water Retention/Phosphorus Removal
11	Ten Mile Creek Water Preserve Area
12	L-28 Modification
13	Loxahatchee Slough Ecosystem Restoration
14	Geodetic Vertical Control Surveys
15	Lake Trafford Restoration
16	L-31East Flow Redistribution
17	Henderson Creek and Belle Meade Restoration
18	Lake Okeechobee Tributary Sediment Dredging
19	Develop & Implement Agricultural BMPs in the C-111 Basin
20	North Fork of the New River Restoration
21	L-8 Canal/Water Catchment Area/Loxahatchee Slough Infrastructure Improvements
22	Florida Keys Tidal Restoration
23	Lake Worth Lagoon Restoration
24	Palm Beach County Wetlands-Based Water Reclamation
25	Lake Okeechobee Demonstration Aquifer Storage and Recovery
26	Miccosukee Water Management Area
27	Six Permanent Water and Meteorological Stations
28	Nutrient Removal and Dosing Studies for Everglades National Park
29	Water Conservation Area 3B Seepage Reduction
30	Hillsboro Pilot Aquifer Storage and Recovery
31	Lakes Park Restoration
32	Town of Ft. Myers Beach
33	Palm Beach County Winsberg Farms Constructed Wetland
34	Spring Creek Reconnection and Rehydration
35	Restoration of Pineland & Tropical Hardwood Hammocks in C-111 Basin

A5.3 APPROVAL PROCESS

Based on the priorities recommended by the Working Group, the Corps evaluates each project and prepares a short letter report (2 to 3 pages) to the ASA(CW). The report is based on available data and includes: 1) a description of the project, 2) an evaluation of how the project addresses each of the selection criteria, 3) a discussion of any environmental concerns, 4) a preliminary project cost estimate, 5) an implementation schedule, and 6) tentative letters of support from a local sponsor and all agencies that must provide approvals or permits for the project. A draft PCA is submitted for approval with the letter report. The report requests approval to expend funds for: 1) finalization and execution of a PCA, 2) preparation of National Environmental Policy Act (NEPA) documentation, and 3) detailed design, permitting, and construction.

A5.4 IMPLEMENTATION

The Corps will utilize the Working Group's priority list as a general guide toward implementing these projects through the Critical Projects program. However, funding or resource constraints of the Critical Projects program may require that some projects on the list be addressed out of sequence. In addition, to ensure that Critical Projects that can not be implemented through the Critical Projects program can be considered through future authorizations, the Restudy addresses all 35 Critical Projects nominated by the Working Group. For additional information regarding implementation of the Critical Projects see Section A5.6 of this Appendix, Appendix M, and Section 10 of the Main Report.

A5.4.1 NATIONAL ENVIRONMENTAL POLICY ACT DOCUMENTATION

Following ASA(CW) approval of the letter report, NEPA documentation will be prepared by the Corps. Individual Critical Projects will undergo environmental review and assessment in accordance with NEPA and other pertinent environmental laws and regulations. This includes coordination with the appropriate Federal, state, and local agencies, the Native American Tribes, interested non-governmental organizations, and the public. For those Critical Projects that can not be implemented through the Critical Projects program, NEPA documentation and coordination will be accomplished through the Project Implementation Report process described in Section 10 of the Main Report.

A5.4.2 DESIGN DOCUMENTATION

The Corps' Jacksonville District will prepare appropriate design documents. In some cases, construction contract plans and specifications will be prepared immediately after approval of the letter report. In other cases that require additional engineering, a design document may be prepared to aid in implementation. Approval of all design documents will be by the Jacksonville District Engineer.

A5.4.3 PROJECT COOPERATION AGREEMENT

A draft PCA is prepared by the Corps and submitted to the ASA(CW) for approval along with the letter report. Delegation of the authority for the Jacksonville District Engineer to execute the PCA is also requested in the letter report. The PCA will be executed following completion of NEPA documentation and compliance with any other applicable Federal laws. The PCA will define the sponsor's allowable credit for inkind services toward the local share of the total project cost.

A5.5 CRITICAL PROJECT DESCRIPTIONS

This section provides a summarized description of each Critical Project as it was nominated to, or revised by, the Working Group. The projects are presented in accordance with the Working Group’s priorities. The relationships of the Critical Projects to the Comprehensive Plan are discussed in Section A5.6 below.

A5.5.1 EAST COAST CANAL STRUCTURES

The project is located in Miami-Dade County, roughly 20 miles due west of Miami. A new structure would be constructed in the C-4 Canal, immediately southeast of the Pennsuco Wetlands. Also to be included in this project will be the removal of the existing G-119 control structure, currently located on the eastern edge of Water Conservation Area 3B. The project purpose is to raise surface and ground water levels to prevent drainage of the Everglades and to reestablish natural hydroperiods. The project would retain, in the Everglades, waters that now drain to the east via the primary conveyance canal system. The project would increase aquifer recharge, and surface and subsurface storage of water, to enhance regional water supplies. Lastly, the project would provide increased habitat for plants and animals that live in the Everglades communities by restoring wetlands and decreasing the potential for the spread of exotic plants.

A5.5.2 TAMIAMI TRAIL CULVERTS

The project is located on the Tamiami Trail (US-41) in Collier County between State Road 92 and 50 Mile Bend (a distance of approximately 43 miles). In 1928, the Tamiami Trail was completed between Miami and Naples. To obtain fill material for the roadbed, a borrow canal was excavated on the northern side of the road alignment. The effect of the Tamiami Trail and adjacent borrow canal has been to intercept existing north-south flowways to the Big Cypress National Preserve, and channelize flows through a few bridges/culverts. Currently, due to the channelization of flowways, some wetland habitats receive too much fresh water, while others do not receive enough. Also, the seasonal hydropatterns (quantity, timing, and distribution of surface water flows) are interrupted. The purpose of this project is to increase the number of north-south flowways by adding water conveyance structures under Tamiami Trail in locations that will restore a more natural hydropattern. In addition, plugs will be installed in the existing borrow canal at appropriate places to reduce east-west flow. This project will help restore a more natural hydropattern to the southern Big Cypress Basin and coastal areas to the south including the Big Cypress National Preserve.

A5.5.3 MELALEUCA ERADICATION PROJECT

Melaleuca and other invasive exotic species are rapidly invading the natural Everglades ecosystem. Even when natural hydrology is restored to the Everglades, species such as Melaleuca will continue to degrade the system by displacing native species and degrading wetlands unless controlled with an integrated plant management strategy. In addition to chemical treatment, mechanical removal, and water manipulation, the use of biological control agents is an important component of a successful plant management strategy. This Melaleuca Eradication Project has three elements that will increase the effectiveness of biological control technologies to manage Melaleuca and other invasive exotic species. Each element is described below:

A5.5.3.1 MELALEUCA ERADICATION PROJECT (PART A) - CONSTRUCT NEW MELALEUCA QUARANTINE AND RESEARCH FACILITY

The purpose of this project is to construct a Melaleuca Quarantine and Research Facility for the testing of candidate organisms for biological control of Melaleuca. This project would enhance and accelerate the highly regulated quarantine process. The facility would be located on one of the following sites:

- University of Florida property, adjacent to the U.S. Department of Agriculture/ Agricultural Research Service (USDA/ARS), Ft. Lauderdale Aquatic Plant Management Laboratory, Davie, Florida.

- University of Florida property, University of Florida Research & Education Center, adjacent to the U.S. Department of Agriculture/Agricultural Research Service Facilities Division, U. S. Horticultural Research Laboratory, Ft. Pierce, Florida.

A5.5.3.2 MELALEUCA ERADICATION PROJECT (PART B) - RENOVATION AND IMPROVEMENTS - BIOLOGICAL CONTROL QUARANTINE AND RESEARCH FACILITY

The project would provide improvements to the Florida Biological Control Laboratory (FBCL) facility in Gainesville, Florida to better meet the needs of testing biological control candidates of exotic aquatic and terrestrial pest plants and arthropod pests of agricultural, native and horticultural plants. The Florida Department of Agriculture and Consumer Services, Division of Plant Industry, is the regulatory agency responsible for protecting Florida's native and commercially grown plants from harmful pests and diseases. The FBCL facility operates in close cooperation with the U.S. Department of Agriculture, Agricultural Research Services, and the University of Florida, Institute of Food and Agricultural Sciences. The primary responsibility of the FBCL is to enforce the quarantine procedures and regulations governing the receipt, handling and release of introduced biological control organisms.

A5.5.3.3 MELALEUCA ERADICATION PROJECT (PART C) - IMPLEMENT BIOLOGICAL CONTROLS

This project calls for the mass rearing, field release, establishment and field monitoring of approved biological control agents for Melaleuca. Production of biological control agents for release requires maintaining large screenhouse colonies at the U.S. Department of Agriculture/Agricultural Research Service (USDA/ARS), Ft. Lauderdale Aquatic Plant Management Laboratory located at Davie, Florida. Melaleuca plants must be continually collected for the colony food source, therefore Melaleuca must be cultured at the laboratory. Insects grown in these screenhouses will be released into Melaleuca stands. Permanent study plots will be established at designated release sites. The 13 existing study plots will be increased to approximately 100 as a result of this project. Periodic monitoring will be conducted in order to quantify the insect's impact upon Melaleuca, thereby evaluating the effectiveness of the biological control agent. Sampling methods will be developed to recover insects for re-release or observation and to estimate the population of insects in the field.

A5.5.4 FLORIDA KEYS CARRYING CAPACITY STUDY

The Florida Keys Carrying Capacity Study (FKCCS) will provide a database and a decision making analysis tool. The analysis tool will be a Carrying Capacity Analysis Model that will determine the impacts of additional land development activities on the Florida Keys ecosystem. The FKCCS will be designed to determine the ability of the ecosystem, and its various components, to withstand impacts of additional land development activities. The carrying capacity analysis will consider aesthetic, socioeconomic (including sustainable tourism), quality of life and community character issues, including the concentration of population, the amount of open space, diversity of habitats and species richness. The analysis will reflect the interconnected nature of the Florida Keys' natural systems, but may consider and analyze the carrying capacity of specific islands or groups of islands and specific ecosystems or habitats, including distinct parts of the Keys' marine system.

A5.5.5 WESTERN C-11 BASIN WATER QUALITY TREATMENT

The purpose of this project is to improve the quality and timing of stormwater discharges to the Everglades Protection Area from the Western C-11 Basin located in south central Broward County. The S-9 pump station currently pumps untreated urban and agricultural stormwater runoff from the Western C-11 Basin directly into Water Conservation Area 3A. The project involves construction of a gated control structure on C-11 to divide western seepage waters (i.e., clean water) from the eastern runoff waters in C-11 canal (i.e., polluted water) and construction of an additional pumping station adjacent to S-9 to pump clean seepage back into the Everglades Protection Area. Both features will be remotely controlled using sponsor-installed telemetry.

A5.5.6 SEMINOLE TRIBE BIG CYPRESS RESERVATION WATER CONSERVATION PLAN

The project is located on the Seminole Tribe Big Cypress Reservation in Hendry County, directly north of the Big Cypress National Preserve and west of Water Conservation Area 3A (WCA 3A). The Big Cypress Reservation is traversed by the L-28 and L-28I canals and the North and West Feeder canals. The proposed comprehensive watershed management system is designed to achieve environmental restoration on the Reservation, the Big Cypress Preserve, and the Central and Southern Everglades. In addition, the project will reduce flood damage and promote water conservation on the Reservation. The overall plan has been divided into east and west portions, each of which can provide independent benefits. Due to the legislated funding limits of the Critical Projects program, only the west portion of this project was nominated as a Critical Project. The Seminole Tribe has also requested the assistance of the Natural Resources Conservation Service (NRCS) to implement the eastern portion of the plan. In light of the uncertainty of the NRCS funding for the east portion and the potential that the west portion may not be funded through the Critical Projects program, the combined project is being recommended as an Other Project Element of the Comprehensive Plan to ensure the complete project will be implemented (see Appendix A6).

A5.5.7 SOUTHERN GOLDEN GATE ESTATES HYDROLOGIC RESTORATION

The Southern Golden Gate Estates (SGGE) project area encompasses approximately ninety-four square miles of sensitive environmental landscape in southwestern Collier County, south of Interstate 75 between the Fakahatchee Strand and Belle Meade watersheds. The project area is an important surface storage and aquifer recharge area with a unique ecology of cypress, wet prairie, pine and hardwood hammock and swamp communities. It also includes three major flowways that contribute freshwater to the Ten Thousand Islands Estuary of the western Everglades watershed. Construction of roads and drainage modifications in the 1960's and 1970's have overdrained the area resulting in reduction of aquifer storage, increased freshwater shock load discharges to the estuaries, invasion of upland vegetation and increased frequency of forest fires. Variations of freshwater discharges at large amplitudes have resulted in large fluctuations of salinity level and have eliminated or displaced a high proportion of the benthic, midwater and fish plankton communities in the estuary. The project involves construction of a combination of spreader channels, canal plugs and pump stations, and removal of roads. Implementation of this plan would accomplish the hydrologic restoration of SGGE by introducing sheetflow, re-establishing the historical flowways, reducing runoff by increased evaporation and groundwater recharge, and replacing point flow discharge through the Faka Union Canal with distributed flow along US 41 into the tidal coastal marshes. The Florida Division of Forestry is responsible for managing the public lands within SGGE and will be a participating partner with the SFWMD through construction of this project.

A5.5.8 SOUTH MIAMI-DADE AGRICULTURAL AND RURAL LAND USE AND WATERS MANAGEMENT PLAN

This project is also known as the "South Miami-Dade Agricultural and Rural Retention Plan and South Biscayne Bay Watershed Management Plan". To avoid confusion the original name in the section heading is used throughout this appendix. The project area is the southern portion of Miami-Dade County covering all lands lying outside Miami-Dade County's Urban Development Boundary designated for agricultural use. The growing demands of the Lower East Coast of Florida are straining the water resources of the area. The development of sustainable, environmentally sensitive agriculture in southern Miami-Dade County would provide a more environmentally superior land use than the prospect of uncontrolled urban expansion throughout these watersheds. In comparison to urban development, agriculture has reduced impacts on water quality and quantity thus minimizing remediation requirements and costs. The purpose of both these initiatives/studies is to develop long range management plans for south Miami-Dade County. The plans will recommend future land use and water resources control within the county. Output will be recommendations that will assist in the regulation of the ever-increasing development/growth in south Miami-Dade County. The rural land use component is an integral part of the overall, larger South Biscayne Bay Watershed Plan. Project work involves the preparation of a study document that will identify and quantify major agribusiness elements (i.e. crop prices, water and soil requirements, production costs, etc.). Combined with socioeconomic information, all parameters will be analyzed to establish economic strategies and incentives to strengthen agriculture. The results will be blended into the South Biscayne Bay Watershed Management Plan.

A5.5.9 SOUTHERN CREW PROJECT ADDITION/IMPERIAL RIVER FLOWWAY

The project is located in southern Lee County, bordering the western boundary of the Corkscrew Regional Ecosystem Watershed (CREW). This environmentally sensitive area east of Bonita Springs has been altered by construction of roads, house pads, agricultural berms, and ditches. These alterations have resulted in restriction of historical sheetflow, unnatural water impoundment and flooding, increased pollutant loading to the Imperial River and Estero River (an Outstanding Florida Water), and disruption of natural wetland functions. Water that historically flowed southwesterly has been partially diverted to the east by roadbeds and single family house pads. This has resulted in decreased hydroperiods (excessive drainage) in wetlands to the west of the CREW and the Corkscrew Sanctuary (Audubon) and increased hydroperiods in the CREW and Corkscrew Sanctuary. The proposed project involves acquisition of approximately 4,670 acres of land and restoration of historic flows over this area. The project will be added to the CREW with perpetual management to maintain natural system qualities. The project will: 1) re-establish historical flow patterns and hydroperiods on the lands proposed for acquisition as well as CREW and Corkscrew Sanctuary wetlands to the east, 2) restore historical storage potential of the Southern CREW lands, 3) reduce excessive freshwater discharges to Estero Bay during the rainy season, 4) decrease saltwater intrusion during the dry season, 5) reduce loading of nutrients and other pollutants to the Imperial River and Estero Bay, 6) increase aquifer recharge, and 7) reduce flooding of homes and private lands west of the project area. This project will also reduce the potential that currently exists for forcing water eastward through the CREW Project and the Corkscrew Swamp Sanctuary and possibly harming these important areas by increasing depth and duration in these natural wetland areas. Hydrologic restoration of this land will include the following modifications: 1) removal of existing road beds, 2) removal of single family homes, 3) removal of junk debris, 4) filling of ditches, and 5) removal of agricultural canals and berms. The Kehl Canal weir located at the headwaters of the Imperial River will be modified. More storage capacity will be provided and gates will be added to allow better water management and control of the Kehl Canal, which flows through the land proposed for acquisition.

A5.5.10 LAKE OKEECHOBEE WATER RETENTION/PHOSPHORUS REMOVAL

This project focuses on specific land parcels (project elements) located within four key basins of the Lake Okeechobee watershed. These four basins are the lower Kissimmee River basins (S-65D Basin, S-65E Basin, and S-154 Basin) and the Taylor Creek-Nubbin Slough basin (S-191). Wetlands account for between 18 and 25 percent of the land classification in these basins (based on data from US Fish and Wildlife Service 1990 National Wetlands Inventory); however, approximately 37 percent of these wetlands have been ditched to drain the land for agriculture (i.e., improved pasture). Many of these wetlands were isolated depressions that once functioned as small water retention areas in the landscape. Others were more expansive and experienced drying from the regional drainage system. The current system causes the accelerated loss of water from the watershed as surface water runoff, which is rapidly transported to the tributary system that drains into Lake Okeechobee. The loss of these isolated wetlands has resulted in various environmental impacts. It has contributed to rapid rises in the stage of Lake Okeechobee resulting in the need for damaging freshwater discharges to the estuaries. There has also been a loss of the water quality treatment function that used to result from retaining water for short periods of time in these wetlands, and the loss of wetland habitat for migratory birds and waterfowl. A two-pronged approach will be taken in this project. The first approach is to restore the hydrology of isolated wetlands by plugging the connection to drainage ditches and the second approach is diversion of the collector canal flows to adjacent wetlands to attenuate peak flows and retain phosphorus in Reservoir-Assisted Stormwater Treatment Areas (RSTAs). The project will result in increased regional water storage north of Lake Okeechobee and restoration of wetland functions in the process. At the sub-basin scale, large land parcels that were once part of the tributary system's historic flood plain will be reflooded to add adjacent and/or isolated wetlands back to the landscape.

A5.5.11 TEN MILE CREEK WATER PRESERVE AREA

The project site is located just south of Ten Mile Creek in St. Lucie County. Ten Mile Creek is the largest subbasin delivering water to the North Fork of the St. Lucie River Estuary (SLE) which has been established as an Outstanding Florida Water (OFW). The SLE discharges into the Indian River Lagoon (IRL) which is also an OFW. The IRL is the most biologically diverse estuary in North America. The entire lagoon is endangered from increased runoff from watershed drainage enhancements. Excess stormwater due to drainage improvements is causing radical fluctuations of the salinity concentration in the SLE. Adverse salinity concentrations are eliminating viable habitat suitable for oysters, seagrasses, and marine fish spawning. The project involves construction of a water preserve area to attenuate flows and improve water quality discharged to the SLE/IRL. The proposed site is approximately 1559 acres. The project includes land acquisition, construction, and operation of an aboveground reservoir with a pump station for filling the reservoir from Ten Mile Creek and a gated water-level control structure for the release of water back to the creek. The foot-print of the reservoir is anticipated to be approximately 550 acres in size with the remaining acreage being utilized as a polishing cell and a natural preserve area. Based upon existing topography, stored water depths average ten feet. Total storage capacity will be approximately 5,000 acre-feet. The project also includes construction of four hydraulic control structures to control intake and discharge from both the deep water storage area and the polishing cell.

A5.5.12 L-28 MODIFICATION

The project is located in the southwest corner of Water Conservation Area (WCA) 3A located in western Broward County. Historic freshwater wetland habitats in south Florida have been reduced spatially, compartmentalized, and hydrologically altered as a result of the C&SF Project. Reestablishing the hydrologic and ecologic continuity of the remaining natural areas is expected to benefit the entire Everglades ecosystem by recovering the pre-drainage functions and habitat values of historic freshwater wetlands, reducing the fragmentation, and restoring more natural hydropatterns including associated sheetflow. The purpose of this project is to re-establish the ecological and hydrological connection between WCA 3A and the Big Cypress National Preserve by removing the L-28 and L-28 Tieback levees and borrow canals.

A5.5.13 LOXAHATCHEE SLOUGH ECOSYSTEM RESTORATION PROJECT

The project area is in Palm Beach County within the C-18 Canal Basin and encompasses approximately 10,000 acres of the original Loxahatchee Slough. The intent of the project is to rehydrate the portion of the Loxahatchee Slough currently being drained by the east leg of C-18. In addition, the project will include the removal of much of the exotic species in the area to be rehydrated. These lands have recently been purchased by Palm Beach County under their Environmentally Sensitive Lands Bond Issue and are targeted for environmental restoration.

A5.5.14 GEODETIC VERTICAL CONTROL SURVEYS

The southern portion of Florida has unique features among which are: 1) very flat topography, 2) a large, highly concentrated human population, and 3) a very unique and fragile ecosystem. Because of this flat topography, a slight change in ground level at one location can significantly impact a large ecosystem. The South Florida Water Management District has found that inconsistencies in water level readings at water gauging stations point to questionable vertical survey bench mark data. As an example, in some cases it has appeared that water is running uphill or there is a station with a lower elevation between two stations with higher elevations, along the same river. This lack of precision in existing vertical control can result in erroneous estimates to important hydrologic variables. Errors can distort data and potentially lead to erroneous water management decisions. The project involves the running of 1,250 miles of second-order class I vertical control over a four-year period. This will consist of approximately 1,250 miles of forward runs and 1,250 miles of back runs, for a total of 2,500 miles. Additionally approximately 250 class “B” bench marks (stainless steel rods driven to refusal) and 1,000 class “C” bench marks (poured concrete monuments 12” by 42” deep with belled bottoms) will be established or recovered.

A5.5.15 LAKE TRAFFORD RESTORATION

Lake Trafford is located in north Collier County and is the largest lake south of Lake Okeechobee with a surface area of approximately 1,494 acres. It is the headwaters of the Corkscrew Swamp Sanctuary to the southwest, the Corkscrew Regional Ecosystem Watershed (CREW) to the west, and the Fakahatchee Strand system, which includes the Florida Panther National Wildlife Refuge, to the south. Lake Trafford has poor water quality, extensive muck accumulations, loss of native submergent plant communities, periodic aquatic weed infestations, and numerous moderate fish kills. A massive fish kill occurred in April 1996 which was caused by poor water quality conditions, including high biological oxygen demand, lethal ammonia levels, and depressed dissolved oxygen content. Poor water quality is attributed to internal nutrient cycling from extensive organic muck deposits throughout the lake basin. The project involves the use of one or more 14-inch portable cutter dredges to accomplish lakewide organic sediment removal. Approximately 8.5 million cubic yards of loose, flocculent, organic materials blanket the bottom of the lake and range from approximately nine inches to nine feet in thickness. The material will be pumped to an upland disposal site on existing farmland less than one mile from the lake. The pipeline to the upland disposal area will be located adjacent to an existing ditch with an easement being provided by the landowner. This ditch will also be used to carry the return flow from the disposal area. The disposal area consists of a 449-acre, diked, agricultural facility, which will be divided into three cells. The sponsors have additional lands identified if, in the design phase, it is determined that additional acreage will be required.

A5.5.16 L-31 EAST FLOW REDISTRIBUTION

The project is located in southern Miami-Dade County adjacent to Biscayne National Park and Biscayne Bay, along a 3.5-mile stretch of the L-31 East levee between structures S-20F and S-21A. Historically, freshwater entered the southern Biscayne Bay Estuary through a series of creeks and sloughs. The L-31 East levee system was constructed in the 1960's and cutoff this natural flow of water. The primary canal system in the southern Biscayne Bay watershed was designed for flood control. Freshwater is indiscriminately discharged from a few control structures into the estuary. Typical estuarine biological communities are not adapted to conditions that allow frequent and wide swings in salinity that currently occur at the mouths of these canals. Studies have documented reduced benthic communities near the canal discharge zones and even destruction of seagrass beds from slugs of freshwater. This project will install a freshwater distribution system to facilitate the restoration of more natural flows of freshwater into Biscayne Bay. Based upon data from ongoing studies, freshwater flow will be restored into the coastal mangrove wetlands at suitable locations such as sloughs or locations identified as historic creeks. The project consists of constructing a freshwater distribution system for the area east of the L-31 East levee. The system will be constructed over a length of approximately 3.5 miles from S-21A to just north of S-

20F. Work will include installing a series of culverts to convey fresh water from the borrow canal along the west side of the levee to the marsh and mangrove area east of the levee. Twelve 36 inch culverts will be placed under the L-31 East levee at locations where historic creeks or sloughs once existed. The culverts will be fitted with flash boards and flap gates and salinity control will be maintained. Freshwater in the spreader ditch will be conveyed into mangrove wetlands fringing Biscayne Bay at appropriate locations to restore historical creeks or sloughs.

A5.5.17 HENDERSON CREEK AND BELLE MEADE RESTORATION

This region of southwest Florida is currently facing a high urban growth rate. Changes in land-use within the primary watersheds that drain into the Rookery Bay Estuary and adjacent waters have been identified in the Rookery Bay National Estuarine Research Reserve (RBNERR) Management Plan as the highest priority resource issue that threatens the long-term preservation of RBNERR estuarine resources. The coastal habitats in Collier County have been impacted by alterations of hydrology and habitat due to channelization of natural systems. Roads, canals, planned unit developments, commercial projects, and agriculture represent primary land-uses within RBNERR watersheds. These alterations have greatly modified the volume, timing and quality of freshwater entering the fragile estuarine ecosystems. In addition, channelized flow in these watersheds has severely restricted the ability of the associated wetlands to filter pollutants. The area known locally as Belle Meade is the primary drainage basin for the Henderson Creek Estuary and is currently targeted for acquisition by the Florida Department of Environmental Protection through the Conservation and Recreation Lands Program. Historically, freshwater traveled across the surface of the land, percolating through wetland flowways before entering Henderson Creek. While channelization and development have disrupted this system, acquisition and restoration of the undeveloped lands surrounding Henderson Creek, which link the watershed and estuary, can stop further hydrologic and habitat disturbance. These estuarine areas provide critical nursery habitat for commercially and recreationally important finfish and shellfish. Land acquisition will assure long-term protection of the upland and wetland communities associated with these parcels. Additionally, the proposed restoration efforts on the acquired lands will return a portion of the historic timing, duration and volume of freshwater inflow, thereby enhancing estuarine habitats.

A5.5.18 LAKE OKEECHOBEE TRIBUTARY SEDIMENT DREDGING

The project would be located in selected tributaries in the Lake Okeechobee watershed. Historically, south Florida waters were low in nutrients (oligotrophic). Elevated phosphorus loading of waterbodies and the resulting increased water phosphorus concentrations (eutrophication) may have various ecological effects. These effects may include increased primary productivity, loss of water column dissolved oxygen, algal blooms, and changes in vegetation and biodiversity. The significance of such phosphorus loading may be the reduction or loss of a waterbody’s habitat and/or recreational values. Sediment found in tributaries to Lake Okeechobee is an important source of phosphorous that contributes to the excessive loading to the lake. This project involves dredging sediments from approximately ten miles of primary canals. As a result, an estimated 150 tons of phosphorous will be removed from potential loading to the lake.

A5.5.19 DEVELOP AND IMPLEMENT AGRICULTURAL BEST MANAGEMENT PRACTICES IN THE C-111 BASIN

Proposed structural and operational changes to the C&SF Project proposed in recommended Comprehensive Plan were evaluated to assess gross changes in regional hydrology. However the temporal and spatial scale of the current modeling tools and the density of the current monitoring system are inadequate to predict and assess the changes in the local water table and localized flooding in the south Miami-Dade agricultural area. This project will: 1) evaluate and enhance the available regional hydrological and water quality data and 2) field calibrate, formulate and develop a model capable of simulating the hydrology in the agricultural area at a spatial and temporal scale that would allow prediction of localized impacts from the proposed structural and operational changes to the C&SF Project.

A5.5.20 NORTH FORK OF THE NEW RIVER RESTORATION

The proposed project is located in the City of Ft. Lauderdale, along the North Fork of the New River between 9th Avenue and Sunrise Boulevard. The North Fork is a shallow, meandering tributary of the New River extending through the northwest section of the City of Fort Lauderdale. Minimal tidal flow within this section of the river results in limited circulatory exchanges of tidal waters. Flow has been restricted by large amounts of sediment and debris. Natural freshwater flow characteristics are further restricted in the upstream section of the North Fork by the S-33 salinity control structure that effectively eliminates freshwater inflow from the western drainage basin. The New River is one of the few naturally occurring surface water bodies in Broward County. Prior to the 1900's, the New River was a prominent drainage feature of the Everglades that seasonally emptied into the Atlantic Ocean. The existing shoreline no longer resembles its historical condition. The shoreline is actively eroding in some places and exotics have replaced native species in some riparian areas. In 1993, Broward County Department of Natural Resource Protection (DNRP) research identified many sources of ongoing and historic pollution. This degradation of water quality and habitat represents a negative impact not only on the environment, but the health and economy of the adjacent communities. DNRP developed "The New River Restoration Plan (1994)" to identify water quality problems, identify the river system's biological diversity, and to develop a plan to create a more natural condition for the inhabitants of this community. The restoration project involves: 1) spot dredging to improve water quality and water circulation, 2) removal of exotic plant species and revegetation with native plants, 3) development of analytical tools, 4) removal of litter and debris, and 5) development of a plan which promotes urban infill consistent with the Eastward Ho! Initiative.

A5.5.21 L-8 CANAL- WATER CATCHMENT AREA LOXAHATCHEE SLOUGH INFRASTRUCTURE IMPROVEMENTS

The project is located in western Palm Beach County along the L-8 Canal. The purpose of the project is to reroute water from the L-8 Canal to the City of West Palm Beach's Water Catchment Area and then into Loxahatchee Slough and Estuary. The project will: 1) benefit approximately 10,000 acres of wetlands in the Loxahatchee Slough, 2) provide additional flow for the restoration of the Loxahatchee River Estuary, and 3) reduce dependency on Lake Okeechobee in dry periods. The project involves: 1) increasing the capacity at Control 2 Pump Station near the intersection of the M-Canal and L-8 Canal, 2) M-Canal dredging and widening to increase conveyance, and 3) removal of a constriction at Control 3 on the M-Canal at the entrance to the Water Catchment Area.

A5.5.22 FLORIDA KEYS TIDAL RESTORATION

The objective of this project is to restore flows to tidal creeks by installing culverts under US Highway 1 at four locations in Monroe County (between mile markers 54 and 57). These projects are similar to a culvert project at Key Colony Beach completed in 1991, which was very successful in improving the near-shore water quality. The individual projects can be described as follows: 1) restore Tarpon Creek just south of mile marker 54 on Fat Deer Key, 2) restore an unnamed creek between Fat Deer Key and Long Point Key south of mile marker 56, 3) restore tidal connection adjacent to Little Crawl Key and 4) restore tidal connection between Florida Bay and the Atlantic Ocean at mile marker 57. The accumulation of organic material in these creeks has resulted in a degradation of water quality and sea grass habitat. Impacts originally occurred as a result of the construction of the Flagler Railroad bed (currently U.S. Highway 1) which blocked tidal flow and circulation in near-shore waters. Restoration benefits expected by installation of these culverts include; 1) enhanced circulation and flushing, 2) improved water quality, and 3) restoration of marine habitats.

A5.5.23 LAKE WORTH LAGOON RESTORATION

In Palm Beach County, the Lake Worth Lagoon Estuary is the receiving water body for most of the urban watershed. Sediment laden flows from C-51 have resulted in accelerated sedimentation of Lake Worth Lagoon (the receiving waters). The restoration project involves three phases. Phase I will examine both the quantity and quality of bottom sediment accumulations within C-51 and the downstream discharge area within the lagoon. Phase II will develop a project plan to provide for sediment removal or capping that could include creating a series of sediment traps along the C-51 where sediment accumulations increase. Phase III will involve the removal of bottom sediments within C-51 as well as implementing a prototype project to either remove or cap the organic bottom layer within the lagoon. The elimination of these sediments from the C-51 discharge will provide for long-term improvements to the lagoon and ensure success of additional habitat restoration projects planned by Palm Beach County.

A5.5.24 PALM BEACH COUNTY WETLANDS-BASED WATER RECLAMATION PROJECT

The Wetlands-Based Water Reclamation Project (WWRP) proposes to treat wastewater from the East Central Regional Wastewater Treatment Facility (ECR) using Advanced Wastewater Treatment (AWT) processes to remove nitrogen and phosphorus. This will then be followed with superior treatment technology to remove phosphorus to approximately 50 parts per billion or less. Phase I of the WWRP will consist of a 10 Million Gallons per Day (MGD) operation with 6 MGD of the water discharged into approximately 1,500 acres of bermed marsh where it will be used to hydrate the marsh as well as manage the hydroperiod and water quality of the wetland environment. The water will then be pumped to another marsh of approximately 300 acres surrounding the City of West Palm Beach wellfield. Infiltration of the water into the wellfield will occur as the wellfield pumps groundwater into the adjacent M Canal where it becomes surface water. The surface water in M Canal will flow towards Clear Lake, which is the surface water source of drinking water for the City of West Palm Beach. At the City's water treatment plant, the surface water will be treated to drinking water standards prior to entering the water supply distribution system for the City as well as the Town of Palm Beach and South Palm Beach. The remaining 4 MGD of the 10 MGD of reclaimed water will be routed from the AWT/superior treatment technology facility to residential lake systems surrounding both the City's wellfield and Palm Beach County's 8W Water Treatment Plant wellfield. The lake systems will be used to recharge the groundwater in the vicinity of both wellfields, thereby decreasing impacts associated with withdrawals from both wellfields.

A5.5.25 LAKE OKEECHOBEE DEMONSTRATION AQUIFER STORAGE AND RECOVERY PROJECT

This project will implement a regional Aquifer Storage and Recovery (ASR) demonstration project at Lake Okeechobee to increase storage in the regional system. This increased storage by itself will provide additional water to meet local agricultural demands in the Everglades Agricultural Area (EAA). Historically, water is brought into the EAA from Lake Okeechobee to supply local agricultural interests. It is the intent of this demonstration project to evaluate the feasibility of storing Class 1 surface water within the basin for use during times of need. The demonstration project will consist of four 5 Million Gallon per Day (MGD) Floridan Aquifer wells and one 20 MGD surface water pump to withdraw water from Lake Okeechobee. Water will be withdrawn from Lake Okeechobee and injected into the Floridan Aquifer System for later retrieval. It is anticipated that extensive discussions with the Environmental Protection Agency and the Florida Department of Environmental Protection will be required for permitting injection of Class 1 surface water into the Floridan Aquifer System. By creating additional storage in the region, less water will be required from the regional system to meet demands of the agricultural areas.

A5.5.26 MICCOSUKEE WATER MANAGEMENT AREA

The Miccosukee Water Management Area (MWMA) is a project to construct a managed wetland on the Miccosukee Tribe’s Alligator Alley Reservation located in western Broward County. The purpose of the project is to provide water storage capacity and water quality enhancement for waters which discharge into the Everglades Protection Area. The project will convert approximately 900 acres of tribally owned cattle pastures into a wetland retention / detention area, which will be designed to filter out harmful nutrients contained in stormwater runoff before the water enters the Everglades Protection Area. Tribal Water Quality Standards dictate a numerical criterion of 10 parts per billion for total phosphorous inside the Everglades Protection Area. The MWMA was sized to treat the nutrient inputs of the Miccosukee Tribal lands.

A5.5.27 SIX PERMANENT WATER AND METEOROLOGICAL STATIONS

The proposal is to establish six permanent water level measuring stations in the Everglades and Biscayne Bay National Parks area. In addition to collecting water levels, all or most of the units will also collect backup water levels (storm surge), wind speed and direction, rainfall, barometric pressure, air and water temperature, relative humidity, solar radiation, and salinity. All data will be transmitted from the field units to the Florida Department of Environmental Protection for data analysis once every three hours via Geostationary Operational Environmental Satellite (GOES). Each station will also be connected to a telephone line or will have a cellular telephone connected to it. The telephone connection will be used for repairs to the units, quality assurance, and transmitting real-time data in emergencies. The units that are hardwired to a telephone line will include a speech synthesis function so the public would have the option of hearing the most current data (real-time) by calling the station. The sites that are located in secured areas with electrical power will also be connected to computers so that Park Service personnel and/or the public will have a real-time graphic display of the data being collected.

A5.5.28 NUTRIENT REMOVAL AND DOSING STUDIES FOR EVERGLADES NATIONAL PARK

The project involves development of water quality standards (i.e., phosphorous thresholds) for waters of Everglades National Park (ENP).

A5.5.29 WATER CONSERVATION AREA 3B SEEPAGE REDUCTION

The project would be located at the southeast corner of Water Conservation Area (WCA) 3B in Miami-Dade County. This project involves installation of an underground seepage barrier using grout technology to a depth of 100 feet. The barrier would be located between two control structures (S-334 and S-335), in an area of extremely steep groundwater gradients. The suggested site is in an area where there are large documented seepage losses out of WCA 3B into the south Miami-Dade canal system. The proposed barrier would significantly reduce these losses and result in improved water deliveries across L-29 to the eastern portion of Everglades National Park.

A5.5.30 HILLSBORO PILOT AQUIFER STORAGE AND RECOVERY PROJECT

The project would be located in Palm Beach County. The project proposes construction of a regional Aquifer Storage and Recovery (ASR) demonstration project in the Hillsboro Canal region to capture and store excess flows that are currently released to tide for later use during dry periods. Recovery of the stored ASR water will be utilized to recharge local utility wellfields helping to prevent further inland migration of the saline interface. Historically, water is brought from the Water Conservation Areas and Lake Okeechobee into the Hillsboro Canal Basin to supply local urban users. The demonstration project would consist of four 5 Million Gallon per Day (MGD) Floridan Aquifer wells and at least eight 2.5 MGD Surficial aquifer wells. Water will be withdrawn from the surficial aquifer and injected into the Floridan Aquifer System for later retrieval. By creating additional storage in the region, less water will be required from the regional system to the urban areas which could then be used to meet restoration needs.

A5.5.31 LAKES PARK RESTORATION

Lakes Park is located east of Cape Coral in Lee County, just west of Highway 41. The park consists of an old rock mine with a series of borrow pit "lakes." The entire area drains south into Hendry Creek, an Outstanding Florida Water, which flows for a few miles before entering Estero Bay. Lee County has developed the area as a regional park with a bathing area along the shoreline of the lakes. Adjacent to the developed area, the remaining natural habitat contains pine flatwoods with some cypress heads. The pits capture runoff from the surrounding developed area (commercial, industrial, and residential). County monitoring has indicated a decline in water quality in the lakes. The lakes are infested with hydrilla and adjacent uplands and islands are covered with exotic plant species such as Australian pine and Brazilian pepper. The project is expected to enhance surface water runoff quality by creating a meandering flowway with shallow littoral zones and removing aquatic and upland exotic vegetation. The littoral zone will be harvested periodically to remove excess nutrients from the system. Exotic vegetation will be removed and replaced with native vegetation on 11 acres of upland.

A5.5.32 TOWN OF FT. MYERS BEACH

The Town of Fort Myers Beach in located on a barrier island of the southwest coast in Lee County. The town has identified the need for the protection of adjacent Estero Bay and local beaches from pollutants transported via stormwater runoff from the island on which the town is located. Most of the town is urbanized and has an inadequate stormwater management system. Components identified for this project include: 1) inventory of stormwater systems, 2) sediment sampling, 3) screening of illicit connections, and 4) implementation of an urban retrofit project. The project is designed to enhance Estero Bay and has received full support of local government and residents of the community. The town has already begun to identify stormwater "hot spots" through inventory and sampling procedures and has converted 48,000 square feet of asphalt to pervious paving materials. Pores in the asphalt of these materials allow runoff from parking lots to flow through the pavement into an underground reservoir of small stones, and then gradually filter into the surrounding soil. Other options for controlling urban runoff that are under consideration include installation of "water quality inlets," which are baffled concrete tanks for solids and oil separation, as well as numerous other best management practices (e.g. encouraging the use of slow-release fertilizers, etc.) The project is expected to provide immediate water quality and ecological benefits to the Estero Bay Aquatic Preserve by reducing pollutant loading to receiving waters.

A5.5.33 WINSBERG FARMS CONSTRUCTED WETLAND

In an effort to reduce the amount of treated water from the Southern Region Water Reclamation Facility (SRWRF) that is currently wasted in deep injection wells, the Palm Beach County Water Utilities Department (PBCWUD) plans to further treat and recycle this water. The PBCWUD has completed construction of a 50-acre constructed wetland located at the County's System 3 site east of Jog Road, just southeast of the Winsberg property. This wetland has been named Wakodahatchee, which is Seminole Indian for "created waters". As part of this wetland, a public access facility with limited parking, boardwalk, kiosks and interpretive signage was designed to educate the public about the importance of wetlands for both treatment of water and creation of wildlife habitat. This project proposes construction of an additional 175 acres of wetlands on the Winsberg property. This will serve to not only recycle and preserve additional water for future use, but will link the Wakodahatchee and Winsberg Farms facilities and provide additional green space in area currently under heavy development. Approximately, 6 to 8 Million Gallons per Day of reclaimed water from the SRWRF would be applied to the area. The wetland would be planted to maximize the diversity of native plant material and habitat for various species of wildlife.

A5.5.34 SPRING CREEK RECONNECTION AND REHYDRATION PROJECT

The project proponent is unclear but appears to be Pueblo Bonito Partnership for Housing, Incorporated, a private developer. The project is located in Lee County. In the early 1960's, a 40-foot wide canal was dug that cut off approximately 2,200 linear feet of Spring Creek which flows into Estero Bay. In 1990, the canal was designated an Outstanding Florida Water (OFW). The project purpose is to restore approximately 2,200 linear feet of the historic Spring Creek floodplain through three components. Reestablish the headwaters of Spring Creek by: 1) constructing a weir to redirect canal inflow into the historic Spring Creek flowway, 2) removing approximately 27,000 cubic yards of spoil which currently segments the floodplain and 3) replanting tress within the restored areas. This project appears to be, at least in part, a compensatory mitigation requirement for permits associated with a private residential development. If so, the ecological benefits of the project are already allocated to offset the adverse impacts of the permitted development. Further analysis is needed to determine the exact scope of this proposal and the allocation of the benefits to be generated.

A5.5.35 RESTORATION OF PINELAND AND TROPICAL HARDWOOD HAMMOCKS IN C-111 BASIN

The project is located in south Miami-Dade County, just east of Everglades National Park, along State Road 9336 in the area known as the Frog Pond. Eighty percent of the Frog Pond was used for agricultural purposes and farmers rock plowed the cap rock to create soil for tomato farming. The Frog Pond has since been purchased by the SFWMD as part of the C-111 Project to restore the Taylor Slough portion of the Everglades. The project involves restoring south Florida slash pine and tropical hardwood hammock species on a 200-foot wide strip on each side of the two miles of State Road 9336 from the C-111 Canal to the L-31W Canal (approximately 50 acres). This project will demonstrate the techniques required to re-establish native conifer and tropical hardwood forests on land that has been rock plowed.

A5.6 CRITICAL PROJECTS IN THE COMPREHENSIVE PLAN

This section describes how the 35 Critical Projects nominated by the Working Group are addressed in the Restudy. Seven Critical Projects are included in the Restudy Without Plan Condition. Three are included as Pilot Projects. Twenty are included as D-13R components or Other Project Elements (OPEs) or sub-features thereof. Five are considered to be stand-alone research or data collection efforts that will be needed during the Preconstruction and Design Phase (PED) of the Project Implementation Report (PIR) process. Two are recommended for additional study. Each of these categories is further described below. (Note: The number of Critical Projects mentioned above totals 37 instead of 35 because; part A of the Melaleuca Eradication Project is listed in the Without Plan Condition while parts B and C are listed as an OPE, and the L-31 East Flow Redistribution project is listed in the Without Plan Condition and as an OPE.)

A5.6.1 FUTURE WITHOUT PLAN CONDITION

With respect to the Critical Projects, the Without Plan Condition is defined as those Critical Projects that have an ASA(CW) approved letter report **and** are anticipated to be funded under the Critical Projects program. As of February 1999, twelve Critical Projects had received ASA(CW) approval:

- East Coast Canal Structures
- Tamiami Trail Culverts
- Melaleuca Eradication Project – New Facility (part A)
- Florida Keys Carrying Capacity Study
- Western C-11 Water Quality Treatment
- Seminole Tribe Big Cypress Water Conservation Plan (west)
- Southern Golden Gate Estates Hydrologic Restoration
- Southern Crew Project Addition/Imperial River Flowways
- Lake Okeechobee Water Retention/Phosphorous Removal
- Ten Mile Creek Water Preserve Area
- Lake Trafford Restoration
- L31 East Flow Redistribution

Of these twelve approved projects, it is anticipated that following seven projects will be funded through the Critical Projects program:

- East Coast Canal Structures
- Tamiami Trail Culverts

- Melaleuca Project – New Facility (part A)
- Florida Keys Carrying Capacity Study
- Western C-11 Water Quality Treatment
- L-31 East Flow Redistribution

Furthermore, it is anticipated that the North Fork of the New River Restoration project will receive ASA(CW) approval and can be funded through the remainder of the Critical Projects program funds. ***Table A5-2*** displays the seven Critical Projects that are included in the Without Plan Condition for the Restudy.

TABLE A5-2
CRITICAL PROJECTS IN THE RESTUDY WITHOUT PLAN CONDITION

Rank	Critical Project Title
1	East Coast Canals
2	Tamiami Trail Culverts
3	Melaleuca Eradication - New Facility (part A)
4	Florida Key Carrying Capacity Study
5	Western C-11 Water Quality Treatment Project
16	L-31East Flow Redistribution
20	North Fork New River Restoration

A5.6.2 PILOT PROJECTS

The Comprehensive Plan includes the early implementation of six demonstration or "pilot" projects. Three of these were nominated as Critical Projects but, in light of the Working Group's priorities and the funding limits of the program, it is not anticipated that they can be implemented through the Critical Projects program. Accordingly, the three Critical Projects listed in ***Table A5-3*** are included in the Comprehensive Plan as pilot projects.

TABLE A5-3
CRITICAL PILOT PROJECTS

Rank	Critical Project Title
25	Lake Okeechobee Aquifer Storage and Recovery Demonstration Project
29	WCA 3B Seepage Reduction
30	Hillsboro Pilot Aquifer Storage and Recovery Project

A5.6.3 D-13R COMPONENTS

The Comprehensive Plan is comprised of the features of Alternative D-13R and the OPEs. The alternative formulation process (described in Section 7 of the Main Report) followed the establishment of the Critical Projects list by the Working Group. As the alternative formulation process progressed, some of the Critical Projects were adopted as D-13R components or sub-features thereof. Detailed design and implementation of the Critical Projects which are included as features and/or concepts of D-13R components will occur during the Project Implementation Report process. ***Table A5-4*** lists the four Critical Projects that are related to D-13R components. Appendix A4 provides detailed descriptions of the D-13R components. The Critical Project features that are included in D-13R components may differ from the original project descriptions provided in Section A5.5 above. This is because the features/concepts were refined during the alternative formulation process.

TABLE A5-4
CRITICAL PROJECTS IN ALTERNATIVE D-13R

Rank	Critical Project Title	D-13R Component Designation and Title
11	Ten Mile Creek Water Preserve Area	UU6 - C-23/24 Northfork and Southfork Reservoirs
12	L-28 Modification	QQ6 - Decompartmentalize WCA 3
13	Loxahatchee Slough Ecosystem Restoration	K6 - Additional L-8 Improvements
21	L-8 Canal/Water Catchment Area/Loxahatchee Slough Infrastructure Improvements	K6 - Additional L-8 Improvements

A5.6.4 OTHER PROJECT ELEMENTS

In addition to the components of Alternative D-13R, the Comprehensive Plan includes a group of projects that could not be evaluated using the modeling tools employed during the iterative alternative plan formulation process. This group of components has been termed Other Project Elements (OPEs). An initial list of potential OPEs was developed from the Critical Projects list; the Governor's Commission's Conceptual Plan, and suggestions by Restudy Team members. ***Table A5-5*** lists the16 Critical Projects that are included in the Comprehensive Plan as OPEs, or sub-features thereof. See Section 9 of the Main Report and Appendix A6 for additional information about OPEs.

TABLE A5-5
CRITICAL PROJECTS INCLUDED IN THE COMPREHENSIVE PLAN AS OPEs

Rank	Other Project Element Title
3	Melaleuca Eradication Project[1] part B – Renovate Existing Facility part C – Implement Biological Controls
6	Seminole Tribe Big Cypress Reservation Water Conservation Plan[2]
7	Southern Golden Gates Hydrologic Restoration
9	Southern CREW Project Addition/Imperial River Flowways
10	Lake Okeechobee Water Quality Treatment Facilities (includes Lake Okeechobee Water Retention/Phosphorus Removal)[3]
15	Lake Trafford Restoration
16	Biscayne Bay Coastal Wetlands (includes L-31 East Flow Redistribution)[4]
17	Henderson Creek and Belle Meade Restoration
18	Lake Okeechobee Tributary Sediment Dredging
22	Florida Keys Tidal Restoration
23	Lake Worth Lagoon Restoration
24	Palm Beach County Wetlands Based Water Reclamation Project
26	Miccosukee Water Management Plan
31	Lakes Park Restoration
33	Winsberg Farms Constructed Wetlands Project
35	Restoration of Pineland & Hardwood Hammocks in C-111 Basin

[1]The New Facility (part A) proposed in the Melaleuca Eradication Project (CP) is included in the Restudy Without Plan condition. The Renovate Existing Facility (part B) and Implement Biological Controls (part C) portions of the Melaleuca Eradication Project (CP) are combined as an OPE.

[2] The west portion of the Seminole Big Cypress Reservation Water Conservation Plan (CP) was combined with the east portion of the project to form a single OPE.

[3] The Lake Okeechobee Water Retention/Phosphorous Removal (CP) project was combined with the proposed OPE titled Lake Okeechobee Watershed Water Quality Treatment Facilities. These are essentially the same type of project thus they were combined as a single OPE.

[4] The L-31 East Flow Redistribution project was incorporated into the Biscayne Bay Coastal Wetlands OPE.

A5.7 PROJECT IMPLEMETATION ACTIVITIES

The five Critical Projects displayed in ***Table A5-6*** are considered to be research or data-collection activities. Some of these activities are expected to provide useful information during the Project Implementation Report (PIR) process for various components of the Comprehensive Plan. Furthermore, some of these activities are expected to improve the region-wide adaptive assessment process. These processes are described in Section 10 of the Main Report and Appendix M.

A6.3.7.2 Melaleuca Eradication Project (Part B) – Renovation And Improvements – Biological Control Quarantine And Research Facility........ 34
A6.3.7.3 Melaleuca Eradication Project – Implement Biological Controls 35

APPENDIX A6
OTHER PROJECT ELEMENTS

The recommended Comprehensive Plan is comprised of the components of Alternative D-13R and a group of projects that could not be evaluated using the modeling tools used during the iterative alternative plan formulation process (See Section 7 of the Main Report). This group of projects has been termed Other Project Elements (OPEs). This Section of the Plan Formulation Appendix describes the OPE formulation and evaluation process.

A6.1 FORMULATION PROCESS

Formulation of the OPEs that are included in the Comprehensive Plan was generally a three-step process. First, a list of potential OPEs was compiled from a variety of sources. Next, an interagency evaluation team conducted an initial evaluation of the OPEs. Finally, in response to comments on the Draft Comprehensive Plan, additional formulation resulted in the array of OPEs included in the recommended Comprehensive Plan. Each of these formulation steps is further described below.

A6.1.1 Initial Screening

The OPEs are defined by the following criteria; 1) the project must be a component that could not be evaluated using the South Florida Water Management Model, 2) the project must support and be consistent with Restudy objectives, 3) the project must have a Federal interest, and 4) the project should not be stand-alone research or data collection. A list of potential OPEs was compiled from the Critical Projects list (see Appendix A5): the Governor's Commission's Conceptual Plan, and suggestions by Restudy Team members. Project proponents were requested to prepare brief "OPE fact sheets" to be used in the evaluation process described in the next section. Information to be provided in the fact sheets included descriptions of: 1) features/operations of the proposed project and its relationship to the Comprehensive Plan, 2) the purpose of the project including a description of the existing condition of the ecosystem in the area, 3) the expected benefits and/or impacts of the project and how they are measured, 4) techniques, models, and procedures that will define project outputs, and, 5) a cost estimate. The resulting list of 38 potential OPEs (the initial list) is displayed in ***Table A6-1***. The table is arranged according to geographic region.

TABLE A6-1 Initial List of Potential Other Project Elements

Kissimmee River Basin and Lake Okeechobee
Additional Storage in Chain of Lakes (above Lake Cypress)
Restore Wetland and Aquatic Habitat at Pool A
Restore Wetland and Aquatic Habitat at Pool E
Restore Wetland and Aquatic Habitat at Paradise Run
Lake Istokpoga Restoration
Lake Okeechobee Tributary Sediment Dredging (CP)
Lake Okeechobee Watershed Water Quality Treatment Facilities (includes CP)
Restoration of Kreamer, Torry, and Ritta Islands
Caloosahatchee River Basin
Restore Natural Flows at Sanibel/Captiva Causeway
Caloosahatchee River Oxbow Restoration
Lower East Coast Region
Pal Mar and Corbett Hydropattern Restoration
Winsberg Farms Constructed Wetland (CP)
Palm Beach County Wetlands-Based Water Reclamation Project (CP)
Central Palm Beach County Water Preserve Area and LNWR Enhancement by Reclaimed Water
West Palm Beach Water Catchment Area Enhancement Reclaimed Water
Acme Basin B Discharge
Protect and Enhance Existing Wetland Systems along LNWR including the Strazzulla Tract
Lake Worth Lagoon Restoration (CP)
North Fork of the New River Restoration (CP)
Northern Broward Regional Reuse
City of Hollywood Reuse
Pond Apple Slough Restoration
South Miami-Dade Agricultural and Rural Area Land Use and Water Management Plan (CP)
Restoration of Pineland and Tropical Hardwood Hammocks in C-111 Basin (CP)
Biscayne Bay Coastal Wetlands (includes L-31E Flow Redistribution (CP))
Western Basin & Big Cypress Basin
Seminole Tribe Big Cypress Reservation Water Conservation Plan (CP)
Henderson Creek Belle Meade Restoration (CP)
Reversing Overdrainage from Barron River Canal
Miccosukee Water Management Area (CP)
Everglades National Park, Florida Bay and Florida Keys
Flamingo Road Improvements to Restore Hydrologic Flows
Restore Natural Flow into Florida Bay by Removal of Causeway at Adams Waterway, MM103,
Florida Keys Tidal Creek Restoration (CP)
Tea Table Fill Removal
Southwest Florida
Lakes Park Restoration (CP)
Southwest Florida Water Management Model
Spring Creek Reconnection and Rehydration Project (CP)
Town of Ft. Myers Beach (CP)
System-wide
Melaleuca Eradication Project (CP) part A – New Facility part B – Renovate Existing Facility part C – Biological Agent Rearing

CP= Critical Project

A6.1.2 Additional Screening And Initial Evaluation

On June 17, 1998, an interdisciplinary team met to evaluate the initial list of potential OPEs. Expected outputs for each project were estimated in four categories: 1) **ecological** outputs based on natural hydrology, spatial extent, habitat quality and improvement in native flora and fauna, 2) urban and agricultural **water supply**, 3) **flood damage reduction**, and 4) **water quality**. The following rating system was used in each of the four output categories:

++ (Major beneficial effect)
+ (Some beneficial effect)
0 (No beneficial or detrimental effect)
- (Some detrimental effect)
- - (Major detrimental effect)

In addition, the team looked at two other parameters 1) **geographic extent** and 2) **significance**. The geographic extent of benefits or detriments was simply designated as having either a Local or Regional effect. The significance parameter reflects the “importance” of the project in support of Alternative D-13R and/or the goals of the Restudy. The significance parameter was rated as High, Moderate, or Low. All six parameters were rated using the team’s collective best professional judgment based on information provided in the fact sheets submitted by the project proponents and/or team members’ personal knowledge of the projects.

The evaluation team began with the initial list of potential OPEs and screened it again based on the sufficiency of the information provided in the fact sheets and personal knowledge of team members. The team recognized that much of the available information about the projects was conceptual. Even so, the team was not able to evaluate eleven of the potential OPEs due to lack of information. Team ratings of the remaining 27 potential OPEs are presented in the matrix displayed in ***Table A6-2***. The eleven potential OPEs that were not rated are included in the matrix and the reasons they could not be rated are noted in the comments column. The table is arranged according to geographic region.

TABLE A6-2
Potential Other Project Elements Evaluation Matrix

OPE TITLE	Geo Extent	Signif-icance	Eco-logical	Water Supply	Flood Control	Water Quality	Comments
Kissimmee River Basin and Lake Okeechobee							
Additional Storage in Chain of Lakes (above Lake Cypress)	REG	HIGH	++	0	-	+	Minimal information in fact sheet. Evaluation based on the concept.
Restore Wetland and Aquatic Habitat at Pool A	REG	HIGH	++	-	0	+	
Restore Wetland and Aquatic Habitat at Pool E	REG	HIGH	++	-	0	+	Evaluation based on FWS OPE report (Draft 16 Jun 98)
Restore Wetland and Aquatic Habitat at Paradise Run	REG	HIGH	++	-	0	+	
Lake Istokpoga Restoration	REG	MOD	++	0	+	0	
Lake Okeechobee Tributary Sediment Dredging (CP) [1]	REG	LOW	+	0	0	+	
Lake Okeechobee Watershed Water Quality Treatment Facilities (incl CP)	REG	MOD	+	0	0	++	
Restoration of Kreamer, Torry, and Ritta Islands	LOC	LOW	+	0	0	0	No fact sheet. Evaluation based on concept that island littoral zones could be rehabilitated to natural emergent vegetation communities.
Caloosahatchee River Basin							

[1] CP = Critical Project.

OPE TITLE	Geo Extent	Signif-icance	Eco-logical	Water Supply	Flood Control	Water Quality	Comments
Restore Natural Flows under Sanibel/Captiva Causeway.	LOC	LOW	++	0	0	+	No fact sheet. Evaluation based on assumption that historic tidal circulation could be restored.
Caloosahatchee River Oxbow Rehabilitation	LOC	MOD	++	0	0	+	
Lower East Coast							
Pal Mar and Corbett Hydropattern Restoration	REG	MOD	++	+	0	+	
Winsberg Farms Constructed Wetland (CP)	LOC	LOW	+	+	0	0	
Palm Beach County Wetlands-Based Water Reclamation Project (CP)	LOC	MOD	+	++	0	0	
Central Palm Beach County Water Preserve Area and LNWR Enhancement by Reclaimed Water							Not enough information to evaluate. Needs regional benefit analysis. Is there a need for this reuse water in the regional system?
West Palm Beach Water Catchment Area Enhancement by Reclaimed Water							Not enough information to evaluate. Needs regional benefit analysis. Is there a need for this reuse water in the regional system?
Acme Basin B Discharge	REG	MOD	+	+	+	+	
Protect and Enhance Existing Wetland Systems along LNWR including the Strazzulla Tract	REG	MOD	+	+	+	+	
Lake Worth Lagoon Restoration (CP)	LOC	LOW	+	0	0	+	

OPE TITLE	Geo Extent	Signif-icance	Eco-logical	Water Supply	Flood Control	Water Quality	Comments
North Fork of the New River Restoration (CP)	LOC	LOW	+	0	0	++	
Northern Broward Regional Reuse							Not enough information to evaluate. Needs regional benefit analysis. Is there a need for this reuse water in the regional system?
City of Hollywood Reuse							Not enough information to evaluate. Needs regional benefit analysis. Is there a need for this reuse water in the regional system?
Pond Apple Slough Restoration	LOC	MOD	+	0	0	+	The purpose of the project is to compensate for potential adverse hydrological effects of D-13R. This is an implementation issue.
South Miami-Dade Agricultural and Rural Land Use and Water Management Plan (CP)							Not evaluated - This is a study not a project.
Restoration of Pineland and Tropical Hardwood Hammocks in C-111 Basin (CP)	LOC	LOW	+	0	0	0	
Biscayne Bay Coastal Wetlands (includes L-31 E Flow Redistribution CP)	REG	HIGH	++	0	0	+	
Western Basin & Big Cypress							

OPE TITLE	Geo Extent	Signif-icance	Eco-logical	Water Supply	Flood Control	Water Quality	Comments
Seminole Tribe Big Cypress Water Conservation Plan (east portion)	REG	HIGH	+	+	+	++	
Henderson Creek Belle Meade Restoration (CP)	REG	MOD	++	+	0	+	
Reversing Overdrainage from Barron River Canal	REG	HIGH	++	+	0	+	
Miccosukee Water Management Area (CP)							Not evaluated - No information available.
Everglades National Park, Florida Bay and Florida Keys							
Flamingo Road Improvements to Restore Hydrologic Flows							Not evaluated - No information available.
Restore tidal flow into Florida Bay at Adams Waterway							Not evaluated – No information available.
Florida Keys Tidal Creek Restoration (CP)	LOC	MOD	++	0	0	+	
Indian Key and Tea Table Fill Removal	REG	HIGH	++	0	0	++	
Southwest Florida							
Lakes Park Restoration (CP)	LOC	LOW	+	0	0	+	No fact sheet. Evaluation based on information from Critical Project summary.
Southwest Florida Water Management Model							Not evaluated - This is an evaluation tool not a project. Necessary for Southwest Florida Feasibility Study.

OPE TITLE	Geo Extent	Signif-icance	Eco-logical	Water Supply	Flood Control	Water Quality	Comments
Spring Creek Reconnection and Rehydration (CP)							Not evaluated - Project may be a compensatory mitigation requirement for permits associated with a private residential development.
Town of Ft. Myers Beach (CP)							Not evaluated - This is a study not a project.
System Wide							
Melaleuca Eradication Project (CP) (parts A,B &C)	REG	HIGH	++	0	0	0	

A6.1.3 Formulation Of The OPEs In The Draft Comprehensive Plan

After initial evaluation of the individual OPEs by the interagency team, the Corps continued the formulation process by considering the team's evaluation findings as well as project costs. This process revealed that the potential OPEs fall into three general categories: 1) cost effective projects with sufficient detail to be included in the Comprehensive Plan, 2) projects recommended for additional study, and 3) projects that are more appropriately defined as Comprehensive Plan implementation activities. The Draft Comprehensive Plan was released for public comment in October 1998. In the Draft Plan, the OPEs on the initial list were distributed among the three categories described above.

A6.1.4 Formulation Of The OPEs In The Final Comprehensive Plan

In the Draft Plan, many of the potential OPEs, including some of the lower-priority Critical Projects, were recommended for additional study under the recommended Feasibility Studies (see Section 9 of the Main Report). In response to public and agency comments recommending that implementation of the Comprehensive Plan be accelerated to expedite ecologic restoration, the plan was modified so that most of the Critical Projects that are not anticipated to be funded through the Critical Projects program are now included as OPEs in the Final Plan.

Assumptions regarding Critical Projects in the Restudy Without Plan Condition were also modified in response to agency comments (See Section 4 of the Main Report and Appendix A5). In the Draft Plan, the ten Critical Projects that had received approval through the Critical Projects program (as of September 1998) were included in the Without Plan Condition. These are displayed in ***Table A6-3*** which also includes columns indicating if a project was included on the initial list of potential OPEs and also how the project was addressed in the Draft Plan.

TABLE A6-3
CRITICAL PROJECTS IN THE WITHOUT PLAN CONDITION (DRAFT)

OPE TITLE	Initial OPE list[1]	Study[2]	D-13R[3]
East Coast Canal Structures			✕
Tamiami Trail Culverts			
Florida Keys Carrying Capacity			
Western C-11 Water Quality Treatment			✕
Seminole Tribe Big Cypress Water Conservation Plan (west)[4]			
Southern Golden Gate Estates Hydrologic Restoration	✕	✕	
Southern CREW Project Addition/Imperial River Flowways	✕	✕	
Lake Okeechobee Water Retention/Phosphorous Removal[5]			
Ten Mile Creek Water Preserve Area			✕
Lake Trafford Restoration			

[1]OPE list = The initial list of potential OPEs evaluated by the team.
[2]Study = Potential OPEs recommended for additional study in the Draft Plan.
[3]D-13R = Project is included in a component of Alternative D-13R.
[4]The east portion of this project is on the initial potential OPE list, see section A6.3.5.1 for details.
[5]This project is similar to the project titled "Lake Okeechobee Water Quality Treatment Facilities" which is on initial list of potential OPEs. See section A6.3.3.3 for details.

In response to agency comments on the Draft Report, the Without Plan Condition was modified to include only the Critical Projects that are both approved **and** are anticipated to be funded through the Critical Projects program. In addition, by February 1999, two more Critical Projects had been approved. These are 1) the New Facility (part A) of the Melaleuca Eradication Project and 2) the L-31 East Flow Redistribution project. At the time this appendix was being written, it was anticipated that seven of the approved Critical Projects will be funded through the Critical Projects program. These are displayed in ***Table A6-4***.

TABLE-A6-4
CRITICAL PROJECTS IN THE WITHOUT PLAN CONDITION (FINAL)

East Coast Canal Structures
Tamiami Trail Culverts
Melaleuca Eradication –New Facility (part A)
Florida Keys Carrying Capacity
Western C-11 Water Quality Treatment
L-31East Flow Redistribution
North Fork of the New River Restoration

The two Critical Projects that were in the Draft Without Plan Condition and on the initial potential OPE list (Southern Golden Gate Estates Hydrologic Restoraiton and Southern CREW Project Addition/Imperial River Flowways) were initially recommended for additional study through the recommended Southwest Florida Feasibility Study. These two are now included in the Final Plan as OPEs. In addition, the west portion of the Seminole Tribe Big Cypress Reservation Water Conservation Plan (the Critical Project) was combined with the east portion of this project which was on the initial list of potential OPEs. Similarly, the Lake Okeechobee Water Retention/Phosphorous Removal Critical Project was combined with the proposed Lake Okeechobee Watershed Water Quality Treatment Facilities OPE. Finally, two Critical Projects: 1) North Fork of the New River Restoration and 2) the New Facility of the Melaleuca Eradication Project (part A) were not included in the final OPE formulation process because they are now included in the Without Plan Condition.

In summary, modification of the Without Plan Condition resulted in the addition of the Lake Trafford Restoration Critical Project to the OPE formulation process and removal of the North Fork of the New River Restoration and part A of the Melaleuca Eradication Project from the process. The Western C-11 Water Quality Treatment and Ten Mile Creek Water Preserve Area Critical Projects are not included in the OPE formulation process because they are included in D-13R components. See Appendix A5 for additional information.

A6.2 FORMULATION CONCLUSIONS

The final OPE formulation process revealed that the potential OPEs again fall into three general categories: 1) cost effective projects with sufficient detail to be included in the Comprehensive Plan, 2) projects recommended for additional study, and 3) projects that are more appropriately defined as Comprehensive Plan implementation activities.

A6.2.1 Other Project Elements In The Comprehensive Plan

The twenty projects displayed in ***Table A6-5*** are now included in the Comprehensive Plan as OPEs

TABLE A6-5
RECOMMENDED OTHER PROJECT ELELMENTS

Melaleuca Eradication Project (CP) – part A) Renovation of Existing Facility part B) Biological Agent Rearing
Seminole Tribe Big Cypress Reservation Water Conservation Plan (combined w/ CP)
Southern Golden Gates Hydrologic Restoration (CP)
Southern Crew Project Addition/Imperial River Flowways (CP)
Lake Okeechobee Watershed Water Quality Treatment Facilities (combined w/ CP)
Lake Trafford Restoration (CP)
Biscayne Bay Coastal Wetlands (includes L-31E Flow Redistribution (CP))
Henderson Creek and Belle Meade Restoration (CP)
Lake Okeechobee Tributary Sediment Dredging (CP)
Florida Keys Tidal Restoration (CP)
Lake Worth Lagoon Restoration (CP)
Palm Beach County Wetlands Based Water Reclamation Project (CP)
Miccosukee Water Management Plan (CP)
Lakes Park Restoration (CP)
Winsberg Farms Constructed Wetlands Project (CP)
Restoration of Pineland & Tropical Hardwood Hammocks in C-111 Basin (CP)
Lake Istokpoga Restoration
Protect & Enhance Existing Wetland Systems along LNWR including Strazzulla Tract
Pal Mar and Corbett Hydropattern Restoration
Acme Basin B Discharge

CP=Critical Project

A6.2.2 OPEs Recommended For Additional Study

Many of the potential OPEs evaluated by the evaluation team are conceptual. Problems and their proposed solutions are described only in general terms in the fact sheets provided by the project proponents. Even so, the evaluation team believes many of these problems should be addressed but more analysis is needed. Problems should be adequately identified and potential alternatives to the proposed OPEs should be evaluated. Accordingly, ten of the potential OPEs are recommended for further study as displayed in ***Table A6-6***.

TABLE A6-6
OTHER PROJECT ELEMENTS RECOMENDED FOR ADDITIONAL STUDY

OPE TITLE	FEASIBILTY STUDY
Restore Natural flows at Sanibel/Captiva Causeway	Southwest Florida
Caloosahatchee River Oxbow Rehabilitation	Southwest Florida
Reversing Overdrainage from Barron River Canal	Southwest Florida
Southwest Florida Water Management Model	Southwest Florida
Spring Creek Reconnection and Rehydration	Southwest Florida
Town of Ft. Myers Beach	Southwest Florida
Restoration of Kreamer, Torry, and Ritta Islands	Comprehensive Integrated Water Quality Plan
Flamingo Road Improvements to Restore Hydrologic Flows	Florida Bay and the Florida Keys
Restore Tidal Flow at Adams Waterway	Florida Bay and the Florida Keys
Indian Key and Tea Table Fill Removal	Florida Bay and the Florida Keys

A6.2.3 Project Implementation Activities

Ten of the projects on the initial OPE list are more appropriately considered as Comprehensive Plan implementation activities rather than stand-alone project features. These projects can be grouped into four categories: 1) wastewater reuse projects that can be considered as contingency water sources, 2) projects that should be considered as water storage options for the conceptual storage areas identified in D-13R, 3) research or data collection activities, and 4) detailed design activities. Each of these categories is further described below.

A6.2.3.1 Potential Water Sources For The Comprehensive Plan

The Comprehensive Plan currently includes the use of reclaimed water from West Miami-Dade Reuse (Component HHH6) and South Miami-Dade Reuse (Component BBB6) facilities. These facilities provide additional water to the regional system and are most important during the dry season. These two reuse components are relatively expensive sources of “new” water, but the benefits to ecosystem restoration and water supply are important to the performance of the Comprehensive Plan. The four projects displayed in ***Table A6-7*** were proposed as OPEs, however, the high cost of reuse could not be justified at this time because less expensive sources of water have been identified. These reuse projects may be able to provide benefits to the regional system should some of the less certain and/or less costly sources in the recommended Comprehensive Plan turn out to be impractical. Accordingly these contingency sources should be considered further in the Project Implementation Report process.

TABLE A6-7
POTENTIAL WATER SOURCE CONTIGENCIES

Central Palm Beach County Water Preserve Area and Loxahatchee National Wildlife Refuge Enhancement by Reclaimed Water
West Palm Beach Water Catchment Area Enhancement Reclaimed Water
Northern Broward Regional Reuse
City of Hollywood Reuse

A6.2.3.2 Potential Storage Alternatives

The proposed OPEs displayed in ***Table* A6-8** should be considered in the appropriate Project Implementation Report (See Section 10 of the Main Report for a complete description of the Implementation Plan). These projects could provide storage in the Kissimmee River Basin as well water quality benefits and increases in the spatial extent of aquatic and wetland habitat.

TABLE A6-8
POTENTIAL STORAGE ALTERNAIVES

Additional Storage in Chain of Lakes (above Lake Cypress)
Restore Wetland and Aquatic Habitat at Pool A
Restore Wetland and Aquatic Habitat at Pool E
Restore Wetland and Aquatic Habitat at Paradise Run

A6.2.3.3 Research And Data Collection Activities

The South Biscayne Bay Watershed Management Plan is considered to be a research and data collection activity that will aid further refinement of the Without Plan Condition for Miami-Dade County. In addition, data collected regarding water quality and development of localized hydrologic models for the area will aid refinement of the performance measures for Biscayne Bay.

A6.2.3.4 Detailed Design Activities

Broward County officials have expressed concern about the effects of the Comprehensive Plan on Pond Apple Slough. Additional modeling of the effects of the proposed hydrologic modifications to flows through S-13 on the slough should be addressed during the Project Implementation Report process.

A6.2.4 Summary Table

Table A6-9 summarizes the results of the OPE formulation process. The table is arranged according to geographic region.

TABLE A6-9 OPEs CONSIDERD IN THE PLAN FORMULATION PROCESS

Kissimmee River Basin and Lake Okeechobee

A6.3 PROJECT DESCRIPTIONS

Each of the potential OPEs that were considered in the formulation process are described in further detail below. The projects are grouped according to geographic region.

A6.3.1 Kissimmee River Basin And Lake Okeechobee

A6.3.1.1 Additional Storage In The Chain Of Lakes Above Lake Cypress

Construction of a water control structure in the C-36 Canal at the outlet of Lake Cypress in the Upper Chain of Lakes would provide additional options in lake stage management. Historically, Lake Cypress had a higher stage than Lake Hatchineha and Lake Kissimmee, but all three are held at roughly the same level. Additional management capabilities in the upper chain could storage requirements in the lower reaches of the Kissimmee River Basin.

A6.3.1.2 Restore Wetland And Aquatic Habitat At Pool "A"

The reach of the Kissimmee River (C-38) from S-65 downstream to S-65A is designated as Pool A. Flow-through marshes could be created adjacent to C-38 by construction of a parallel watercourse separated from C-38 by levees. Culverts and weirs could divert water to the marsh. Approximately 3,000 acres of pasture could be converted to wetlands. Benefits would include additional storage of floodwater and improvement in water quality.

A6.3.1.3 Restore Wetland And Aquatic Habitat At Pool "E"

The reach of the Kissimmee River (C-38) from S-65D downstream to S-65E is designated as Pool E. The restoration of Pool E was originally included in the Kissimmee River Restoration plan, but was not included in the final authorization because of concerns about flooding of homes in the area. This remains a potential storage option within the basin.

A6.3.1.4 Restore Wetland And Aquatic Habitat At Paradise Run

The reach of the Kissimmee River (C-38) from S-65E downstream to the outlet at Lake Okeechobee is known as Paradise Run. Flow-through marshes could be created adjacent to C-38 by construction a parallel watercourse separated from C-38 by levees. Culverts and weirs could divert water to the marsh. Approximately 3,600 acres of pasture could be converted to wetlands. Benefits would include additional storage of floodwater and improvement in water quality.

A6.3.1.5 Lake Istokpoga Restoration

This feature includes development of a plan to address water resource problems in the Lake Istokpoga Basin. Lake Istokpoga is a natural lake located in Highlands County, a tributary of Lake Okeechobee and the Kissimmee River via the C-41A Canal. The major focus of this plan is to create a balance between the environmental needs, water supply and flood control in the Lake Istokpoga Basin. The purpose of this plan is to examine the Istokpoga Basin with a view towards enhancing fish and wildlife benefits and developing a long-term comprehensive management plan. It has been noted that operation of S-68, beginning in 1962, reduced the maximum annual fluctuation of the lake (SFWMD, 1978). While the littoral zone expanded, the amount of quality habitat was reduced by this formation of extensive floating tussocks and dense cattail communities. Persistently lowered lake levels has reduced the natural frequency of seasonal drying and inundation. Without natural dewatering events, germination of diverse aquatic plant seeds is reduced, consolidation and compaction of organic sediments cannot occur, and the formation and expansion of floating mats of water hyacinths and other species common to tussock communities are promoted. These mats reduce overall productivity and diversity of the marsh. The plan will also address the need for flood protection to the perimeter and upstream tributaries, and downstream areas west and east of C-41A. Water supply needs for agriculture and the Seminole Tribe of Florida will also be addressed.

A6.3.1.6 Lake Okeechobee Tributary Sediment Dredging

The project would be located in selected tributaries in the Lake Okeechobee watershed. Historically, south Florida waters were low in nutrients (oligotrophic). Elevated phosphorus loading of waterbodies and the resulting increased water phosphorus concentrations (eutrophication) may have various ecological effects. These effects may include increased primary productivity: loss of water column dissolved oxygen, algal blooms, and changes in vegetation and biodiversity. The significance of such phosphorus loading may be the reduction or loss of a waterbody's habitat and/or recreational values. Sediment found in tributaries to Lake Okeechobee is an important source of phosphorous that contributes to the excessive loading to the lake. This project involves dredging sediments from approximately ten miles of primary canals. As a result, an estimated 150 tons of phosphorous will be removed from potential loading to the lake.

A6.3.1.7 Lake Okeechobee Watershed Water Quality Treatment Facilities

Many of the problems identified in Lake Okeechobee result from poor water quality and altered timing of the runoff from its watershed. Many former wetlands in the watershed have been ditched and drained for agriculture and flood control purposes. In many cases the runoff problems associated with these past modification are best solved at, or near, the individual sources. Restoring the hydrology of selected isolated and riverine wetlands in the region by plugging these drainage ditches will help attenuate peak flows in the basin and retain phosphorus within the restored wetlands. In some basins, construction of reservoir-assisted stormwater treatment areas (RSTAs) will be needed to meet hydrologic and water quality targets. The Critical Project titled Lake Okeechobee Water Retention/Phosphorous Removal employs these concepts. The features of the Critical Project can not exceed the funding cap for individual Critical Projects.

An OPE titled Lake Okeechobee Watershed Water Quality Treatment Facilities was proposed to further the concept of restoring additional wetlands beyond those areas being planned in the Critical Project. In light of the modification to the without plan condition regarding the Critical Projects (see appendix A5), the Critical Project has been combined with the OPE to ensure implementation of these important features.

The combined project focuses on restoring approximately 3,500 acres of wetlands on specific land parcels located within four key lower Kissimmee River Basins (S-65D Basin, S-65E Basin and S-154 Basin) and the Taylor Creek-Nubbin Slough Basin (S-191). Two RSTAs in the basins with the poorest water quality are also planned. The initial design of these RSTAs assumes a 1,775-acre facility in the S-154 Basin in Glades County and a 2,600-acre facility in the S-65D sub-Basin of the Kissimmee River Basin in Highlands and Okeechobee Counties.

A6.3.1.8 Restoration Of Kreamer, Torry, And Ritta Islands

Kreamer, Ritta and Torry Islands are located near the south shore of Lake Okeechobee. These islands have been used for agricultural purposes and small levees and drainage ditches have been constructed. A project plan has not been identified, but restoration of these islands would involve degrading selected levees to allow more natural water levels and transplanting native vegetation. These actions would result in additional habitat for water birds, fish, and other wildlife. Contaminant studies would need to be completed prior to restoration design.

A6.3.2 Caloosahatchee River Basin

A6.3.2.1 Restore Natural Flows At Sanibel/Captiva Causeway

The Sanibel/Captiva causeway consists of two fill sections and three bridge sections connecting Sanibel and Captiva Islands with the mainland at Ft. Myers, in Lee County. The causeway was constructed in the mid-1960s and shortly thereafter, the scallop fishery in San Carlos Bay collapsed. It is uncertain as to what degree this collapse was caused by construction of the causeway, because the Intracoastal Waterway channel and the Franklin Lock (S-79) on the Caloosahatchee River were also completed in the mid-1960s. Coupled with Comprehensive Plan features that will capture regulatory releases from Lake Okeechobee and store excessive runoff from the Caloosahatchee Drainage Basin, removal of the Sanibel Causeway would promote restoration of Pine Island Sound and San Carlos Bay. A coupled circulation and water quality model for the greater Charlotte Harbor Estuary is currently being developed. This model should allow more detailed study of the circulation problems and the formulation of potential solutions.

A6.3.2.2 Caloosahatchee River Oxbow Rehabilitation

Historically, the Caloosahatchee River originated in marshes just west of Lake Okeechobee and meandered slowly to the estuary at San Carlos Bay. Modifications begun in the late 19^{th} century involved construction of a channel to allow navigation to Lake Okeechobee. Construction of the C-43 Canal for navigation and floodwater conveyance involved further channelization of the naturally meandering course of the Caloosahatchee River. Flows within the remnant bends, or oxbows, in the natural river course were reduced or cut off by C-43. The remnant oxbows receive reduced flows and are subject to accelerated bottom sedimentation, deteriorating water quality, exotic/nuisance vegetation invasion, deteriorating habitat function, and diminishing historical value. This project is a rehabilitation effort that will improve ecological conditions within C-43 and will also improve the timing and quality of water delivered to the Caloosahatchee Estuary. The methods tested and shown to be productive in the study of remnant channels of the Kissimmee River Restoration project will be used in this project.

A6.3.3 Lower East Coast Region

A6.3.3.1 Pal Mar And Corbett Hydropattern Restoration

This project involves the acquisition of 3,000 acres between Pal-Mar and the J.W. Corbett Wildlife Management Area (WMA) to extend the spatial extent of protected natural areas. The project will also provide hydrologic connections between the Corbett WMA and: 1) the Moss Property, 2) the C-18 Canal, 3) the Indian Trails Improvement District, and 4) the L-8 Canal. These connections would relieve the detrimental effects on native vegetation frequently experienced during the wet season. Pal-Mar is a large pine flatwood/wet prairie/depression marsh complex located in Palm Beach and Martin Counties, northeast of the Corbett WMA. Acquisition of this remaining privately owned parcel of land consisting of approximately 3,000 acres between Pal-Mar and Corbett would form an unbroken 126,000-acre greenbelt extending from the Dupuis Reserve near Lake Okeechobee across the Corbett WMA, and connecting with Jonathan Dickinson State Park.

A6.3.3.2 Winsberg Farms Constructed Wetland

In an effort to reduce the amount of treated water from the Southern Region Water Reclamation Facility (SRWRF) that is currently wasted in deep injection wells, the Palm Beach County Water Utilities Department (PBCWUD) plans to further treat and recycle this water. The PBCWUD has completed construction of a 50-acre constructed wetland located at the County's System 3 site east of Jog Road, just southeast of the Winsberg property. This wetland has been named Wakodahatchee, which is Seminole Indian for "created waters". As part of this wetland, a public access facility with limited parking, boardwalk, kiosks and interpretive signage was designed to educate the public about the importance of wetlands for both treatment of water and creation of wildlife habitat. This project proposes construction of an additional 175 acres of wetlands on the Winsberg property. This will serve to not only recycle and preserve additional water for future use, but will link the Wakodahatchee and Winsberg Farms facilities and provide additional green space in area currently under heavy development. Approximately, 6 to 8 Million Gallons per Day of reclaimed water from the SRWRF would be applied to the area. The wetland would be planted to maximize the diversity of native plant material and habitat for various species of wildlife.

A6.3.3.3 Palm Beach County Wetlands-Based Water Reclamation Project

The Wetlands-Based Water Reclamation Project (WWRP) proposes to treat wastewater from the East Central Regional Wastewater Treatment Facility (ECR) using Advanced Wastewater Treatment (AWT) processes to remove nitrogen and phosphorus. This will then be followed with superior treatment technology to remove phosphorus to approximately 50 parts per billion or less. Phase I of the WWRP will consist of a 10 Million Gallons per Day (MGD) operation with 6 MGD of the water discharged into approximately 1,500 acres of bermed marsh where it will be used to hydrate the marsh as well as manage the hydroperiod and water quality of the wetland environment. The water will then be pumped to another marsh of approximately 300 acres surrounding the City of West Palm Beach wellfield. Infiltration of the water into the wellfield will occur as the wellfield pumps groundwater into the adjacent M Canal where it becomes surface water. The surface water in M Canal will flow towards Clear Lake, which is the surface water source of drinking water for the City of West Palm Beach. At the City's water treatment plant, the surface water will be treated to drinking water standards prior to entering the water supply distribution system for the City as well as the Town of Palm Beach and South Palm Beach. The remaining 4 MGD of the 10 MGD of reclaimed water will be routed from the AWT/superior treatment technology facility to residential lake systems surrounding both the City's wellfield and Palm Beach County's 8W Water Treatment Plant wellfield. The lake systems will be used to recharge the groundwater in the vicinity of both wellfields, thereby decreasing impacts associated with withdrawals from both wellfields.

A6.3.3.4 Central Palm Beach County Water Preserve Area And Loxahatchee National Wildlife Refuge Enhancement By Reclaimed Water

The project involves the discharge of 45 million gallons per day (MGD) of highly treated reclaimed water from the Southern Region Water Reclamation Facility (SRWRF) to the Central Palm Beach County Water Preserve Area and/or the Loxahatchee National Wildlife Refuge. Reclaimed water discharged to the Central Palm Beach County Water Preserve Area will meet agricultural water supply demands. Reclaimed water discharged to the Loxahatchee National Wildlife Refuge will be for meeting environmental water supply demands. This reclaimed water will be used to augment water availability in the regional system, or to use this reclaimed water instead of water from Loxahatchee National Wildlife Refuge and Lake Okeechobee, thereby keeping additional water in the regional system. Water discharged into the Loxahatchee National Wildlife Refuge will be of suitable quality. This constant flow would occur both during the wet season and the dry season. Excess flows and reject water would be disposed of via deep injection wells (the current disposal method).

A6.3.3.5 West Palm Beach Water Catchment Area Enhancement By Reclaimed Water

The West Palm Beach Water Catchment Area (WPBWCA) is about 20 square miles of sedge and cypress wetlands. It is part of the historical Loxahatchee Slough system that fed both wetlands north of Northlake Boulevard in the Loxahatchee Slough as well as the Everglades to the south. Currently, the WPBWCA is a collection point for rainfall as well as inflows from L-8 Canal and M Canal. Discharge from the WPBWCA presently is to the east to provide urban water supply for the City of West Palm Beach, Town of Palm Beach, and South Palm Beach. In the future, as a consequence of the L-8 Option implementation under the Interim Plan for Lower East Coast Water Supply, the WPCWCA will discharge north to restore wetlands in the Loxahatchee Slough outside of Water Conservation Area 1, as well as providing water for public water supply to Jupiter and Seacoast in addition to the aforementioned cities. This component includes the discharge of 56 MGD on an average daily basis of highly treated reclaimed water into the WPBWCA to meet future demands. This constant flow would occur both during the wet season and the dry season. Excess flows and reject water would be disposed of via deep injection wells (the current disposal method). The flows would be derived from a new state of the art reclaimed water production facility at the East Central Regional Wastewater Facility (ECR) operated by the City of West Palm Beach. The ECR is currently located about two miles from Water Conservation Area 1. The supplemental treatment facility would be built at the site of the existing ECR. A pipeline would be extended west to discharge reclaimed water directly into Water Conservation Area 1 at a continuous rate of 56 MGD.

A6.3.3.6 Acme Basin "B" Discharge

This project involves the construction of a 620-acre temporary storage reservoir and a 310-acre wetland treatment area to treat Acme Basin "B" runoff discharged to the Loxahatchee National Wildlife Refuge. An alternative to the wetland treatment area may be chemical treatment. Estimated runoff discharged from Acme Basin "B" is estimated at 20,000 acre-feet per year. This runoff will be sent to the 620-acre reservoir to attenuate peak flows until such time as the water can be discharged to one of two alternative locations: 1) Component VV6 Palm Beach County Agricultural Reserve Reservoir or 2) Component GGG6 C-51 and Southern L-8 Reservoir. Runoff will be directed to the temporary attenuation storage area until full, then additional runoff will be directed to the treatment area prior to discharge into the LNWR. Once peak flows have dissipated, runoff will be sent to the more feasible of the two alternative locations cited above for storage until the dry season dictates release for water supply purposes to meet regional demands. Discharge to the Palm Beach County Agricultural Reserve Reservoir will require improvement to an existing drainage ditch plus a small pump station. Discharge to the C-51 and Southern L-8 Reservoir will require Acme Canal #25 upgrade plus possibly a new pump station or upgraded existing pump station.

A6.3.3.7 Protect And Enhance Existing Wetland Systems Along Loxahatchee National Wildlife Refuge Including The Strazzulla Tract

This project involves the acquisition of 3,335 acres to expand the spatial extent of protected natural areas. This project will make a hydrologic and ecologic connection to the LNWR and may need water control structures. This land will act as a buffer between higher water stages to the west and agriculture lands to the east that must be drained. This increase in spatial extent will provide vital habitat connectivity for species that require large unfragmented tracts of land for survival. It also contains the only remaining cypress habitat in the eastern Everglades and one of the few remaining sawgrass marshes adjacent to the coastal ridge. This is a unique and endangered habitat that must be protected. This area provides an essential Everglades landscape heterogeneity function.

A6.3.3.8 Lake Worth Lagoon Restoration

This project involves three phases. Phase I will examine both quantity and quality of bottom sediment accumulations within the C-51 Canal and downstream discharge area within the lagoon. Phase II will develop a project plan to provide for sediment removal or capping that could include creating a series of sediment traps along the C-51 where sediment accumulations increase. Phase III will involve the removal of bottom sediments within C-51 Canal as well as implementing a prototype project to either remove or cap the organic bottom layer within the lagoon. The elimination of these sediments from the C-51 discharge will provide for long-term improvements to the lagoon and ensure success of additional habitat restoration projects planned by Palm Beach County.

A6.3.3.9 North Fork Of The New River Restoration

The proposed project is located in the City of Ft. Lauderdale, along the North Fork of the New River between 9th Avenue and Sunrise Boulevard. The North Fork is a shallow, meandering tributary of the New River extending through the northwest section of the City of Fort Lauderdale. Minimal tidal flow within this section of the river results in limited circulatory exchanges of tidal waters. Flow has been restricted by large amounts of sediment and debris. Natural freshwater flow characteristics are further restricted in the upstream section of the North Fork by the S-33 salinity control structure that effectively eliminates freshwater inflow from the western drainage basin. The New River is one of the few naturally occurring surface water bodies in Broward County. Prior to the 1900's, the New River was a prominent drainage feature of the Everglades that seasonally emptied into the Atlantic Ocean. The existing shoreline no longer resembles its historical condition. The shoreline is actively eroding in some places and exotics have replaced native species in some riparian areas. In 1993, Broward County Department of Natural Resource Protecion research identified many sources of ongoing and historic pollution. This degradation of water quality and habitat represents a negative impact not only on the environment, but the health and economy of the adjacent communities. DNRP developed “The New River Restoration Plan (1994)” to identify water quality problems, identify the river system's biological diversity, and to develop a plan to create a more natural condition for the inhabitants of this community. The restoration project involves; 1) spot dredging to improve water quality and water circulation, 2) removal of exotic plant species and revegetation with native plants, 3) development of analytical tools, 4) removal of litter and debris and 5) development of a plan which promotes urban infill consistent with the Eastward Ho! Initiative.

A6.3.3.10 Northern Broward Region Reuse Project

The current treatment capacity of the Broward County North Regional Wastewater Treatment Facility (NRWWTF) is 80 MGD. If the treatment process is upgraded to meet regulatory requirements, the flow could be discharged to the secondary canal systems located in northern and central coastal areas of the County. This would help recharge groundwater, enhance remnant wetlands, and stabilize the saltwater interface.

A6.3.3.11 City Of Hollywood Reuse Project

Currently, the City of Hollywood’s wellfields are threatened by saltwater exfiltration from the C-10 Canal. The recommended Comprehensive Plan includes a structure on C-10 that will provide some relief, but a constant water supply to the canal may be required. The Southern Regional Wastewater Treatment Plant, owned and operated by the City of Hollywood through a partnership with the Cities of Miramar, Pembroke Pines, Pembroke Park, Dania and Hallandale, and with Broward County, may be a source of this supply. The treatment facility serves over 240,000 people. This project could provide water for maintaining coastal canal levels so that saltwater migration toward eastern wellfields could be minimized. The project would provide 50 to 60 MGD to the drainage basin during low flow/precipitation periods. This project was proposed to restore and enhance the amount of water in the C-10 Basin to prevent saltwater intrusion, and to protect coastal wellfields. Implementation of the project would also improve the water quality of coastal wetlands and the Atlantic Ocean by improving water quality from the wastewater facility.

A6.3.3.12 Pond Apple Slough Restoration

The Pond Apple Slough/New River Forest is defined as the remnant freshwater-forested wetlands along the South Fork New River and North New River Canal east of the salinity control structures. Over $20 million of public funds have been spent to acquire, restore and enhance over 200 acres of this freshwater-forested wetland. Broward County is in the early phases of a rehydration project to help offset salinity increases in the adjacent waterways. Approximately 100,000 acre-feet of water per year is presently discharging over the S-13 Structure into the South Fork New River and Dania Cut-off Canal. This freshwater discharge presently reduces the salinity within these water bodies which have grown more saline with the construction of the Dania Cut-off Canal and channelization of the South Fork New River. The reduction of freshwater discharge that is proposed in the recommended Comprehensive Plan will allow increases in salinity within these water bodies and negatively affect the adjacent historic freshwater wetlands which include the Griffey Tract, Secret Woods Nature Center, Florida Power and Light Company's Lauderdale Power Plant Site and adjacent mitigation area for the South County Resource Recovery Plant. The proposed rehydration project, currently underway for the Griffey Tract and Pond Apple Slough, is anticipating redirecting approximately 10 million gallons per day of the freshwater that is presently being discharged through the S-13 Structure into this herbaceous marsh and forested resource before it returns to the South Fork New River through a series of tributaries within the Pond Apple Slough. Broward County is concerned that loss of freshwater inputs from S-13 will further exacerbate the salinity threat that they are currently trying to reverse. The primary components of this project will include: 1) modeling the ecological effect reduced discharges into the South Fork New River and Dania Cut-off Canal through the S-13 Structure will have on the remaining freshwater forested resources along these waterways, 2) determination of the freshwater hydrology needs of the various components of the system and 3) identification of freshwater sources and distribution systems, and surface water management features to meet those needs.

A6.3.3.13 South Miami-Dade Agricultural And Rural Land Use And Water Management Plan

The project area is the southern portion of Miami-Dade County covering all lands lying outside Miami-Dade County's Urban Development Boundary designated for agricultural use. The growing demands of the lower East Coast of Florida are straining the water resources of the area. The development of sustainable, environmentally sensitive agriculture in southern Miami-Dade County would provide a more environmentally superior land use than the prospect of uncontrolled urban expansion throughout these watersheds. In comparison to urban development, agriculture has reduced impacts on water quality and quantity thus minimizing remediation requirements and costs. The purpose of both these initiatives/studies is to develop long range management plans for south Miami-Dade County. The plans will recommend future land use and water resources control within the county. Output will be recommendations that will assist in the regulation of the ever-increasing development/growth in south Miami-Dade County. The rural land use component is an integral part of the overall, larger South Biscayne Bay Watershed Plan. Project work involves the preparation of a study document that will identify and quantify major agribusiness elements (i.e. crop prices, water and soil requirements, production costs, etc.). Combined with socioeconomic information, all parameters will be analyzed to establish economic strategies and incentives to strengthen agriculture. The results will be blended into the South Biscayne Bay Watershed Management Plan.

A6.3.3.14 Restoration Of Pineland And Tropical Hardwood Hammocks In C-111 Basin

The project is located in south Miami-Dade County, just east of Everglades National Park, along State Road 9336 in the area known as the Frog Pond. Eighty percent of the Frog Pond was used for agricultural purposes and farmers rock plowed the cap rock to create soil for tomato farming. The Frog Pond has since been purchased by the SFWMD as part of the C-111 Project to restore the Taylor Slough portion of the Everglades. The project involves restoring south Florida slash pine and tropical hardwood hammock species on a 200-foot wide strip on each side of the two miles of State Road 9336 from the C-111 Canal to the L-31W Canal (approximately 50 acres). This project will demonstrate the techniques required to re-establish native conifer and tropical hardwood forests on land that has been rock plowed.

A6.3.3.15 Biscayne Bay Coastal Wetlands

This project incorporates the L-31 East Flow Redistribution Critical Project list. The ability of the Comprehensive Plan to provide hydrologic benefits to the southern Everglades is supported in large part by the Biscayne Bay Coastal Wetlands Component FFF5 which replaces freshwater inputs to the Biscayne Bay

Estuary that are reduced by some D-13R components (i.e., seepage control components along the protective levee and the capture of other discharges to tide). The project is necessary to properly distribute these additional flows to the estuary. The project has five sub-components located in southeast Miami-Dade County, covering the southwest shoreline of Biscayne Bay from the Deering Estate at C-100C south to Florida Power and Light Company's Turkey Point Power Plant, generally along the L-31 East levee.

- **Sub-component 1 - Deering Estate Flowway** - Operation of this sub-component involves pumping water from the SW 160th Street ditch (a tributary to C- 100C) through property adjacent to the Deering Estate and ultimately into Cutler Drain which runs through the Deering Estate. The design involves: 1) adding a 50-cfs pump station at end of SW 160th Street Canal, 2) filling in mosquito ditches in coastal mangroves, and 3) constructing weirs to delay water passage in Old Cutler Drain.

- **Sub-component 2 - Cutler Wetlands** - Operation of this sub-component involves: 1) routing water south from C-100A to the Cutler Wetlands Proposal Area via a shallow distribution swale on the surface of the marl to C-100B, 2) pumping water from C-100B to a spreader swale, and 3) pumping water from C-100A south into a spreader swale to allow sheetflow to Biscayne Bay. Depending on water quality, flows may need to be routed through Stormwater Treatment Areas (STAs). Design involves constructing: 1) a spreader swale from C-100A south to C-100B, 2) a levee west of the spreader swale, and 3) a 200-cfs pump along the north end of the spreader swale at C-100A. If water quality dictates, the design may also involve construction of: 4) an STA adjacent to C-100B, 5) a 200-cfs pump adjacent to the STA and C100B, and 6) a levee seepage canal along the north and south ends of the STA.

- **Sub-component 3 - L-31 East Flowway** – The purposes of this sub-component are: 1) to reestablish conditions for living oyster bars along the shoreline of the bay and 2) to hydrologically isolate the Miami-Dade County landfill. A flow redistribution system will be created west of L-31 East and existing wetlands will be restored in the area between L-31 East and the western boundary of the redistribution system. A distribution swale with a western levee will be constructed along this boundary. The wetland area west of L-31 East should be used for short-term, shallow ponding of water to maintain wetlands and help drive freshwater flow to the nearshore Bay out of the east bank of L-31 East. Depending on water quality, flows may need to be routed through an STA. Design involves: 1) installation of culverts and risers under L-31 East, 2) construction of a spreader swale east of L-31 East, 3) backfilling Military Canal, 4) construction of a plug in C-100B, 5) construction of a canal west of the landfill to intersect with L-31 East borrow canal, and 6) filling in mosquito ditches. If water quality dictates, the design may also involve construction of: 7) a STA from C-102 to C-103 and east of Homestead Air Force Base, 8) a seepage collection ditch on the west side of the STA, 9) a 200-cfs pump at C-102 to the STA, and 10) a 200-cfs pump at C-103 to the STA.

- **Sub-component 4 - North Canal Flowway** – The operation of this sub-component involves pumping available water from C-103 and Florida City Canal to re-establish sheetflow across freshwater and coastal wetlands to Biscayne Bay. Depending on water quality, flows may need to be routed through an STA. Design involves: 1) construction of a 200-cfs pump on C-103, 2) construction of a 200-cfs pump on Florida City Canal, 3) installation of culverts and risers under the L-31 East levee, 4) construction of a delivery canal from C-103 south to North Canal, 5) construction of a spreader swale east of the L-31 East levee, 6) backfilling North Canal east of SW 112th Avenue and 7) construction of a flowway south from Florida City Canal from SW 127th Avenue to SW 107th Avenue. If water quality dictates, the design may also involve construction of: 8) an STA on the western edge of the coastal wetlands in between C-103 and Florida City Canal, 9) an STA associated with the flowway south of Florida City Canal, and 10) seepage management facilities around the STAs.

- **Sub-component 5 - Barnes Sound Wetlands** – Operation of this sub-component involves pumping available water from Florida City Canal to a shallow east-west spreader canal. Depending on water quality, flows may need to be routed through an STA. Design involves construction of: 1) a 50-cfs pump at Florida City Canal, and 2) a new canal south from Florida City Canal to a shallow spreader swale along the edge of the coastal wetlands. If water quality dictates, the design may also involve construction of an STA and seepage management facility.

There are some general problems or considerations that apply to the entire area. These include existing ditches, which are extensive, the presence of exotic plants and animals, potential water quality problems, and land ownership constraints. The areas under review for restored sheet flow were extensively ditched early in the twentieth century. This cross ditching interferes with providing restored historic flow patterns. For these reasons, the ditches may need to be filled. In addition, the area would require an extensive and possibly ongoing invasive exotic plant removal program. Most of the 13,600 acres of land to be acquired are under current acquisition efforts by the state and county.

A6.3.4 Western Basin And Big Cyress Basin

A6.3.4.1 Seminole Tribe Big Cypress Water Conservation Plan

The project is located on the Seminole Tribe Big Cypress Reservation in Hendry County, directly north of the Big Cypress National Preserve and west of Water Conservation Area 3A (WCA 3A). The Big Cypress Reservation is traversed by the L-28 and L-28I Canals and the North and West Feeder Canals. The proposed comprehensive watershed management system is designed to achieve environmental restoration on the Reservation, the Big Cypress Preserve, and the central and southern Everglades. In addition, the project will reduce flood damage and promote water conservation on the Reservation. The overall plan has been divided into east and west portions, each of which can provide independent benefits. Due to the legislated funding limits of the Critical Projects program, only the west portion of this project was nominated as a Critical Project. The Seminole Tribe has also requested the assistance of the Natural Resources Conservation Service (NRCS) to implement the eastern portion of the plan. In light of the uncertainty of the NRCS funding for the east portion and the potential that the west portion may not be funded through the Critical Projects program, the combined project is being recommended as an OPE.

A6.3.4.2 Southern Golden Gate Estates Hydrologic Restoration

The Southern Golden Gate Estates (SGGE) project area encompasses approximately ninety-four square miles of sensitive environmental landscape in southwestern Collier County, south of Interstate 75 between the Fakahatchee Strand and Belle Meade watersheds. The project area is an important surface storage and aquifer recharge area with a unique ecology of cypress, wet prairie, pine and hardwood hammock and swamp communities. It also includes three major flowways that contribute freshwater to the Ten Thousand Islands Estuary of the western Everglades watershed. Construction of roads and drainage modifications in the 1960’s and 1970’s have overdrained the area resulting in reduction of aquifer storage, increased freshwater shock load discharges to the estuaries, invasion of upland vegetation and increased frequency of forest fires. Variations of freshwater discharges at large amplitudes have resulted in large fluctuations of salinity level and have eliminated or displaced a high proportion of the benthic, midwater and fish plankton communities in the estuary. The project involves construction of a combination of spreader channels, canal plugs and pump stations, and removal of roads. Implementation of this plan would accomplish the hydrologic restoration of SGGE by introducing sheetflow, re-establishing the historical flowways, reducing runoff by increased evaporation and groundwater recharge, and replacing point flow discharge through the Faka Union Canal with distributed flow along US 41 into the tidal coastal marshes. The Florida Division of Forestry is responsible for managing the public lands within SGGE and will be a participating partner with the SFWMD through construction of this project.

A6.3.4.3 Southern Crew Project Addition/Imperial River Flowways

The project is located in southern Lee County, bordering the western boundary of the Corkscrew Regional Ecosystem Watershed (CREW). This environmentally sensitive area east of Bonita Springs has been altered by construction of roads, house pads, agricultural berms, and ditches. These alterations have resulted in restriction of historical sheetflow, unnatural water impoundment and flooding, increased pollutant loading to the Imperial River and Estero River (an Outstanding Florida Water), and disruption of natural wetland functions. Water that historically flowed southwesterly has been partially diverted to the east by roadbeds and single family house pads. This has resulted in decreased hydroperiods (excessive drainage) in wetlands to the west of the CREW and the Corkscrew Sanctuary (Audubon) and increased hydroperiods in the CREW and Corkscrew Sanctuary. The proposed project involves acquisition of approximately 4,670 acres of land and restoration of historic flows over this area. The project will be added to the CREW with perpetual management to maintain natural system qualities. The project will: 1) re-establish historical flow patterns and hydroperiods on the lands proposed for acquisition as well as CREW and Corkscrew Sanctuary wetlands to the east, 2) restore historical storage potential of the Southern CREW lands, 3) reduce excessive freshwater discharges to Estero Bay during the rainy season, 4) decrease saltwater intrusion during the dry season, 5) reduce loading of nutrients and other pollutants to the Imperial River and Estero Bay, 6) increase aquifer recharge, and 7) reduce flooding of homes and private lands west of the project area. This project will also reduce the potential that currently exists for forcing water eastward through the CREW Project and the Corkscrew Swamp Sanctuary and possibly harming these important areas by increasing depth and duration in these natural wetland areas. Hydrologic restoration of this land will include the following modifications: 1) removal of existing road beds, 2) removal of single family homes, 3) removal of junk debris, 4) filling of ditches, and 5) removal of agricultural canals and berms. Also, the Kehl Canal weir located at the headwaters of the Imperial River will be modified. More storage capacity will be provided and gates will be added to allow better water management and control of the Kehl Canal, which flows through the land proposed for acquisition.

A6.3.4.4 Henderson Creek And Belle Meade Restoration

This region of southwest Florida is currently facing a high urban growth rate. Changes in land-use within the primary watersheds that drain into the Rookery Bay Estuary and adjacent waters have been identified in the Rookery Bay National Estuarine Research Reserve (RBNERR) Management Plan as the highest priority resource issue that threatens the long-term preservation of RBNERR estuarine resources. The coastal habitats in Collier County have been impacted by alterations of hydrology and habitat due to channelization of natural systems. Roads, canals, planned unit developments, commercial projects, and agriculture represent primary land-uses within RBNERR watersheds. These alterations have greatly modified the volume, timing and quality of freshwater entering the fragile estuarine ecosystems. In addition, channelized flow in these watersheds has severely restricted the ability of the associated wetlands to filter pollutants. The area known locally as Belle Meade is the primary drainage basin for the Henderson Creek Estuary and is currently targeted for acquisition by the Florida Department of Environmental Protection. Historically, freshwater traveled across the surface of the land, percolating through wetland flowways before entering Henderson Creek. While channelization and development have disrupted this system, acquisition and restoration of the undeveloped lands surrounding Henderson Creek, which link the watershed and estuary, can stop further hydrologic and habitat disturbance. These estuarine areas provide critical nursery habitat for commercially and recreationally important finfish and shellfish. Land acquisition will assure long-term protection of the upland and wetland communities associated with these parcels. Additionally, the proposed restoration efforts on the acquired lands will return a portion of the historic timing, duration and volume of freshwater inflow, thereby enhancing estuarine habitats.

A6.3.4.5 Reversing Overdrainage From Baron River Canal

Big Cypress National Preserve (BCNP) is a unique water-dependent ecosystem. As much as 90 percent of BNCP is inundated to depths ranging from a few inches to more than three feet during the wet season (May to October). During the dry season (November to April) water levels recede, reducing the area of inundation to approximately 10 percent. The ecology of BNCP is finely tuned to the seasonal flow of non-polluted water and changes in this condition can adversely affect this sensitive habitat. Two primary canals, namely the Barron River Canal on the western periphery, and the Turner River Canal in the west central portion of the BCNP allow channelized overdrainage from the watershed. During the dry season, these canal systems can lower the water levels to the point of causing water shortages, increasing fire hazards and allowing salt-water intrusion in freshwater environments. The canals provide a direct hydraulic connection between freshwater wetlands and the saline estuaries within Everglades National Park. The rapid drainage of fresh water also reduces the productivity of cypress forests and wet prairie ecosystems. The project involves plugging or backfilling the canals in order to restore sheetflow over a broad area. This project would provide hydrologic restoration to approximately 500 square miles of impacted wetlands in BNCP. The project area has a unique ecology of cypress, pine, and hardwood hammocks. It contains expansive areas of pristine wilderness and some of the most biologically diverse plant and wildlife communities on the North American continent. The restoration of the historic flowways is expected to reintroduce the historic flora and fauna and eliminate nuisance exotic species. Adjacent sensitive lands, including Everglades National Park, Fakahatchee Strand State Preserve, and the Florida

Panther National Wildlife Refuge, will benefit from this plan with enhanced habitat quality.

A6.3.4.6 Miccosukee Water Management Area

The Miccosukee Water Management Area (MWMA) is a project to construct a managed wetland on the Miccosukee Tribe's Alligator Alley Reservation located in western Broward County. The purpose of the project is to provide water storage capacity and water quality enhancement for waters which discharge into the Everglades Protection Area. The project will convert approximately 900 acres of tribally owned cattle pastures into a wetland retention / detention area, which will be designed to filter out harmful nutrients contained in stormwater runoff before the water enters the Everglades Protection Area. Tribal Water Quality Standards dictate a numerical criterion of 10 parts per billion for total phosphorous inside the Everglades Protection Area. The MWMA was sized to treat the nutrient inputs of the Miccosukee Tribal lands.

A6.3.5 Everglades National Park, Florida Bay, And The Florida Keys

A6.3.5.1 Flamingo Road Improvements To Restore Hydrologic Flows

Flamingo Road is located in Everglades National Park and it currently acts as a levee, impeding sheet flow towards Florida Bay. Although Flamingo Road is located within the domain of the SFWWM, the model resolution is not fine enough to evaluate alternative designs that would restore historic hydropatterns. Further analysis is recommended through hydrologic modeling at the appropriate scale to determine the best options for restoring the desired sheetflow.

A6.3.5.2 Restore Flows To Florida Bay At Adams Waterway

There is no information on this project and the proponent could not be identified.

A6.3.5.3 Florida Keys Tidal Restoration

The objective of this project is to restore flows to tidal creeks by installing culverts under US Highway 1 at four locations in Monroe County (between mile markers 54 and 57). These projects are similar to a culvert project at Key Colony Beach completed in 1991, which was very successful in improving the near-shore water quality. The individual projects can be described as follows: 1) restore Tarpon Creek just south of mile marker 54 on Fat Deer Key, 2) restore an unnamed creek between Fat Deer Key and Long Point Key south of mile marker 56, 3) restore tidal connection adjacent to Little Crawl Key and 4) restore tidal connection between Florida Bay and the Atlantic Ocean at mile marker 57. The accumulation of organic material in these creeks has resulted in a degradation of water quality and sea grass habitat. Impacts originally occurred as a result of the construction of the Flagler Railroad bed (currently U.S. Highway 1) which blocked tidal flow and circulation in near-shore waters. Restoration benefits expected by installation of these culverts include: 1) enhanced circulation and flushing, 2) improved water quality, and 3) restoration of marine habitats.

A6.3.5.4 Indian Key And Tea Table Fill Removal

The proposed project would remove all causeway fills between Upper Matecumbe, Lower Matecumbe, and Long Keys and replace them with bridges.

A6.3.6 Southwest Florida Region

A6.3.6.1 Lake Trafford Restoration

Lake Trafford is located in north Collier County and is the largest lake south of Lake Okeechobee with a surface area of approximately 1,494 acres. It is the headwaters of the Corkscrew Swamp Sanctuary to the southwest, the Corkscrew Regional Ecosystem Watershed (CREW) to the west, and the Fakahatchee Strand system, which includes the Florida Panther National Wildlife Refuge, to the south. Lake Trafford has poor water quality, extensive muck accumulations, loss of native submergent plant communities, periodic aquatic weed infestations, and numerous moderate fish kills. A massive fish kill occurred in April 1996 which was caused by poor water quality conditions, including high biological oxygen demand, lethal ammonia levels, and depressed dissolved oxygen content. Poor water quality is attributed to internal nutrient cycling from extensive organic muck deposits throughout the lake basin. The project involves the use of one or more 14-inch portable cutter dredges to accomplish lakewide organic sediment removal. Approximately 8.5 million cubic yards of loose, flocculent, organic materials blanket the bottom of the lake and range from approximately nine inches to nine feet in thickness. The material will be pumped to an upland disposal site on existing farmland less than one mile from the lake. The pipeline to the upland disposal area will be located adjacent to an existing ditch with an easement being provided by the landowner. This ditch will also be used to carry the return flow from the disposal area. The disposal area consists of a 449-acre, diked, agricultural facility, which will be divided into three cells. The sponsors have additional lands identified if, in the design phase, it is determined that additional acreage will be required.

A6.3.6.2 Lakes Park Restoration

Lakes Park is located east of Cape Coral in Lee County, just west of Highway 41. The park consists of an old rock mine with a series of borrow pit “lakes.” The entire area drains south into Hendry Creek, an Outstanding Florida Water, which flows for a few miles before entering Estero Bay. Lee County has developed the area as a regional park with a bathing area along the shoreline of the lakes. Adjacent to the developed area, the remaining natural habitat contains pine flatwoods with some cypress heads. The pits capture runoff from the surrounding developed area (commercial, industrial, and residential). County monitoring has indicated a decline in water quality in the lakes. The lakes are infested with hydrilla and adjacent uplands and islands are covered with exotic plant species such as Australian pine and Brazilian pepper. The project is expected to enhance surface water runoff quality by creating a meandering flowway with shallow littoral zones and removing aquatic and upland exotic vegetation. The littoral zone will be harvested periodically to remove excess nutrients from the system. Exotic vegetation will be removed and replaced with native vegetation on 11 acres of upland.

A6.3.6.3 Southwest Florida Water Management Model

As part of the south Florida ecosystem restoration initiative, there is a desire to either maintain or reestablish more natural (i.e., pre-drainage) patterns of hydroperiod and water flow in parts of southwest Florida, particularly the Big Cypress National Preserve, the Fakahatchee State Preserve, the Florida Panther National Wildlife Refuge, Southern Golden Gate Estates, Corkscrew Swamp Sanctuary, and the Ten Thousand Islands, including Rookery Bay. Elsewhere in southwest Florida, many changes are being made to the hydrologic system to accommodate growing urban and agricultural uses. These changes could affect neighboring or downstream natural areas. Existing hydrologic models are more geared toward stormwater management and are inadequate in their structure to provide meaningful information about how a change in the hydrologic system will affect the overall ecosystem. Knowledge of hydroperiod effects is essential to evaluating ecosystem effects. Needed for southwest Florida are: 1) a grid-based (spatially explicit) connected surface and surficial groundwater model that contains the existing network of canals and water control structures; and 2) a corollary model without any control structures that approximates the natural response of the system to rainfall. The proposed pair of models for southwest Florida will be like the South Florida Water Management Model (SFWMM) and the Natural System Model (NSM), which presently are being used to evaluate proposed Restudy alternatives. The proposed models will be used to design and evaluate restoration scenarios and other proposed alterations to the hydrologic system (i.e., flood reduction along the Imperial River.) The proposed Southwest Florida Natural System Model could be used to simulate the hydrologic system's natural response to rainfall, flows and hydropatterns if canals and control structures had not been built. This is valuable information because the natural system supported the mixtures of plant communities and wildlife that are objectives of the restoration effort. The proposed Southwest Florida Water Management Model will be used to simulate outcomes of proposed alternative restoration strategies, which could be compared to the proposed Natural System Model output. The coverage of these two models is incomplete in southwest Florida. The South Florida Water Management Model covers the Big Cypress National Preserve and fringing mangrove system to State

Road 29 but does not include most of Hendry County. The existing NSM has broader coverage and includes Hendry County to a longitude that aligns with the southern part of State Road 29, but does not include the part of southwest Florida west of State Road 29. The proposed models would improve the ability to evaluate alternatives in the Restudy and to design restoration and other types of projects for Southwest Florida through the Southwest Florida Feasibility Study. Models developed for southwest Florida should be designed to connect seamlessly to the South Florida Water Management and Natural System Models to minimize boundary effects and to enable reliable addressing of questions near the boundary between these areas or large-scale questions that affect both areas.

A6.3.6.4 Spring Creek Reconnection And Rehydration

The project proponent is unclear but appears to be Pueblo Bonito Partnership for Housing, Incorporated, a private developer. The project is located in Lee County. In the early 1960’s, a 40-foot wide canal was dug that cut off approximately 2,200 linear feet of Spring Creek which flows into Estero Bay. In 1990, the canal was designated an Outstanding Florida Water (OFW). The project purpose is to restore approximately 2,200 linear feet of the historic Spring Creek floodplain through three components. Reestablish the headwaters of Spring Creek by: 1) constructing a weir to redirect canal inflow into the historic Spring Creek flowway, 2) removing approximately 27,000 cubic yards of spoil which currently segments the floodplain and 3) replanting tress within the restored areas. This project appears to be, at least in part, a compensatory mitigation requirement for permits associated with a private residential development. If so, the ecological benefits of the project are already allocated to offset the adverse impacts of the permitted development. Further analysis is needed to determine the exact scope of this proposal and the allocation of the benefits to be generated.

A6.3.6.5 Town Of Ft. Myers Beach

The Town of Fort Myers Beach in located on a barrier island of the southwest coast in Lee County. The town has identified the need for the protection of adjacent Estero Bay and local beaches from pollutants transported via stormwater runoff from the island on which the town is located. Most of the town is urbanized and has an inadequate stormwater management system. Components identified for this project include: 1) inventory of stormwater systems, 2) sediment sampling, 3) screening of illicit connections, and 4) implementation of an urban retrofit project. The project is designed to enhance Estero Bay and has received full support of local government and residents of the community. The town has already begun to identify stormwater “hot spots” through inventory and sampling procedures and has converted 48,000 square feet of asphalt to pervious paving materials. Pores in the asphalt of these materials allow runoff from parking lots to flow through the pavement into an underground reservoir of small stones, and then gradually filter into the surrounding soil. Other options for controlling urban runoff that are under consideration include installation of "water quality inlets," which are baffled concrete tanks for solids and oil separation, as well as numerous other best management practices (e.g. encouraging the use of slow-release fertilizers, etc.) The project is expected to provide immediate water quality and ecological benefits to the Estero Bay Aquatic Preserve by reducing pollutant loading to receiving waters.

A6.3.7 System-Wide

A6.3.7.1 Melaleuca Eradication Project (Part A) – Construct New Melaleuca Quarantine And Research Facility

The purpose of this project is to construct a Melaleuca Quarantine and Research Facility for the testing of candidate organisms for biological control of Melaleuca. This project would enhance and accelerate the highly regulated quarantine process. The facility would be located on one of the following sites:

- University of Florida property, adjacent to the U.S. Department of Agriculture/ Agricultural Research Service (USDA/ARS), Ft. Lauderdale Aquatic Plant Management Laboratory, Davie, Florida.

- University of Florida property, University of Florida Research & Education Center, adjacent to the U.S. Department of Agriculture/Agricultural Research Service Facilities Division, U.S. Horticultural Research Laboratory, Ft. Pierce, Florida.

A6.3.7.2 Melaleuca Eradication Project (Part B) – Renovation And Improvements – Biological Control Quarantine And Research Facility

The project would provide improvements to the Florida Biological Control Laboratory (FBCL) facility in Gainesville, Florida to better meet the needs of testing biological control candidates of exotic aquatic and terrestrial pest plants and arthropod pests of agricultural, native and horticultural plants. The Florida Department of Agriculture and Consumer Services, Division of Plant Industry, is the regulatory agency responsible for protecting Florida's native and commercially grown plants from harmful pests and diseases. The FBCL facility operates in close cooperation with the U.S. Department of Agriculture, Agricultural Research Services, and the University of Florida, Institute of Food and Agricultural Sciences. The primary responsibility of the FBCL is to enforce the quarantine procedures and regulations governing the receipt, handling and release of introduced biological control organisms.

A6.3.7.3 Melaleuca Eradication Project – Implement Biological Controls

This project calls for the mass rearing, field release, establishment and field monitoring of approved biological control agents for Melaleuca. Production of biological control agents for release requires maintaining large screenhouse colonies at the U.S. Department of Agriculture/Agricultural Research Service (USDA/ARS), Ft. Lauderdale Aquatic Plant Management Laboratory located at Davie, Florida. Melaleuca plants must be continually collected for the colony food source, therefore Melaleuca must be cultured at the laboratory. Insects grown in these screenhouses will be released into Melaleuca stands. Permanent study plots will be established at designated release sites. The 13 existing study plots will be increased to approximately 100 as a result of this project. Periodic monitoring will be conducted in order to quantify the insect's impact upon Melaleuca, thereby evaluating the effectiveness of the biological control agent. Sampling methods will be developed to recover insects for re-release or observation and to estimate the population of insects in the field.

APPENDIX B
HYDROLOGIC MODELING

B.1 INTRODUCTION

Two methods of hydrological modeling were implemented by the Restudy Team to evaluate alternatives. They are explained in this Appendix. The first method of modeling is referred to as the *screening phase.* This method was scaled to allow a large number of model runs to be performed utilizing various models. The primary purpose of this allowance was to enable evaluation of each component prior to larger scale, integrated system-wide modeling. The second method of modeling is referred to as the *alternative development phase.* This method incorporated the South Florida Water Management Model (denoted herein as SFWMM). The SFWMM met the requirements for a larger scale, integrated system-wide model.

B.2 SCREENING OF COMPONENTS

B.2.1 Introduction

A modeling effort was conducted to evaluate potential project features, or *components*, individually prior to combining them into planning alternatives. The modeling was scaled so that a large number of model runs could be made for each component. This modeling effort was referred to as the screening phase. Components investigated included basin storage reservoirs, Aquifer Storage and Recovery wells (denoted herein as ASR), and seepage management. Explicit investigations were conducted to evaluate the sizing of reservoirs, effectiveness of ASR, and setting of operational guidelines. *Screening investigations were performed to assist the modelers in the development of alternatives rather than to establish absolute criteria for each component.*

The screening effort primarily evaluated one component at a time, for example, storage. The main objective was to understand how each component acted individually within the future base configuration, before combining components together forming alternatives. Additionally, this provided initial size ranges and operational information for each component. However, some modeling investigations did include multiple components.

The strength of the screening models was the capability to perform multiple evaluations in a relatively short time. The screening provided insight into blatant hydrologic realities rather than trying to determine subtle differences. Evaluations included parameter sensitivity, operational scenario, and trend analysis, as well as comparing results from a large number of alternative scenarios. The modeling for the screening phase was intended to provide basic information required for more detailed comprehensive modeling of the alternatives.

Although the screening models and some results were made readily available to the public, the modeling effort itself had limited participation. However, the results of the screening effort were discussed in the Alternative Development Team meetings before they were used in the alternative development phase.

B.2.2 Computer Model Selection

Prior to the Restudy, there were two hydrologic models utilized to evaluate the hydrologic conditions of South Florida: the South Florida Water Management Model (SFWMM) and the South Florida Regional Routing Model (SFRRM). The SFWMM was designed to perform a relatively detailed analysis based on a limited number of runs. The SFRRM is less sophisticated in hydrologic analysis and can be used to quickly evaluate many scenarios of water resource features with less detail. Although the SFRRM approach was more suited to the screening effort, the model did not include potential Restudy components. It was also considered too cumbersome to rewrite for the Restudy. The most recent documentation for the SFWMM was provided in a draft report (SFWMD, 1997. DRAFT Documentation for the South Florida Water Management Model. Hydrologic Systems Modeling division, Planning Department, South Florida Water Management District, West Palm Beach, Florida) and is described further in ***Section B.3.1.1***. Documentation for the SFRRM is provided in two publications: South Florida Regional Routing Model, Technical Publication 86-3, June 1986; and in Lake Okeechobee Regulation Schedule Simulation, Special Report, April 1994. Both are available from the SFWMD. Detailed descriptions of input data, rainfall, evapotranspiration, seepage, existing hydrologic features, rules of operation, and calculation routines are described in the documentation.

For the screening effort, three hydrologic models were developed: the Everglades Screening Model (ESM), the Object-enhanced Screening Model (OSM), and the Central and South Florida Systems Analysis Model (SFSAM). The three models represent three different approaches to the modeling of the south Florida region. The ESM uses a traditional sequential solution technique where variables are determined in the order they are required. Both the OSM and SFSAM include linear programming routines, but with different optimization goals. The OSM optimizes the operation of the system within each time step. The SFSAM uses the entire period of record in one time interval to determine the best operation for that period. Similar to SFRRM, each screening model treats each WCA, lake, and reservoir as a “pot” of water, and only average parameters are used (e.g. average stage of the entire area or average inflow and outflow).

At the initiation of the Feasibility Study, the OSM and SFSAM were developed to be the primary models for the screening effort. When the study period was shortened by WRDA 96, however, the ESM was designated as the primary investigation model, while both OSM and SFSAM were designated as secondary investigation and verification models. Each of the three models provided a unique perspective into the water management response of the C&SF Project.

Water Preserve Areas (WPAs) were not sufficiently defined to be included in the development of the OSM and SFSAM. Therefore, WPAs were not included in the investigations conducted by those models. However, some WPA features were included in the ESM and investigated. ESM, OSM, and SFSAM included the future base condition (future water supply demands, environmental demands, STAs, and all water control features proposed to be in place by the year 2050, including Modified Water Deliveries). The southern limit of these models was the flow line along Tamiami Trail into the ENP. Hence, C-111 features were not included.

B.2.2.1 Object-Enhanced Screening Model

Water Resources Management, Inc developed the OSM. The model uses input data and similar algorithms found in the SFRRM, but utilizes linear programming techniques for operational decisions at a weekly time step. A complete description of the model with investigative results are documented (Object-enhanced Screening Model (OSM) Final Report for the Jacksonville District of the U.S. Army Corps of Engineers, October, 1997).

B.2.2.2 Central and South Florida Systems Analysis Model

The SFSAM is a special application of the Prescriptive Reservoir Model (PRM) developed by the Hydrology Engineering Center, Davis, California. The model uses input data and similar algorithms found in the SFRRM, but incorporates a monthly time-step. SFSAM utilizes a special linear programming technique for making operational decisions for the entire period of record as the “best” operational solution to meet identifiable needs. The rules of operations for storage areas (e.g. Lake Okeechobee, WCAs, and reservoir components) in the model were less constrained than the existing system in order to learn from the solution. A complete description of the model with investigative results are documented (Central and South Florida Systems Analysis Using HEC-PRM, Draft Report for the Jacksonville District of the U.S. Army Corps of Engineers, July, 1998).

B.2.2.3 Everglades Screening Model

The ESM is a rewrite of the SFRRM into an object oriented modeling environment that allows quick and easy development of new components. The ESM uses the same input data set and rule structure as the SFRRM, SFRRM having already been documented and proven. The ESM was developed to quickly explore many structural and operational possibilities, parameter sensitivities, as well as the interaction effects with other major water control features in South Florida (both present and future). Accordingly, the ESM was utilized for screening a large number of alternatives. However, the SFWMM was utilized for high-level detail evaluations for a small number of planning alternatives. At the time of the screening effort, the ESM ran in about six minutes as compared to the six hours required by the SFWMM .

The ESM was developed in a modeling environment called STELLA II (High Performance Systems, Hanover, New Hampshire) and was completed by Dr. Richard Punnett of the Corps of Engineers, Jacksonville District. The rewrite was coordinated with the staff of SFWMD. The time step used for the ESM was one week with a 26-year period of record (1965 to 1990). As ESM was being developed, copies of the model were continuously available for review and comment by any interested party. Additionally, a two-day workshop was held in the summer of 1996 to present and explain the ESM. The workshop was opened to the public. The findings from the ESM are discussed in ***Section B.2.6.***

B.2.3 Hydrologic Historical Perspective

B.2.3.1 Predrainage Flow Patterns

To investigate the natural system, it was necessary to establish some preliminary hydrologic targets and utilize projected future water supply and hydrologic budgets. During the screening phase, the Natural System Model (denoted herein as NSM, version 4.2) was utilized for average stage and flow targets in the ENP and the WCAs. Additionally, the NSM flows to tide were used as a guideline to estimate the volume that could be captured from the flow currently going to tide.

The Technical Advisory Committee of the Governor's Commission for a Sustainable South Florida completed a review of the water budget changes in South Florida and described the findings in a presentation (Everglades Water Budget – Principles and Overview Slide Presentation. Technical Advisory Committee of the Governor's Commission for a Sustainable South Florida, October, 1994). Although the report was based on NSM Version 4.1, it characterizes the overall changes that have been observed between historical and present conditions.

B.2.3.2 Original C&SF Design

In the original C&SF Project report (1949), flood control was recognized as the major impetus of the study by noting that the development of the region was "retarded by destructive floods." Fires were reported as problems during droughts, in addition to that of "too much water." Water conservation was noted as important, but primarily for the maintenance of water levels to combat fire destruction of the muck lands within the Everglades. Other project purposes were addressed to a lesser extent (including the prevention of salt-water intrusion and improvement of water supply, navigation, recreation, and fish and wildlife enhancement). Several other interesting design characteristics were also noted and are mentioned as follows:

- Because the water supply demand on Lake Okeechobee was less, fluctuations in water levels were much less than they are today and were far more ecologically beneficial to the Lake.

- Because the water supply demands on the WCAs were less, there was more water available to flow into the ENP.

Prior to 1928, some flood discharges from Lake Okeechobee were directed to the east and west estuaries. The canals leading to the estuaries were enlarged after the 1949 report.

- Discussions of minimum flow requirements to the natural system were in reference to the prevention of muck fires during droughts.

- Because some of the land south of WCA 3B was privately owned, the flows into the ENP were primarily passed from WCA 3A through the S-12 structures.

- Seepage management from the eastern protective levee consisted primarily of draining the excess seepage water to tide in most areas (L-67 A and C were added later to reduce the stages; therefore, seepage from WCA 3B).

- Lake Okeechobee was the ultimate source of water during dry seasons for water supply; however, no flow demands from the WCAs or ENP were included.

B.2.4 Hydrologic Objectives of the Restudy

B.2.4.1 General

The Restudy objectives that directly relate to hydrology are:

- Natural Hydrologic Patterns
- Flood control
- Water supply

To achieve these objectives, many new components to the C&SF project are required. The screening of the hydrologic components was intended to support these objectives. Although creating storage was not an objective, the need for storage and other water management features to achieve the objectives is self-evident. For example, storage could be used for flood storage to prevent losses and damages to the estuaries, in addition, it can be used for a dry season source of water. The management of water to meet present and future dry season demands requires new sources of water during those times.

B.2.4.2 Hydrologic Pattern Targets

Hydrologic changes in the natural areas have been identified as the major factor in the ecological decline of the system. Key hydrologic indicators are hydroperiod, distribution, timing and quantity of water. The screening effort used NSM values (no substantial historic records were made) as the initial targets for restoring natural hydrologic conditions. In the modeling of each component, several indicators were used to determine if changes were positive and significant. For example, the amount of water added to the ENP (as well as the timing and distribution) could be evaluated for significant improvements to assist in determining the amount of storage needed upstream. Additionally, changes in the average depth of a WCA could be evaluated for improvements in high or low water stage conditions.

The screening models treated the WCAs as individual “pots” of water; therefore, screening investigations of hydropatterns within each WCA was not possible–only average conditions could be evaluated. Nor was it possible to evaluate the internal ponding effects of the *severed flow lines* (flow paths along the eastern side of the WCAs that historically ran southeastward into the LEC). The natural flow paths from the WCAs were permanently altered when the eastern protective levees were constructed. The evaluation of this effect was conducted utilizing the SFWMM while investigating the possibility of either full or partial decompartmentalization of the WCAs.

B.2.4.3 Flood Control

Today, the designated areas for flood control are Lake Okeechobee, the WCAs, the ENP, estuaries, and bays. The wet-season effects of flood control in urban and agricultural areas are higher flows in rivers and estuaries, and higher peak stages in the Lake and WCAs. Conversely, the dry-season effects are lower flows and stages. Water mass moved to tide in the wet seasons, via estuaries or bays, is not available for dry seasons and is thereby lost from the system. With the addition of storage features, both flood control and dry season flows can be enhanced.

Increased seepage management will have incidental effects benefiting flood control by the reduction of water flow through populated areas. Although some seepage management features were included in the screening phase, this flood control benefit was not identified.

Flood control generally meets design requirements in South Florida with few exceptions. Site specific flood control was not evaluated in the screening phase.

B.2.4.4 Water Supply

Perhaps the best-defined water demand of the system is the water supply requirements of the LEC and the EAA. Estimated water demand for the year 2050 was used for the screening effort and water was distributed according to *existing state water allocation rules*. The primary water supply source for the service areas around Lake Okeechobee (EAA, St. Lucie, Caloosahatchee, North Palm Beach Basins, Seminole demands, and peripheral cities) comes from local and groundwater storage. A secondary source is from the receiving of supplemental releases from the WCAs. When the LEC water supply from local groundwater is low, it is supplemented initially by the WCAs before being met by supplemental releases from Lake Okeechobee. Therefore, all urban and agricultural water supply needs are ultimately dependent on Lake Okeechobee.

In contrast, the WCAs and the ENP are not entitled to Lake Okeechobee releases to maintain minimum flows or levels. The ENP is only entitled to water released from the WCAs in accordance with the Rainfall Plan. If the WCAs are low, no water is released to the ENP and the Rainfall Plan requirement is unmet. The minimum flows and levels rules (currently under consideration) only restrict the withdrawal of water from the Lake and WCAs when these areas are at or below a minimum stage/level. The rule does not require a minimum flow of water to maintain minimum stages or levels.

Some evaluations for the screening phase were made assuming potential flow requirements to the ENP, such as a minimum flow rate or flow rates equivalent to NSM conditions.

A state requirement for water management districts to plan for a one year-in-ten drought was not in place during the screening phase and was not evaluated in the screening phase.

B.2.4.5 "New" Water

A blatant hydrological reality is that there is not enough water stored in the system to meet all dry-period water supply demands–past, present or future. The demands come from agriculture, urban, and natural areas. A water manager's definition of a drought should be when dry conditions prevail under which normal water supply demands are not met. Droughts have occurred in the 1970's and 1980's where the demands exceeded the supply. However, the adverse impacts during those events were not severe. Recognizing that water supply demands have increased significantly over time, it is realistic to believe that the same hydrologic conditions of the 1970's and 1980's will have increasingly more severe shortage impacts in the future. Mild hydrologic droughts that have occurred in the past without shortages will have shortages in the future because of these increased demands.

The identification and quantification of potential "new" sources of water were important during the screening phase. Three obvious sources were evaluated: (1) regulatory water released from Lake Okeechobee (LOK) to the estuaries; (2) "excess" runoff in the Caloosahatchee Basin; and (3) water sent to tide along the Lower East Coast. The modeling for the screening phase focused on the capability to create new sources of water from the water currently being lost to tide. Identification and modeling of reuse water as a dry-season source was neither completed nor included during the screening phase.

B.2.5 Descriptions of Hydrologic Components

B.2.5.1 Overview

The components that were investigated in the screening phase included storage north of and in Lake Okeechobee, storage in the Caloosahatchee and St. Lucie Basins, storage in the EAA, storage and seepage management throughout the LEC, and ASR. Additionally, several factors that affect the efficacy of the components were also included in the modeling such as evapotranspiration (ET), seepage, ASR efficiency, storage location, and operational flexibility.

Two of the guiding principles in deciding where to investigate water resource components were: (1) to solve the problem in the basin where the problem exists; and (2) to take advantage of the opportunities in the basins where they exist. For example, it was far more effective to store excess Caloosahatchee River water in the Caloosahatchee River Basin than to transport the water to another basin for storage (e.g. the EAA Basin). Pumping rates are often significantly less in comparison to the magnitudes of flood flow. Not only would pumping to another basin be expensive, but also the rate at which water could be captured would be reduced if canal flow over a distance is necessary. This would be notably true when deliveries back to the original basin were needed for water supply. Although backpumping from the Caloosahatchee River Basin to Lake Okeechobee can be effective in some years, in other years it is not–whereas storage within the Caloosahatchee River Basin is effective almost every year (discussed further in ***Section B.2.6.1***). The actual location *within* a basin was much less important due to the nature of the screening effort. As long as sufficient canal connections to an inflow source were identified, the performance of a reservoir could be investigated.

The problem or opportunity presented often defined the type of water resource component evaluated. For example, if multi-year carry-over of water was needed, then ASR was the most likely candidate to fulfill that function. Another example, if a rapid collection of flood flow was needed, then a reservoir was the most likely candidate. Additionally, the water resource component could be a combination of two or more features (e.g. a reservoir with ASR facilities and seepage management).

Evapotranspiration (denoted herein as ET) was modeled in all water management features except ASR. The method utilized to model ET was that incorporated by SFRRM and was explained in the SFRRM documentation (see ***Section B.2.2***). Simply stated, the incremental ET that would be created by raising water levels to above ground conditions was calculated and subtracted from the water budget. The modeling of marshes was performed identically to that of above-ground reservoirs.

Seepage is critical to the LEC water budget during dry seasons. It is important to note that *not all seepage is a loss*. However, during flood times, it can be considered a loss or even a contributor to downstream flooding conditions. Supplemental releases from the WCAs or LOK are needed for the LEC when seepage does not meet demands. Seepage management along the eastern protective levee was evaluated by utilizing either a step-down water level approach or a backpumping approach. The effects of underground barriers or “curtain walls” along the eastern protective levee were not evaluated in the screening phase since the impacts to the LEC could not be evaluated with the screening models.

Consideration of seepage management was also necessary in scenarios where an above-ground reservoir was modeled. In those cases, it was assumed and included in design estimates that sufficient seepage management facilities would be able to collect and return seepage to the reservoir. This would be particularly important during periods of high water levels; however, the seepage could be used to help meet dry-season demands in the LEC and EAA, for example, reducing the amount of pumping (thereby also reducing costs as an added benefit).

In the modeling of ASR, 70 percent efficiency was assumed with a 30 percent loss. The 70 percent efficiency is consistent with the ASR report as referenced to the Governor’s Commission on a Sustainable South Florida. In some wells of south Florida, much higher efficiencies have been observed (e.g. in Hialeah, Florida), while some ASR wells have not been productive (e.g. in Marathon, Florida). In the Peace River, not only have efficiencies been noted, but also withdrawals from multi-year storage have been demonstrated. Multi-year storage capability was modeled in the screening phase incorporating this technology. The screening effort attempted to determine if significant benefits could be realized rather than to size the amount of ASR needed in a particular basin. The actual sizing would occur in the alternative development phase as the configurations of other features were modeled.

Storage areas with extensive drainage capabilities are able to use the storage more effectively than an area without drainage, unless the land is significantly sloped. Complete use of the storage volume was assumed in reservoirs with drainage features. In reservoirs without drainage features; however, the last half-foot of storage was assumed not available since it could not be pumped readily.

Multi-purpose operations and operational flexibility were two important considerations in the modeling of components. The goals for a management feature must be identified before the rules of operation can be developed. Multiple goals were considered when possible. For example, when determining goals for EAA storage: local flood control, local water supply, reductions in estuary discharges, and reductions of WCA peak stages were also considered. If a single goal of preventing estuary releases was used, then the size of a reservoir would be significantly larger than a reservoir designed only to maximize water supply. Operational flexibility was more important in the development of alternatives when a combination of effects could be evident. Additionally, operational flexibility is an important consideration for adaptive management.

The alternative development phase was not limited to the findings from the screening phase, but it was made more efficient by having some experience in modeling most of the features.

B.2.5.2 North of Lake Okeechobee Storage

The Kissimmee River Basin was once a classic Florida marsh-type river system. As flood control was developed in the basin, the connections between lakes and rivers were enhanced and the river was made straighter and deeper. Thus, peak flows in the river were increased, water travel times were faster, and low flows were reduced. The current restoration effort for the Kissimmee River was assumed to be part of the future base condition and was included in the modeling. The overall increase in flood flow rates into LOK causes an increase of releases to the estuaries from the Lake.

The primary goals for storage north of Lake Okeechobee were to avoid releases to the estuaries on the east and west coasts, reduce high lake stages, and improve dry-season stages in the Lake. Thus, the storage area was filled by capturing floodwater when the Lake was nearing regulatory release stages. When the Lake Okeechobee stage began to recede below regulatory levels, the stored water was released directly to the Lake for water supplies. To reduce the losses associated with ET, the storage would only be used in abnormally wet years. During the dry-to-normal years, the reservoir area may be used for other purposes (e.g. grazing or recreation).

For modeling purposes, it was not necessary to identify a specific location of the storage facility except to determine that it was near the inflow source. In the case noted above, the storage was designed to interact with Lake Okeechobee directly by either taking water from or putting water back into the Lake. If the facility was located further upstream of the Lake, considerations of stream flow may limit the amount of water collectable. However, some flow improvements in the Kissimmee River can be constructed. The need for water quality improvements to LOK inflow had not been identified during the screening phase and storage for that purpose was not evaluated.

A maximum storage depth of 10 feet deep was initially set for the reservoir. The reservoir was modeled as a flat-bottom reservoir. For the Kissimmee River Basin, the actual site may be in a sloped area; therefore, the important design consideration from a modeling standpoint was the overall storage capacity and not the surface area. A smaller surface area is more desirable when considering ET losses.

B.2.5.3 Caloosahatchee Storage

The Caloosahatchee River once had an undistinguishable connection to Lake Okeechobee and probably received overflow from the Lake only in abnormally wet years. The river was shallow and had numerous oxbows. Flooding along the river was common. A viable connection to the Lake was made in the early 1900's and Lake Okeechobee experienced its first major drainage and lowering of its water levels. As flood control was developed in the river basin, high flows to the estuaries were increased while low flows to the estuary diminished. The magnitude of the flood flows from the local basin easily exceeds the magnitude of the regulatory releases from Lake Okeechobee. However, regulatory releases from the Lake increase flows to the estuary and become a part of the salinity-balance problem. The need for dry-season water supply increased with agricultural development in the basin. The diminished low flows of the basin, coupled with the increase in the agricultural water supply demand causes the basin to be highly dependent on water supply releases from Lake Okeechobee in dry seasons.

The primary goals of storage in the Caloosahatchee Basin were to reduce peak flood flows to the estuary; capture excess runoff and help meet dry-season water demand; and provide for minimum flows to the estuary. “Excess” runoff, or water in excess of estuary requirements, has been defined as part of the Lower East Coast Regional Water Supply Plan (LECRWSP). The modeling performed in the screening phase was utilized to evaluate the sizing of the reservoir that could balance the goals. ASR was not included in the basin design during the screening phase. The volume of “excess” water available during the screening phase was significantly less than the volume ultimately used in the alternative development phase. Although backpumping into Lake Okeechobee was evaluated to a minor extent in the screening phase, it became a more important consideration when the volume of excess water increased in the alternative development phase.

A maximum storage depth of 8 feet deep was initially set for the reservoir. The reservoir was modeled as a flat-bottom reservoir and assumed to be in proximity of the Caloosahatchee River. The actual reservoir could be divided into multiple reservoirs to enhance the capture of basin water and to make siting easier, since one contiguous area would not be necessary. Although construction costs would be increased, the land cost may be significantly reduced.

B.2.5.4 St. Lucie Storage

The St. Lucie Basin was once not connected to Lake Okeechobee. Flows from the local basin entered into a basically freshwater lagoon. After a direct opening from the lagoon to the ocean was created and maintained, an estuarine community was established. A canal from Lake Okeechobee was created in the early 1900's that, on occasion, greatly increased the fresh water flows to the estuary. With the development of flood control in the basin, the local basin peak flows to the estuary were increased to the point that the estuary sustains occasional damage from too much fresh water. Today, the regulatory releases from the Lake can far exceed the local basin peak flows and may alone cause damage to the estuary. The diminished low flows of the basin due to flood control, coupled with an increase in agricultural water supply demand, causes the basin to be highly dependent on water supply releases from Lake Okeechobee in dry seasons.

The primary goals of storage in the St. Lucie Basin were to reduce peak flood flows to the estuary; capture excess runoff and help meet dry-season water demand; and provide for minimum flows to the estuary. "Excess" runoff, or water in excess of estuary requirements, has been defined as part of the LECRWSP. The modeling performed in the screening phase was utilized to evaluate the sizing of the reservoir that could balance the goals. ASR was not included in the basin design during the screening phase. The volume of "excess" water available during the screening phase was significantly less than the volume ultimately used in the alternative development phase. No additional backpumping was considered in the screening phase since back flows from the St. Lucie Canal currently exist.

A maximum storage depth of four feet deep was initially set for the reservoir. While the area could support a greater depth, a more marsh-like reservoir with water quality enhancement was desired. From a modeling standpoint, the capacity was the most important design parameter, but clearly greater surface areas would result in increased ET losses. The reservoir was modeled as a flat-bottom reservoir and assumed to be in proximity of the St. Lucie Canal. The actual reservoir could be divided into multiple reservoirs to enhance the capture of basin water and make siting easier, since one contiguous area would not be necessary. Although construction costs would be increased, the land cost may be significantly reduced.

B.2.5.5 EAA Storage

Runoff in the EAA once flowed at a relative low rate southward to the areas now known as the WCAs, to the Everglades National Park, and ultimately to estuarine boundaries with Florida Bay. Contributing, the overflow from Lake Okeechobee flowed southward across the EAA region and combined with the local runoff, thus providing a prolonged flow into the ENP. In today's system; however, the runoff from the EAA is efficiently collected and moved quickly into the WCAs for flood control purposes. Additionally, most of the overflow from Lake Okeechobee is released to estuaries both east and west of the Lake because of flood control concerns in the EAA. While the development of the EAA has created a highly productive and important agrarian community, it also resulted in major changes in the timing and quantity water entering the WCAs, the ENP, and bays. Water passed to the WCAs is supposed to support a natural wetland community, provide some flows to the ENP, and provide dry-season water supply for the LEC. The overall result when compared to predrainage is damaging flows to the estuaries, higher stages in the WCA's during wet periods, and lower stages in the WCAs during dry times.

The primary goals of storage in the EAA were to improve flood control, water supply, and environmental restoration--improved timing of flows to the WCAs and ENP--while reducing the volume of water currently lost to tide. Storage in the EAA can capture flood waters from two sources: local runoff associated with flood control for agriculture, and high-stage releases from Lake Okeechobee. Storage in the EAA was the only viable option available that could store EAA runoff for use in the dry seasons. By the storing of flood waters, both flood control and water supply management can be improved. There is a loss of water due to increased ET as with all reservoirs. Therefore, the rules of operation were evaluated to minimize this loss. However, even a diminished water budget can be important both to human needs and to the environment when stored water is delivered in dry seasons. Investigations within the EAA also included flowways and various ET management approaches.

The screening model was used to evaluate a great number of sizing issues associated with storage in the EAA. The sizing issues included parameter sensitivity analysis and operational rule making evaluations. This was considered necessary since numerous model runs could not be performed in the alternative development phase. More than a hundred runs were completed to evaluate storage in the EAA, as well as many more evaluations of feature combinations with EAA storage.

The location of the reservoir modeled in the screening effort was assumed to be between the Miami and North New River Canals. The potential inflows included the local inflows to those canals and regulatory releases from Lake Okeechobee. Some modeling investigations included the redirection of local runoff from the

Hillsboro and West Palm Beach Canals. The maximum depth was initially set to be six feet.

B.2.5.6 Lake Okeechobee Storage

In Lake Okeechobee water levels, before drainage, only fluctuated about two feet with a maximum stage around 21 to 22 feet above sea level. At the onset of a wet season, the Lake would be below its banks due to ET. Well into the wet season, the Lake would fill causing water to flow freely over the southern rim (about two years out of every three) and begin a slow-flowing trek through the Everglades marshes, wet prairies, and sloughs. The Lake was more expansive and the littoral zone was higher than it is today. Drainage to the Caloosahatchee and St. Lucie estuaries in the 1900's caused profound lake level changes in the Lake and major changes to the water budget of the remaining Everglades. Not only were the high stages reduced, but as water supply demands increased in the surrounding basins, the lower lake levels were also reduced. Accordingly, a new littoral zone was established at a lower zone (roughly 11 to 15 feet above sea level). Today, the Lake normally fluctuates over a seven-foot range with a maximum elevation of about 18 and a lower elevation of about 11 feet (extreme hydrologic events can cause exceedance of the seven-foot range). Lake level fluctuations for extended periods above 15.5 feet and below 12 feet can cause severe damage to the existing littoral zone and create other water quality problems within the Lake.

The goals of evaluating storage in Lake Okeechobee was to prevent discharges to the estuaries, provide water supply, and maintain lake levels consistent with both levee stability and healthy lake conditions. Obviously, these goals are competitive and the effort is primarily a balancing act. At the time of screening, the Lake Okeechobee Regulation Schedule Study (LORSS) was considering a number of potential changes in the rules of operation for the lake. Model investigations in the screening phase were primarily limited to major operational changes, such as the elimination of all regulatory releases by the holding of water in the Lake. As a result of screening efforts, a multi-purpose lake operation was developed and was included in the LORSS as the Corps plan.

B.2.5.7 Water Preserve Areas

The LEC was once characterized by deep water sloughs, an eastern coastal ridge (a few miles wide and suitable for human habitation), and occasional cuts through the ridge that allowed some surface flows to tide. Along with surface flows, seepage through the eastern ridge prevented saltwater intrusion into the underlying Biscayne aquifer. As the LEC was developed, a strip about 20 miles wide was drained by a series of canals east of a protective levee along the WCAs. The seepage through the eastern coastal ridge was reduced and seepage along the protective levee was created. Flood control activities resulted in a quicker and greater removal of rainfall (and WCA seepage) to tide in wet seasons and lower water table levels throughout the year. As the LEC water supply demand increased, management of the local water table required additional flows from the WCAs and Lake Okeechobee during dry periods.

The creation of WPAs is a concept, which consists of several components that are combined to meet five primary goals. The goals are: (1) to preserve existing high-quality wetlands; (2) to provide a buffer between natural and developed areas: (3) to increase regional water supplies by capturing excess water that goes to tide for dry season releases; (4) to maintain natural freshwater flows to estuaries; and (5) to reduce of excess seepage from natural areas such as the WCAs and the ENP. The components could include marshes, step-down water levels, recharge areas, reservoirs, seepage collection systems, curtain walls (impervious underground barriers), and stormwater treatment systems (marsh or filtering facilities). The actual configuration has not been determined as of today; however, the *form should be determined by both function and opportunity*. As part of the Lower East Coast Regional Water Supply Plan (LECRWSP) studies, the SFWMD evaluated the potential of the buffer concept. The buffer concept serves as the first draft of potential WPA sites. Additionally, the National Audubon Society prepared a report (Water Preserve Areas: Defining Biological Functions and Spatial Extent. Draft Workshop Report. National Audubon Society, December, 1996). This analysis provided information concerning the opportunities for components, such as marsh sites and potential reservoir sites, as well as identification of areas where land would not be available. Any potential site was considered to have a potential for multi-purpose operation.

The screening level evaluation of a potential WPA configuration was also studied. The WPA configuration consisted of the marshes just east of the eastern protective levee, seepage collection features, and reservoirs. The WPAs were designed to include backpumping of suitable water to the WCA and the ENP, water supply for the LEC, and reduction of seepage from the WCAs. Although other configurations were not studied, notably configurations that included curtain walls, several significant findings will be discussed.

An initial set of variables was assumed prior to the modeling of any configuration. Consequently, other sets of variables were tested to determine sensitivity. The variables included in this evaluation were maximum depth, surface areas, percent of excess water to tide available for capture, pump capacities, and seepage management. The shape of marshes and reservoirs were assumed to be essentially rectangular surface features. The most sensitive parameters are surface area, depth, percent of retrievable seepage, and percent of tide water available for capture. The development of a good set of operational rules was a critical guide for the effectiveness of the components.

B.2.5.7.1 Surface Area

Initially, the size of the marshes and reservoirs were consistent with the land suitability analysis. Sizes of the reservoirs were then varied ranging from 0.5 to 2.5 times that of the initial size.

B.2.5.7.2 Maximum Depths

Increasing the depth of a reservoir is typically desireable with the perspective to maximize effectiveness and minimize the areal extent. However, in south Florida, deep surface reservoirs are not practical due to high transmissivity rates of the substrate. The maximum depths considered for reservoirs next to the Loxahatchee National Wildlife Refuge (LNWR) were four and six feet. In reservoirs near WCA 3A and northern WCA 3B, the investigated maximum depth was four feet. For reservoirs in Miami-Dade County, the investigated maximum depths were two and four feet. For marshes, the maximum depth was assumed to be either 1.0 or 1.5 feet.

B.2.5.7.3 Percent of “excess water to tide”

About one million acre-feet of water goes to tide each year from C-4 to C-16 Canals. Although both seepage and runoff account for the amount, it is primarily LEC flood control activities that produce the releases to tide. Compared to pre-drainage values, the amount of water that goes to tide each year is about three times greater today according to NSM version 4.4. Theoretically, about 66 percent of the water that is sent to tide is “excess” (greater than predrainage). However, it is unreasonable to assume that such amount is available for capture without some undesirable environmental consequences. For the initial evaluation, the target percentage for capture was assumed to be 40 percent for the upper half of the LEC and 30 percent for the lower half of the LEC.

The amount of water that goes to tide is about two times greater today than pre-drainage values estimated by NSM version 4.5, the version utilized in the alternative development phase.

B.2.5.7.4Location

It was important to consider the reservoir location relative to the source of canal water for the water budget analysis. Location determined where water from the marsh or reservoir would be backpumped or which water supply demand could be augmented. In only one case was a new site considered not previously identified in the land suitability analysis. The sites evaluated in this report may help meet the water supply demands of the sub-region and help capture excess water to tide.

B.2.5.7.5 Pump capacities

The amount of water required to manage the maximum depth of marsh areas, supplied by backpumping, was determined by the model and is subject to change due to varying conditions downstream as well as upstream.

For reservoirs, the pump capacity was a function of reservoir size and depth. It was assumed that the pumps could fill the reservoir during a one-week major event, although the flow to tide was never reduced more than the target percentage for capture (above). Thus the model automatically provided the pump sizing for the screening evaluation. Other factors, such as actual backpumping limitations of the canal system, would have to be considered as well.

Backpumping from the reservoirs to the natural areas was included in the analysis. The backpumping rate was a function of the reservoir storage capacity and was automatically sized by the model to move one-fourth of the volume of storage in a week.

A modeled variable allowed for pumping a percentage of the eastward seepage from marshes and reservoirs to the natural areas. As initial values, a return of 30 percent for the marshes and 15 percent for the reservoirs were assumed. The utilization of these variables characterized the degree of seepage management assumed for the evaluation and greatly enhances the effectiveness of the reservoirs.

B.2.5.7.6 Seepage management

For the initial evaluation, only step-down water levels and backpumping collected seepage were considered. The marshes along the WCA boundaries were assumed to have an eastern berm and a collection canal that would allow for managing water levels and seepage collection. Additionally, marshes along the WCA boundaries provide a step-down water level seepage management benefit. The screening model was not utilized to evaluate underground barriers (curtain walls) because the impact to the LEC water table could not be evaluated with the ESM. The SFWMM was utilized to evaluate the effects of underground barriers for seepage control as part of the alternative development phase.

In reservoir operations, the backpumping of canal water would not only include runoff and seepage from the WCAs, but also seepage from the reservoir itself. This is more a physical reality than design assumption. Any seepage loss from a reservoir during backpumping of canal water would automatically be retrieved. During the periods of time when canal water is not being pumped, seepage alone could be pumped back or be allowed to meet LEC water supply. The modeled assumption was that any eastward seepage became part of the LEC water budget without being counted as water supply. An operational assumption was made that allowed a variable percentage of seepage to be collected and backpumped to WCAs or the ENP. There was a concomitant assumption that either the seepage water would be of suitable water quality for the natural areas or the water would be cleaned to suitable standards.

B.2.5.7.7 Operational Rules

Initially, the marshes were allowed to fluctuate according to hydrologic conditions. Only when the depth in the marsh exceeded the maximum desired depth was backpumping into a WCA or the ENP initiated. Pumping was then assumed to be at a rate to preclude depths greater than the maximum design depth.

For reservoirs, a constant rate of backpumping into WCAs or the ENP was assumed in addition to a percentage of seepage. Backpumping was only allowed when the WCAs were below regulatory schedules or when flow to the ENP was below predrainage values. Any direct backpumping from the reservoir to the Everglades Protection Area (EPA) would most likely have to include water quality treatment. LEC water supply demands were met from the reservoir if water was available.

B.2.5.8 Aquifer Storage and Recovery

ASR is a water management technique that can be applied to any basin where water is “excess” for an extended period of time and a suitable aquifer exists. The concept includes pumping the excess water to an aquifer as underground storage, then reversing the pumps in dry times to meet water supply demands. ASR has advantages and disadvantages over surficial reservoirs. Advantages include no ET losses, long-term storage (multi-year drought management), and a large volume potential. Disadvantages include losses to the aquifer when stored in saline aquifers, and low recharge and recovery rates.

ASR is not sufficient for flood control because of the low flow rates associated with well pumps. For example, a large ASR well may pump up to 15 cubic feet per second (cfs) whereas a flood flow can easily be greater than 3000 cfs. The largest well currently used in south Florida is capable of about 8 cfs. However, when used in conjunction with a storage area, ASR wells can provide some flood protection by making storage available, over time, in the reservoir. Once a storm surge is captured in a reservoir, pumping into an ASR well over several weeks may significantly reduce the reservoir level and make storage space available to capture subsequent flood surges.

A good description of the ASR technology was completed for the Governor’s Commission for a Sustainable South Florida (Aquifer Storage and Recovery (ASR) Presentation. Technical Advisory Committee to the Governor’s Commission for a Sustainable South Florida, May, 1996). Potential uses of ASR were evaluated as part of the screening phase in several locations over the study area.

B.2.5.9 Flowways

A flowway is generally described as a broad shallow marsh area that is used to flow water freely from Lake Okeechobee to one or more of the WCAs. The concept includes creation of an Everglades-type environment having both storage and water quality benefits. Evaluation of the concept shows several erroneous assumptions about the feasibility. Problems with soil subsidence, ET, seepage management, vegetation, timing of flows, and lack of flow events is evident. Addressing other EAA issues would be required if a flowway cuts through and dividing the area, including numerous roads, bridges, and railroad relocations.

Soil subsidence in the EAA has substantially reduced the hydraulic head that drives the southward flow of water; hence, velocities and flow rates are greatly reduced. By spreading the water over shallower areas (as opposed to reservoirs) and maintaining proper hydration of a functioning marsh habitat, the ET loss could easily be doubled. A long, rectangular configuration can have a 75 percent longer levee than a squared one, thus increasing seepage management features. Because nutrient-laden soil would be flooded for the flowway, cattails would most likely dominate the vegetation and not the desirable Everglades habitat. Flowways would not be able to hold back water going to the WCAs. The continuous delivery of that water would exacerbate the already high stages in the northern parts of the WCAs. Thus, the timing of flows from flowways would not be manageable or beneficial for the remaining Everglades. Perhaps the most crucial element–water flowing from the Lake to the WCAs–is not present in dry or even normal years! For example, during the long periods from 1970-1982 or 1985-1994, no significant excess Lake water was available for the flowway. Only demand releases to the Everglades were made from the Lake during those periods. Water delivered to the Everglades on a demand basis <u>through a flowway</u> would not be effective because of increased travel times and increased ET losses. The only years where water could flow for a long duration are wet periods similar to 1969-1970, 1982-1983, and 1994-1995. In those years, the stages in the WCAs are already too high and additional flow from flowways would be damaging, not beneficial.

Summarizing, the flowway is a concept that creates a water supply burden on the system without clear hydrologic benefits. The need for flowways would have to be justified for other reasons rather than hydrology alone.

B.2.6 General Findings

B.2.6.1 Operational Rules

No attempt in the screening phase was made to create a system-wide operational plan since the system is under review by the LECRWSP. Although having storage in all the basins as described, modeling evaluations in the screening phase did not create the water resources necessary to meet all water supply demands and match NSM flow volumes to the ENP. Clearly, operational changes alone cannot catch all the water currently being lost to tide in the Caloosahatchee, St. Lucie, and LEC Basins.

Evaluations of the effects of operational rule changes for individual components were important to the performance of each component. The successful performance of any component was dependent upon a capable set of operational guidelines. It is easier to develop a set of rules that results in poor performance of a reservoir than to develop an effective set. The evaluations discussed in the following sections were extremely valuable to the alternative development phase as a guide to modeling the proposed components.

Before developing operational rules, the evaluation of a potential component first involved an examination of each basin to determine hydrologic opportunities and limitations. Once the goals, limitations and opportunities were identified, the rules could be drafted. The following discussion of Lake Okeechobee provides the kind of hydrologic evaluation that will guide how components can be developed to match goals and opportunities.

Perhaps the most instructive visualization with regard to understanding how Lake Okeechobee behaves is shown in ***Figure B.2-1***. Lake levels over a 31-year period (1965 to 1995) are presented. The upper set of episodic dashed lines represent the regulatory release zones. Different flood discharge rules are invoked when the Lake goes above those lines. The black solid and red dashed lines represent the 1995 Base and 2050 Base cases, respectively. The lower episodic dashed line represents the Supply-Side Management (SSM) zone. Shortages in the basins around the Lake are invoked when the Lake goes below that line. Shortages in the LEC are not directly related to the SSM curve, but are “triggered” by other drought indicators.

Several blatant hydrologic realities with regard to Lake Okeechobee are evident in ***Figure B.2-1***:

- Regulatory releases from the Lake only occur on a periodic basis – not annually. As a result, there is no annual allotment of water that can be saved in the Lake by simply raising the regulatory release zones.

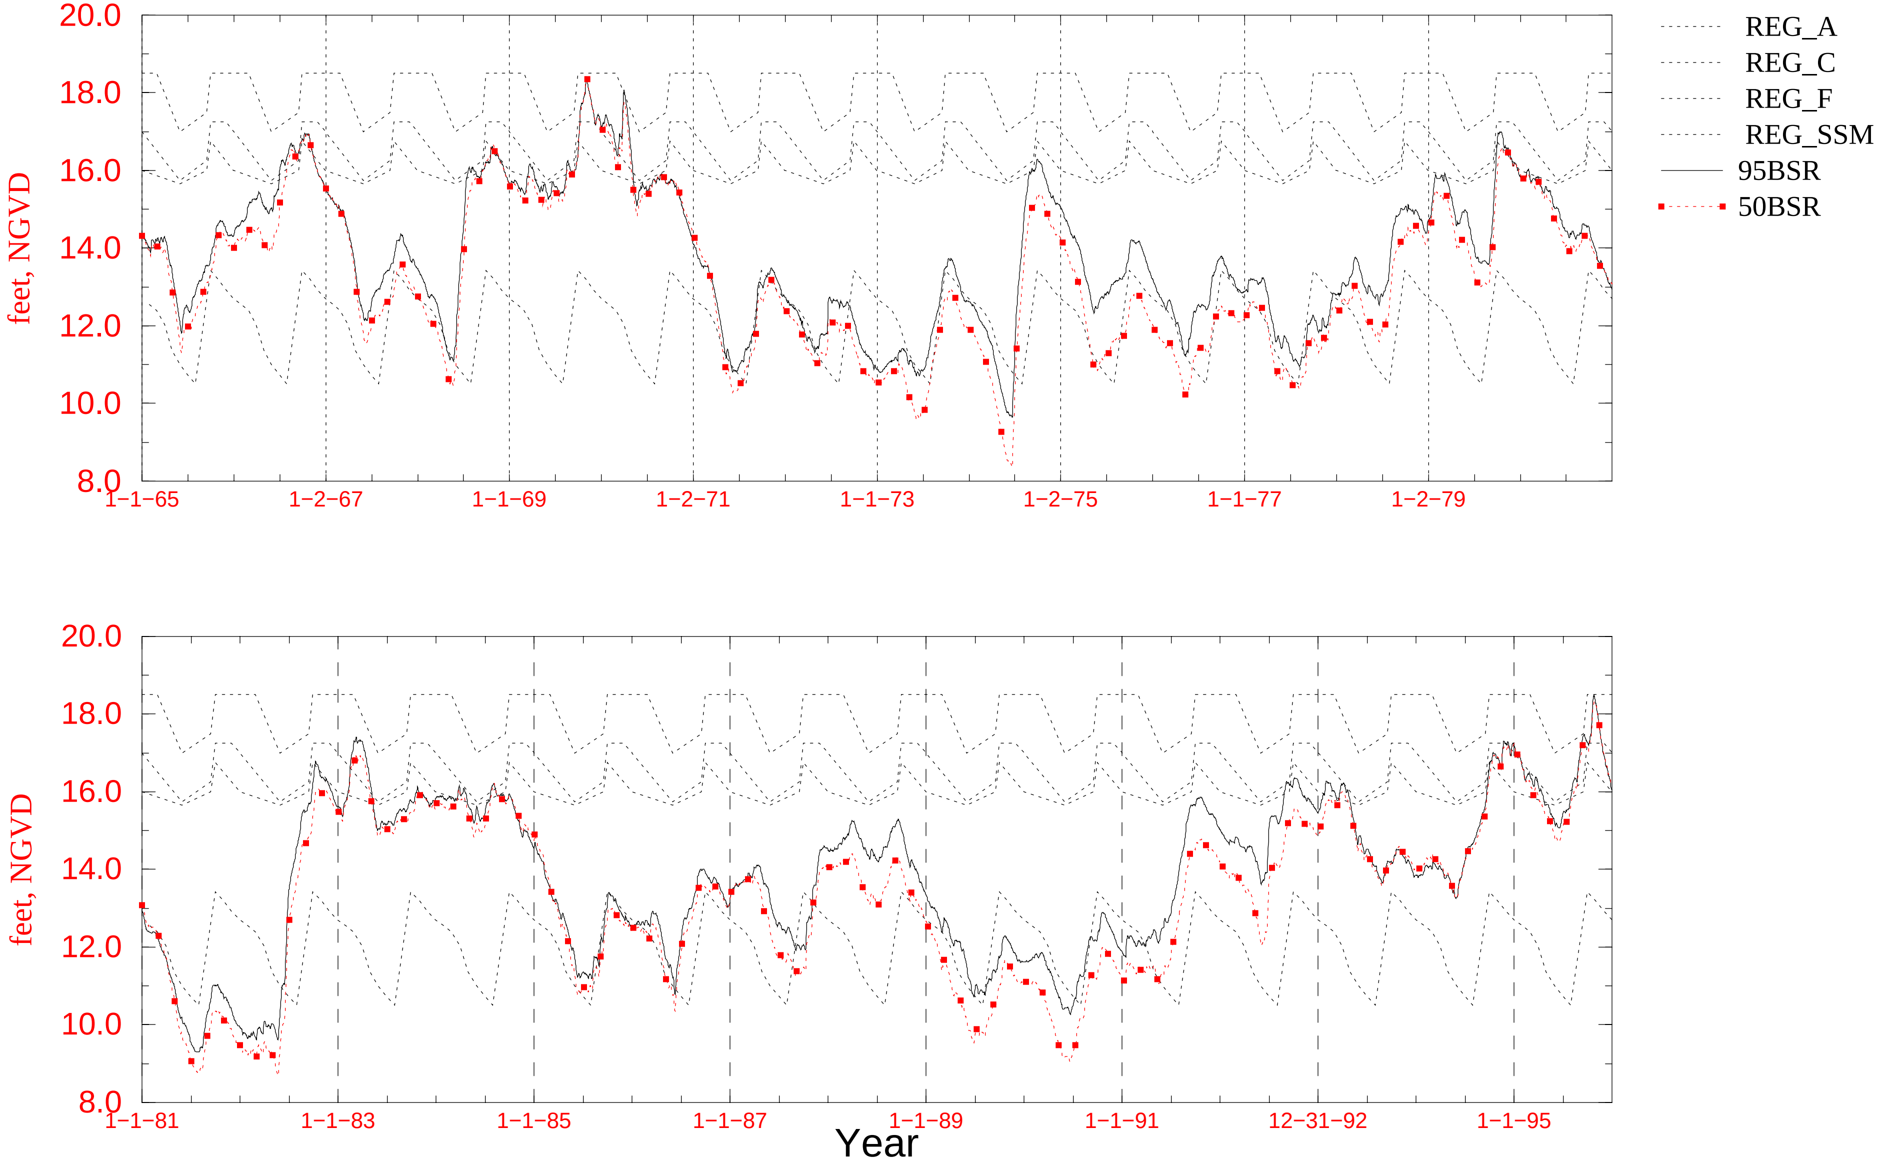
- The frequency of regulatory releases can be significantly reduced by either raising the lowest regulatory zone, storing some lake water in other areas, storing water in ASR wells, or by releasing more water for supply deliveries (e.g. the 2050 Base line). Discharges can be easily eliminated in years similar to 1966, 1974, 1979, 1984, 1992, and 1993 when the Lake crested near the lowest zones; whereas abnormally wet periods similar to 1969-1970, 1982-1983, and 1994-1995 are difficult to eliminate.

- Significant drought periods have followed soon after periods when regulatory releases were made (1966, 1970, 1974, 1980, and 1984). If the discharges could have been saved, the subsequent dry years would have had significant water supply benefits.

- There was no water supply value attached to the backpumping of water into the Lake if a regulatory release was required before the subsequent years enter the SSM zone (e.g. 1969, 1978, 1982, 1991, 1992, and 1994). Any additional water stored in the Lake in some years may have to be released in subsequent years as a regulatory release.

- Reservoirs sized to catch the wettest years (1969-1970, 1982-1983, and 1994-1995) would only be partially filled, if at all, in other years. Reservoirs that rely upon excess water from Lake Okeechobee would only fill periodically and would be unused for storage for several consecutive years.

Figure B.2−1 Daily Stage Hydrographs for Lake Okeechobee



Run date: 06/19/98 01:32:19
For Planning Purposes Only
SFWMM V3.5

Wet seasons (June to October) in other parts of the system (e.g. the Caloosahatchee River Basin, St. Lucie Canal Basin, EAA Basin, and the LEC) produce significant runoff almost annually. Reservoirs in these basins would have water supply benefits almost annually as well. Reservoirs in the Caloosahatchee River, St. Lucie, and EAA Basins could be filled with water from local runoff as well as Lake Okeechobee releases. The goals and operational assumptions for each reservoir can dramatically affect the optimal amount of storage for the area.

B.2.6.2 North of Lake Okeechobee Storage

Generalized discussions of the goals, sources of water, location concerns, and maximum depth considerations are presented in ***Section B.2.5.2***. The section covered important background information about the basin.

Storage north of Lake Okeechobee was effective at reducing regulatory releases from Lake Okeechobee – enough to substantially reduce the need for regulatory discharges to the St. Lucie Basin. However, the site alone could not substantially reduce the regulatory discharges to both estuaries.

Storage sizes from 5,000 to 200,000 acres were investigated. The most efficient size for storage north of the Lake was 20,000 to 40,000 acres, but the upper range was not clearly defined. Essentially, the larger the reservoir, the more water that can be caught in abnormally wet periods (e.g.1969-1970 and 1983-1984); however, the area would only be partially filled, if at all, in most years. Although, a storage area of 20,000 acres with a depth of 10 feet is equivalent to about a half-foot of storage in the Lake, the storage area was effective in storing a significant portion of the regulatory releases that would have been made. In dry years, the reservoir would not be used so that no ET loss would be incurred. In abnormally wet years when the reservoir would fill, the additional ET loss came from the water that would normally have been discharged to tide.

Operationally, filling the area when the Lake is above the regulatory zone and releasing back to the Lake when the Lake is below the zone is not an effective management scheme. Two operational problems were identified. First, the rate of pumping (5,000 cfs – about the size of the S-5A pumping facility) into the reservoir was not sufficient to significantly reduce some regulatory releases to the estuaries. Secondly, pumping reversals would occur when the Lake was near the bottom of the regulatory zone since the Lake could fluctuate up or down on a weekly basis. To solve these problems, water was assumed to have come from the Lake when the Lake level was rising and within 0.5 feet below the first regulatory release zone. The storage area would continue to fill until the Lake level begins to fall if it remained below the regulatory zone. Then, releases from the storage area back to the Lake would not begin until the Lake was at least 1 foot below the regulatory zone. By starting the pumping sooner, more storage was available in the Lake, thereby effectively reducing the discharges to the estuaries. By holding the water until the Lake was lower, a smoother operation (no reversals) was created.

B.2.6.3 Caloosahatchee Storage

Generalized discussions of the goals, sources of water, location concerns, and maximum depth considerations are presented in ***Section B.2.5.3***. The section covered important background information about the basin.

Storage in the Caloosahatchee River Basin was effective at catching excess local basin runoff and improving the water supply to the basin. Storage sizes from 5,000 to 60,000 acres were investigated. The most efficient size for storage of the local basin flows was about 20,000 acres with up to eight feet deep. Essentially, there was a finite amount of excess water and well-defined water supply needs that, consequently, fairly well defined an optimal range. The reservoir was not sized to capture Lake Okeechobee regulatory releases because of the magnitude of the local runoff. In abnormally wet periods, the reservoir would remain full and have little water supply benefits (supply being greater than demand in those years). However, in most years, the reservoir could meet a significant portion of the basin demand, thereby reducing dependency on Lake Okeechobee water supply releases. Only in the abnormally dry years did the reservoir fail to fill.

An additional amount of runoff was declared “excess” during the alternative development phase. At that time, backpumping to Lake Okeechobee was re-evaluated and included in the alternatives.

Although, modeling of storage in the Caloosahatchee River Basin included water supply for the local basin, the storage was never meant to be the only water supply for the basin. However, the storage was considered to be the first source used for water supply when needed. *Lake Okeechobee is considered to be the ultimate source of water supply releases for the Caloosahatchee River Basin.*

B.2.6.4 St. Lucie Storage

Generalized discussions of the goals, problems, opportunities, sources of water, location concerns, and maximum depth considerations are presented in ***Section B.2.5.4.*** The section covered important background information about the basin.

Storage in the St. Lucie Canal Basin (C-44) was effective at catching excess local basin runoff and improving the flow characteristics into the estuary. Storage sizes from 2,000 to 40,000 acres were investigated. The most efficient size for storage of the local basin flows was about 20,000 acres with a maximum four feet depth. There was a finite amount of excess water from runoff; however, because the C-44 Basin flows combine with several other major canals into the estuary, it was difficult to establish a well-defined optimal range. The modeling did not include other canal flows to the estuary such as C-23, C-24, C-25, and the South and North Forks of the St. Lucie River. The reservoir was not sized to capture Lake Okeechobee regulatory releases because of the magnitude of the lake releases. The lake releases are often many times greater than that of the local runoff. The reservoir could meet a portion of the basin water supply demand thereby slightly reducing dependency on Lake Okeechobee water supply releases. The reservoir would have nearly annual benefits.

B.2.6.5 EAA Storage

Generalized discussions of the goals, problems, opportunities, sources of water, location concerns, and maximum depth considerations are presented in ***Section B.2.5.5.*** The section covered important background information about the basin.

Evaluating causes and effect relationships are difficult for the EAA because of its central location in the system. Impacts originating from storage in the EAA literally affect every basin to some degree. As a result, more modeling was done concerning EAA storage than any other component in the screening phase. The operational assumptions for the EAA storage area could easily result in an inefficient operation. However, many significant improvements to water supply, hydropatterns, and reductions of discharges to the estuaries could be accomplished using EAA storage. Storage in the EAA is anticipated to have water quality benefits both within the storage area and in STAs by moderating the inflows. The water quality issues are addressed in Appendix D, Appendix H, and Attachment F.

B.2.6.5.1 Sizing

The goals of storage dramatically affect the sizing of it in the EAA. Assuming all discharges to tide are to be stored only in the EAA could result in the conversion of 200,000 acres to storage; although, it would only be filled two times over the 26-year period of record used in the screening models. Utilizing a multi-objective approach with both environmental and urban/agricultural water supply being optimized, the screening analysis concluded that a storage area ranging from 40,000 to 60,000 acres with a six- foot maximum depth was appropriate. In that range, significant reductions to tide and improvements to water supplies were noted.

B.2.6.5.2 ET Management

Several management techniques were evaluated to minimize ET losses: by dividing storage into separate cells, by only storing excess water, by dry season operations, and by utilizing drainage systems.

By dividing the storage area into two or more compartments, ET can be reduced by more efficient use of the areas. This is because the amount of water stored each year varies and only one cell may fill in drier years. By using one cell to capacity, there will be less ET loss incurred than by spreading the same amount of water over a greater area (shallower depth). By dividing the storage area into two cells, about a 15 percent reduction in ET was realized.

Losses associated with ET can be taken from water not currently used by filling under two conditions only: when Lake Okeechobee would normally make discharges to the estuaries and when the WCAs do not need the EAA runoff. By using these “excess” sources, any additional ET loss would come from water not needed or currently lost during the wet season, as long as this water can be brought and stored in the storage areas.

How a storage area is used during dry periods can also have a dramatic effect on ET. In years when there is not enough runoff available to fill an area, it can either be operated as a dry area or a wetland. If the area is operated as a wetland, there is an associated dry season demand for water to keep it wet. If the rain that falls on the area is kept inside to create marsh-like conditions, that amount of water is removed from the current water budget of the WCAs. Alternatively, if the area is operated as a dry area, there would be little or no additional ET loss and small, if any, reductions to the WCAs. A dry area operation when not needed for wet year storage could be used for recreation or agriculture.

In reservoirs, depending on the bottom characteristics, the last several inches are assumed to be not retrievable. Therefore, the effective storage is somewhat less that the actual volume in the reservoir. However, reservoirs that have a drainage system, the volume of water removed from the reservoir can include groundwater as well. By assuming the storage area incorporated a drainage system, not only would the full volume be available for storage, but also the area could be drained so that no additional ET loss would occur in dry periods.

B.2.6.5.3 Canal Capacities

The existing canal system in the EAA is effective at removing the local runoff while having little capability during wet periods to pass additional lake releases. Additionally, the amount of water in the WCAs (in some years) would also limit the southward releases from the Lake. For this reason, discharges to the estuaries are often the only release path available for Lake Okeechobee. In the modeling of EAA storage, about a three-fold increase in the capacity of the Miami and the North New River Canals was required to pass both, Lake releases and local runoff, to the storage areas simultaneously. This does not assume that the canal would be three times wider, only that the hydraulic capacity was increased.

B.2.6.6 Lake Okeechobee Storage

Generalized discussions of the goals, problems, opportunities, sources of water, location concerns, and maximum depth considerations are presented in ***Section B.2.5.6***. That section, in addition to ***Section B.2.6.1***, covered important background information about the basin.

The LORSS process (discussed in ***Section B.2.5.6***) introduced the problems and opportunities associated with balancing operational changes in Lake Okeechobee in far more detail that could be presented from the screening effort. In the LORSS process, all water management components (both in place and planned) are known; in the Restudy, a large number of potential components are under consideration. The alternative development phase addresses the proper balance of components and changes to the lake regulation schedules. In support of the LORSS, the SFWMD has prepared a draft report that presents detailed findings of several operational scenarios for Lake Okeechobee (DRAFT Simulation of Alternative Operational Schedules for Lake Okeechobee. SFWMD, April, 1997). Because the draft report covers the issues associated with changes to the lake operational rules, the findings in this section will be limited to presenting findings of more extreme considerations.

There is a general recognition that storage in Lake Okeechobee can be maximized at the expense of ecological health for the Lake. Actions supporting maximization would be cost effective and hydrologically efficient; however, there is a concern that the littoral zone of the Lake could not be relocated to help offset the adverse ecological impacts. The effects of storage in Lake Okeechobee were studied in the screening phase by removing all regulatory schedules in the Lake. During the abnormally wet periods, Lake levels can rise to elevations above 24 feet; during prolonged dry periods, Lake levels will fall to about current levels. Assuming the levee on the northwest side of the Lake could be moved back to incorporate a littoral zone, the base elevation would be about 19 feet. As a result, the higher zone would only be flooded occasionally (3 times in 31 years) and would not have the hydrologic characteristics of a littoral zone. Therefore, the higher zone would act more like a marsh adjacent to the Lake instead of a littoral zone. The level of the existing littoral zone would be submerged far more often than under current conditions and for far greater periods of time. Recent floods have demonstrated the damage to the existing littoral zone during high water levels. In short, wider variations in Lake levels would not be conducive to the establishment and preservation of a littoral zone at high or low lake levels. Even extensive shaping of the existing littoral zone by adding several feet of low-nutrient muck soils over 100,000 acres may not create a healthy littoral zone at an intermediate level. Notwithstanding the adverse ecosystem effects caused by adding storage in Lake Okeechobee, both water supply and the health of the estuaries would be greatly improved.

When storage north of the Lake and in the EAA were considered, only minor changes to the lake regulation schedule were needed to significantly reduce all discharges to the St. Lucie Estuary. However, the two storage areas were not sufficient to significantly reduce the Caloosahatchee Estuary discharges as well. This was demonstrated in the screening and alternative development phase.

B.2.6.7 Water Preserve Areas

B.2.6.7.1 General

Generalized discussions of the goals, problems, opportunities, sources of water, location concerns, and maximum depth considerations are presented in ***Section B.2.5.7***. The summary provided in this section was based primarily upon findings related to reservoir performance. The effect of marshes located along the eastern protective levee has been reported as part of the LECRWSP. Additionally, the areas identified by the Land Suitability Report were included in the analysis. In-ground lakes were not evaluated in the screening phase, although information from screening supported the development of such reservoirs. Additionally, potential WPAs north of, and including C-51 were not evaluated in the screening phase. The results of the screening efforts are presented by LEC service areas as follows.

B.2.6.7.2 Service Area 1

Service Area 1 (SA 1) is primarily defined as the LEC area east of WCA1. SA 1 receives water supply releases from the LNWR. Supplemental water releases also come from Lake Okeechobee (via LNWR) when the LNWR is too dry.

The land suitability analysis reports 5,913 acres of high-quality marsh along 10 miles of the eastern protective levee. Additionally, 1,639 acres along LNWR (Site 1), just north of the Hillsboro Canal, have been identified as a potential water management area for a reservoir. Reservoir sizes of 827, 2,440, 3,267, and 4,093 acres were evaluated.

For the reservoir sizes evaluated with four-foot maximum depths, only 14 to 28 percent of the excess water to tide was captured (from 40,000 to 75,000 acre-feet per year). Of that amount, only about half was available for use, the rest was lost to ET and seepage. Backpumping opportunities were limited by the frequency of times that LNWR was full. LEC water supply received the most benefit (about 60 percent of the benefits), with backpumping (about 25 percent of the benefits), and returned seepage being much less backpumped (about 15 percent of the benefits). If the reservoir sizes were evaluated at a six-foot maximum depth, about 25 percent more excess water to tide was captured with about the same effectiveness of use.

For SA 1, the current reservoir site is not located near the potential sources of C-15 and C-16. Since the Site 1 area would only be suitable for capturing 14 percent of the excess flow to tide, an additional site of about 900 acres would be effective for improving the capture to 22 percent. If the reservoir site was adjacent to the LNWR in the Agricultural Reserve area, seepage management, flood control, and local water supply could be enhanced, as well as solving the locality issue of C-15 and C-16 flows.

B.2.6.7.3 Service Area 2

Service Area 2 (SA 2) is primarily defined as the LEC area east of WCA 2A, 2B, 3A, and northern half of 3B. SA 2 receives water supply releases primarily from WCA 2A. Supplemental water releases also come from Lake Okeechobee when WCA 2A is too dry.

The land suitability analysis reports about 6,180 acres of high-quality marsh along 5.5 miles of the eastern protective levee along WCA 3A; another 1,649 acres of high-quality marsh were identified along 5.5 miles of the eastern protective levee bordering WCA 3B. Additionally, 2,880 acres in the area have been identified as potential water management areas for reservoirs. Reservoir sizes of 1,443, 2,880, 4,330, 5,773 and 7216 acres were evaluated.

For the reservoir sizes evaluated at four feet maximum depth, only 14 to 30 percent of the excess water to tide was captured (about 80,000 to 165,000 acre-feet per year). Of that amount, only about 35 to 40 percent were available for use, the rest being lost to ET and seepage. Backpumping was significantly higher when based on “in-kind” releases to WCA 3A since WCA 2A was often full; hence releases to WCA 2A were simply passed on to WCA 3A for potential hydropattern benefits. LEC water supply releases were about 15 percent of the total benefit, while backpumping and backseepage were about 35 percent and 50 percent of the total benefit, respectively.

B.2.6.7.4 Service Area 3

Service Area 3 (SA 3) is primarily defined as the LEC area east of the lower half of WCA 3B and the ENP. SA 3 receives water supply releases primarily from WCA 3A via WCA 3B. Supplemental water releases also come from Lake Okeechobee when WCA 3A is too dry.

The land suitability analysis reports about 12,893 acres of high-quality marsh along 13.5 miles of the eastern protective levee of WCA 3B (PENNSUCO lands). Additionally, up to 2,877 acres have been identified as a potential water management area for a reservoir. Reservoir sizes of 1,408, 2,877, 4,224, 5,632 and 7,040 acres were evaluated.

For the reservoir sizes evaluated at four feet maximum depth, only 15 to 30 percent of the excess water to tide was captured (about 40,000 to 80,000 acre-feet per year). Of that amount, only about 40 to 60 percent were available for use, the rest being lost to ET and seepage. Backpumping benefits from SA 3 were sent to the ENP for potential hydropattern improvements; releases were made when flows across Tamiami Trail were less than "natural" flow patterns (as predicted by the NSM). Because the LEC water supply demands were large in comparison to the storage evaluated, only a percentage of water supply demands were released dependent on reservoir size. LEC water supply releases were about 25 percent of the total benefit. Backpumping and backseepage were about 40 percent and 35 percent of the total benefit, respectively.

Because the identified reservoir site is located just south of C-4, the potential water sources of C-6 through C-8 would have to be connected via an aqueduct from north to south, <u>or</u> some storage would have to be provided in the northern part of SA 3. If the aqueduct solution is pursued, it would have to be lined to prevent interaction with the water in the lake belt area because of water quality concerns and the transmissivity would greatly reduce the effectiveness of the aqueduct.

B.2.6.7.5 Regional Perspective

The amount of benefits derived from the capture and subsequent use of excess water to tide was greatly impacted by the operational assumptions. For example, if the water in the reservoir was held to meet a specific water supply need, the effectiveness of the reservoir would be reduced due to ET and seepage losses. However, by passing some water into the WCAs and the ENP when those areas were below regulatory schedules or natural flows, the use of the captured water was more effective. Future investigations will likely determine better operational strategies.

The reservoir in SA 1 acted like a traditional impoundment with long periods of inundation and most losses being associated with ET. However, the more transmissive nature of SA 3 resulted in a reservoir that behaved more like a dynamic marsh with quick filling and drawdowns. Therefore, resulting in a site that would probably look more like a marsh than an impoundment.

Increases in hydropatterns were evident in the WCAs due to the combination of backpumping, backseepage, and meeting some of the LEC water supply demand from the reservoirs. No specific hydropattern target was used in this analysis.

At the SA 1 and SA 2 sites, the percentages of tide captured were 10 percent less than the target percentages, even at acreage 2.5 time larger than the identified sites. Only in SA 3 was the size of an identified reservoir site approximately suited to capturing the target percent of excess water to tide. Although the returns were diminishing for larger size reservoirs in each SA, benefits still accrued with size for the acreage evaluated.

SA 2 had as much potential to capture canal water as did SA 1 and 3 combined. Not the case for 95BSR and 30BSR). Future evaluations may consider moving part of excess water in the C-9 Basin southward into the reservoir site of SA

3, or move excess water from C-14 northward to SA 1. This analysis did not include the effects of what may happen to the current flows through S-9 into WCA 3A.

The benefits of capturing LEC excess flows to tide are essentially annual, unlike the capture of flood releases from Lake Okeechobee (occurring once every fourth or fifth year). While annual benefits are possible with the WPA reservoirs, the benefits do not carry over to succeeding years. A percentage of the early dry season LEC water supply demands were met from the reservoirs; after which, the water supply demands were met using existing rules, i.e. from WCAs and Lake Okeechobee.

In-ground lakes were not evaluated in the screening phase; however, the need for storage sites was evident in the screening analysis since the maximum surface areas previously identified did not catch all the available water. Additionally, the region where the central and north lake belt sites are located has high transmissivities that make above ground storage less desirable due to high seepage rates.

B.2.6.8 Aquifer Storage and Recovery

B.2.6.8.1 General

Generalized discussions of the goals, problems, opportunities, and sources of water are presented in ***Section B.2.5.8.*** The section covered important background information about the basin.

ASR in the Caloosahatchee River Basin was not evaluated in the screening phase. Additionally, the number of ASR wells in any basin would be highly dependent upon other water management components that would be determined as part of the alternative development phase. Therefore, no effort was made to optimize the number and sizing of the ASR facilities.

B.2.6.8.2 ASR in LEC

ASR was evaluated in association with excessive canal flow periods and with local reservoirs in the screening phase (e.g. Site 1). The potential operation would be consistent with normal ASR operations. Normal being that an ASR system would store (pump down) part of the year and recover (pump up) part of the year. The potential effectiveness varied between service areas. In SA 1, there was a good match between the periods of storing and recovering; thus, a good potential in water supply storage was observed. In SA 2;however, there was more opportunity to pump down than to recover. Thus, the system was not as efficient, although plenty of storage water was available . In SA 3, similar to SA1, there was a fairly good match between periods of storage and recovery. Because flood discharges throughout the LEC tend to come in surges, ASR was not effective in reducing the peak discharges. However, the effectiveness of ASR was greatly improved when used in conjunction with potential reservoirs along the LEC.

B.2.6.8.3 ASR around the Lake

ASR around Lake Okeechobee was not effective at reducing flood peaks in the Lake as initially modeled in the screening phase. This was because of the relatively small pumping rate of ASR wells compared to the rate at which water flowed into the Lake – even when 200 wells (at 5 mgd) were considered.

A different set of rules was screened and demonstrated to be a significantly positive component during the alternative development phase, in terms of managing lake stages, reducing estuary discharges, and meeting water supply. The change in operation involved a substantial lowering of the level at which the ASR wells began operating. The earlier operation in wet periods accounted for an increase in the amount of water that could be stored which helped to reduce high lake stages. By releasing the ASR water back to the Lake during dry times and low stages (Lake levels below 13 feet), improvement in water levels was noted.

B.2.6.8.4 ASR in WCAs

Modeling ASR in association with high stages in the WCAs was conducted but not recommended for four reasons. The first being that ASR wells have little effect on WCA stages Second, water levels in the regulatory zone did not indicate a surplus of water (it was only a signal to send it southward, ultimately to the ENP). Third, reductions in water quality (higher salinity) are less tolerable in the natural system than in urban and agricultural water supplies. Lastly, the WCAs were not in regulatory zones for an effective period of time.

B.3 MODELING OF ALTERNATIVES

B.3.1 Simulation of Alternative Plans

B.3.1.1 Model Used: South Florida Water Management Model (SFWMM)

B.3.1.1.1 Background

The hydrology of South Florida is unique in response to flat topography, high water table, sandy soils, and an extremely transmissive surficial aquifer. Given the complexity of the Everglades system, computer simulation is perhaps the only way to devise long-range water management plans. These plans are needed for sustainable development and balancing the competing water needs of the environment, agriculture, and the urban communities. The South Florida Water Management Model (SFWMM) is the model utilized in simulating alternatives for the Restudy.

The SFWMM is an integrated surface water-groundwater model that simulates the hydrology and existing/proposed water management plans in the South Florida region. The model uses the climatic data for the time period 1965-1995. The model simulates the major components of the hydrologic cycle in South Florida that includes rainfall, evapotranspiration, overland flow, groundwater flow, canal flow, and seepage across levees. Additionally, the model simulates the operations of the C&SF system components including major wellfields in the urbanized east coast, impoundments, canals, pump stations and other water control structures. The ability to simulate key water shortage policies effecting urban, agricultural, and environmental water demands allows the modeler to investigate trade-offs among different users and sub-regions. Two dimensional regional hydrologic processes are simulated on a daily time step utilizing a mesh of 2 mile x 2 mile (3.22 km x 3.22 km) grid cells. The simulation produces an extensive output that can be summarized into numerous indicators and measures of performance for evaluating a plan. In addition, the model simulates inflows from Kissimmee Basin, runoff and managed discharges in the St. Lucie and Caloosahatchee Basins, and inflows to and outflows from Lake Okeechobee.

B.3.1.1.2 Documentation

The most recent documentation for the model is available from the following reference: South Florida Water Management District. 1997. Draft Documentation for the South Florida Water Management Model. Hydrologic Systems Modeling Division, Planning Department, South Florida Water Management District, West Palm Beach, Florida. Additionally, it is currently available on the internet at http://www.sfwmd.gov/org/pld/hsm/models/sfwmm.

B.3.1.1.3 Time Step

A fixed time step of one day is used in the model. The selection of this time step is consistent with the minimum time increment for which hydrologic data such as rainfall, evaporation and structure discharge are generally available. Rainfall and potential evapotranspiration (PET) are the primary driving processes. The longest total simulation time for the model is a function of the available historical rainfall and PET data. The model can be run for time periods ranging from one month to 31 years (between January 1, 1965 and December 31, 1995). The hydrologic processes are modeled sequentially within one time step. To simplify programming and reduce computational time, no iteration is performed between surface water and groundwater routines within a time step. Calculations for more transient phenomena (e.g. channel flow routing) are performed before less transient phenomena (e.g. groundwater flow). The total execution time for a typical Restudy alternative may run approximately 5 hours on a Sun™ Ultra2.

B.3.1.1.4 Scale

The gridded portion of the model domain, south of Lake Okeechobee, describes the extent of the finite difference solution to the governing overland and groundwater flow equations. The network is comprised of 2-mile square grid cells that cover the large coastal urban areas of Palm Beach, Broward and Miami-Dade counties; the Everglades Agricultural Area (EAA); the Water Conservation Areas (WCAs) and Everglades National Park (ENP). The total coverage of the model is 1,746 grid cells. The model assumes homogeneity in physical as well as hydrologic characteristics within each grid cell.

The 2-mile discretization in the SFWMM is sufficiently fine to describe the solution to the overland and groundwater flow equations with reasonable resolution and to prevent excessive numerical errors (Lal, 1998b).

Other areas in the model (e.g. Lake Okeechobee and northern lake service areas) are conceptualized at a different level of detail due to varying degrees of data availability. The SFWMM employs both lumped and distributed modeling techniques. Specifics on these techniques can be found in SFWMD (1997).

B.3.1.1.5 Overland Flow

A diffusion wave approximation to the full equations for overland flow is utilized in the gridded portion of the model. Specifically, the components of the cell-to-cell flow are computed using the following expressions:

$$u = 1.49 \frac{h^{\frac{2}{3}}}{n\sqrt{S_n}} \frac{\partial H}{\partial x} \qquad (1)$$

$$v = 1.49 \frac{h^{\frac{2}{3}}}{n\sqrt{S_n}} \frac{\partial H}{\partial y} \qquad (2)$$

Where u and v are the velocity components in the x and y directions, respectively. Other variables defined: n is the overland flow roughness coefficient that depends on the depth of flow (according to the formula: $n=A*h^{B)}$; S_n is the maximum energy slope; and H is the water level above a given datum. An Alternating Direction Explicit (ADE) scheme with four six-hour time slices is utilized to solve for the overland flow from one cell to another.

B.3.1.1.6 Groundwater Flow

The following vertically-averaged, groundwater flow equation is solved:

$$\frac{\partial}{\partial x}\left(T_{xx}\frac{\partial h}{\partial x}\right) + \frac{\partial}{\partial y}\left(T_{yy}\frac{\partial h}{\partial y}\right) = S\frac{\partial h}{\partial t} - R \qquad (3)$$

Where T is transmissivity, S is storage coefficient, and R is recharge to the groundwater table. The model utilizes a variation of the Saul'yev (1964) method to solve the above equation. This technique is unconditionally stable and explicit. To minimize bias, the numerical formulation is solved in four different directions in four successive time steps. Highly concentrated groundwater flow across levees cannot be simulated with a 2 mile x 2 mile scale model, therefore separate regression equations were developed to simulate levee under-seepage (SFWMD, 1997).

B.3.1.1.7 Canal/Structures Flow

Over 1,400 miles of levees and canals, 18 major pump stations, and more than 180 water control structures are simulated in the model. The SFWMM utilizes a mass balance approach to account for changes of storage in the canal due to inflows and outflows. The model computes flows into and out of canals via water control structures, interaction between the wetlands and the canals, and the groundwater seepage. Canals are assumed to pass through the center of a grid cell or group of grid cells and calculations are performed for each canal reach, i.e. a canal with known or calculated upstream inflow and outflow. A seasonal hydraulic gradient is assumed for each canal reach. For a given canal reach, the model calculates the end-of-day stage at the most downstream grid cell or node. Intermediate grid cells are assumed to have stages proportional to seasonal hydraulic gradient, according to their relative distance from the extreme nodes of the reach. A complex set of release and inflow rules are followed in the model (SFWMD, 1997) to regulate flow into and out of canals and storage areas.

B.3.1.1.8 Rainfall and ET

The SFWMM uses a time-varying (daily), spatial database that has been preprocessed using rainfall records at more than 600 rain gages distributed throughout South Florida. In the absence of a more rigorous and practical spatial interpolation scheme, cell-by-cell rainfall has been estimated using a "nearest station" technique.

The algorithms to calculate actual ET in the model vary geographically. For Lake Okeechobee, the Penman-Monteith (Monteith, 1965) method is used to calculate open water and marsh zone ET. For the EAA, total ET is the sum of it's components from the saturated, unsaturated, and open water zones. For the LEC urban area, unsaturated ET is pre-processed using the Agricultural Field-Scale Irrigation Requirements Simulation model (Smajstrla, 1990) that also computes the irrigation requirements for selected land cover types. The reference-crop (turf grass) evapotranspiration, ET_0, for most areas of the model is computed utilizing the Penman-Monteith formula:

$$l\, ET_0 = \frac{\Delta(R_n - G) + r\, C_p (e_a - e_d) \frac{1}{r_a}}{\Delta + g \left(1 + \frac{r_c}{r_a} \right)} \qquad (4)$$

where,

ΣET_0 = latent heat flux of evaporation, (KJ m^{-2} s^{-1});
ET_0 = mass flux of evapotranspiration, (kg m^{-2} s^{-1});
Σ = latent heat of vaporization, (KJ kg^{-1});
– = slope of vapor pressure curve, (kPa $^oC^{-1}$);
R_n = net radiation flux at surface, (KJ m^{-2} s^{-1});
G = soil heat flux, (KJ m^{-2} s^{-1});
Ψ = atmospheric density, (kg m^{-3});
C_p = specific heat of moist air, (KJ kg^{-1} $^oC^{-1}$);
e_a = saturation vapor pressure at surface temperature, (kPa);
e_d = actual ambient vapor pressure at dew point, (kPa);
(e_a-e_d) = vapor pressure deficit, (kPa);
K = psychometric constant, (kPa $^oC^{-1}$);
r_c = crop canopy resistance, (s m^{-1}); and
r_a = aerodynamic resistance, (s m^{-1}).

Actual ET is related to ET_0, as follows,

$$ET = K * ET_0 \qquad (5)$$

Where K is an adjustment factor that takes into account depth of water above or below the ground surface, land cover type, and the depths of shallow and deep root zones.

B.3.1.1.9 Reservoirs

Water-holding facilities or reservoirs serve a variety of functions. The Holey Land can be modeled as an above-ground reservoir that acts as a wetland preserve. Examples of reservoirs in the Lower East Coast service areas are the West Palm Beach Catchment Area and the Indian Trails Water Control District reservoir. Proposed reservoirs in the EAA are the Stormwater Treatment Areas (STAs) whose function is to improve the quality of runoff generated from the EAA and releases from the Lake as part of the Everglades Construction Project. In the development of the Restudy alternatives two EAA reservoir compartments are proposed. One compartment stores EAA runoff and supplies water to the EAA during dry periods. The other compartment stores excess Lake Okeechobee water and helps meet environmental water supply demands in the Everglades. If a STA and a non-STA (e.g. EAA reservoir) exist in the same EAA Basin, the SFWMM assumes that the non-STA reservoir receives runoff/LOK regulatory releases first while the remainder of the excess water goes directly to the STA reservoir for treatment.

Reservoirs in the Lower East Coast service areas are generally proposed as part of the Water Preserve areas whose two functions are stated. First, store excess water from a drainage basin that may result in improved flood control for the basin and reduced seepage volumes from the Water Conservation areas. Second, release the stored water for water supply purposes and/or environmental enhancement to decrease the dependence of the LEC service areas on Water Conservation area and Lake Okeechobee deliveries. ASR wells may accompany a reservoir to enhance the system's ability to store water and then use the excess water more effectively during times of demand.

All the reservoirs are assumed to have vertical walls for modeling purposes. The model identifies reservoirs by a hydrologic basin number that is assigned to appropriate grid cells. The model accounts for differences in the actual area of the reservoir and the area represented by the grid system, i.e. multiples of four square miles. Since rainfall and evapotranspiration depths are assumed to occur uniformly for each grid cell, their effect on reservoir stage is transformed by a proportionality factor relating reservoir area and the area of the grid cell(s) where the reservoir is located. For a given reservoir,

sfactor = total_reservoir_area / (no of grid cells * grid cell area)
change_reservoir_stage(t) = RF(t) - ET(t) + LSEEP(t) + GWIN(t) - [RF(t)-ET(t)] * [(1 - sfactor)]
where
RF(t) is rainfall into grid cell (ft);
ET(t) is evapotranspiration out of grid cell (ft);
LSEEP(t) is equivalent depth of levee seepage into grid cell; and
GWIN(t) is equivalent depth of net groundwater inflow into grid cell (ft).
reservoir_stage(t) = reservoir_stage(t-1) + change_reservoir_stage(t)

Reservoir_ stage is used in determining available storage in the reservoir. It is also the basis for calculating discharges through inlet and outlet structures of a reservoir. The outlet structures can be managed for water supply, flood control, or environmental enhancement.

B.3.1.1.10 Accuracy

Water budget post-processing tools are available to demonstrate model accuracy and to summarize water budget components on a monthly, seasonal or annual basis for individual grid cells or groups of grid cells. Likewise, routine calibration exercises are performed on the model in order to demonstrate its history-matching capabilities (SFWMD, 1997).

Several publications and presentations have been produced in the past to address model accuracy and model applicability (e.g., Lal, 1998a; Bales, et al., 1997).

B.3.1.1.11 Flood Control Application

The SFWMM has been the primary modeling tool for evaluating regional scale effects of major water management projects associated with the Everglades system. In particular, the model has been used for the following projects:

- Development of Lower East Coast Regional Water Supply Plan
- Everglades Construction Project
- Comprehensive Review Study of the Central and South Florida System.
- Other studies related to the hydrologic restoration of the Everglades
- Development of Regulation Schedules for Lake Okeechobee

The SFWMM is an appropriate tool for evaluating large-scale, long-term hydrologic effects from structural and/or operational changes. Since the model has a coarse scale (2-mile by 2-mile grid cells) and a daily time step, it cannot adequately evaluate local-scale, highly transient events like individual storms and flooding to individual farms or urban developments.

The model can provide a general indication of the potential for increases in groundwater stages for sub-regions. By utilizing the difference between two simulations versus the result of a single simulation, an increase in groundwater stage can indicate a potential increase in flood risk. The peak stage difference maps are a useful performance indicator, which displays a relative comparison. However, more detailed site-specific investigations utilizing finer-resolution tools are necessary to make quantitative estimates of changes in flood risk and associated damages.

B.3.1.2 Specific Assumptions/Routines Developed for Restudy

B.3.1.2.1 Lake Okeechobee Operations

Water levels in Lake Okeechobee (LOK) are managed through regulatory and non-regulatory releases (flood control). Regulatory releases are conducted according to the current regulation schedule named "RUN25". The non-regulatory releases are made to meet: (1) agricultural/irrigation demands in the Lake Okeechobee service area; (2) water supply requirements of the LEC service areas; (3) environmental demands in the Everglades, and Caloosahatchee and St Lucie estuaries; and (4) diversion of water when appropriate into reservoirs and/or ASR wells. Lake Okeechobee is the backup source of water to the Water Conservation areas and proposed reservoirs in meeting environmental and water supply demands. Flood control releases are first made to the WCAs via EAA Canals, subject to conveyance limitations, then to Caloosahatchee and St Lucie estuaries after non-regulatory releases occurred.

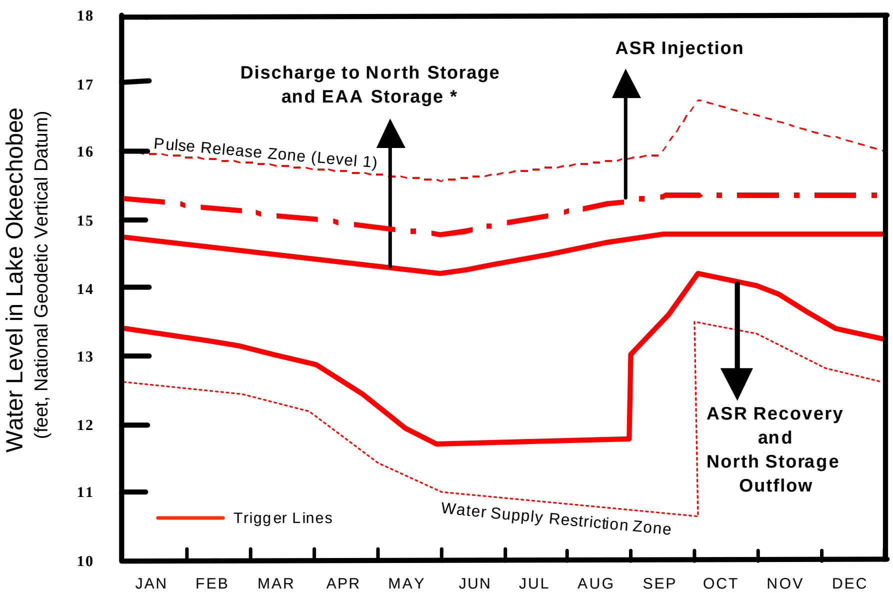
The current regulation schedule, Run 25, is used in the evaluation of alternatives with the exception that all regulatory discharges to St Lucie and Caloosahatchee estuaries are eliminated except Zone A emergency releases. Storage reservoirs north of Lake Okeechobee (North Storage), in Caloosahatchee and St Lucie Basins, in the EAA, and Lake Okeechobee ASR wells are proposed to increase the capacity of the hydrologic system to better meet the water management objectives. These objectives are associated with flood protection, water supply, and environmental enhancement. A climate-based forecast of inflow into Lake Okeechobee is incorporated as a guideline to more effectively divert LOK water to the reservoirs and Lake Okeechobee ASR systems during times of excess and retrieved during dry periods. Zhang and Trimble (1996) developed a methodology for predicting LOK inflows from solar and global indices with the application of an artificial neural network. The forecasts of Lake Okeechobee inflow were preprocessed, and inputted into SFWMM for the simulation period. Although the specific forecast methodology utilized in the real system may differ from the Zhang and Trimble (1996) method, Lake Okeechobee is proposed to be operated with the help of climate based forecasting to more efficiently satisfy competing needs.

Figure B.3-1 summarizes the operation of Lake Okeechobee for reservoir storage and retrieval as well as ASR. Discharge to North Storage and EAA storage generally occurs before ASR injection. If the Lake Okeechobee stage is above the Pulse release zone line (level 1), or forecasted to be above the "Discharge to Storage" line within the next three months, then the lake water is diverted to North Storage and EAA storage (when storage capacity exists). Similarly, if the Lake Okeechobee stage is above the Pulse release zone or forecasted to be above the "ASR Injection" line within three months, the lake water is injected into ASR wells. Water is retrieved from North storage and ASR wells if the lake stage is below, or forecasted to be below the "ASR Recovery and North Storage Outflow" line in six months for recovery during the dry season. During the wet season; however, water is retrieved if the lake stage is below the "ASR Recovery and North Storage Outflow" line and if the climate based inflow forecast is less than 1.5 million acre-ft for the next six months.

Climate-based forecasting is not used in the interaction of Lake Okeechobee with the Caloosahatchee and St Lucie Basins. In ALTD13R excess water is back-pumped from Caloosahatchee reservoir to Lake Okeechobee if the depth of water in the reservoir is greater than six feet and the stage in the Lake is below the Pulse release zone. However, when the stage in the Lake is above the Pulse release zone, water is released from the Lake to the Caloosahatchee reservoir when the depth of water in the reservoir is less than eight feet. Additionally, water is released to the St Lucie reservoir when the depth of water in that reservoir is less than four feet.

Figure B.3-1. Operation Criteria for Lake Okeechobee

and Surrounding Storage Components



* Discharge to North and EAA Storage if Lake Okeechobee stage is forecasted to be above "Discharge to ... Storage" line, or if stage is above Pulse Release Zone (level 1) line.

B.3.1.2.2 Everglades Rain Driven Operations

Historically the operational schedules for the Water Conservation Areas have been calendar-based on an annual cycle. The schedules typically specify the release rules for a Water Conservation Area based on the water level at one or more key gages. Regulation schedules do not contain rules for the importation of water from an upstream source. For Alternative D13R (ALTD13R); however, the rain-driven operational concept includes rules for importing water from upstream sources (i.e. EAA runoff, EAA Storage area, andLake Okeechobee) to the appropriate Water Conservation Areas. Additionally, the rules cover importing and exporting water from the appropriate Water Conservation Areas in order to mimic a desired target stage hydrograph at key locations within the Everglades system. Water Conservation Area 1 is proposed to remain under the current calendar-based regulation schedule rules. Rotenberger and Holey Land Wildlife Management

Areas (WMA's) are also operated under the rain-driven concept. Target stage hydrographs, based on an estimate of the pre-drainage water level response to rainfall using the Natural System Model (NSM), or variations thereof, were used as operational targets for achieving hydrologic restoration of the Everglades.

The term "trigger" refers to a gaged or ungaged location whose water level is utilized to trigger action at an upstream or downstream structure. These water levels or "trigger levels" are related to the target stage hydrographs by simple offsets of ± 1.5 feet. There is one level for the import rules and two levels associated with the exportation of water. The two export trigger levels define two release zones. The lower zone is a conditional release zone such that releases are made only if the downstream area has a "need". The upper zone is an unconditional or flood control release zone such that releases are made in this zone even if the downstream area does not "need" the water.

A general description of the SFWMM implementation of the rainfall-driven operations within the Everglades system is presented in the Draft Documentation of the SFWMM (SFWMD, 1997). A more detailed representation of ALTD13's rainfall delivery scheme in the SFWMM is presented in ***Figure B.3-2*** and ***Table B.3-1***. Deliveries from upstream sources (i.e. EAA runoff, EAA Storage area, andLake Okeechobee) are routed through the Stormwater Treatment Areas (STAs) prior to release into the Water Conservation Areas or the WMA's. The distribution of STA outflow is designed to improve hydropatterns. In ALTD13R, flows to Everglades National Park and Big Cypress National Reserve are represented by flow paths DC1, DC2 and DC3 in ***Figure B.3-2*** The flow paths are uncontrolled since the S-12, S-333, S-355 and S-343A and B structures, as well as L-29, L-28 and L-29 borrow canals were removed to allow overland flow from WCA-3 to these areas.

This page is intentionally left blank.

Table B.3-1. Description of Proposed Environmental Water Supply Deliveries within the Everglades for ALTD13R

Flow Path	Source	Trigger Location (Source)	Destination	Trigger Location (col,row) (Target)	Additional Comments
A1	LOK	N/A	STA-3 & 4	3A-NE (23,40) or 3A-NW (18,40) or 3A-4 (21,29)	Flow via Miami Canal in EAA
A2	LOK	N/A	STA-2	2A-N (28,45)	Flow via Hillsboro Canal in EAA
B1	STA-3&4	N/A	WCA-3A	3A-NE (23,40)	Flow through gravity structures when stage at 3A-NE is in import zone
B3	STA-3&4	N/A	NW corner of WCA-3A	3A-NW (18,40)	Assume 50% of gravity outflow toward this destination. Flow occurs if stage at 3A-NE (23,40) is > 0.2 ft. above NSM target
B4	STA-3&4	N/A	WCA-3A via G-404 and through S-140A via L-4 and L-28 borrow canal	3A-4 (21,29)	Assume 50% of gravity outflow if have B3 100% of outflow if strictly excess flow (B1 & B3 do not occur)
HL1	Holey Land	(20,43)	WCA-3A	N/A	Flow occurs if stage at 3A-NW (18,40) is above NSM target
HL2	Holey Land	(20,43)	NW corner of WCA-3A	3A-NW (18,40)	
R1	Rotenber-ger	(16,43)	NW Corner of WCA-3A via G-404	3A-NW (18,40)	
R2	Rotenber-ger	(16,43)	Through S-140A via G-404, L-4, L-28	3A-4 (21,29)	Flow occurs if stage at 3A-NW is above NSM target
R3	Rotenber-ger	N/A	Holey Land		Flow occurs if stage in Holey Land is less than 0.2 ft. above NSM target
C1	STA-1W	N/A	WCA-1	N/A	Flow occurs if depth of water in STA-1W exceeds 1.25 ft.
C2	STA-2	N/A	WCA-2A	N/A	Flow occurs if depth of water in STA-1W exceeds 1.25 ft.
D1	WCA-1	1-7 (31,48)	WCA-2A	N/A	Flow through S-10A, S-10B and S-10C. Operations based on calendar based regulation schedule.
D2	WCA-1	1-7 (31,48)	Northern WCA-2A	N/A	Flow through S-10E. Operations based on calendar based regulation schedule.

Table B.3-1. (cont.) Description of Proposed Environmental Water Supply Deliveries within the Everglades for ALTD13R

Flow Path	Source	Trigger Location (Source)	Destination	Trigger Location (col, row) (Target)	Additional Comments
D3	WCA-2A	2-17 (29,40)	WCA-3A	3A-3 (25,37)	Excess flow occurs if stage at 2A-17 is sufficiently above the NSM stage target
D4	WCA-2A	2-17 (29,40)	WCA-2B	N/A	Excess flow occurs if stage at 2A-17 is sufficiently above the NSM stage target
E1	WCA-2B	2B-C (30,36)	NESRS	N/A	Flow through proposed WCA-2B outlet structures and into NESRS via S-356A&B
E2	WCA-3A	3A-E (26,33)	Proposed Central Lake Belt Reservoir	G-1502 (24,17)	Flow through proposed outlet structure near S-9 (WC3TLB)
E3	WCA-3B	3B-N (27,30)	Proposed Central Lake Belt Reservoir	N/A	Flow through S-31 if excess in northern WCA-3B exists
E4	Central Lake Belt Reservoir	N/A	NESRS	G-1502 (24,17)	Flow through proposed 800 cfs structure and into NESRS via S-356A&B
E5	WCA-3A	3A-E (26,33)	WCA-3B	Avg. of stages at NESRS-1 (22,20) and NESRS-2 (25,21)	Flow occurs if stages at 3A-E (26,33) is sufficiently above NSM stage target
S-140A	L-28 borrow canal	N/A	WCA-3A	3A-4 (21,29)	Excess flow occurs even if stage at 3A-4 is above NSM target
ST1	STA-6 Outflow	N/A	NW corner of WCA-3A	N/A	Excess flow to NW corner if stage at 3A-4 is above import zone
ST2	STA-6 Outflow	N/A	WCA-3A	3A-4 (21,29)	Flow occurs if stage at 3A-4 is in import zone, otherwise STA-6 outflow is directed to NW corner of WCA-3A
DC1	WCA-3A	N/A	NESRS	N/A	Overland Flow Path. Levee removed as part of WCA -3A decompartmentalization
DC2	WCA-3A	N/A	NWSRS	N/A	Same as previous
DC3	WCA-3A	N/A	BCNP	N/A	Same as previous

note: WCA Floor elevations (represented by conveyance canal stages)
WCA-3A (S12HW): Minimum (7.5, 3 gage average [3A-3, 3A-4, 3A-28] of NSM stage targets)
WCA-2A (S11BHW): Minimum (10.5, NSM stage at [29,40] 2A-17 gage location)
WCA-1 (S10HW): Minimum (14.0, NSM stage at [31,48] 1-7 gage location)
If (LOK stage > WCA-1 stage - 1.0, at 1-7) then floor elevation is adjusted to represent simulated water level so that water must come from LOK to meet LEC needs in SA1.

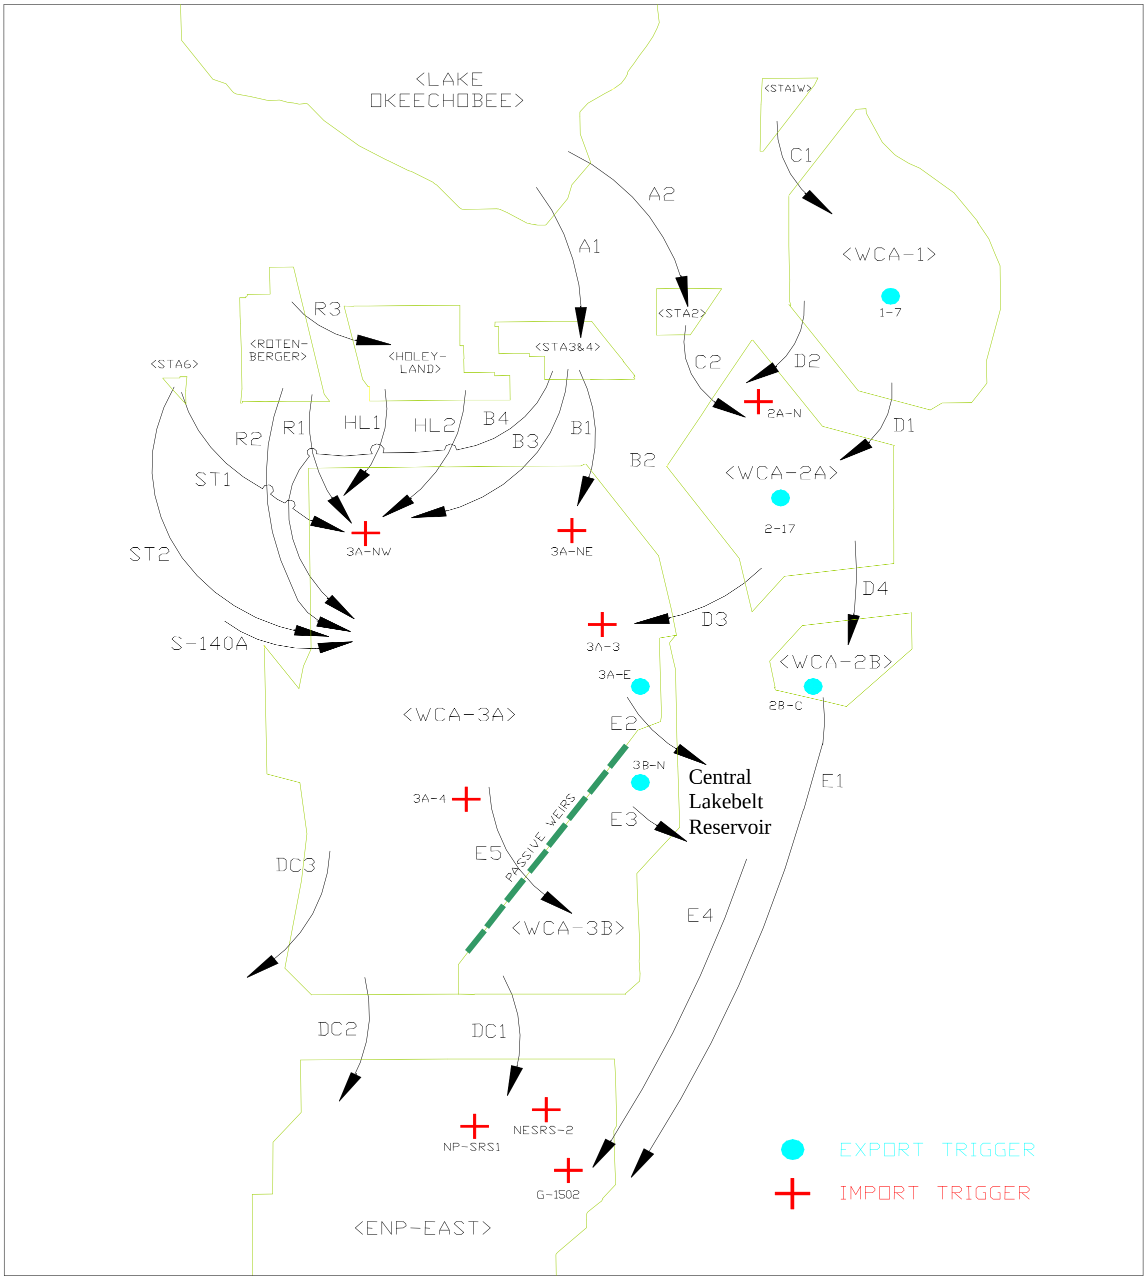


Figure B.3-2. Flow Routing Associated with the Proposed Environmental Deliveries as Implemented in the SFWMM (Restudy ALTD13R)

B.3.1.2.3 Seepage Management

The term "seepage management " refers to controlling groundwater flow underneath levees of various systems (e.g. Water Conservation Areas, Everglades National Park, or proposed reservoirs). Total groundwater flow beneath a levee is the sum of regional groundwater flow and levee seepage. Levee seepage refers to the more localized movement of groundwater beneath a levee into its adjacent borrow canal. The SFWMM's solution to the general groundwater flow equations represents the regional groundwater flow, while empirical levee seepage functions are used to solve for levee seepage from the Water Conservation Areas and Everglades National Park. The empirical equations were derived from the output of a two-dimensional (vertical plane) model; SEEP2D (a.k.a. SEEPN) developed at the U.S. Army Corps of Engineers Waterways Experiment Station. Utilizing stepwise linear regression analysis, ten sets of regression coefficients were derived. The coefficients were fine-tuned during the SFWMM calibration. The form of the equation and the coefficients are presented in the draft Documentation for the SFWMM (SFWMD, 1997).

Levee seepage and regional groundwater flow volumes are significant for the protective levees of WCA-2B,WCA-3 and ENP, and in the surficial aquifers around the coastal areas of southern Palm Beach, Broward, and Miami-Dade counties. Because of large seepage losses, some form of seepage control is necessary for Everglades restoration or when building reservoirs in coastal areas for the purposes of water supply or environmental enhancement. The extent of seepage control depends on the magnitude of the seepage losses, the purpose of the storage area or reservoir, and flood control considerations in nearby areas.

In the SFWMM several options exist for simulating levee seepage and its management. These include; 1) allowing the seepage to occur with no diversion or management, 2) pump the seepage collected in the canal back to the source, 3) divert the seepage collected to another location that would benefit from the added seepage volumes, and 4) impose a barrier that would reduceor eliminate levee seepage losses (e.g. make levee seepage under protective levee(s) equal to zero). Management of levee seepage can be changed temporally at a grid cell location along a levee on a wet season-dry season basis and can vary spatially over the length of the levee as a function of grid cell location.

Total seepage control will require more extensive field technology. The specific technology required for eliminating seepage losses through a boundary or perimeter of a levied system is not a concern in regional modeling for planning purposes. For planning purposes the primary interest is the regional impacts of total seepage control in areas of concern assuming the technology will work. The technology proposed may be total seepage barriers or curtain walls. Total seepage barriers allow; 1) maximum fluctuation of water levels in a reservoir that maximizes a reservoir's effectiveness for water supply and/or environmental enhancement without adversely effecting or being adversely effected by surrounding areas, and 2) hydrologic restoration of the Everglades such as ENP west of L-31N, where seepage losses are high. Total seepage barriers are proposed for the Lakebelt reservoirs year round and along L-31N bordering NESRS in Everglades National Park during the wet season. For modeling purposes seepage barriers, as with levees, are located at the boundaries of grid cells. Seepage barriers are identified in the model by specifying the appropriate boundary faces (east, west, north, or south) of effected grid cell locations (column, row). By temporarily fixing the head in the neighboring grid cell across a seepage barrier to be identical to the head at a computational grid cell, a zero head gradient is established between the two grid cells. The solution of the groundwater flow equations will yield zero flow across the common boundary where the seepage barrier is proposed, but the final end-of-day heads at either grid cell will still respond to the head gradients established at the other boundary faces where no seepage barrier(s) exist.

B.3.1.2.4 St. Lucie Interface

The St. Lucie Estuary receives freshwater inflow from Lake Okeechobee and five local basins: C-23, C-24, Northfork, Southfork and the C-44 Basins. As part of the alternative development effort, salinity conditions in the estuary were maintained to support a range of aquatic vegetation seagrass, invertebrates and fish communities. To achieve this goal, a series of reservoirs and associated operating rules were proposed in all five contributing basins. The SFWMM simulates the operation of the reservoir proposed for the C-44 Basin only. The operation of the other basins and reservoirs are performed off-line and the resulting time series of releases are inputted to the SFWMM. The model then makes decisions on how and when water will be released from Lake Okeechobee and the C-44 Basin/reservoir based on a pre-defined St. Lucie Estuary target inflow time series.

B.3.1.2.5 Passive Weir Structures

The simulation of passive weir structures in the Everglades is a part of component QQ that includes the decompartmentalization of Water Conservation Area 3. Eight weir structures along the entire length of L-67A are proposed to promote sheet-flow during high flow conditions. Iterations were required to determine the size and elevation of the weirs that, in the judgement of the Restudy ADT, have potential to help achieve the goals of the restoration of WCA-3A, WCA-3B, and NESRS.

The algorithm in the SFWMM that computes the flow over the passive weirs is an integral part of the overland flow computations, which are performed at six-hour time steps. The equation used to calculate the flow is:

$$qweir = c*L*(H^{3/2})*[(1 - reduc\_fact)^{(1/4)}]$$

where,

qweir = the weir flow (ft^3/sec);
c = the discharge coefficient for broad crested weirs;
L = the length of the weir crest (ft);
*(for modeling purposes the product c*L is specified as one parameter);
H = the depth of headwater above weir crest (ft);

reduc_fact = (tailwater - crest elevation) / (headwater- crest_elevation);

If tailwater is less than or equal to crest elevation, then reduc_fact is equal to zero making the submergence factor equal to one (free flow). When the tailwater is greater than the crest elevation the submergence factor is approximated by $(1 - \text{reduc\_fact})^{1/4}$**.** Qweir is the volume of flow over the weir (ft^3) for six-hour time step, i.e.

Qweir = qweir * length of time step (seconds).

The mean daily flow over the weirs, in cfs, is the sum of Qweir over 1 day divided by number of seconds in a day (86,400).

Weir inputs to the SFWMM include the grid location of the weir structure(s) (column, row) that corresponds to the headwater location, parameter c*L, weir crest elevation, and direction of flow for the weir structure (eastward, westward, northward, or southward). The weir flow equation governs the flow from the headwater location to the tailwater location (column, row) over each weir structure, since the weirs are assumed to be along levee(s) which prohibit any additional flow of surface water. Since the weirs are passive, reverse-flow can also occur and is computed when the depth of tailwater above the crest is greater than the depth of headwater above the crest. In this case the tailwater is considered the headwater and headwater becomes tailwater in the flow computations and the sign of flow is made negative to indicate flow reversal.

B.3.1.2.6 Wastewater Reuse

The existing South District Reclaimed Wastewater Treatment Plant (SDRWTP) located north of the C-1 Canal will use superior treatment technology to provide reclaimed water of acceptable quality to the South Biscayne Bay and Coastal Wetlands Enhancement (SBBCWE) Project. The reclaimed water will be discharged to the C-1 Canal (Black Creek), upstream of S-21A, and then delivered southward towards the C-102 and C-103 Canals, and northward towards the C-100 Canal. The wastewater treatment facility will provide advanced treated water to L-31E. Flow southward in L-31E towards C-102 and C-103 will be 202 acre-feet per day. Flow northward in L-31E towards C-100 will be 200 acre-feet per day (through a canal extension) for a combined 402 acre-feet per day inflow into L-31E. This supplemental water will restore overland flow in the coastal area and provide groundwater recharge to enhance groundwater discharge into Biscayne Bay. It is anticipated that a reduction of saltwater intrusion in the southern part of Miami-Dade County will occur. Discharge capacity at S-123, S-20F, S-21 and S-21A is assumed to be sufficient to pass basin runoff and inflows from the reuse facility during storm events.

The future West Miami-Dade Wastewater Treatment Plant (WDWTP) will provide wastewater treatment coupled with superior treatment technology to supply reclaimed water to the Bird Drive Recharge Area. The WDWTP will pump the reclaimed water to the Bird Drive Recharge Area at a rate of 307 acre-feet per day when the elevation of the Recharge Area is equal to or less than 3 feet above the natural ground level. The water will be supplied year round as needed to enhance groundwater recharge. Excess water, when available, will be sent as a second priority to the South Dade Conveyance System; as a third priority to Northeast Shark River Slough; and lastly to deep injection wells when there are no other demands from the three designated areas. The superior treatment technology will treat the Advanced Wastewater Treatment (AWT) effluent to remove phosphorous and nitrogen to the low levels desired to meet State water quality standards.

B.3.2 Simulation of Pre-drainage Conditions

B.3.2.1 Model Used: Natural System Model (NSM)

B.3.2.1.1 Background

The Everglades consisted of 3 million acres of subtropical wetlands that covered much of South Florida prior to the major drainage activities that began early this century. The Everglades region was characterized by an extremely low gradient, heterogeneous mosaic landscape that evolved over 5000 years (Science Sub Group Report, 1993). This immense wetland system south of Lake Okeechobee sprawled from the south shore of Lake Okeechobee to the mangrove estuaries of Florida Bay and Gulf of Mexico. The Immokalee Ridge to the west and the coastal ridges to the east generally marked the hydrologic boundaries of the historic Everglades, although numerous connections through the coastal ridge overflowed from the Everglades to the Atlantic Ocean. The primary characteristic of the pre-drainage wetland ecosystem in the Everglades was the hydrologic regime that featured slow sheetflow and natural recession due to storage, large spatial scale, and heterogeneity in habitat.

The Natural System Model (NSM, Van Zee, 1998) simulates the hydrologic response, not the hydrology, of a pre-drained Everglades system to current climatic input. Although one may wish to recreate the hydrologic conditions of the late 1800's or early 1900's, the input data necessary to perform such a simulation does not exist. However, the use of recent input data (e.g. rainfall, potential evapotranspiration, tidal and inflow boundaries) allows for meaningful comparisons between the current managed system and the natural system under identical climatic conditions.

The landscape of present day south Florida has been greatly effected by the land reclamation, flood control and water management activities that have occurred since the early 1900's. The complex network of canals, structures and levees in the current system are replaced in the NSM with the rivers, creeks and transverse glades which were present prior to the construction of drainage canals. The vegetation and topography used by the NSM are based on pre-drainage conditions. The landcover simulated by the NSM is static, i.e. the model does not attempt to simulate vegetation succession.

The NSM is closely linked to the South Florida Water Management Model (SFWMM). The SFWMM is a regional scale hydrologic model that simulates the hydrology and managed water system in south Florida. The design of the SFWMM takes into consideration south Florida's unique hydrologic processes and geologic features, including the integrated surface and ground water hydrology and the operation of the Central and South Florida (C&SF) Project. The NSM uses the same climatic input, model parameters and computational methods as the SFWMM. Physical features, such as topography, vegetation types and river locations are adjusted to represent the pre-drainage condition. Since traditional calibration/verification methods can not be applied to the NSM, model parameters are based on the calibrated and verified SFWMM.

B.3.2.1.2 Physical Data

The NSM encompasses an area from Lake Istokpoga to Florida Bay. The western boundary extends southward from Lake Istokpoga to near the Gulf of Mexico, and continues along the coastal marsh fringe, turning southward to Shark River Slough and Florida Bay. The eastern boundary extends across the northern Indian Prairie Region to the Kissimmee River, and continues around the northern rim of Lake Okeechobee and turning eastward to the Atlantic Ocean. The eastern boundary follows the coastline southward to Biscayne Bay and Florida Bay. The model domain is divided into 2328 (2mi $\times$ 2mi or 3.22 km $\times$ 3.22km) square grid cells. Vegetation class, land surface elevation and aquifer parameters are assigned to each cell and are assumed uniform within each cell.

McVoy and Park (1997) based the vegetation coverage (***Figure B.3-3***) on the estimated landscape of the pre-drained Everglades. Eleven landscape types are identified, based on an evaluation of hydrology (water depth, hydroperiod, flow direction and velocity), vegetation community, soil type and topographic relief. The NSM utilizes vegetation-based parameters to compute ET and overland flow. The utilization of SFWMM parameters implies that the ET and flow characteristics of the current landscape are comparable to the pre-drainage landscape and are transportable, e.g. parameters calibrated in the Everglades National Park can be applied to areas outside of the Park boundaries.

Seven of the eleven pre-drainage landscape types, have been identified in the current system, including mangroves, forested uplands, marsh, sawgrass plains, wet prairie, shrubland and forested wetlands. Parameter values for the non-existent types (ridge and slough, marl marsh, edge marsh and grassland) are based on the landscape most closely resembling them in the current system. The ET characteristics of the ridge and slough landscape most closely resemble the modified ridge and slough of central Water Conservation Area 3A, and the flow characteristics most closely resemble the modified ridge and sawgrass invaded slough in Shark River Slough. The vegetation and flow characteristics of the marl marshes on either side of Shark River Slough most closely resemble the marl prairie now found in those same areas. Edge marsh and grassland most closely resemble the wet prairie and shrubland landscapes identified in the current system.

Surface elevations in the NSM approximate the pre-drainage topography of south Florida. Land surface elevations are generally consistent with current land surface elevations except in areas impacted by soil subsidence. Land surface elevations in the Eastern Flatwoods, Loxahatchee Slough, Atlantic Coastal Ridge, Miami Rock Ridge, Everglades National Park, Big Cypress and Lake Okeechobee are consistent with the SFWMM. Land surface elevations in other non- subsidence areas, including Immokalee Ridge, Caloosahatchee River Basin, Fisheating Creek and Istokpoga / Indian Prairie regions are estimated from U.S.Geologic Service and U.S. Army Corps of Engineers sources.

The most severe soil subsidence occurred along the Okeechobee Rim, Central Everglades and Northern Transverse Glades regions. Land surface elevations in these areas are based on land surface profiles, which were surveyed during or prior to the construction of the drainage canals (***Figure B.3-4***).

The aquifer parameters (i.e. depth, permeability and soil storage coefficient) are consistent with the SFWMM. In areas outside the SFWMM boundaries, aquifer depth and permeability are based on published well log data.

The location of rivers, creeks and transverse glades are described through a series of x-y coordinates. The location of these pre-drainage flow-ways is based on government survey plats completed between 1855 and 1870 and the SFWMD Primary Hydrography Coverage. River cells and associated river segments are identified by the intersection of the grid cell mesh with the river coordinates.

B.3.2.1.3 Time Variant Data

The hydrology of south Florida is primarily rainfall driven and is influenced by other hydrologic processes, e.g. ET, overland and ground water flow. This phenomena is simulated in the NSM by applying external stimuli (i.e. rainfall, potential ET and boundary flow) to effected cells and moving water between cells in response to hydrologic processes.

The NSM utilizes a rainfall database, which contains daily estimated rainfall for each cell in the respective model domain. Estimates for each cell are based on rainfall data collected at the station nearest to the cell center. Rainfall data from 671 stations in ten counties were used to develop the database.

Daily potential ET is computed for eleven stations using a modified Penman - Monteith Method (Giddings and Restrepo, 1994). An inverse distance method is used to weigh the contribution of each station to each cell.

Daily inflows along the northern boundary are defined by a series of inflow points into Lake Istokpoga and Lake Okeechobee. These flows represent the "natural" inflow, which would have occurred under pre-drainage conditions. The Lake Istokpoga and Fisheating Creek Basins have not been greatly altered by water management projects, such as lake regulation schedules, canalization, and impoundments. The rainfall-runoff relationship is assumed to be comparable to that of pre-drainage conditions. Natural inflows from these basins are approximated by observed flows at Arbuckle and Josephine Creeks, and unguaged local inflow at Lake Istokpoga, and Fisheating Creek.

The Kissimmee River Basin has been effected by water management projects, including the connection and regulation of lakes in the upper basin, and canalization of the Kissimmee River. Natural inflow from the Kissimmee Basin is estimated using a rainfall-runoff model calibrated to the earliest available flow data (1934-1942). A set of synthetic flows is generated using 1965-1995 rainfall and potential ET data. Inflow from peripheral basins north of Lake Okeechobee (Nubbins Slough, Taylor Creek and S154) are assumed to be proportional to the lower Kissimmee Basin runoff.

Tidal boundaries are effective flow boundaries, in that water is removed or added as water levels are adjusted to coincide with the tidal stage. Tidal boundaries are established in ocean cells, which include cells along the Atlantic Ocean and Florida Bay. Tidal stages are based on long term monthly averaged tide data at six tidal gaging stations along the Atlantic Ocean, Biscayne Bay and Florida Bay.

B.3.2.1.4 Hydrologic Processes

Water is distributed within the model domain by a set of hydrologic processes. Processes are modeled separately within each time step with more transient phenomena computed before less transient phenomena.

Infiltration and ET processes simulate the vertical movement of water within a cell. The infiltration process simulates the downward movement of water from surface water ponding to the water table. The ET process simulates the release of water from surface water ponding and ground water table to the atmosphere through evaporation and plant transpiration, respectively.

The overland flow process simulates surface water movement between adjacent cells. The NSM utilizes an alternating-direction explicit finite difference method to solve the overland flow equations (SFWMM, 1997, Fennema, 1994, Lal, 1998). No-flow boundaries are established for the non-ocean cells along the northern, eastern, and most of the western limits of the model domain. Fixed head boundaries based on the tidal stage are imposed in ocean cells. Fixed gradient boundaries are imposed in cells along the southwest boundary. Lake Okeechobee, Lake Istokpoga and Lake Hicpochee are treated as level pools.

Ground water flow is simulated by solving for ground water level in a finite difference approximation of the two-dimensional, transient, subsurface flow equation for unconfined aquifers. A zero-gradient ground water boundary condition is established along the perimeter of the model domain. The head values in ocean cells coincide with stages established by the tidal boundary.

The river flow process simulates the influence of rivers on water levels. Rivers are represented as storage volumes in the model. Downstream discharge can be released to a cell, defined as inflow to another river, or removed from the model (tidal release). An iterative bisection technique is utilized to compute the river stage for condition when net inflow is equivalent to change in storage.

B.3.2.1.5 Results

Surface water processes driven by rainfall and ET dominate the hydrology of the pre-drained Everglades.. Water generally moves slowly as surface water from north to south in response to the low hydraulic gradient (***Figure B.3-5***). The buffering capacity required to transform large lake outflows into a slow moving, low gradient release to the south is provided by the large storage capacity of Lake Okeechobee coupled with its long overflow perimeter. Within the Everglades boundary, the magnitude of the overland flow vectors is uniform with a south to southeast direction in the upper/central Everglades. The relatively uniform magnitude of the overland flow vectors begins to concentrate in what is now Water Conservation Area 2B. This concentration continues through the northern transverse glades area south to Shark River Slough and southwest towards the Gulf of Mexico.

Water levels are uniform throughout the upper and central Everglades with median ponding depths between 0.5 and 1.0 ft (***Figure B.3-6***). Water levels are more variable in the lower Everglades with depths up to 4.0 ft in the northern transverse glades region, 2.0 ft in Shark River Slough, and ±0.5 ft of the land surface in the marl wetlands in ENP. Outside the historic Everglades boundary, median water levels generally range from near land surface to more than 4.0 ft below land surface along the Atlantic Coastal Ridge and the Highlands Ridge.

Water levels within the Everglades boundary generally fluctuate between 2.0 and 2.5 ft annually. Water levels fluctuate with a somewhat smaller range (1.75 ft) in Lake Okeechobee, Hillsboro Lakes and Shark River Slough (***Figure B.3-7***). Water levels in virtually all of the Everglades drop below land surface at some point during the simulation. Conversely, virtually all of the Everglades have extended periods (up to 12 months) of inundation. Under these “wet” conditions, annual low water ponding depths between 0.5-1.0 ft and 2.0 ft persist in the upper/central Everglades and Shark River Slough, respectively.

Although much of the Everglades is subject to annual low water levels that drop below land surface, the duration of the dry-down is very short. The median number of days of inundation per year or "hydroperiod" for the Everglades is generally greater than 330 days/year (*Figure B.3-8*). Even under abnormally dry conditions, hydroperiods in the upper/central Everglades are generally greater than 150 days/year and the Shark River Slough to northern transverse glades area still exceed 335 days/year.

B.3.2.2 Modifications to Create NSM v4.5 Final From NSM v4.5 Provisional

When the Restudy process began, a provisional NSMv4.5 was available while undergoing peer review.. The final version of NSMv4.5, referred to herein as NSM45, was implemented after modifications were made in November, 1997. NSM45 was utilized in the evaluations of the final array of alternative development plans. Output maps of NSM45 and the provisional NSM were posted on the hydrologic performance measures (HPM) webpage. The modifications made to establish the final NSM45 are summarized below.

B.3.2.2.1 Overland Flow Resistance Parameters

Ridge and slough (R&S) vegetation is the most extensive Everglades landscape in the NSM. The ET characteristics most closely resemble that of modified ridge and slough (MRS) in central WCA3A. The resistance to flow characteristics most closely resembles that of the modified ridge and sawgrass invaded slough in Shark Slough. This differs from the provisional NSM where both ET and resistance to flow, i.e. Manning's 'n', were based on MRS. Since the calibrated Manning's 'n' in Shark Slough is much lower (0.725 vs. 1.055), there is less resistance to flow in the R&S landscape, thereby contributing to lower ponding depths in central WCA3a and increased flows across Tamiami Trail.

B.3.2.2.2 Rivers/Transverse Glades

Prior to NSM45, the definitions for the river/transverse glades and topography were generally developed independently. River location was based on government survey plats and hydrography coverages. Topography was based on the SFWMM, supplemented by a variety of topography maps and surveys. In NSM45, there is an attempt to reconcile the two and provide a more representative model of the transverse glades. Survey plats typically establish the location of a well-defined river or creek. Since most of the well-defined portions of the rivers and creeks are east of the coastal ridge, the model provided very little direct connection with the Everglades. In reality, rivers were connected to transverse glades, which provided a flow-way through the coastal ridge. NSM45 establishes this connection by extending rivers through the coastal ridge and/or lowering ground surface elevations near the end of the river. In either case, all adjustments are based on soil survey maps, which clearly delineate the location of the transverse glades. Rivers were then "calibrated" by comparing simulated river stages with the Corps estimated average and maximum pre-drainage water levels.

B.3.2.2.3 Topography

Topography for the Everglades south of Lake Okeechobee and north of Tamiami Trail is based on an interpolation of "nearly" pre-drainage land surface profiles--this is true for both the provisional and final version of NSM45. Following the release of NSM45 provisional, these profiles were revised resulting in a revised topography data set. These revisions were relatively minor (generally less than 0.5 ft).

B.3.2.3 Uncertainty

Uncertainty of the Natural System Model develops primarily as a result of three forms of uncertainty; parameter, input, and algorithm or numerical errors.

Parameter uncertainty is an important contributor to total uncertainty, partly because the NSM cannot be calibrated against measured data. NSM stage and flow estimates are therefore less certain than SFWMM flow estimates. Additionally, parameter uncertainty is significant partly due to the spatial and temporal aggregation of parameters that are generally carried out during modeling. The aggregation is carried out in simplifying land use types and assigning simple seasonal estimates. The ET crop coefficient was identified as the parameter that the model output was most sensitive to, followed by the Manning's coefficient (Lal et al., 1994, 1997). With a high parameter uncertainty assumed, output uncertainty in the daily estimates of stage was found to be within 0.3 ft for the ENP and the Water Conservation Areas 90 percent of the time, with few exceptions.

Input uncertainty is due to the uncertainty in rainfall and ET data as calculated when using a sparse network of gages when the spatial variability is high.

Uncertainty due to numerical errors alone have been demonstrated to be very small (Lal, 1998). In areas of deeper water subject to canal level fluctuations, errors are less than 7 percent of the disturbing amplitude.

The total uncertainty of the NSM can not be obtained because the NSM can not be calibrated.. However, an estimate of the likely total uncertainty of the NSM can be obtained by examining the total uncertainty of the SFWMM. The SFWMM estimation is obtained by the linear regression of observed versus simulated values. The standard error estimate of the linear fit was considered to be the total error (uncertainty) in the SFWMM. This method showed that the 90 percent total uncertainty band for stages in a fully calibrated SFWMM is six to seven inches in the Everglades National Park and about six inches for most areas of Water Conservation Area 3 (Lal, 1994). According to the regression method (Flaville, 1992) the SFWMM is capable of explaining about 50-80 percent of the total variance in water levels (Trimble, 1995). Lal (1994) showed that the uncertainty in the estimate of stage was reduced when daily stages were aggregated to longer time periods.

B.3.2.4 Proper Interpretation of Overland Flow

The NSM developers recommend that the NSM be utilized to estimate the spatial patterns and the temporal variability of overland flow, rather than the flow volumes. Relative comparisons of overland flow volumes between alternatives simulated by the SFWMM are also acceptable. This is a typical and appropriate use of a simulation model since model uncertainty, as manifested particularly in data and parameter uncertainty, is relatively consistent between two alternatives –(both simulated with the same model). To compare the exact volumes between the NSM and SFWMM is not appropriate since simulated overland flows from the NSM are subject to larger uncertainties than those of the SFWMM. The NSM has a larger uncertainty in overland flow estimates because overland flow plays a larger role (broader spatial extent) in the NSM relative to the SFWMM, in addition to the inability to calibrate the NSM.

The developers of the NSM caution against using NSM flow volumes as hydrologic restoration targets. They do recommend that it is more appropriate to use water depths and patterns as targets because of the relatively large uncertainty in NSM overland flow estimates as compared to those from the SFWMM. Small changes in flow depths can result in relatively large non-linear changes in overland flow. Although the SFWMM can account for 50 to 80 percent of the variations of low to average discharge, the variability that can be accounted for is much lower for deep water (Lal, 1998). Thus, inaccuracies in stages are magnified when examining corresponding flows. Fennema et al. (1994) suggested that the application of predevelopment flow rates to a modified and much smaller natural system may not necessarily produce a positive ecological response. The maintenance of acceptable water levels and hydroperiods, rather than flows, is probably the key to restoration of the Everglades (Van Lent et al., 1993).

B.3.3 Hydrologic Performance Measures

B.3.3.1 Performance Measures and Indicators

Performance measures are quantitative indicators of how well or poorly an alternative meets a specific objective. Features of good performance measures: are quantifiable; have a specific target; indicate when that target has been reached; or measure the degree of improvement toward the target when it has not been reached. Hydrological performance measures quantify changes in hydrological conditions relative to hydrologic targets. Although it was understood that achieving hydrologic targets did not necessarily guarantee achieving ecological restoration, it was assumed that recapturing the hydrological characteristics of the natural or pre-drained system would provide the maximum opportunity for recovery of the remaining Everglades landscape patterns. Hence, recovery of Everglades wildlife.

Performance Indicators, in contrast to performance measures, do not have a specific target, but are used to provide an indication of the relative behavior of alternatives. Performance measures and performance indicators are herein referred to generically as "performance measures".

B.3.3.2 Process of Developing Performance Measures

Performance measures that were developed as part of the Restudy process were first brought to the Alternative Evaluation Team (AET) for approval. Then, if the performance measure could be produced directly utilizing output from the SFWMM, it was passed to the Hydrologic Systems Modeling Division, SFWMD for development and automation with each model run. If the performance measure could not be produced directly from SFWMM output, it became the responsibility of the developer to produce and post the measure on a web site linked to the Hydrologic Performance Measures Web Page. Many of the performance measures (formerly developed as part of the Lower East Coast Regional Water Supply Plan) were also used in the C& SF Restudy process.

B.3.3.3 Dissemination Via the Hydrologic Performance Measures Web Page

The Hydrologic Performance Measures (HPM) web page was designed to *be the prime communication tool* for the hydrological modeling and alternative evaluation phase of the Restudy feasibility analysis. Participants in the design and evaluation of restoration alternatives for the Restudy included federal and state agencies, environmental groups, the agricultural industry, municipal water utilities, consultants, other interested parties and the general public. The World Wide Web was chosen as the best means to disseminate regional scale hydrological modeling results to, and obtain feedback from, such a wide group of participants. The HPM web page was designed to do the following:

- Allow regular posting of a large number of performance measures. A set of performance measures was generated for selected groups of simulation runs. Each set could compare up to six model simulation runs. Typically one or two alternatives were compared with the existing condition (1995 Base), the future without project condition (2050 Base) and the pre-drained condition as simulated by the NSM. Each performance measure set consisted of more than 900 graphics, maps and tables. Unix shell scripts were used to automate the posting of each performance measure set and the associated maps and tables for the SFWMM runs.

- Require minimum maintenance with each posting. The HPM web page was designed for easy maintenance, with a minimum number of files that needed to be edited manually with the posting of each alternative.

- Permit feedback and evaluation of the alternatives by anyone with a desire to so. An evaluation form provided a means by which all interested parties could provide comments on simulated alternatives. Comments were relayed electronically to the relevant Alternative Evaluation Sub-teams, depending on subject or geographical area to which the comment pertained. Additionally, all comments were sent to the Restudy AET scribe for inclusion in the records.

- Provide details on design of the components utilized in each modeled alternative. After the Restudy Alternative Design Team (ADT) undertook the design of each alternative, following the Restudy Alternative Evaluation Team (AET) evaluation, details of the component designs were posted on the HPM web page.

- Act as a mechanism for disseminating the evaluation of each alternative undertaken by the AET using comments provided by the HPM web page feedback. The AET report for each alternative was posted on the HPM web page. The report provided a complete amalgamation of all the comments received and the AET's analysis of the performance of the particular alternative.

- Provide status updates on new performance measures, posting of modeled scenarios, and information on any model revisions. A “What's New” button was used to provide the latest information on the status and schedule of the Restudy simulation results and posting of alternatives on the HPM web page.

B.3.4 Special Investigations: Summary

Special investigations included modeling to assess the sensitivity of the selected alternative (ALTD13R) to the removal of individual components, and the modeling and evaluation of scenarios proposed at various stages during the restudy alternative development process. Simulation of scenarios was undertaken at various stages in the Restudy alternative development process specifically to assist in the design of the alternatives or investigate particular effects that could not be built into the alternatives. Special investigations that relate the sensitivity of ALTD13R to the removal of components are reported first, followed by the scenarios. Each investigation typically only discusses the performance measures that changed.

It is important to understand that the overall system performance may not change significantly when certain components are removed as indicated by sensitivity analyses. This result does not necessarily mean that the component is not important or needed. Although no operational modifications or structural components were explicitly added to replace the function of the removed components, closer inspection of the analyses reveal that one or more of the other components are typically utilized more extensively in an effort to compensate for the deficit.

This section comprises a summary of the special investigations. A more detailed description of each investigation follows later.

B.3.4.1 Caloosahatchee Basin Aquifer Storage and Recovery (ASR)

B.3.4.1.1 Purpose

To estimate system-wide impacts particular to the Caloosahatchee Basin (water supply and estuary criteria) caused by reducing the ASR recovery efficiency and by removing the ASR component.

B.3.4.1.2 General Assumptions

Three simulations were evaluated; ALTD13R and two scenarios based on ALTD13R. The first scenario reduced the ASR recovery efficiency from 70 to 35 percent. The second scenario removed the ASR component. The C-43 Basin reservoir and Lake Okeechobee backpumping components were kept in the simulations.

B.3.4.1.3 Major Findings

- ASR injection volumes do not change with recovery efficiency.
- The 35 percent ASR scenario and the no-ASR scenario decrease the ASR supplies to the C-43 Basin. The deficit is made-up by Lake Okeechobee and the proposed C-43 reservoir.
- The ASR reduction scenarios decrease the ASR supplies to the Caloosahatchee Estuary. The deficit is somewhat compensated by Lake Okeechobee. The total exceedances of low and high flow criteria remain within the acceptable targets.
- The no-ASR scenario allows for an increase in C-43 backpumping to Lake Okeechobee, since the C-43 reservoir has more water available for backpumping purposes.

B.3.4.2 Lake Okeechobee Aquifer Storage and Recovery (ASR)

B.3.4.2.1 Purpose

To estimate system-wide impacts particular to the Lake Service Area (water supply and estuary criteria) caused by reducing the ASR recovery efficiency and by removing the ASR component.

B.3.4.2.2 General Assumptions

Three simulations were evaluated: Alternative D-13R (ALTD13R) and two scenarios based on ALTD13R. The first scenario reduced the Lake ASR recovery efficiency from 70 to 35 percent (REDEFF). The second scenario removed the Lake ASR component (NoASR). All other components of ALTD13R were kept in the scenarios.

B.3.4.2.3 Major Findings

- Injection volumes for the 35 percent efficiency scenario were similar to that of ALTD13R (250 kac-ft/yr) since the ASR injections do not depend on the recovery efficiencies.

- Recovery volumes were 136 kac-ft/yr, 55 kac-ft/yr and 0, for the ALTD13R, 35 percent efficiency, and NoASR scenarios, respectively.

- Higher high and lower low Lake Okeechobee stages resulted without ASR. There were 5 additional occurrences of ecologically undesirable stage events without ASR. With the reduced ASR efficiency there was only one additional undesirable Lake stage event.

- Southward discharges from the Lake to the EAA surge tanks and WCA's increased by 67,000 ac-ft/yr or 15 percent (from 380,000 ac-ft/yr to 447,000 af/yr).

- Water shortages in the LOSA (measured as mean annual demands not met) increased from about 6 to 11 percent for both the NoASR and the 35 percent efficiency scenarios. During major drought years only a 1 to 2 percent increase was resulted.

- Without the Lake ASR component, the number of Zone A discharges to the Caloosahatchee Estuary more than tripled (31 to 95 days), and discharges to the St. Lucie Estuary more than doubled (24 to 65 days).

- The number of LECSA water restriction months increased due to the increase in Lake Okeechobee-triggered restrictions. Locally-triggered restrictions did not change significantly.

- Flows to ENP increased slightly under the NoASR scenario. NESRS undesirable low stage events increased by 1.

B.3.4.3 Everglades Agricultural Area Storage Reservoirs

B.3.4.3.1 Purpose

To estimate the sensitivity of regional system performance to changes in the configuration and size of the EAA reservoir component.

B.3.4.3.2 General Assumptions

Four scenarios based on ALTD13R were simulated and compared to ALTD13R. ALTD13R has three reservoir compartments: one 20kac for capturing EAA runoff and supplying EAA irrigation needs, and two 20kac surge tanks for storing flood control releases from Lake Okeechobee and supplying the Everglades. The first scenario (SGT4020) increased the size of the first surge tank from 20kac to 40kac. The second scenario (SGT1x20) removed the second surge tank. The third scenario (EAARS) removed both surge tanks. And the fourth scenario (NEAARS) removed all three reservoir compartments.

B.3.4.3.3 Major Findings

Other components of ALTD13R helped to compensate for deficiencies caused by changing the size or configuration of the reservoirs. The resulting system-wide performance of the scenarios depends on full implementation and efficient operation of all the other ALTD13R components. Thus, any conclusions from these analyses regarding the importance of the EAA reservoir component must be made with care.

Impacts to hydropatterns were summarized from a hydrological perspective. The ecological effects of these hydrologic changes should be assessed to determine their significance.

*Scenario SGT4020 resulted in:

- A decrease in EAA runoff and a slight decrease in total flows to the EPA.
- No change in EAA water supply performance.
- An increase in volume of excess water diverted from Lake Okeechobee to the surge tank, a similar decrease in environmental water deliveries from the Lake, and an increase in flows from the surge tanks to the WCAs.
- Reduced utilization of the Lake Okeechobee ASR component.

* Scenario SGT1x20 resulted in:

- An increase in EAA runoff and slight increase in total flows to the EPA.
- No change in EAA water supply performance.

- A decrease in volume of excess water diverted from Lake Okeechobee to the surge tank, an increase in volume of environmental water deliveries from the Lake, and a decrease in flows from the surge tank to the WCAs.
- No change in volume injected into Lake Okeechobee ASR system.

* Scenario EAARS resulted in:
  - An increase in EAA runoff to the EPA.
  - 250kac-ft/yr average reduction in discharges of excess Lake water to surge tanks.
  - An increase in utility of the Lake ASR system, both injection and recovery volumes.
  - Higher stages in Lake Okeechobee, even during drought years; but no significant change in number of ecologically undesirable lake stage events.
  - An increase in flood control discharges to the St. Lucie and Caloosahatchee Estuaries, but no increase in the number of exceedances of the salinity envelope criteria.
  - The percentage of EAA demands met was better than any of the other scenarios.
  - Significant increases in the dependence on Lake Okeechobee for Everglades water supply deliveries.
  - The volume of flows to the EPA was lower than any of the other scenarios and resulted in slightly lower water levels; the significance of which should be evaluated by the ecologists.

* Scenario NEAARS resulted in:
  - Significant increase in EAA runoff to the EPA.
  - Significant increases in the dependence on Lake Okeechobee for Everglades water supply delivery.
  - The volume of flows to the EPA was higher than any of the other scenarios, and resulted in higher water levels in WCA-3A during wet periods.
  - An increase in exceedances of high and low water criteria in the WCAs; the significance of which should be evaluated by the ecologists.
  - An increase in diversions of excess water in WCA-3A to the Central Lake Belt Storage Area.
  - An increased contribution of dry season deliveries to NESRS from the Central Lake Belt Storage Area.
  - Deliveries from Lake Okeechobee to meet EAA irrigation demands more than doubles, but the percentage of EAA demands met decreases due to lower Lake stages during dry periods.
  - An increase in number of months of LECSA cutbacks due to lower Lake stages results.

B.3.4.4 L-8/C-51 Reservoir

B.3.4.4.1 Purpose

To estimate impacts to LECSA-1 water supply and Lake Worth Lagoon caused by removing the L-8/C-51 reservoir component.

B.3.4.4.2 General Assumptions

The 1200-acre L-8/C-51 reservoir was removed from ALTD13R. The runoff from the southern L-8 and western C-51 Basins that was diverted to the reservoir in ALTD13R was discharged to the Lake Worth Lagoon.

B.3.4.4.3 Major Findings

- Reductions in dry period inflows to, and lower low stages within the WPB WCA.
- Increase in dependence on C-51 ASR, WCA-1 and Lake Okeechobee for recharging canals in LECSA-1.
- An increase in flows to the Lake Worth Lagoon on average of 52,000 acre-feet per year; 90 percent of the increase occurred during the wet season.

B.3.4.5 Lower East Coast Aquifer Storage and Recovery (ASR)

B.3.4.5.1 Purpose

To estimate impacts particular to Lower East Coast (water supply and discharges to tide) caused by reducing the LEC ASR recovery efficiencies and by removing LEC ASR components.

B.3.4.5.2 General Assumptions

Three simulations were evaluated; ALTD13R and two scenarios based on ALTD13R. The first scenario reduced the ASR recovery efficiency from 70 to 35 percent for the four LEC ASR components (WPBCAT, C51, CPBRES, and SITE1). The second scenario removed all four LEC ASR components. All other ALTD13R components were kept in the scenarios.

B.3.4.5.3 Major Findings

- ASR injection volumes do not change with recovery efficiency. Thus, flows to tide did not change significantly for the 35 percent efficiency scenario.
- For the no ASR scenario, LECSA-1 discharges to tide increased to 32 percent and 28 percent for the wet and dry seasons, respectively.
- The number of high flow exceedances for the Lake Worth Lagoon increased by 50 percent (from 96 to 144 months) with no ASR.

- Water levels in the Site 1 and Central Palm Beach County reservoirs had virtually no change with the 35 percent efficiency scenario, but increased significantly with the no ASR scenario.
- Locally-triggered water restrictions did not change with the scenarios (zero restrictions).
- On an annual average basis, the 35 percent efficiency scenario required 50 percent more (~14 kac-ft/yr) deliveries from WCA-1 and Lake Okeechobee to maintain canals in LECSA-1. The no ASR scenario required more than a 100 percent increase (~25 kac-ft/yr) in deliveries.
- Slightly lower water levels in the northern region of WCA-1 resulted with both the 35 percent efficiency scenario and the no ASR scenario.
- Lake Okeechobee stages were marginally lower. However, the number of undesirable stage events did not change.
- Water supply performance for the Lake Service Area had no significant change on a mean annual basis or for the five major drought years.

B.3.4.6 North Lake Belt Storage Area

B.3.4.6.1 Purpose

To estimate the impacts to LECSA water supply and Biscayne Bay caused by removing the north Lake Belt storage component.

B.3.4.6.2 General Assumptions

The 4,500-acre north Lake Belt storage area and its associated perimeter seepage barrier were removed from ALTD13R. The runoff from the C-9 and C-6 Basins that was diverted to north storage in ALTD13R was discharged to tide. And the western C-11 Basin runoff that was diverted to north storage was pumped to WCA-3A via S-9.

B.3.4.6.3 Major Findings

- Significant increase (~130 percent) in the surface water deliveries from Lake Okeechobee and WCA-3A to maintain canals in LECSA3.
- Up to a 0.3ft reduction in Lake Okeechobee stages during dry periods; this resulted in a slight increase in Lake Service Area demands not met, and one additional undesirable lake stage event.
- Reduction in ability to maintain stages in C-4, C-6, and C-9; this contributed to an increase of 19 months of water restrictions in LECSA-2.
- A redistribution of canal/structure discharges to Biscayne Bay. Total discharge volumes were not significantly different; however, the removal of the storage area resulted in a shifting of flows from Central Bay to the Miami River and Snake Creek. Additionally, the seasonal distribution shifted more of the Central Bay flows to the wet season, further away from the target wet and dry season distributions.

B.3.4.7 Central Lake Belt Storage Area

B.3.4.7.1 Purpose

To estimate the impacts to Everglades hydropatterns, water deliveries, and discharges to Biscayne Bay caused by removing the central Lake Belt storage component.

B.3.4.7.2 General Assumptions

The 5200-acre central Lake Belt storage area and its associated perimeter seepage barrier were removed from ALTD13R. Excess water from WCA-3A and 3B was still allowed to discharge east and then south to ENP via the proposed S-356's.

B.3.4.7.3 Major Findings

- A significant increase (more than 100 percent or 187,000 af/yr) in eastward diversions of excess water from WCA-3A and 3B resulted since the available storage capacity in central storage was no longer a limiting factor.
- Seepage from WCA-3 to the LECSA increased by 16 percent (~44,000 ac-ft/yr) as a result of the removal of the perimeter seepage barrier.
- Stages in WCA-3A and 3B were lowered as a result of the increased outflow to the east. There was a resulting 10 percent reduction in flows to NESRS across the Tamiami Trail flow section.
- Although total discharge to NESRS via the S-356's did not change significantly, there was a marked change in the seasonal flow distribution (from 63 percent dry season flows to 42 percent).
- Stages in NESRS were reduced up to 0.5 ft during April and May.
- A 28 percent increase in discharges to central Biscayne Bay due to increased seepage from WCA-3.
- No effect on LECSA water restrictions and minimal effect on Lake Okeechobee.

B.3.4.8 Miami-Dade County Wastewater Reuse

B.3.4.8.1 Purpose

To estimate the impacts on LECSA-3 water supply and discharges to Biscayne Bay caused by removing the wastewater reuse components.

B.3.4.8.2 General Assumptions

Three simulations were evaluated; ALTD13R and two scenarios based on ALTD13R. The first scenario removed the western re-use component (component

BBB), and the second scenario removed the southern re-use component (component HHH). All other ALTD13R components were kept in the scenarios.

B.3.4.8.3 Major Findings

- Removal of the western component significantly lowered the stages in the Bird Drive reservoir and in L-31N. Removal of the southern component has insignificant effects on these areas.
- Water deliveries from the regional system to Service Area 3, particularly Lake Okeechobee, increased to compensate for the reduced supply from the re-use components.
- Lake Okeechobee stages are lowered during drought events, more so when the western re-use component is removed. Additional occurrences of ecologically undesirable low Lake stage events resulted.
- Locally-triggered water restrictions in LECSA-3 increase from 5 to 12 when the southern re-use component is removed. No change in locally-triggered restrictions occurs when the western component is removed.
- Lake Okeechobee and dry season - triggered restrictions in all the LECSA's increase slightly when the western reuse component is removed.
- Removal of the southern component reduces discharges to central and southern Biscayne Bay by 12 percent (25 kac-ft/yr), and 34 percent (94 kac-ft/yr), respectively.
- Removal of the western component has lesser impact on Biscayne Bay. Discharges to central and southern sections decrease by 6 percent (13 kac-ft/yr), and 3 percent (8 kac-ft/yr), respectively.
- The removal of the western reuse component results in a decrease in the S-356A&B discharge of about 40 kac-ft/yr (from 264,000 to 224,000). A reduced inflow to ENP from central Shark River Slough also resulted. No difference in ENP inflows occurs when the southern reuse component is removed.
- The number of low water, high water, and inundation events in Northeast Shark River Slough changes marginally when the reuse components are removed.

B.3.4.9 Partitioning Lake Okeechobee Scenario

B.3.4.9.1 Purpose

To estimate region-wide impacts caused by partitioning Lake Okeechobee into two compartments: one for water supply and flood flow storage and one for the preservation of the littoral zone. However, the analysis of this scenario was hydrological only. No ecological, water quality, or engineering analysis has been conducted for this scenario.

B.3.4.9.2 Assumptions

- Three simulations were evaluated: (1) the future without plan condition (aka 2050 Base), and two split-lake scenarios; (2) the 2050 Base with the Lake partitioned but without Supply-side management, and (3) the 2050 Base with the Lake partitioned but with a Supply-side management plan included.
- The SFWMM net inflow time series for the Lake was assumed to be split 60 percent to the western (littoral) compartment and 40 percent to the eastern compartment. Therefore, the areas of the western and eastern compartments were modeled to be 60 percent and 40 percent of the total lake area, respectively.
- The western compartment was managed to provide maximum benefit for the littoral zone. A single line regulation schedule ranging from13.5 -to 15.5 ft, NGVD was assumed. Excess water above this schedule was routed to WCA-3A via STA-3&4. A 4,000-cfs pump was modeled to lift any additional excess water to the reservoir compartment.
- The eastern compartment had no regulatory discharge rule. Its primary purpose is to meet water supply needs for agriculture, urban and environmental uses.

B.3.4.9.3 Major Findings

- Significant reductions in the mean annual percentage of Lake Service Area demands not met.
- Increased carry-over storage capability of the reservoir compartment. Stages ranged from 1 to 34 ft, NGVD.
- Significant improvement in the littoral zone. The number of ecologically undesirable lake stage events decreased from 12 to 5.
- Discharges of excess water to the WCAs more than doubled and there were no discharges of excess water to the St. Lucie or Caloosahatchee estuaries. A greater than 20 percent reduction in the number of months that the high flow criteria for both estuaries was exceeded.
- Hydropatterns in the WCAs and ENP improved.
- The number of LECSA water restrictions triggered by Lake Okeechobee was reduced.

B.3.4.10 Lower East Coast Public Water Supply Scenarios

B.3.4.10.1 Purpose

To investigate the sensitivity of the regional system to different Lower East Coast public water supply demands. Three scenarios utilizing Alternative 5's components were simulated, theses included:

- No LEC public water demands (ALT5NOPWS)
- Reduced public water demands based on the 95 Base (ALT95BSPWS), and
- Alternative 5 demands doubled (ALT52XPWS)

B.3.4.10.2 General Assumptions

- In ALT52XPWS, extractions from the same wells as in Alternative 5 were assumed to satisfy the increased demand.
- LEC irrigation demands were assumed the same as in Alternative 5 in each case.
- The same urban landscape irrigation demand was utilized in all 3 scenarios (turning this demand off in the no public water demand scenario would have resulted in unintended increased groundwater withdrawals to meet unsaturated zone demands).

B.3.4.10.3 Major Findings

- Decreasing the public water demand to zero resulted in relatively small benefits to other parts of the regional system and a large increase in flow to tide.
  - Lake Okeechobee levels increased marginally.
  - Overland flow increased; 5 percent (+43,000 ac-ft/yr) across Tamiami Trail, 12 percent (+123 kac-ft/yr) in Shark River Slough and 8 percent (+13 kac-ft/yr) into Florida Bay. Flow from the LEC through structures to the ENP increased 27 percent (+161 kac-ft/yr).
  - Flow to tide from the LEC Service Areas increased 41 percent (+905 kac-ft/yr) indicating that under Alternative 5 local runoff and local storage are used extensively to recharge the aquifer and supply public demand.
  - LEC water supply from the regional system decreased; 80 percent (-70,000 ac-ft/yr) from the WCA's, 27 percent (-15 kac-ft/yr) from Lake Okeechobee, and 99 percent (-66 kac-ft/yr) from reservoirs.
- Decreasing public water demand to that of 95 Base demands had similar, but less noticeable effects than by reducing the demands to zero.
  - Overland flow increased; 2 percent (+16 kac-ft/yr) across Tamiami Trail, 5 percent (+55 kac-ft/yr) in Shark River Slough and four percent (+6 kac-ft/yr) into Florida Bay. Flow from the LEC through structures to the ENP increased 13 percent (+77 kac-ft/yr).
  - Flow to tide from the LEC Service Areas increased 12 percent (+262 kac-ft/yr)
  - LEC water supply from the regional system decreased; 30 percent (-26 kac-ft/yr) from the WCA's, 20 percent (-11 kac-ft/yr) from Lake Okeechobee, and 45 percent (-30 kac-ft/yr) from reservoirs.

- Doubling the public water demand caused relatively large effects on Lake Okeechobee, the Water Conservation Areas, the ENP and the LEC Service Areas.
  - Lake stages dropped by 1.5 to 2.0 ft on several occasions and the time that the Lake was below 14 ft increased from 14 to 34 percent. The lake regulatory releases decreased by 24 percent (183 kac-ft/yr).
  - Water levels in south WCA-1, WCA-2B, WCA-3B and Shark River Slough were lowered. Hence, improving ponding matches in the WCA's and ponding matches in the ENP.
  - Overland flow decreased; 17 percent (-149 kac-ft/yr) across Tamiami Trail, 22 percent (-242 kac-ft/yr) in Shark River Slough and 12 percent (-20 kac-ft/yr) into Florida Bay. Flow from the LEC through structures to the ENP decreased 40 percent (-239 kac-ft/yr).
  - Flow to tide from the LEC Service Areas decreased by 23 percent (-516 kac-ft/yr)
  - LEC water supply from the regional system increased substantially; nearly four-fold (+250 kac-ft/yr) from the WCA's, 3-fold (+166 kac-ft/yr) from Lake Okeechobee, and 170 percent (+122 kac-ft/yr) from reservoirs.
- The western portions of the regional system such as Holey Land and Rotenberger WMA's, the BCNP, western WCA-3A and the western ENP were unaffected by changes in public water demands.

B.3.4.11 Modification of L-31N and C-111 Canal Stage Operations

B.3.4.11.1 Purpose

To estimate impacts on ENP hydropatterns and south Miami-Dade County water levels caused by lowering the flood control stages in the L-31N and C-111 canals. This effort was performed as part of the development of Restudy Alternative 4. The operational criteria evaluated in this effort were utilized for Alternative 4 and subsequent Restudy alternatives.

B.3.4.11.2 General Assumptions

Two simulations were evaluated; Alt3 and Alt3 with about 0.5 to 1.0 feet lower canal stage operations. G-211 operations were about 0.5 ft lower. S-331, which in Alt3 was closed during the wet season, was opened during the wet season in the L31FC simulation. S-176 operations were lowered about 1.5 ft. S-332A, B, D pumping began about 0.7ft lower. And operations at S-177 and S-18C began about 0.9ft lower. For further details on specific assumptions, refer to ***Table B.3-2*** in the section; Special Investigations: Details (***Section B.3.5***). Note that the canal stage operations for Alt3 were generally higher than those currently used for the actual operations.

B.3.4.11.3 Major Findings

- L-31N Canal stages upstream of S-174 were about 0.5ft lower for 70 percent of the time.
- Increased pumping at the proposed S-332 structures improved hydropatterns in ENP adjacent to the L-31N and C-111 Canals south of S-331. However, much of the increased pumpage was due to an increase in seepage from ENP eastward to L-31N, particularly during the wet season. More-detailed analyses of the localized impacts to marsh hydropatterns near the canals are necessary.
- Water budget results indicate a net increase in flow to ENP as a result of lower canal stage operations.
- Peak stages increased in marshes west of L-31N and in the marshes east of C-111 south of Florida City. Peak stages east of L-31N in the developed areas were lowered.
- Although the regional-scale simulation (2 mile x 2 mile) is too coarse to assess site-specific changes in flood risk, the results indicate lower water levels in the agricultural lands east of L-31N and C-111. Thus, there may be some decrease in flood risk in the region. Site-specific inferences cannot be made until a more-detailed analysis using finer-scale models is performed.

B.3.4.12 Sea Level Rise

B.3.4.12.1 Purpose

To simulate the effect that a sea level rise of 0.5 feet would have on the 2050 Base case. This effort was performed prior to simulation of the alternatives and was posted on the HPM web page (October 14, 1998). Further details of the scenario are presented in the section, Special Investigations: Details.

B.3.4.12.2 General Assumptions

The sea level boundary condition was adjusted to be 0.5 ft higher than that of the 2050 Base. Coastal canal levels were maintained 0.5 feet higher where feasible, and the initiation of flood control releases were delayed to permit the maintenance of higher canal stages. The water level at which maximum releases were made was not altered. Trigger levels for water use restrictions (cutbacks) were also raised by 0.5 ft except for one interior trigger in Palm Beach County.

B.3.4.12.3 Major findings

- For the Lower East Coast, water use cutbacks increased significantly with sea level rise, particularly in LECSA1 and LECSA2 where the number of months of cutbacks more than doubled.

- Water supply deliveries increased significantly in order to maintain the canals at higher stages.
- Mean groundwater levels and peak stages were increased in the lower East Coast flood protection area indicating a potential increase in flood risk with sea level rise.
- The hydrology of the interior regions was largely unaffected by sea level rise
- Estuaries would likely be impacted by sea level rise, but the additional volume of water that would be needed by the estuaries to maintain 2050 Base salinity levels was not determined.

B.3.4.13 Water Conservation Area Decompartmentalization Scenarios

To assist with the design of components for Alternative 4, three WCA decompartmentalization scenarios were developed and simulated utilizing the SFWMM. These 3 scenarios are intended to provide preliminary indications of the benefits and possible inadvertent consequences of removing levees and water control structures from the C&SF Project. The three scenarios progressively remove more C&SF Project components and use Alternative 3 as the base to build from. Alternative 3 was utilized since it contains the necessary upstream storage facilities, levee under-seepage, and groundwater management features for L-30 and L-31N. Alternative 3 also has the most relevant operational rules for the rain-driven delivery component. The full set of performance measures comparing the three decompartmentalization scenarios was posted on the HPM web page (January 30, 1998). A summary of the results was presented during the Restudy Team meeting in West Palm Beach, February 9, 1998. Hence, details of these decompartmentalization scenarios are not presented in the section, Special Investigations: Details.

Following Alternative 4 (WCA-2A and WCA-2B were still compartmentalized), another scenario was simulated to illustrate the severity of inadvertent consequences that would result by removing the levee, L-35B (separating WCA-2A from WCA-2B). The results were posted on the HPM web page (February 25, 1998). Hence, it is not presented in the section, Special Investigations: Details.

In the process of building Alternative 6, two other decompartmentalization scenarios were simulated based on Alternative 5. These are referred to as Alternative 5 Decomp scenario 1 (DCMP1) and Alternative 5 Decomp scenario 2 (DCMP2). They were posted on the HPM web page on March 31, and April 7, 1998 respectively. They are not presented in the section; Special Investigations: Details.

B.3.4.13.1 Description of Scenarios

B.3.4.13.1.1 WCA 3 Decompartmentalization

Denoted as SO3ALR on performance measure graphics (SOuthern WCA-3A Levee Removal).

This scenario uses the same assumptions and components as Alternative 3, but includes the removal of the following levees, canals, and associated water control structures:

a. L-28 and L-28tieback, L-28 borrow canal, and structures S-344, S-343A&B.

b. L-29 and L-29 Canal, S-12's, S-333, S-334, S-355, S-356 (already relocated to L-31N as part of Alternative3.

c. L-67A&C and L-67A Canal up to the Miami Canal, and structures S-345 and S-151.

The Miami Canal was not removed since it is a necessary feature for providing water supply to Miami-Dade County and the South Dade Conveyance System. The Miami Canal also plays an important role in making environmental water supply deliveries to the north central portion of WCA-3A (north of S-339 and S-340).

Operational changes from Alternative 3 included:

a. Removal of rain-driven trigger gages in northeast and northwest Shark River Slough. These were no longer considered useful since control at L-29 was removed.

b. Removal of the 3A-28 import trigger for bringing water from Lake Okeechobee (note that all the other northern and central WCA triggers were not changed from Alt 3.

B.3.4.13.1.2 WCA 3 and 2 Decompartmentalization

Denoted as CA2ALR on performance measure graphics (WCA-2A Levee Removal).

This scenario used the same assumptions and components as the WCA3 Decompartmentalization scenario, but includes the removal of the following levees, canals, and associated water control structures:

L-38E, L-38W, and L-35B, and structures S11, S-144, S-145, S-146, S-141, S-142, and S-143 (S-34 remains for providing water supply deliveries to LECSA-2).

There were no operational changes from the WCA3 Decompartmentalization scenario.

B.3.4.13.1.3 WCA 3 and 2 and 1 Decompartmentalization

Denoted as SCA1LR on performance measure graphics (Southern WCA-1 Levee Removal).

This scenario used the same assumptions and components as the WCA3&2 Decompartmentalization scenario, but included the removal of the levee that separates the Loxahatchee National Wildlife Refuge (LNWR) from WCA-2A and the associated water control structures:

L-39, and structures S-10A, C, D and E, (Hillsboro Canal and S-39 left intact to provide water supply deliveries to LECSA-1).

Operational changes from the WCA3&2 Decompartmentalization scenario included:

Removing the rule that limited LECSA-1 water supply deliveries based on the difference between WCA-1 stages and Lake Okeechobee stages (this rule is described on the current interim regulation schedule for WCA-1).

B.3.4.13.1.4 L-35B Removal

The scenario denoted as NOL35B on the graphics and maps, was posted to illustrate the severity of the inadvertent consequences that would result from removing the levee, L-35B (separating WCA-2A from WCA-2B). It compares Alternative 4 with the scenario denoted as Alternative 4 with L-35B Removed. A full set of performance measures for this scenario was posted on the HPM web page (February 25, 1998).

B.3.4.13.1.5 Alt 5 Decompartmentalization Scenario 1 (DCMP1)

This scenario utilized the same components as Alternative 5 except for the following:

- Alt 5 was more decompartmentalized by the removal of the weirs between WCA 3A and 3B.
- The Miami, Hillsboro and North New River Canals were removed from the EAA southward.
- WCA-2B water was routed via existing conveyance to NESRS with increased conveyance capacity.
- Interior canals within the Loxahatchee National Wildlife Refuge were removed. The LNWR remained connected to the Lake via WPB Canal with existing capacity

- A conceptual pipeline along the filled in North New River Canal was used for LEC water supply

B.3.4.13.1.6 Alt 5 Decompartmentalization Scenario 2 (DCMP2)

This scenario utilized the same components as Alternative 5 except for the following:

- There are no Lake Okeechobee ASR wells,
- WCA-2B excess discharges are sent to NESRS versus stored in the central Lake Belt storage.
- East-central WCA-3A excess water was stored inside the WCAs (no diversion to central Lake Belt storage area).
- WCA-3B excess was stored inside the WCA's versus diverted to central Lake Belt storage.
- Targets were modified as follows: Discharges to meet target stages in NESRS (average of gages 1 and 2) were provided by S-345 and S-140 discharges. S-140 discharges were triggered by either 3A-4 or NESRS targets.

B.3.5 Special Investigations: Details

B.3.5.1 Caloosahatchee Basin Aquifer Storage and Recovery Sensitivity

B.3.5.1.1 Description of Simulations

A sensitivity analysis of the proposed ASR system in the Caloosahatchee (C-43) Basin was completed using the SFWMM. Model outputs from three simulation runs: (1) 220-MGD Caloosahatchee ASR with 70 percent efficiency; (2) no Caloosahatchee ASR; (3) 220-MGD and Caloosahatchee ASR with 35 percent efficiency; were summarized and compared using the same set of performance measure graphics used in the Restudy. The first or reference model run corresponds to the Restudy ALTD13R that was posted on the Restudy HPM Web page (June 19, 1998). This alternative proposes an ASR wellfield with a total of 22, 10-MGD ASR wells (equal inflow and outflow capacities). The other two models are scenarios derived from the first. Scenario 1 was simulated by having ASR injection and withdrawal capacities equal to zero MGD. The configuration and rules governing the operation of the Caloosahatchee ASR as simulated in ALTD13R was maintained in scenario 2--only the efficiency was changed from 70 to 35 percent. In the SFWMM, the Caloosahatchee ASR efficiencies are applied upon injection so that the size of the ASR "bubble" at the end of each time step truly represents the available storage in the ASR well. The intent or purpose of the Caloosahatchee ASR is defined in the description of Component D5 in ALTD13R.

B.3.5.1.2 Assumptions

For both scenarios , no operational adjustments or physical components were added or substituted to compensate for the reduction in efficiency or elimination of the Caloosahatchee ASR. The remaining components utilized in the scenario runs were identical to the ones incorporated in ALTD13R.

B.3.5.1.3 Summary of Results

Performance measure graphics comparing selected model output summaries are presented next. The reference run is designated as ALTD13R. Scenario 1 (without ASR) and scenario 2 (ASR with 35 percent efficiency) are designated NOCASR and 35CASR, respectively, in the attached graphics. Unless otherwise noted, trends in either scenario are expressed relative to the reference run, e.g. increase in discharge or lowering of stages. The 1995 and 2050 base runs are plotted in all PM graphics for reference only. The major findings in this analysis are shown in the following:

- The annual average injection rate from the reservoir into the ASR well for ALTD13R and 35CASR are similar: approximately 98 kac-ft/yr with a 74/26 percent wet/dry season split. The logic in the model does not reduce or increase the injection of reservoir water into the ASR well as a function of ASR efficiency. (Note: Excess Lake water and C-43 Basin runoff are pumped into the reservoir and not directly into the ASR well.)

- The components of the water budget for the Caloosahatchee reservoir in 35CASR did not significantly change from ALTD13R. Outflow into the ASR well remained fairly constant (see preceding bullet). The water budget for NOCASR; however, shows a more significant change relative to ALTD13R. Reservoir water in ALTD13R that went to the ASR well (98.0 kac-ft/yr) was redirected in NOCASR primarily to: 1) Lake Okeechobee (54.1 kac-ft/yr or +35.4 percent), 2) C-43 Basin (7.1 kac-ft/yr or +16 percent); and 3) C-43 Estuary (4.5 kac-ft/yr or +11.0 percent). Losses due to evapotranspiration, seepage and spillover also increased for the NOCASR scenario (7.6 kac-ft/yr or +5.7 percent). Excess basin runoff pumped into the reservoir decreased (21.7 kac-ft/yr or -5.8 percent) while the lake inflow decreased (2.9 kac-ft/yr or -14.7 percent).

- The average annual supplemental irrigation demand for C-43 Basin is 125.3 kac-ft/yr. Reduction in ASR efficiency by one-half, i.e., from 70 to 35 percent, resulted in a reduction of ASR contribution in meeting basin demand from 31.5 kac-ft/yr to 21.1 kac-ft/yr or about -33 percent. Mean annual deliveries from Lake Okeechobee (36.8 kac-ft/yr in ALTD13R) to C-43 Basin increased by a factor of 25 percent in 35CASR (46.1 kac-ft/yr) and by 64 percent in NOCASR (60.5 kac-ft/yr). Mean annual contribution from the Caloosahatchee reservoir (43.5 kac-ft/yr in ALTD13R) to C-43 Basin did not significantly change in 35CASR but increased by a factor of 16 percent in

NOCASR (50.6 kac-ft/yr). ***Figure B.3-9*** shows C-43 Basin demand-not-met of 2.6 percent, 3.1 percent and 3.6 percent for ALTD13R, NOCASR and 35CASR, respectively. The reservoir-LOK configuration simulated in ALTD13R, given the same set of operating rules, is more effective in meeting C-43 Basin demand than a reservoir-LOK configuration with a less efficient ASR system as simulated in 35CASR.

- On an annual average basis, the Caloosahatchee ASR in ALTD13R released 16.0 kac-ft/yr to meet estuarine requirements. It decreased by 34.7 percent in 35CASR and its contribution was zero in NOCASR. More significantly, both scenarios resulted in four more months with low flow violations (<300 cfs, top graph in ***Figure B.3-10***), and extended dry conditions in terms of maximum consecutive months with flows below 300 cfs (ALTD13R, four months; and NOCASR or 35CASR, six months at the bottom graph in ***Figure B.3-10***). Even with the decrease in performance due to the changes incorporated into the scenario runs, the number of low and high flow exceedances are still better than the recommended targets (***Figures B.3-10*** and *B.3-11*).

- ***Figure B.3-12*** shows the stage duration curve for Lake Okeechobee. (note: The ALTD13R line is located between the lines describing the two scenario runs.) An increased withdrawal from the Lake to meet basin demand (ALTD13R, 78.1 kac-ft/yr; 35CASR, 87.5 kac-ft/yr; NOCASR, 105.1 kac-ft/yr) and satisfy estuarine requirements occurred (ALTD13R, 22.7 kac-ft/yr; 35CASR, 28.4 kac-ft/yr; NOCASR, 33.9 kac-ft/yr). The stage duration curve corresponding to 35CASR is slightly below ALTD13R, which is consistent with the above noted trends in the lake water supply releases to the basin and estuary. However, the lake stage duration curve for NOCASR is slightly above ALTD13R. This occurrence can be explained by an increase from ALTD13R to NOCASR, in the backpumping of excess Caloosahatchee runoff into the Lake (ALTD13R, 153.0 kac-ft/yr; 35CASR, 151.7 kac-ft/yr; NOCASR, 207.1 kac-ft/yr) that more than offsets the increase in a Lake release to meet downstream needs (C-43 Basin and Estuary). The slight increase in Lake storage, from ALTD13R to NOCASR, could have translated into better C-43 Basin and C-43 Estuary performance (refer to Figures B.3-9 and B.3-10, respectively) if a corresponding adjustment in operating rules in conjunction with the removal of the Caloosahatchee ASR had been in place. As mentioned in the first bullet above, the amount of reservoir water injected into the ASR is not a function of the ASR efficiency. More excess water in the C-43 Basin can be diverted into the Lake via the reservoir if there were no ASR, but not with a less efficient ASR.

- The trends observed in ***Figure B.3-12*** are consistent with those in ***Figure B.3-13*** that shows a slight decrease (35CASR) and a slight increase (NOCASR) in the total volume of lake regulatory discharges.

- The performance of the St. Lucie (C-44) Basin changed marginally due primarily to the slight decrease (35CASR) or slight increase (NOCASR) in Lake stage. The C-44 Basin supplemental irrigation demand is 27.7 kac-ft/yr. Demand-not-met for the three runs are ALTD13R, 6.7 percent; 35CASR, 6.8 percent; and NOCASR, 5.2 percent (***Figure B.3-14***). No apparent change in the St. Lucie Estuary performance measures resulted from either scenario runs.

- The EAA did not experience a significant change in its performance in terms of mean annual supplemental irrigation and demand-not-met during the entire simulation period (***Figure B.3-15a***), or during the drought years (1971, 1975, 1981, 1985 and 1989, ***Figure B.3-15b***). The top-right graphs in Figures B.3-15a and B.3-15b show the additional dependence on lake water due to the removal and reduction in efficiency of the Caloosahatchee ASR. (Note: The legend "DMD met by RES" denotes the combined water supply deliveries from a reservoir and an ASR, if any.) On an annual average basis for the entire simulation period, the Lake water supply deliveries to the other, i.e. non-EAA, Lake Okeechobee Service Areas (LOSAs) increased by 9.0 kac-ft/yr (+5.0 percent) and 24.0 kac-ft/yr (+13.4 percent) for 35CASR and NOCASR, respectively (***Figure B.3-15a***). (Note: The combined C-43 and C-44 Basin supplemental irrigation requirement accounts for slightly more than one-half the total requirement for the other LOSAs.)

B.3.5.2 Lake Okeechobee Aquifer Storage and Recovery

B.3.5.2.1 Description of Simulations

The objectives of this analysis are two-fold. The first objective is to estimate the portion of the benefits realized in ALTD13R (Restudy HPM Web Page, June 19, 1998) that are associated with the Lake Okeechobee ASR system. The second objective is to estimate the sensitivity of regional hydrologic system performance to the assumed recovery efficiency of this ASR system.

The proposed Lake Okeechobee ASR system in ALTD13R is composed of a 200-well wellfield, each having a pumpage capacity of 5 million gallons a day (MGD) for a total pumpage capacity of 1000 MGD. This pumpage capacity is assumed to be reversible so that maximum flow to and from the ASR system are equal. The reusable recovery efficiency is assumed to be 70 percent in ALTD13R. In the SFWMM (SFWMD, 1998), the efficiency of the ASR is measured so that the computed size of the freshwater aquifer storage (freshwater bubble created by injection) actually represents the available storage for reuse. In the sensitivity analysis the recovery efficiency is reduced by one-half, or to 35 percent. Key performance measures are compared for the 2050 Base Case, ALTD13R, ALTD13R without Lake Okeechobee ASR, and ALTD13R with reduced Lake Okeechobee ASR recovery efficiency.

B.3.5.2.2 Assumptions

Two SFWMM simulation runs were made:

1. ALTD13R with the removal of Lake Okeechobee ASR,

2. ALTD13R with Lake Okeechobee ASR recovery efficiency reduced from 70 (ALTD13R) to 35 percent in this model simulation.

B.3.5.2.3 Summary of Results

Performance measures graphics comparing selected model outputs are attached (***Figures B.3-16 – B.3-22***). The 2050 Base Case, ALTD13R, ALTD13R with no Lake Okeechobee ASR (NOASR) and ALTD13R with Lake Okeechobee ASR recovery efficiency reduced by one-half (REDEFF) are sequentially displayed on each plot. The major findings of this analysis are as follows:

- **Lake Okeechobee ASR Injection Volumes -**

The average annual injection volume for ALTD13R with a reduced ASR recovery efficiency was decreased from 263.6 kac-ft (ALTD13R) to 246.9 kac-ft (REDEFF). This represents a slight decrease of about 6 percent. This decrease is due to the lower water levels in the Lake, meaning less water available for injection. The logic of the model does not alter the injection of Lake water into the ASR as a function of ASR efficiency. The dry season to wet season injected volumes were split 55 percent/45 percent for both ALTD13R and REDEFF.

- **Lake Okeechobee and Lower East Coast Water Supply**

LOSA sub-areas experienced average annual shortages of about 25 percent in the 2050 Base. ALTD13R reduced these shortages to about 6 percent. Removing the Lake Okeechobee ASR increases the shortages to about 11 percent. When the recovery efficiency of the ASR is cut in half, the percentage of demands not met only decreases slightly from the no-ASR scenario (***Figure B.3-16***). During drought years the water shortages reduce from 33 percent in the 2050 Base to 13 percent with ALTD13R. Removing the Lake ASR only slightly increases the volume of water use demands not met for the selected drought years. This is because the Lake ASR storage is depleted during the drought years. The low efficiency ASR results in slightly worse performance than the NOASR scenario during drought years.

The marginal performance of the lower efficiency ASR (***Figure B.3-16*** and ***Figure B.3-17***) may be explained by comparing the average annual volume recovered to that injected for the two Lake ASR simulations. For the lower efficiency ASR the annual average recovery to injection ratio is 55.3/246.9 or a 22 percent actual recovery. (Note: the computed volume efficiency is less than the assumed efficiency because a large volume of ASR storage exists at the end of the simulation). The ratio for the higher efficiency ASR is 135.7/264.6 or about 51 percent. From another perspective, the annual volume gained from the low efficiency ASR (55 kac-ft) is about one-third of that lost (172 kac-ft), while for the more efficient ASR the average volume gained (136 kac-ft) is almost twice that which is lost (79 kac-ft). Of course, the 2050 Base and the ALTD13R with no ASR had no aquifer injection or recovery.

The number of LECSA water use cutbacks was substantially reduced with ALTD13R. In general, the number of cutback months for ALTD13R are less than 20 percent of those of the 2050 Base except for LECSA3 which was about 25 percent of the 2050 Base. Removing the Lake ASR from the ALTD13R reduced this overall benefit; however, the other components of this alternative still allowed significant decreases in cutback months. The number of cutback months were still less than one-third of the 2050 Base in all LEC Services Areas except LECSA3. The cutback months in LECSA3 were 47 percent of the 2050 Base. The reduced efficiency ASR is only slightly better than the Lake no-ASR simulation for reducing the number of months of cutbacks within the LEC Service Areas. ***Figure B.3-18*** summarizes the cutback months for each LEC Service Areas and for each model simulation. Note that locally-triggered cutback months were nearly the same for the three ALTD13R simulations except for a slight increase by one cutback in LECSA2 for the simulation without the Lake ASR.

- **St. Lucie and Caloosahatchee Estuaries**

ALTD13R reduced from 29 to 2 months where the St. Lucie and Caloosahatchee Estuary salinity criteria were not met due to high flows from the Lake. This is due to the redistribution of Lake regulatory discharges away from the estuaries and to other outlets as illustrated in ***Figure B.3-19***. ALTD13R had only six months where the St Lucie Estuary salinity envelope criteria were violated due to high flows from the Lake. A similar pattern of results was obtained for the Caloosahatchee Estuary. Without the Lake ASR, the number of Zone A discharges to the Caloosahatchee Estuary more than tripled (31 to 95 days), and discharges to the St. Lucie Estuary more than doubled (24 to 65 days). Finally, as would be expected, the lower efficiency ASR was just as effective as the high efficiency ASR in reducing the large, high impact discharges to the estuaries. Additionally, the number of days with high impact Zone A discharges was the same or slightly less for the low efficiency ASR. These performance measures are summarized in ***Figure B-3-20a*** and ***B.3-20b*** for the St. Lucie and Caloosahatchee Estuaries respectively.

- **Lake Okeechobee Littoral Zone**

ALTD13R reduced the number of undesirable Lake water levels from 12 events (2050 Base) to 4 events (ALTD13R). This alternative was especially effective in reducing the large number of undesirable low water levels events of less than 11 feet NGVD from 7 (2050 Base) to 1 (ALTD13R). When the ASR is removed from the Lake (NOASR), the overall number of undesirable events increased from 4 to 9. However, only two of these events are associated with extended periods of Lake water levels below 11 feet. The lower efficiency ASR performs similar to the higher efficiency ASR in terms of reducing the undesirable events for Lake Okeechobee. It does contain one additional event associated with extended periods of Lake water levels below 11 feet. These results are summarized in ***Figure B.3-21***.

- **Everglades National Park**

ALTD13R significantly improves the spatial distribution of flows to ENP compared to the 2050 Base. Removing the Lake ASR increases this magnitude slightly due to the increase in regulatory releases from the Lake to the Everglades. ***Figure B.3-22*** summarizes the changes in annual average flow across Tamiami Trail for each simulation. NESRS (Indicator Region 11) had a significant reduction in the number of undesirable low water events and average duration of each with ALTD13R. Nine events (2050 Base, average duration 6 weeks) of undesirable low water level was reduced to 3 events (ALTD13R, average duration 2 weeks). Removing the Lake ASR (NOASR) reduced the undesirable low water events by 1 from ALTD13R. The average annual flows from the Lake to the Everglades were 161.6, 149.4, 144.6, and 151.2 kac-ft for the 2050 Base, ALTD13R, NOASR, and REDEFF model simulations, respectively. Flows from the EAA storage reservoirs were 0.0, 273.6, 245.4 and 263.4 kac-ft for the same set of model simulations.

B.3.5.3 Everglades Agricultural Area Storage Reservoirs

B.3.5.3.1 Description of Simulations

The simulated scenarios for reservoirs in the EAA were performed to investigate the sensitivity of the regional system to changes in the configuration and size of the EAA reservoir component, as defined for ALTD13R of the Restudy.

B.3.5.3.2 Assumptions

Note that this sensitivity analysis is performed with the assumption that all the components proposed in ALTD13R are in place and fully operational. Other components of the system in ALTD13R, particularly Lake ASR, increase the system's total storage capacity such that impacts of changes in the EAA reservoirs on key performance indicators are minimized. Because of the uncertainty attributed to some of the components proposed in ALTD13R, decisions or interpretations with regard to the importance of the EAA reservoir component or any part thereof must be made with caution. The simulated impacts of changes in EAA reservoir(s) are highly dependent on the state (condition governed by existing and/or proposed operating policies) of the rest of the system in the simulation. The same is true for all the other components analyzed.

All the simulations related to the EAA reservoirs were derived from ALTD13R input data by modifying the size or by completely removing one or more reservoir compartments in the EAA (Component G5). ***Table B.3-2*** summarizes the conveyance capacity factors for the canals north of the reservoir(s), and the configurations for the reservoirs in each simulation. Compartment 1 supplies water for EAA irrigation requirements only. Compartment 2A provides for environmental demands. If no environmental demands are imposed on 2A then it provides for EAA irrigation demands not met by Compartment 1. Compartment 2B provides only for environmental demands. Compartments 2A and 2B are also known as the surge tanks. The outflow from the surge tanks for environmental demands is routed through STA 3 and 4 before entering WCA-3A. A total of four scenarios were simulated and compared to ALTD13R.

Table B.3-2. Scenario Definitions for the EAA Reservoirs Sensitivity Analysis

Run Legend	Canal Conveyance Factor [1]		Compartment Surface Areas (acres)		
	Miami Canal	NNR Canal	1	2A	2B
ALTD13R	3.0	3.0	20,000	20,000	20,000
SGT4020	3.0	3.0	20,000	40,000	20,000
SGT1x20	3.0	3.0	20,000	20,000	0
EAARS	1.0	2.0	20,000	0	0
NEAARS	1.0	2.0	0	0	0

1 = Canal conveyance factor applies only for the portion of the canals north of the reservoir(s) that convey excess Lake Okeechobee water to appropriate reservoir(s).

For the scenarios where Compartments 2A and 2B do not exist, the canal conveyance factor corresponds to the flow-through capacity for discharges from Lake Okeechobee to the Everglades Protection Area (EPA). The flow-through capacity is the same for all the simulations.

Two of the four scenarios (SGT4020, SGT1x20) involve changing the size of the surge tanks only as indicated in ***Table B.3-2***; no major functional component is removed. It is important to note that Compartment 2A, which is the surge tank used first for excess Lake water, increases 20,000 acres in SGT4020 simulation. Compartment 2B, which is used less often, is removed in the SGT1x20 simulation. The EAARS simulation completely removes the surge tanks altogether. The NEAARS simulation takes a step further by removing Compartment 1 as well, hence, no EAA reservoirs remain.

All reservoirs were kept to maximum depth of six feet. In each case, the addition or removal of 20,000 acres of reservoir surface area generates the conversion of modeling cells to wetland or sugar cane land use types, respectively. When a given reservoir is removed, associated inflow and outflow control structures and internal canals are also removed.

Summary of Results

In this analysis, the simulated scenarios are compared with ALTD13R. Significant findings unique to each scenario will be presented first, then findings common to other scenarios will be presented.

1. Increasing the size of Compartment 2A (north surge tank) from 20,000 acres (ALTD13R) to 40,000 acres (SGT4020) results in the following:

- Increase in the diversion of Lake Okeechobee excess water to the surge tanks by about 40 kac-ft/year (***Figure B.3-31***). The additional storage in the surge tanks translates to 28 kac-ft/year increase in outflow from the surge tanks to meet Everglades needs (***Table B.3-4).***
- Slight decrease (10 kac-ft/year) in environmental water supply releases from Lake Okeechobee (***Table B.3-4*** and ***Figure B.3-28***).
- Decrease in EAA runoff south from 610 to 579 kac-ft/year (***Table B.3-4***) and a decrease in LOK water supply volumes, from 174 to 160 kac-ft/year, in meeting EAA demands due to the decrease in the EAA production area.
- Decrease in injection volumes into LOK ASR from 264 to 249 kac-ft/year as a consequence of the increase in diversion of excess LOK water to surge tanks (***Table B.3-4*** and ***Figure B.3-31***), which decreased stages in LOK (<0.05 ft) enough to marginally decrease the opportunity for ASR injection.

2. Removing Compartment 2B (south surge tank) from ALTD13R results in the following:

- Decrease in the diversion of excess Lake Okeechobee water to EAA storage from 278 to 258 kac-ft/year (***Figure B.3-31***). The 20 kac-ft/year decrease in inflow of LOK water resulting from the removal of Compartment 2B is less than the 39 kac-ft/year increase in inflow of LOK water into EAA storage as a result of increasing the size of Compartment 2A by the same acreage (20,000 acres). This is because Compartment 2A is first priority in receiving excess LOK water and is utilized more often.
- Slight increase by7 kac-ft/year in environmental water supply releases from Lake Okeechobee (***Table B.3-4***).
- Increase in EAA runoff south from 610 to 641 kac-ft/year (***Table B.3-4***) and in LOK deliveries to meet EAA demands from 174 to 182 kac-ft/year due to the 20,000 acre increase in the EAA production.
- No change in injection of LOK water into ASR compared to ALTD13R. The 20 kac-ft/year decrease in the diversion into EAA storage of excess LOK water is largely offset by the increase in LOK releases for environmental water supply and in meeting EAA demands. This results in an insufficient change in LOK storage (or stage) to increase the duration of injection of LOK water into ASR wells.

Thus far the analyses have only involved changing the total area of the surge tanks without removing major components that would significantly affect the storage capacity of the EAA reservoir system. No significant system-wide performance gains or losses were obtained from increasing Compartment 2A size from 20,000 to 40,000 acres or from removing Compartment 2B. Varying the size of the surge tanks produced no change in percent of demand not met in EAA (***Figures B.3-33 and B.3-34***). In general, a decrease in the storage capacity of the surge tanks generated a slight increase in flows to WCA-3A, hence, to the ENP (***Tables***

B.3-4 and ***B.3-5***). However, this does not significantly affect the monthly distribution (timing) of overland flow in northern WCA-3A (***Figure B.3-38*** and ***B.3-39***) or in the ENP (***Figures B.3-40*** and ***B.3-41***).

3. The next scenario run removes Compartments 2A and 2B (EAARS). The total storage capacity of the EAA reservoir is significantly reduced. In addition, the ability to remove excess LOK water is also significantly reduced. The significant findings for the EAARS simulation are the following:

   - The EAARS produces the highest stages in Lake Okeechobee than any of the other scenarios (***Figure B.3-26***). The average increase in LOK stage is about 0.25 feet with a maximum increase of 0.5 feet during drought years when compared to ALTD13R. The main reasons for this are: (1) elimination of releases of excess LOK water to the surge tank(s), which averaged over 250 kac-ft/year (Figure B.3-31), in conjunction with (2) Compartment 1 providing approximately 150 kac-ft/year in meeting EAA demands. The diversion of excess LOK water to the surge tanks in ALTD13R occurred before ASR injection. As a consequence of reducing the capacity of the system to remove excess water from LOK, the LOK stages are forecasted to rise above the ASR injection line more often. This increases the volume injected into ASR wells from 264 kac-ft/year (ALTD13R) to 333 kac-ft/year with surge tanks removed (***Figure B.3-31*** and ***Table B.3-4***). Since most of the water injected into the ASR is assumed to be retrievable, more storage is available during dry times for meeting demands, hence, keeping stages in LOK higher. For example, ***Figure B.3-32*** shows a comparison of annual injections and recoveries for the Lake Okeechobee ASR component (SGT1x20 and EAARS). The EAARS not only stores more water in ASR, but also provides more water from ASR to Lake Okeechobee during the years 1977, 1981, and 1990. Note that this is when the ASR in SGT1x20, and most likely the other simulations with surge tanks could not supply any water. As expected, EAARS exhibits the largest mean LOK ASR recovery volume for the drought years (***Table B.3-4***) since the opportunity for ASR injection is the greatest.
   - The higher Lake Okeechobee stages produced in EAARS reflected into higher stages for the North Storage, C-44, Taylor Creek-Nubbin Slough reservoirs, and slightly higher stages in the C-43 reservoir (Figures B.3-42 to B.3-45). The higher stages for North storage, C-44, and C-43 reservoirs are largely a result of the increased opportunity for excess Lake Okeechobee water to be routed to these reservoirs. In addition, backpumping volumes from the C-43 reservoir to Lake Okeechobee, which occurs only when LOK stage is below the pulse zone, decreases slightly (153 kac-ft/year in ALTD13R to 148 kac-ft/year in EAARS) due to the increased stages in Lake Okeechobee. This decrease in C-43 reservoir backpumping contributes to the increase in stages in C-43 reservoir relative to ALTD13R. Similarly, the increase in stages in the Taylor Creek-Nubbin slough reservoir is due to a decrease in outflow from

the reservoir to Lake Okeechobee (93 to 81 kac-ft/year) because LOK stages in EAARS are below the maximum threshold for outflow from the reservoir less often.

- The number of undesirable Lake Okeechobee stage events having stages below 11.0 feet for longer than 100 days increased from 1 to 2 (Figure B.3-30). This is a misleading statistic, however. The reason for this increase is that EAARS breaks another event lasting from May 1981 to June 1982 in the other simulations into two events below 11.0 feet.
- For water supply to Lake Okeechobee service areas, this scenario performs best. The percent of demand not met for the EAA decreased from 5 percent for simulations with surge tanks, including ALTD13R, to 3 percent in EAARS for the entire simulation period. During the drought years, the percentage decreases from 14 percent for simulations with surge tanks to 9 percent for EAARS(Figures B.3-33 and B.3-34).
- The total number of cutback months triggered by the Lake and by the dry season criteria decreased by 50 percent for all service areas (Figure B.3-35). In response to the decrease in regionally triggered cutbacks, the number of locally triggered cutback months increased by one in Service Area 2.
- The dependence on Lake Okeechobee for environmental water supply to the Everglades increased significantly. The volume of LOK environmental water supply releases increased from 149 kac-ft/year in ALTD13R to 296 kac-ft/year in EAARS (***Table B.3-4***). Additionally, LOK water supply volumes to meet EAA demands increased from 174 to 204 kac-ft/year (***Table B.3-4***) due to the elimination of Compartment 2A and the increase in EAA production area due to the removal of the surge tanks. Compartment 2Aprovided 5 kac-ft/year for meeting EAA demands.,. The average total water supply delivery from Lake Okeechobee to EAA and Everglades increased from 323 kac-ft/year in ALTD13R to 500 kac-ft/year for the simulation period, an increase of 177 kac-ft/year (***Table B.3-4***). However, the diversion of excess water to the surge tanks from LOK (***Figure B.3-31***) averaged 278 kac-ft/year in ALTD13R, which no longer occurs in EAARS. The decrease in outflows from LOK to EPA is evident in ***Figure B.3-27***. The Miami Canal (S-354) was used first in delivering excess water to the EAA surge tanks. As a result, nearly 90 percent of the excess water was delivered to the surge tanks via the Miami Canal through S-354. Thus, S-354 flows were effected much more from the removal of the surge tanks.
- In going from ALTD13R to EAARS, Lake Okeechobee flood control releases to the St. Lucie Estuary, Caloosahatchee Estuary, and WCAs increase by 4 (21 percent), 5 (32 percent) and 13 kac-ft/year (13 percent), respectively (Figure B.3-31). The elimination of Lake Okeechobee flood control releases to the EAA surge tanks (278 kac-ft/year) is compensated mainly by large increases in environmental releases to the Glades (147 kac-ft/year), in LOK ASR injection (69 kac-ft/year), in supplemental irrigation to the EAA (20 kac-ft/yr), in flood control releases (21 kac-ft/year) and in Lake evapotranspiration (12

kac-ft/year). The increase in evapotranspiration is a consequence of the increases in Lake stage.

- Total volumes of upstream inflow into the EPA are the lowest in EAARS. The total flow is 1091 kac-ft/year (EAARS) compared to 1135 kac-ft/year (ALTD13R, ***Table B.3-4*** and ***Figure B.3-28***). The increase in EAA runoff south and in LOK environmental water supply volumes totaling 217 kac-ft/year does not fully compensate for the elimination of environmental water supply releases from the EAA reservoirs provided in ALTD13R (See ***Table B.3-4***).
- The decrease in total structural inflow into the EPA and overland flow volumes across the EPA (***Tables B.3-4*** and ***B.3-5***, ***Figures B.3-39 – B.3-41***) translates to slightly lower stages for several of the indicator regions in the EPA (***Figures B.3-23*** and ***B.3-24*** and ***Table B.3-3***). The lowering of weekly stages never exceeds 0.1 feet on average as indicated in ***Figures B.3-23*** and ***B.3-24.***

4. The last scenario, called NEAARS, completely removes all compartments of the EAA reservoir. The EAA production area is similar to the future without project condition. The consequences of this are the following:

- Significant increases in the EAA runoff south. The EAA runoff south increases from 610 kac-ft/year (ALTD13R) to 870 kac-ft/year (NEAARS, ***Table B.3-4***). This increase was the result of transforming 60,000 acres of reservoir back to agricultural land and removing the diversion of EAA runoff to Compartment 1, which was removed in the NEAARS simulation.
- Significant increase in the dependence on LOK for environmental water supply deliveries. The volume of the deliveries increased from 149 kac-ft/year (ALTD13R) to 251 kac-ft/year (NEAARS). The increase in environmental releases in NEAARS is not as great as in EAARS, mainly because the EAA runoff south is so much greater in NEAARS (200 kac-ft/year greater) due to the removal of Compartment 1, that the demand for environmental water supply deliveries decrease slightly (See ***Table B.3-4***).
- The removal of Compartment 1 increases the percentage of mean annual demand not met in the EAA from 5 percent (ALTD13R) to 8 percent (NEAARS, Figure B.3-33). During the drought years, the percentage increased from 14 to 19 percent (Figure B.3-34). The corresponding figures for the 95 Base are 12 percent for the simulation period and 18 percent during the drought years. In NEAARS, Lake Okeechobee is the sole source of water supply to the EAA. The LOK deliveries in meeting EAA demands more than doubles from 174 kac-ft/year (ALTD13R) to 357 kac-ft/year (NEAARS). As a result, LOK stages significantly decrease (approx. 0.5 feet) during dry periods (Figure B.3-26), thus increasing the demand not met in the Lake Okeechobee service area.

- The total inflow to the EPA is the highest in this scenario (***Table B.3-4*** and *Figure B.3-28*) largely due to the increase in the EAA runoff volume south. The total inflow increases from 1,135 kac-ft/year (ALTD13R) to 1225 acre-ft/year, an increase of 90 kac-ft/year into WCA-3A. The stages in eastern WCA-3A increase about 0.1 to 0.2 ft during wetter times (***Figure B.3-23***). The increase in overland flow in northern WCA-3A compared to ALTD13R occurs in the wet season which reflects the timing of the substantial increase in EAA runoff south (***Figures B.3-38*** and ***B.3-39***). However, during the early part of the dry season (October – December), the overland flow volumes in northern WCA-3A are slightly less than the volumes in the simulations with surge tanks (ALTD13R, STG4020, and STG1x20). This is because NEAARS depends solely on Lake Okeechobee for environmental water supply, while ALTD13R, STG4020 and STG1x20 have storage available in the surge tanks, in addition to Lake Okeechobee during the early dry season for environmental water supply deliveries. The effects of these on stages are evident in Indicator Region 17 (south central WCA-3A), where the average duration of high water violations (>2.5 ft. depth) increases from 9 to 11 weeks due to the increased EAA runoff into WCA-3A. Additionally, the average duration of low water violations (<-1.0 ft. depth) also increase from 2 to 4 weeks (***Table B.3-3***). Moreover, the number of low water violations in the northwest corner of WCA-3A (Indicator Region 22) increases by one (5 to 6) and the average duration of low water violations increases from 3 weeks (ALTD13R) to 5 weeks (NEAARS).
- Due to the remoteness of these indicator regions, they do not receive the benefits of increased storage in areas such as the Central Lake Belt region during the dry periods. ***Table B.3-3*** also shows that for eastern WCA-3A (Indicator Region 19), there are 27 events with an average duration of 12 weeks of high water in ALTD13R; and 30 events with an average duration of 12 weeks of high water in NEAARS . The increased volumes of water into WCA-3A get diverted into Central Lake Belt Storage for use during dry periods (***Figure B.3-25*** and ***Table B.3-4***). Farther south, inflows into the ENP with the help of Central Lake Belt storage, increase in the dry season as well.
- The monthly distribution or timing of flows into the ENP is similar to ALTD13R. The result is a 5 percent increase (46 kac-ft/year) in overland flow across Tamiami Trail and 10 percent (26 kac-ft/year) increase in S-356 A & B flows (***Table B.3-4***). The increased flows into NESRS raised water levels in NESRS during dry times (***Figure B.3-24*** and ***Table B.3-3***, Indicator Region 11).
- The total number of LECSA cutback months triggered by Lake Okeechobee and dry season criteria increased from 15 to 40 for the simulation period (***Figure B.3-35***).

5. Findings common to some or all of the scenario simulations are the following:

- The following performance indicators and components of the system in ALTD13R show practically no sensitivity to changes in EAA reservoir: (1) Biscayne Bay flows, (2) LECSA discharges to tide, and (3) regional water supply deliveries to the LEC service areas, but the total number of water restrictions for all LEC service areas increase.
- With the exception of the releases to the EAA reservoirs and to ASR, the inclusion or exclusion of EAA reservoirs does not have a major effect on the magnitude of other flood control releases from Lake Okeechobee. For examples, to the estuaries, to the WCAs, nor to the North Storage facility (Figure B.3-31).
- The performance of Compartment 1 is basically independent of the other two compartments, since they contribute only 1 to 2 percent of the EAA demands. Compartment 1 has priority in meeting EAA demands. Changes in the EAA production area contribute to the variations (138 kac-ft/year in SGT4020 to 149 kac-ft/year in EAARS) in the mean outflow from Compartment 1. The variations in outflow are quite small, since the storage capacity of Compartment 1 does not vary. Note that the Lake Okeechobee deliveries that back up the EAA reservoir in meeting EAA demands vary more (***Table B.3-4***) as a result of the variations in EAA production area, as expected.
- The number of St. Lucie Estuary low-flow criteria exceedances decrease slightly in comparison of ALTD13R to EAARS (***Figure B.3-36***). The decrease is noted by the number of months average flow is less than 350 cfs and is due to higher LOK stages. The number of estuary high-flow criteria exceedances does not change for the St. Lucie Estuary for any scenario.
- The performance of the Caloosahatchee Estuary in terms of low and high flow violations does not change for any simulation when compared to ALTD13R. Only in EAARS does the number of months for which average flows exceeds 2800 cfs decreased from 10 to 9 (***Figure B.3-37***). The change is in events lasting 1 consecutive month only.
- The number of undesirable stage events for Lake Okeechobee remains the same for all of the simulations (***Figure B.3-30***) excepting EAARS, which was discussed earlier.
- This analysis was performed from a hydrologic perspective. The ecological effects of the hydrologic changes in the EAA reservoir system should be assessed to determine their significance.
- The EAA reservoir components are part of a complex system with many components. In general, the Central and South Florida Project is highly complex and interdependent. Although a component is a separate entity, such as the EAA reservoirs, other components in the system respond to changes to a particular component. Changes in the configuration or operations for the EAA reservoir system, which interacts heavily with Lake Okeechobee, EAA, and the Everglades, have potentially far-reaching

consequences. In ALTD13R, additional storage such as LOK ASR and Lake Belt storage compensate for changes in the EAA reservoir performance, lessening the impact of such changes. Thus, the impact of changes in EAA reservoir on any other component depends on the assumed state of the rest of the system.

B.3.5.4 L-8/C-51 Reservoir

B.3.5.4.1 Description of Simulation

Simulation is based on ALTD13R with L-8/C-51 reservoir (component GGG) and its functions completely removed. In ALTD13R the reservoir covers 1,200 acres with a total storage depth of 40 feet. The reservoir is filled with excess water from southern L-8 and C-51 Basins. Subsequently, the water is released from the reservoir to: (1) C-51 when discharges through S-155 are less than 100 cfs (off-peak discharges), and (2) WPB Catchment Area when M-Canal stage is 18 feet NGVD or lower.

B.3.5.4.2 Assumptions

- L-8/C-51 reservoir is removed
- Excess water diverted to the reservoir from L-8 and C-51 Basins in ALTD13R is allowed to go to tide.
- Water supply releases to WPB Catchment Area and C-51 from L-8/C-51 reservoir are now routed from other reservoir/ASR systems or Water Conservation Area 1 and Lake Okeechobee.

B.3.5.4.3 Summary of Results

The removal of L-8/C-51 reservoir results in the following:

- Decrease in water levels by about 0.2 ft. in WPB Catchment Area, as shown in Figure B.3-48. The decrease is not substantial enough to affect stages in Loxahatchee Slough (Figure B.3-49) or the duration of cutbacks in public water use in Northern Palm Beach County (Figure B.3-50).
- Increase in dependence on WCA-1 and Lake Okeechobee for water supply to Service Area 1 (62 to 76 kac-ft/year during drought years, 28 to 38 kac-ft/year over simulation period), as shown in Figures B.3-51 and B.3-52. Figures B.3-51 and B.3-52 also show an increase in recovery from the ASR wells along C-51 with L-8/C-51 reservoir removed. The reservoir provides up to 300 cfs to C-51 when discharges through S-155 are less than 100 cfs, which occurs mostly during the dry season. This causes a decrease in need to recover water from the ASR wells for water supply purposes with the reservoir present, as indicated in ***Table B.3-6***. Note that the total system deliveries to Service Area 1 increase slightly with the reservoir removed. This is because the off-peak discharges the reservoir provided to C-51 are eliminated, resulting in an increase in demand for SA1.
- As seen in ***Table B.3-6***, 67 percent of the diversion of excess C-51 water to the reservoir in ALTD13R occurs in the wet season while over 75 percent of the outflow from the reservoir to C-51 occurs in the dry season. Thus, when L-8/C-51 reservoir is removed, nearly 90 percent of the total increase of 52 kac-ft/year in outflow to Lake Worth Lagoon occurs in the wet season. A comparison of mean daily S-155 discharges during the wet seasons of 1968

and 1995 of the simulations is shown in Figures B.3-53 and B.3-54. Injection of excess water into ASR wells along C-51 increases as well in the wet season (***Table B.3-6***).

Table B.3-6 Average Seasonal Values (thousand acre-feet)

	ALTD13R		NOL8RS	
	Dry Season	Wet Season	Dry Season	Wet Season
Outflow to Lake Worth Lagoon	75	162	81	208
C-51 ASR Injection	38	40	31	47
C-51 ASR Recovery	23	1	31	2
C-51 Diversion to Reservoir	30	61	0	0
Reservoir Outflow to C-51 (off-peak discharges)	65	19	0	0
L-8 Outflow via C-51 to Tide	13	50	20	60

B.3.5.5 Lower East Coast Aquifer Storage and Recovery

B.3.5.5.1 Description of Simulations

A sensitivity analysis of the proposed ASR systems in the LEC was completed utilizing the SFWMM. Outputs from three model simulations were compared.

The first or base model run corresponds to ALTD13R that was posted on the HPM Web page (June 19, 1998). This alternative proposes four major locations for ASR wells in the vicinity of West Palm Beach Catchment Area (WPBCAT), C-51 Canal (C51), proposed Central Palm Beach County agricultural reserve reservoir (CPBRES), and proposed Site 1 reservoir. These ASR systems are one of the many features described in components K6, LL6, VV6 and M6, respectively, of ALTD13R. A recovery efficiency of 70 percent is assumed for all ASR wells. Injection and retrieval capacities are identical in all ASR locations. All LEC ASRs are proposed to be built in LEC Service Area (LECSA) 1. Their magnitudes are shown as follows:

ASR designation*	WPBCAT	C51	CPBRES	SITE1
Size, MGD	50	170	75	150

*ASR designation refers to variable name used in SFWMM to identify the ASR.

The other two model runs are scenarios derived from the base run. Scenario 1 was simulated by having ASR injection and withdrawal capacities equal to zero MGD. The configuration and rules governing the operation of the ASRs as simulated in the base run was maintained in scenario 2--only the efficiency was changed from 70 to 35 percent. In the SFWMM, ASR efficiencies are applied upon injection so that the size of the ASR "bubble" at the end of each time step truly represents the available storage in the ASR well.

B.3.5.5.2 Assumptions

In both scenario runs, no operational adjustments or physical components were added or substituted to compensate for the reduction in efficiency or elimination of the LEC ASRs. The rest of the components incorporated in ALTD13R are identical to the ones utilized in both scenario runs. The modification by elimination or reduction in efficiency of LEC ASRs were done simultaneously in all locations.

B.3.5.5.3 Summary of Results

Performance measure (PM) graphics comparing selected model output summaries follow. The base run is designated as ALTD13R. Scenario 1 (without ASRs) and scenario 2 (ASRs with 35 percent efficiency) are designated as NOLASR and 35LASR, respectively. Unless otherwise noted, trends in either scenario run, e.g. increase in discharge or lowering of stages, are expressed relative to the base run. ALTD13R as the base run should be differentiated from the Restudy 1995 and

2050 base runs. Model output corresponding to the 1995 and 2050 base runs are plotted in all PM graphics for reference only. The major findings in this analysis are:

- For Lake Worth Lagoon, the number of high-flow violations significantly increased in the NOLASR scenario relative to the base run (from 96 to 144). For the same estuary, the 35LASR scenario showed a slight increase in the number of low-flow violations compared to the base run (from 24 to 27, Figure B.3-55).

- Mean annual surface flows to tide did not significantly change for the majority of service areas when ASR efficiencies were lowered from 70 to 35 percent. However, LECSA 1 exhibited an increase in the mean annual wet season and dry season flows to tide when the ASRs were completely removed ((+32 and +28 percent respectively, Figure B.3-56).

- The saltwater intrusion criteria as measured at S-155 (Figure B.3-57) and G-56 were not compromised with or without the proposed LEC ASRs (Figure B.3-58).

The CPBRES and SITE1 ASRs receive water from their respective reservoirs. The duration curves for Site 1 reservoir do not show a significant difference between the base run and 35LASR scenario (Figure B.3-59). The Central Palm Beach County reservoir dried up approximately 3 percent of the simulation period more often with a less efficient ASR (Figure B.3-60). The annual/wet season/dry season injection rates, in kac-ft/yr, for ALTD13R and 35LASR are 55.7 / 39.2 / 16.4 and 55.3 / 38.9 / 16.4, respectively.

- Water restrictions were not effected with or without ASRs in LECSA 1 in terms of the number of months in simulated water supply cutbacks (Figure B.3-61). Locally-triggered cutbacks in Service Area 1 did not exist even without ASRs.

- Figures B.62 and B.3-63 show the average annual regional system water supply deliveries to LEC Service Areas for the entire simulation and the five drought years (1971, 1975, 1981, 1985 and 1989), respectively. The mean annual water supply deliveries, in kac-ft/yr, by source to Service Area 1 during the five drought years are summarized in the table following. The values in parentheses represent the percent contribution of a given source to the total delivery for each model run.

SA-1 Water Supply Deliveries, (kac-ft/yr)

	Model Run		
Source	ALTD13R	35LASR	NOLASR
LEC ASR	125 (60%)	80 (41%)	0 (0%)
WCA/EAA runoff	53 (26%)	71 (37%)	91 (53%)
LEC Reservoir	20 (10%)	21 (11%)	42 (24%)
Lake Okeechobee	9 (4%)	21 (11%)	40 (23%)
Total	207	193	173

- Reducing the ASR efficiencies from 70 to 35 percent will do the following: (1) reduce the ASR contribution by 36 percent (from 125 to 80 kac-ft/yr); (2) increase WCA/EAA runoff contribution by 34 percent (from 53 to 71 kac-ft/yr); (3) approximately maintain the level of contribution from the reservoir; (4) increase Lake Okeechobee (LOK) contribution by 133 percent (from 9 to 21 kac-ft/yr); and (5) decrease the overall supply by 7 percent (from 207 to 193 kac-ft/yr). Additionally, totally the total elimination of ASRs in LEC Service Area 1 will do the following: (1) increase regional delivery (LOK + WCA/EAA runoff) by 111 percent (from 62 to 131 kac-ft/yr); (2) increase reservoir contribution by 110 percent (from 20 to 42 kac-ft/yr); and (3) decrease the overall supply by 16 percent (from 207 to 173 kac-ft/yr).

- Based on stage duration curves, slight lowering of water levels in WCA-1 can be noted as a trend from ALTD13R to 35LASR and from 35LASR to NOLASR for indicator regions 26 and 27 (Figures B.3-64a and B.3-64b). Relative to ALTD13R both scenario runs show that the southern indicator region exhibited greater interannual variation in mean weekly stage compared to the northern indicator region during the first half of the year (Figures B.3-65a and B.3-65b). Inundation duration summaries for indicator regions 26 and 27 in WCA-1 are given in the table following. Both scenario runs show an increase in number of continuous ponding events, a reduction in average flooding duration, and a reduction in average annual hydroperiod.

WCA-1 Inundation Durations (Region 26 and 27)

```
Indicator Region      #Events| Avg Flood Dur(Wks/Event)| Avg Ann Hydper(% of year)
Number  Name                 ALTD13R        35LASR          NOLASR
_______________________________________________________________________________
26    South LNWR           7| 228|  99    12| 132| 98    14| 112|  98
27    North LNWR          16|  96|  95    19|   80| 94    18|   84|  94
```

notes: #Events = number of continuous ponding events over the period of record
Average Flood Duration = [sum(days of ponding)/7]/#Events
Average Annual Hydroperiod = 100 x [sum(weeks of ponding per year)]/[52 x #years]

- The mean annual EAA/LOSA supplemental irrigation for both the entire simulation (Figure B.3-66a) and the five drought years did not change significantly (1971, 1975, 1981, 1985 and 1989, Figure B.3-66b).

- Both scenarios marginally lowered stages in Lake Okeechobee (Figure B.3-67). The NOLASR scenario showed an increase in both the percent (from 9 to 11 percent) and the number of times (from 10 to 13) of low stage or 12 ft, NGVD criteria exceedance. Likewise, the 35LASR scenario showed an increase in the percent (from 9 to 10 percent) but no change in the number of times (10) of low stage criteria exceedance (Figure B.3-68).

B.3.5.6 Removal of North Lake Belt Storage

B.3.5.6.1 Description of Simulation

Simulation is based on ALTD13R with North Lake Belt storage (Component XX) and its functions completely removed. This scenario run is denoted as NONLKB. In ALTD13R the North Lake Belt Storage area covers 4,500 acres with a maximum storage depth of 20 feet. The storage area is filled with excess water from western C-11, C-9 and C-6 Basins. In general, the North Lake Belt Storage provides water to maintain C-2, C-4, C-6 and C-9 and to increase canal discharges to Central Biscayne Bay.

B.3.5.6.2 Assumptions

- Perimeter seepage barrier is completely removed (Figure B.3-69).
- Excess water that is diverted into North Lake Belt storage from C-9 and C-6 in ALTD13R is allowed to go to tide.
- Excess water that is diverted into North Lake Belt storage in ALTD13R from Western C-11 Basin via proposed canal along US 27 (US27S canal in the model) is routed through S-9 into WCA-3A if US27S canal stage is sufficiently high. As in ALTD13R, the outflow from C-11 reservoir is routed directly into US27S canal.

B.3.5.6.3 Summary of Results

The removal of North Lake Belt storage results in the following:

- Significant increase in the dependence on Lake Okeechobee and WCA-3A, for water supply to LECSA3. Figure B.3-70 shows an increase from an average of 41 kac-ft/yr over the simulation period in ALTD13R to 95 kac-ft/yr with North Lake Belt removed. Note that from Figure B.3-70 the remaining 19 kac-ft/yr supplied to SA3 from a reservoir represents the supply from the Bird Drive Reservoir component. The increase in LOK releases is 24 kac-ft on an annual average basis. As a consequence, the stages in Lake Okeechobee decrease slightly during dry periods (up to 0.3 ft.) as shown in the stage duration curve of LOK stages (ALTD13R and NONLKB in Figure B.3-71). One additional undesirable Lake low stage event occurred (Figure B.3-72).
- Increase in total number of Phase 1 cutback months (from 20 to 39) in Service Area 2. Figure B.3-73 shows an increase of eight (from 5 to 13) locally-triggered cutback months and an increase of one (from 5 to 6) LOK stage induced cutback month in Service Area 2. The other LEC service areas experienced only an increase of one LOK stage induced cutback month.
- The increase in locally-triggered cutbacks is due to the inability to maintain canal stages. Minimum stages in C-9, C-6, and C-4, i.e. canals supplied by the North Lake Belt storage reservoir in ALTD13R, are maintained only 90

to 95 percent of the time as opposed to virtually 100 percent of the time in ALTD13R (See Figures B.3-74 through B.3-76).

- Slight increase in demand not met (<1 percent) in LOK Service Area due to the increased dependence on LOK for water supply to Service Area 3 (Figure B.3-77).
- A redistribution of surface water flows to Biscayne Bay. ***Table B.3-7***, which is a supplement to ***Figure B.3-78***, gives the seasonal breakdown of outflows to Biscayne Bay effected by the removal of North Lake Belt Storage. An average of 200 kac-ft/yr of surface water flowed into Central Biscayne Bay in ALTD13R, of which 103 kac-ft/yr was provided by North Lake Belt Storage. Note that North Lake Belt Storage contributed 90 percent of the surface water flow in the dry season (54 out of 61 kac-ft/yr). Thus, the seasonal distribution of flow into Central Biscayne Bay is less desirable without North Lake Belt Storage: 30 percent dry, 70 percent wet in ALTD13R; 25 percent dry, 75 percent wet without Lake Belt; target is 33 percent dry, 67 percent wet. The removal of Lake Belt Storage decreased the total surface water flow into Central Biscayne Bay from 200 to 138 kac-ft/yr. However, the removal increased the total surface water flow from the Miami River north (S-26) and Snake Creek Estuary (S-29) from 165 to 221 kac-ft/yr. This redistribution of outflow resulted in a 6 kac-ft/yr decrease in outflow to Biscayne Bay with North Lake Belt Storage removed. Seasonally the outflow decreased by 10 kac-ft/yr in the dry season and increased by 4 kac-ft/yr in the wet season as shown in ***Table B.3-7***.

Table B.3-7. Seasonal Breakdown of Outflows to Biscayne Bay Effected By Removal of North Lake Belt (1,000 acre-feet)

	Wet Season		**Dry Season**	
	ALTD13R	**NONLKBLT**	**ALTD13R**	**NONLKBLT**

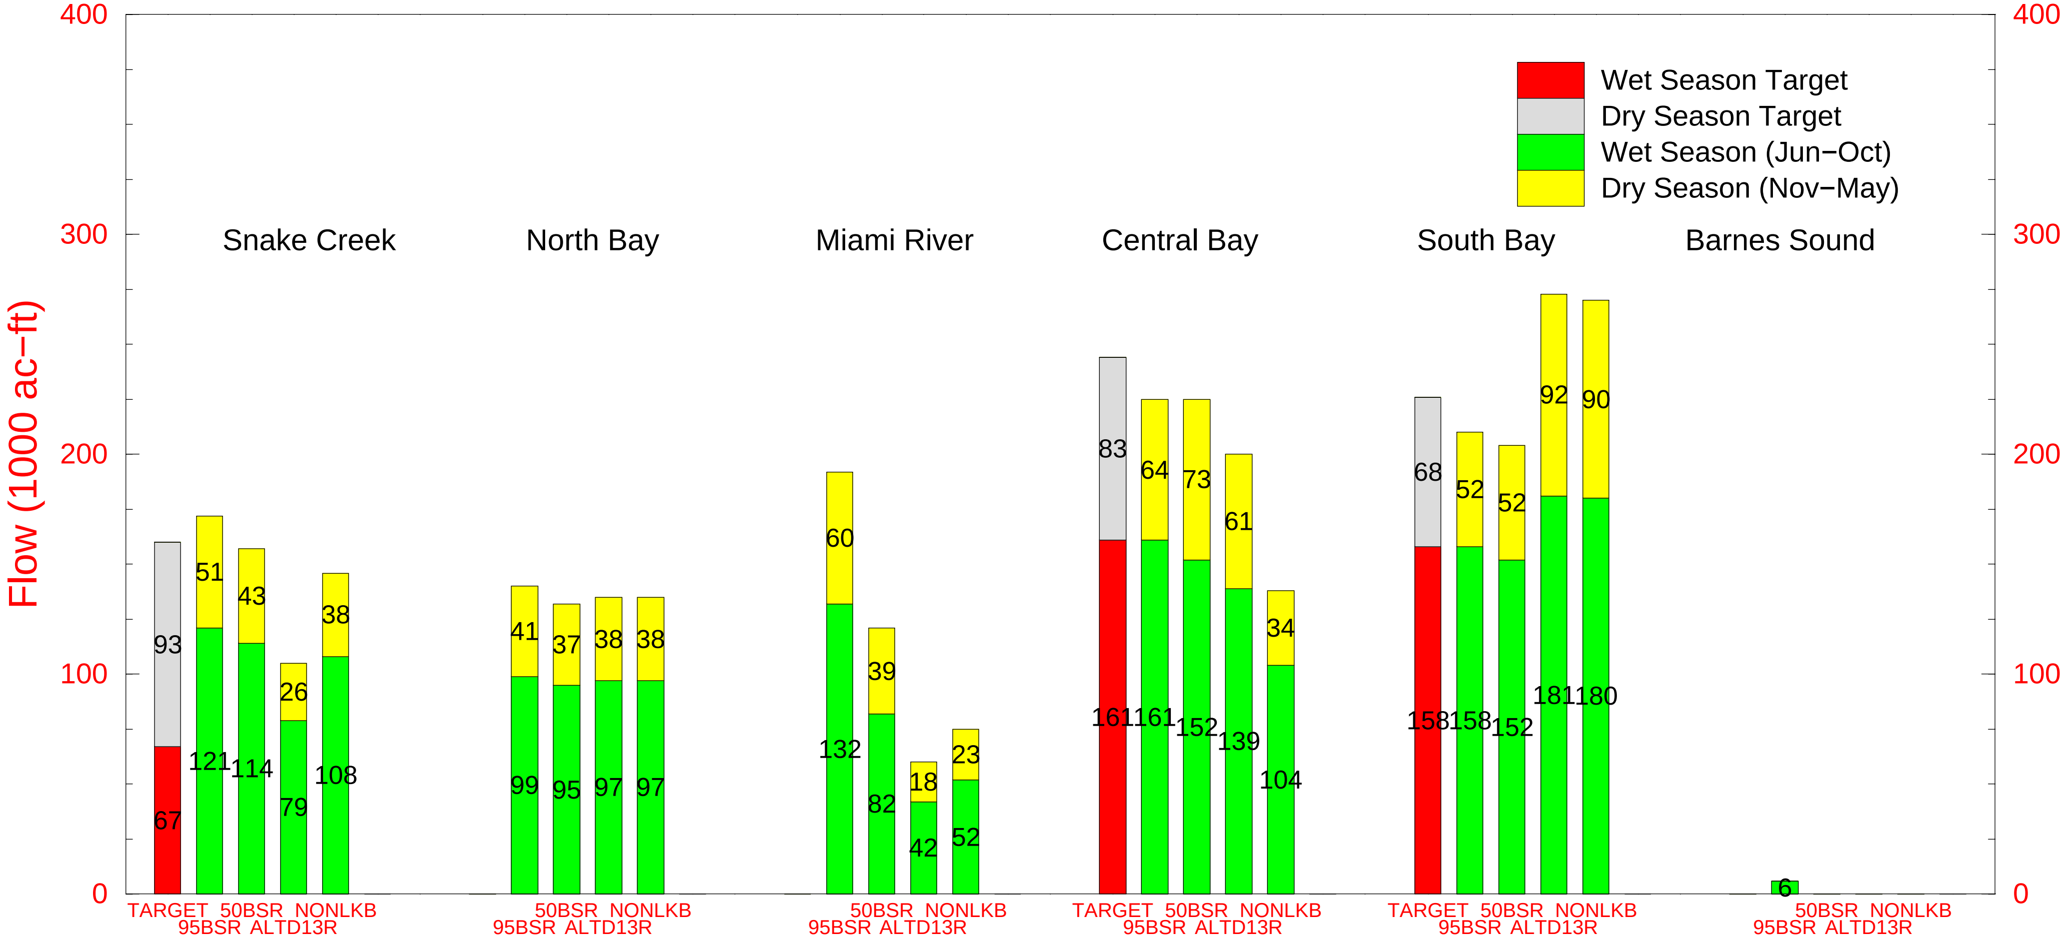
Figure B.3-78 Simulated Mean Annual Surface Flows Discharged into Biscayne Bay for the 1965 - 1995 simulation period



Note: Snake Creek=S29; North Bay=G58+S28+S27; Miami River=S26+S25B+S25; Central=G97+S22+S123; South=S21+S21A+S20F+S20G; Barnes Sound=S197

Targets for Central and South Bay reflect a 30% increase in mean annual dry season flows over the 95 Base

Targets for Snake Creek reflect a minimum monthly flow volume of 13,300 ac−ft (x 5 months for wet season and x 7 months for dry season) to maintain salinity levels below 20 ppt.

B.3.5.7 Removal of Central Lake Belt Storage

B.3.5.7.1 Description of Simulation

Simulation is based on ALTD13R with Central Lake Belt Storage (component S) removed. The scenario run is denoted as NOCLKB. In ALTD13R the Central Lake Belt Storage covers 5,200 acres with a maximum storage depth of 36 feet. The storage area is filled with excess water from WCA-3A and WCA-3B. The area releases water to NESRS via S-356 A/B if the stage at G1502 falls below desired levels.

B.3.5.7.2 Assumptions

- Central Lake Belt Storage (CLBSA) and the perimeter seepage barrier are completely removed (Figure B.3-79).
- WCA-3A and WCA-3B excess water that flows into CLBSA, under ALTD13R, would be sent via borrow canals and the S-356's to ENP with no diversion.

B.3.5.7.3 Summary of Results

The removal of the Central Lake Belt storage results in the following:

- Significant increase in structural outflow from WCA-3A (WC3TLB ***in Table B.3-8***) and in seepage from WCA-3 to LEC, as shown in ***Table B.3-8***. The increased outflow lowered the stages in WCA-3B and eastern WCA-3A during high and low water conditions, as evident in ***Table B.3-10***. The increase in structural outflow from WCA-3A toward ENP is mainly a result of available storage in CLBSA no longer being a limiting factor. Consequently, approximately 10 percent less volume (508 to 450 kaf/yr) of overland flow occurred across Tamiami Trail to NESRS.

- A marked change in the seasonal distribution of flows through S-356 A/B, even though the average annual flow is similar as indicated in ***Table B.3-8***. In ALTD13R the seasonal split is 37 percent wet , 63 percent dry; without Central Lake Belt, the seasonal split is 58 percent wet , 42 percent dry . Reason being that in ALTD13R, 90 percent of the outflow from CLBSA occurs in the dry season when NESRS needs water. This seasonal redistribution of S-356 flows to NESRS from L31N has a direct impact on the seasonal distribution of overland flow westward into NESRS, as shown in Figure B.3-80.

- The preceding discussion translates to a significant reduction in stages in NESRS. Figure B.3-81 shows that the maximum decrease is about 0.5 feet, which occurs during April and May. The effect on durations of inundation and low water conditions in the Shark River Slough region is shown in ***Table B.3-9***. This illustrates the importance of timing in routing excess water to

ENP and the necessity of additional storage in achieving the desired result in ALTD13R.

- Increased surface water flows to Biscayne Bay, as shown in Figure B.3-82. The greatest increase (56kac-ft/yr) is to the central part of the Bay. This result is attributed to an increase in seepage from WCA-3B and groundwater flow eastward caused by the removal of the Central Lake Belt reservoir and its seepage barrier.

- Increased water depths in the Pensucco wetlands during the wettest times (more like NSM) and decreased during the drier times, as shown in Figure B.3-83. This is caused by the shift in timing of available water for NESRS as illustrated by the redistribution of S-356 flows.

- Removal of Central Lake Belt storage had no effect on frequency of water restrictions in LEC and minimal effect on Lake Okeechobee.

Table B.3-8. Average Annual Flow Comparisons at Selected Locations (units are in thousand acre-feet)

Location or Model Flow Variable Name*	ALTD13R	NOCLKB	Change

Note: Normalized stage is stage referenced to Land Elevation. Thus, values above zero indicates ponding while below zero indicates depth to the water table.

B.3.5.8 Miami-Dade County Wastewater Reuse

B.3.5.8.1 Description of Simulations

Both the No West and No South Miami-Dade Reuse simulations (NoWDR and NoSDR, respectively) were derived from ALTD13R by removing the reuse component. For NoWDR a 307.0 ac-ft/day reduction was modeled. For NoSDR a cumulative 402.0 (202.0 + 200.0) ac-ft/day reduction was modeled.

B.3.5.8.2 Assumptions

The reuse components BBB and HHH are physically removed in the proposed scenario runs.

The function of the inflow and outflow rules were not explicitly transformed or redirected elsewhere in the system; however, it is expected that other ALTD13R components will perform differently in an effort to meet system-wide objectives.

B.3.5.8.3 Summary of Results

- Removing the WDR component (NoWDR) lowered the stage in Bird Drive Reservoir two feet for approximately 70 percent of the simulation and between one to two feet for the remaining 30 percent of the simulation (Figure B.3-84). NoWDR also lowered the L-31N Canal stage at S-174 between 0.2 to 0.4 ft for approximately 20 percent of the time (Figure B.3-85).

- Simulated wet and dry season surface flows into Biscayne Bay from LECSA-3 decreased significantly for NoSDR and to a smaller extent for NoWDR. For NoSDR, decreases in mean annual dry and wet season flows were 60 and 62 kac-ft/yr, respectively, as compared to ALTD13R (Figure B.3-86). These decreases were most significant in Central and South Bay (Figure B.3-87)

- NoWDR simulated a five to six month (26-35 percent) increase in the number of water supply cutback months for each LECSA. The increase was primarily due to a Lake Okeechobee SSM trigger with a corresponding dry season trigger that occurred in 1991. NoSDR simulated an eight month (50+ percent) increase in the number of water supply cutback months for LECSA3. This increase was primarily due to an increase of local triggering in 1985, 1988 and 1989 (cutback volumes shown in Figure B.3-88).

- Mean annual water supply deliveries to the LECSA3 for the five drought years increased for both the NoSDR (18 kac-ft/yr) and the NoWDR (23 kac-ft/yr) compared to ALTD13R (Figure B.3-89). For NoWDR, there was also a significant decrease in Bird Drive Basin reservoir contributions (from 108 to 74 kac-ft/yr) to maintain canals in LECSA3 during drought years. This was attributed to the excessive lowering of stages in the reservoir (Figure B.3-84).

For the entire 31 year simulation, LECSA3 supply deliveries for NoSDR increased by 9 kac-ft/yr and for NoWDR by 14 kac-ft/yr compared to ALTD13R deliveries (Figure B.3-90). These supply delivery increases were satisfied by water flow from Lake Okeechobee. In general, NoWDR showed a more significant impact on the regional system's capacity to supply water to LECSA3.

- NoWDR simulated a four percent increase in the number of times Lake Okeechobee experienced minimum stages (Figure B.3-91), as well as an increase in undesirable stage events (Figures B.3-92 and B.3-93). Mean Annual LOSA irrigation demands not met increase by one percent (Figure B.3-94).

- NoWDR simulated a reduction in overland flow through Central Shark River Slough (40,000 ac-ft less, Figure B.3-95) and within the ENP (39,000 ac-ft less to west of L-31N and 37 thousand ac-ft less across L-67) as compared to ALTD13R (Figure B.3-96).

- Indicator region 11 in Northeast Shark River Slough showed the following:

  - One less inundation event (from 7 to 6 events) when the western reuse component is removed, but no change in the average annual percent of time the region was inundated.
  - Three fewer high water events (from 10 to 7 events) when the western reuse component is removed, and one less event (from 10 to 9) when the southern reuse component is removed. The average annual percent of time that the area exceeds the high water criteria (depth > 2.5 ft) does not change significantly (~4 percent of the time).
  - One less low water event (from 3 to 2 events) when the western reuse component is removed, and a slight increase (from 0 to 1 percent) in the percent of time that the area exceeds the low water criteria (depth < -1.0ft). No change resulted when the southern reuse component was removed.

B.3.5.9 Partitioning Lake Okeechobee Scenario

B.3.5.9.1 Description of Simulation

An initial investigation of the effect caused by partitioning Lake Okeechobee into two compartments (split-lake concept) was completed using the 2050 Base Run as a reference. Various system responses simulated with the split-lake concept were compared to 2050 Base . Performance measure graphics presented for this scenario do not show comparisons with any of the other Restudy alternatives.

B.3.5.9.2 Assumptions

Background information regarding the nature of the simulation of the split-lake concept is listed as the following:

- The simulations essentially reflect the Restudy 2050 Base Run with Lake Okeechobee divided into two compartments (littoral on the west and reservoir on the east) by an interior levee. This levee was assumed to be impervious and runs along the 2-foot contour line of the lake bathymetry. It joins the north and southeastern portions of the exterior Lake levee (Hoover Dike) as shown in Figure B.3-97. The littoral and reservoir compartments occupy 60 percent and 40 percent, respectively, of the total Lake Okeechobee surface area.

- A single-line regulation schedule was assumed for the littoral compartment. If the littoral compartment stage exceeds the lower limit of Zone D (proposed WSE operational schedule, Figure B.3-98), then excess water, i.e. the amount beyond what is required from this compartment to meet downstream needs, is routed south to WCA-3A via STA 3/4, subject to conveyance limitations. A 4,000 cfs capacity pump was utilized to lift water from the littoral to the reservoir compartment. Pumping occurred if the regulatory discharge to south was insufficient to bring water levels in the littoral compartment below the regulation schedule.

- No flood control or regulatory release rule was implemented for the reservoir compartment. Its primary function was to meet downstream needs (i.e. environmental, agricultural and LEC water supply) when the littoral compartment stage is below regulation schedule, subject to conveyance limitations. A dead storage concept was applied to the reservoir compartment if the stage decreased below 2 ft, NGVD., When the application was operating, downstream needs could then be met from the littoral compartment, subject to conveyance limitations.

- Supply-side management (SSM) can be implemented for the littoral compartment during times when it is used to meet downstream needs because the reservoir compartment is unable to provide water to meet those needs (stages below 2 ft NGVD). Note that dead-storage can be defined to correspond to zero storage in future split-lake scenarios.

B.3.5.9.3 Significant Findings

Results from two model runs are presented (split-lake with no SSM or SLNSSM and split-lake with SSM or SLWSSM). A standard set of performance measure graphics were generated to evaluate the performance of the two split-lake scenarios relative to the 2050 Base Run or 50BSR. A limited assessment of the feasibility of the split-lake concept can be summarized as follows:

- Significant reductions in the percentage demands-not-met on an annual average basis occurred in the EAA (50BSR, 24; SLNSSM, 1; SLWSSM, 6) and other Lake Okeechobee Service Areas (50BSR, 25; SLNSSM, 7; SLWSSM, 11). The simulation without SSM indicated that conveyance limitations alone contributed to demands-not-met (Figure B.3-99).

- The stages in the reservoir ranged from less than 2 ft NGVD in 1977, 1978, 1981-82, and 1989-91 to more than 25 ft NGVD for over a year starting in 1970 and towards the end of 1995. The carryover storage from the peak event in 1970 lasted over five years (Figure B.3-100).

- Generally, the stages in the littoral zone were much more favorable relative to the 2050 Base Run. Figure B.3-101 illustrates the number of undesirable LOK stage events reduced from a total of 12 in 50BSR to 5 in either split-lake scenarios. Figure B.3-102 illustrates that the percent of time LOK stages exceeded 15.0 ft NGVD decreased from 25 to 16; and the number of times the littoral zone was flooded over 182 consecutive days decrease from 8 to 1. Additionally, the time series of water levels crossed through the desired spring recession window approximately 10 more years (over 31 years of simulation) for either split-lake scenario compared to the 2050 Base Run (Figure B.3-103).

- Minimum stages in the littoral compartment during the simulation period for SLNSSM was about 7 ft, NGVD in 1981-1982 and 1990, and for SLWSSM about 8 ft, NGVD (Figure B.3-100). Both were lower than the 50BSR case. However, the duration of time that the stages in the littoral compartment were below 10 to 12 ft was significantly reduced in both as well. Thus, the long-term range and timing of stages in the littoral zone markedly improved with the split-lake concept. Also, supply-side management policy for the littoral compartment minimizes the number of occurrences of excessively low stage events.

- Short-term dry-outs were less frequent, thus less desirable, in the split-lake runs compared to the 2050 Base Run, as shown in Figure B.3-104. A more logical operation of the littoral compartment should be proposed to circumvent this drawback.

- The cumulative storage over the 31-year simulation for either scenario run was about 2 million ac-ft greater than the total cumulative storage for 2050 Base Run.

- Flood control discharges from the littoral compartment to the Caloosahatchee and St. Lucie estuaries were eliminated, although the discharges south to the WCAs more than doubled (Figure B.3-105). The increase was primarily due to the difference in the regulation schedules utilized in the 2050 Base Run (RUN25 schedule) and the split-lake scenarios (WSE schedule). The WSE schedule commences flood control releases south at levels (range 13.50 to 15.50 ft, NGVD) lower than the RUN25 schedule (range 15.65 to 16.75 ft, NGVD).

- A positive consequence of the increased lake discharges to the south was some improvement in NSM hydroperiod matching for the WCAs and the ENP as a whole, and most of the individual WCAs (Figure B.3-106, B.3-107).

- There was a significant decrease in the number of SSM and dry-season-triggered public water supply cutback months for all LEC Service Areas. Locally-triggered cutbacks for all three runs were essentially equal (Figure B.3-108).

- The average annual LOK water supply deliveries to LEC Service Areas 1 and 2 for the three runs are similar. At the same time surface water delivery to Service Area 3 decreased (Figure B.3-109). This was likely the result of increased LOK releases to the Everglades. This result could be caused by: (1) greater storage in WCA3B and ENP; (2) more seepage across the protective levees into LECSA3, thus effectively recharging the underlying aquifer in the service area; and (3) reduction of water required from LOK and WCAs to maintain LECSA3 canals that provide groundwater recharge to the same aquifer (Figure B.3-110).

- For the Caloosahatchee Estuary, significant reductions in the number of high flow violations were due to the elimination of LOK regulatory releases in the split-lake scenarios . Low-flow violations did not significantly change from 50BSR to either SLWSSM or SLNSSM (Figure B.3-111).

- For the St. Lucie Estuary, the same reductions in high-flow violations were obtained (Figure B.3-112). The number of low-flow violations (monthly average flow <350 cfs) increased from the 2050 Base Run. In all three runs, St. Lucie Basin (C44) runoff was assumed to flow naturally to the west (of S-

308), instead of to the east (of S-80), into the estuary when stages in the Lake (or reservoir for the split-lake scenario) were less than 14.5 ft, NGVD. Most of the increased violations of low-flow criteria were thought to have occurred during the 1970's. This was when the reservoir compartment stage was consistently below 14.5 ft, NGVD. Imposing an explicit minimum estuarine flow requirement that can be met by C-44 Basin runoff can offset this drawback. Note that no minimum estuarine flow requirement is imposed in the 2050 Base Run.

SFWMM V3.5

B.3.5.10 Lower East Coast Public Water Supply Scenarios

B.3.5.10.1 Definition of the Simulations

All the SFWMM simulations included in the Public Water Supply (PWS) sensitivity analysis were built from the Alternative 5 run (ALT5). For each run the LEC PWS demands were modified from the levels specified in Alternative 5 as follows:

ALT5NOPWS: Demands in Alternative 5 were reduced to zero.
ALT595BSPWS: Demands from the 95 BASE case were used.
ALT52XPWS: Demands in Alternative 5 were multiplied by a factor of two.

The first two runs represent a decrease in PWS demands compared to Alternative 5, while the last run is an increase in PWS. The Performance measure graphics compare four runs: ALT5, ALT5NOPWS, ALT595BSPWS and ALT52XPWS.

B.3.5.10.2 Assumptions

The runs were implemented taking into account the following considerations and assumptions:

- Location of PWS wells remained the same for all runs as in ALT5, except for ALT595BSPWS where the PWS wells were located as in the 95BASE.

- LEC irrigation demands remained at the same level for all runs as in ALT5. The PWS demands used in ALT5 included water conservation for the LEC Service Areas listed as follows:
  SA-1: 16 percent SA-2: 18 percent
  SA-3: 18 percent SA-4 (North Palm Beach County): 17 percent

- For all the runs, the same fraction of the urban landscape irrigation demand resulting in a volume of 254.7 kac-ft/yr is supplied from PWS, even though NOPWS turns off public water demands completely. If the volume of the urban landscape irrigation demand supplied from PWS is zeroed, the unsaturated zone will impose an extra load on the groundwater resource to satisfy the landscape irrigation demands. The end result could be to increase groundwater withdrawals when PWS is reduced.

B.3.5.10.3 Summary of Results

The general results are summarized in the following points. In the summary, comparisons are mainly against the ALT 5 run unless otherwise specified.

B.3.5.10.3.1 General

- The results from decreasing PWS were marginal in most of the modeling domain areas. In contrast to the PWS reduction case, an increase in PWS generates more significant effects on several components of the system (e.g. Lake Okeechobee, WCAs, ENP, and LEC Service Areas). The system does not appear to behave linearly under changes to the PWS demands.

- In general, the west portions of the system (e.g. Rotenberger WMA, Holey Land, BCNP, western WCA-3A, and western ENP), were not effected by either change in PWS. The closer a system element was to the Service Areas the more sensitive that element was to changes in PWS.

B.3.5.10.3.2 Lake Okeechobee and Lake Okeechobee Service Area:

- Lake Okeechobee stages marginally increase with a decrease in PWS. An increase in PWS causes a large decrease in stages. Lake Okeechobee is largely effected by an increase in PWS. For example, the percent of the time the stage is at or below 14 ft rises from 14 to 34 percent for ALT5 and 2XPWS, respectively. At some points, the stage drops 1.5 or 2.0 ft. For the same run, regulatory releases from the Lake also decrease by 183 kaf/yr (24 percent) with respect to ALT5. Also, the number of undesirable low stage events increases.

- The percent of demands not met for the Lake Okeechobee Service Areas behaves in a non-linear manner. A decrease in PWS generates a slight decrease in the percent of demands not met, while major increases are observed in the indicator when PWS is doubled. This results from impacts on Lake Okeechobee stages that influence the water use cutbacks in the Lake Service Area.

B.3.5.10.3.3 Remaining Everglades and Big Cypress National Preserve

- Most of the Indicator Regions in the Big Cypress Preserve and the western portion of WCA-3A show no changes in stages when PWS is increased or decreased.

- Most of the Indicator Regions for WCA-1, WCA-2A and eastern WCA-3A show a moderate decrease in stages when PWS is increased, with virtually no variation under PWS reductions. An increase in PWS causes large decreases in stage for south WCA-1, WCA-2B and WCA-3B. Generally, the closer a particular region is to the East Coast Protective Levee, the more effected it is by an increase in PWS demands.

- Indicator Regions for Shark River Slough in the ENP show marginal changes in stages when PWS is decreased. Increased PWS translates into a reduction in stages for Shark River Slough. The stage reductions caused by increased PWS were larger than the stage increases generated by decreased PWS.

- ***Table B.3-14*** shows how flows related to major sections in the ENP behave in different runs. Again, major changes are associated with an increase in PWS. NOPWS generates an increase in magnitude of the flows entering and leaving the ENP. This is caused mainly by an increase in the discharges from the LEC to ENP via the S-332 and S-356 structures.

Table B.3-14 Mean Annual Flows (kac-ft/yr) for Major Sections in the ENP

Run	Overland flow south of Tamiami Trail		Overland flow west Shark River Slough		Overland flow south Florida Bay		Structure flows from LEC	
	Flow	% (*)	Flow	% (*)	Flow	% (*)	Flow	% (*)
ALT5	890		1083		169		598	
NOPWS	933	5	1206	12	182	8	759	27
95BSPWS	906	2	1138	5	175	4	675	13
2XPWS	741	-17	841	-22	149	-12	359	-40

(*) % change with respect to ALT5

- In terms of hydroperiod improvement and matches, no run was identified that would produce a definite improvement for the Remaining Everglades when compared to ALT5. For ponding matches with the NSM, 2XPWS results in an improvement for the WCA system. The ENP is worse in terms of ponding matches when comparing 2XPWS to ALT5. This behavior is the result of less water available in the remaining Everglades, which causes a reduction in ponding depths, or a shift towards smaller depths for the ponding depth distribution. Coincidentally, this results in an improvement for most of the WCAs. Reduction in PWS produces virtually no changes in hydroperiod matches, yielding another example of non-linear behavior of the system.

- An increase in PWS tends to decrease hydroperiods in the WCA system, especially for cells close to the East Coast Protective Levee. Shorter hydroperiods are also experienced in northern WCA-3A and the ENP, especially around NE Shark River Slough and the regions close to the SDCS. A decrease in PWS slightly increases hydroperiods in the northern portion of WCA-1 and around NE Shark River Slough.

- Hydroperiod matches change to shorter durations around Shark River Slough and North WCA-1 when PWS was increased. The changes in the indicators for hydroperiod improvement and matches generated by an increase in PWS tend to be larger than the changes induced by the reductions in PWS.

- An increase in public water demands causes shallower ponding depths in Shark River Slough, WCA-3B and Eastern WCA-3A. A decrease in PWS generates slightly higher ponding depths at the south-western tip of Shark River Slough.

B.3.5.10.3.4 Lower East Coast Service Areas

- The amount of water discharged to tide from the Service Areas increases when PWS is decreased and decreases when PWS is doubled, as shown in ***Table B.3-15*** and ***Figure B.3-113***. Volumes discharged to tide is the only indicator for which decreasing PWS has a larger or similar response when compared to the simulation increasing PWS. The large volumes discharged to tide when PWS is turned off indicates that ALT5 makes large use of local runoff and local storage to recharge the aquifer and supply the public demand. Notwithstanding the good use of local sources noted previously, reductions observed in 2XPWS were still substantial. Note how the effects tend to be more drastic as the analysis moves south from Service Area 4 or North Palm Beach County Service Area to Service Area 3. The slope values in Figure B.3-113 indicate that SA-3 and SA-4 will yield the largest decrease in flows to tide per unit increase in PWS. This is a direct result of the lower subsurface storage capability (lower land elevation and smaller depth to the water table) in Service Areas 3 and 4.

- Duration curves for the indicator regions and individual cells in the LEC illustrate that stages in the Service Areas tend to be <u>equally</u> effected by either reduction or increase in PWS. For LEC individual cells, changes in stage ranged from a small magnitude (up to 0.2 ft) to as high as 2.0 to 3.0 ft (40 percent of cells) in either direction. This was the only indicator that appears to behave linearly with PWS demand changes for most cases. Also, of particular interest for this indicator is the fact that changes for several cells are substantial in both directions. Because of the averaging operation incorporated in the indicator region performance measure, the changes observed in stage duration in the indicator regions are smaller than the ones for the individual cells.

- For some cells in the LEC, ALT595BSPWS will generate stages similar to or lower than those found in ALT5. This is due to the 95 BASE location of the PWS wells. The 95 BASE has more wells located closer to the coast.

- Regional water supply deliveries are directly, but not proportionally related to PWS, as shown in ***Table B.3-16***. When PWS was increased, the amounts required from Lake Okeechobee and the WCA system quadrupled and the dependency on reservoirs increased by a factor of three when compared to ALT5. Note how deliveries from ASR are effected in a different manner when compared to the other sources. The volume of regional water supply deliveries was another indicator, which exemplifies the non-linear behavior of the system. When PWS demands decrease, the dependence on the regional system decreases, but to a much lesser degree than the increase in PWS increases the dependency.

Table B.3-15. Mean Annual Flows (kac-ft/yr) to Tide for each Service Area

SA	SA-1		SA-2		SA-3		SA-4		Totals	
Run	**Flow**	**% (*)**	**Flow**	**% (*)**	**Flow**	**% (*)**	**Flow**	**% (*)**	**Flow**	**% (*)**

(*) % change with respect to ALT 5

Figure B.3-113

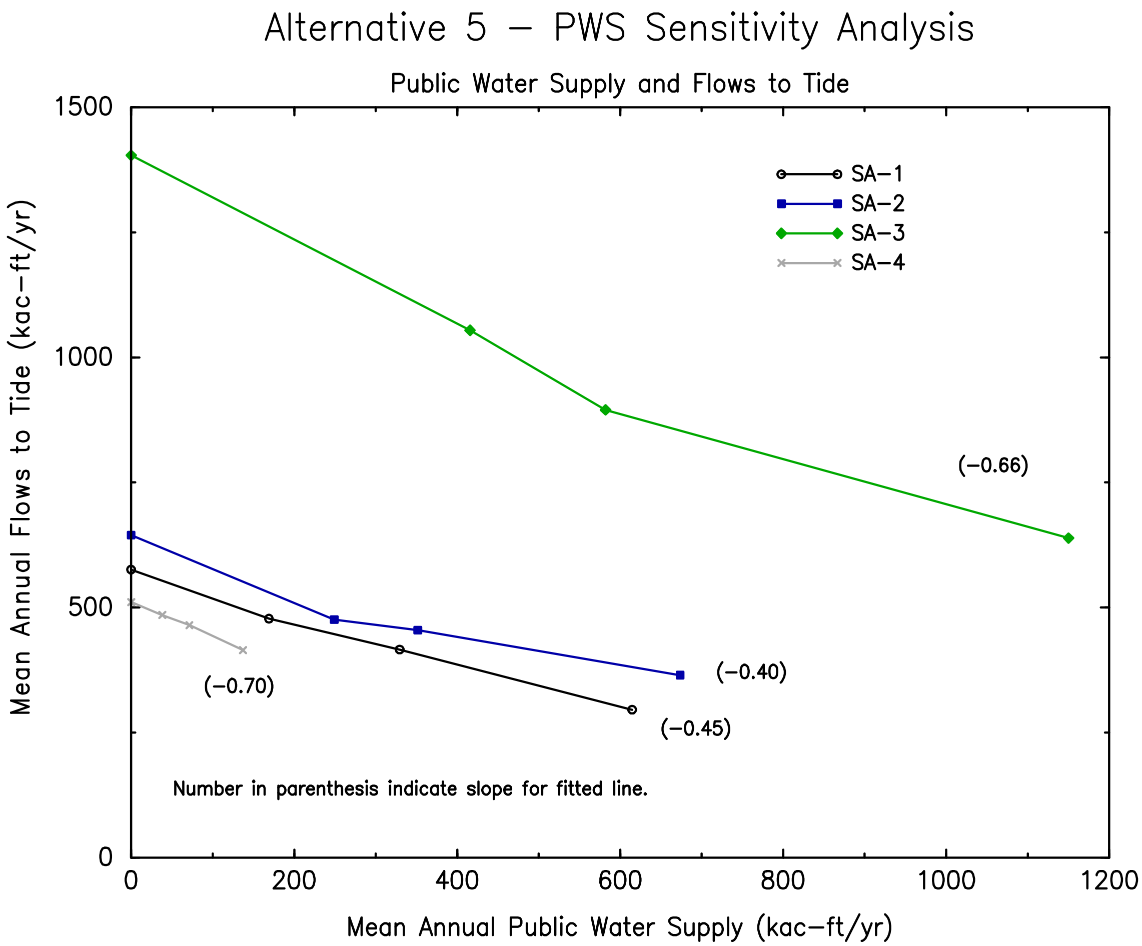

Table B.3-16 Summary of Average Annual Regional Water Supply Deliveries (kac-ft/yr) to SA-1, SA-2 and SA-3.

Run	Source of Deliveries			
	WCA System	Lake Okeechobee	ASR	Reservoirs
ALT5	88	56	103	67
NOPWS	18	41	40	1
95BSPWS	62	45	62	37
2XPWS	338	222	94	179

- An increase in PWS generates substantial increases in the frequency, level and severity of PWS cutbacks for most of the LEC Service Areas (***Table B.3-17***). In some cases, 95BSPWS appeared to increase the frequency of water restrictions. However, this is attributed to well locations in 95BASE that are typically closer to the coast where salt water intrusion trigger wells are more effected. Also, in 2XPWS public water demands are not redistributed in space.

- Even though NOPWS imposes no PWS demands on the system, certain long water restriction periods remain in the simulation. These periods and their duration are identified as follows:
  - LOSA: 16 months, March 1981 to June 1982
  - SA-1: 14 months, November 1977 to May 1978 and November 1981 to May 1982
  - SA-2: 18 months, November 1977 to May 1978, November 1981 to May 1982 and February 1990 to May 1990
  - SA-3:14 months, November 1977 to May 1978 and November 1981 to May 1982
  - SA-4:14 months, November 1977 to May 1978 and November 1981 to May 1982

With NOPWS, other demands, such as LEC irrigation and LOSA demands remain in the system. Also, the model still attempted to maintain the LEC canals at specified minimum elevations so that saltwater intrusion was minimized.

Table B.3-17 summarizes supply and cutback volumes for the LEC Service Areas for the different demand types. It can be easily verified that demands for 2XPWS and ALT5 runs are in a 2:1 ratio. Irrigation demands for the LEC remained constant across the different model runs. As expected, major cutbacks for all type of demands appeared with the 2XPWS run.

Table B.3-17 Supply and Cutback Volumes in (1,000 ac-ft) for different demand types and for each Service Area, for the 1965 to 1995 Simulation Period.

B.3.5.11 Modification of L-31N and C-111 Canal Stage Operations

B.3.5.11.1 Description of Simulation

Simulation or run was based on the ALT3 with modifications to the operational criteria of structures to the south of G-211 on the L-31N and C-111 Canals to lower their stages. The intent of the simulation was to determine the affect on the ENP and the potential reduction in flood risk to the LEC Service Areas resulting from lower canal operational criteria.

B.3.5.11.2 Assumptions

Operational criteria for structures on the L-31N and C-111 Canals were changed for this run (denoted as L31FC for flood control) according to ***Table B.3-18***. Only structures for which the operational criteria are different from those of ALT3 are shown in ***Table B.3-18***. Note that the structure operational criteria depicted in ***Table B.3-18*** changed when the base simulations were revised and ALT3 became Alt. A.

B.3.5.11.3 Summary of Results

- Hydroperiod matches with NSM within the ENP improved from 84 to 90 percent. As a result of the increased pumping through the S-332 structures, several model cells to the west of the C-111 Canal were ponded to within 30 days of NSM in L31FC (Figure B.3-115, compared to hydroperiods 30 to 90 days shorter than NSM in ALT3 (Figure B.3-114).,).

- Groundwater and levee seepage from the ENP to LECSA increased by 31 percent from 292 to 383 kac-ft (***Table B.3-19***). The increase in seepage was more in the wet season (+57 percent) than in the dry season (+14 percent). Increased seepage was due to a larger difference between stages in the ENP and LECSA as a result of L-31N and C-111 Canal stages being operated lower.

- Increased seepage resulted in slightly wetter (closer to NSM) Indicator Regions (IR, refer to Figure B.3-116) to the east of C-111, namely in the C-111 Perrine Marl Marsh (IR 4, Figure B.3-117), and in the North C-111 (IR 47, Figure B.3-118). Similarly, marsh areas to the west of L-31N in the Rockland Marl Marsh (IR 8, Figure B.3-119) and to the west and southwest of C-111 in the Mid-Perrine Marl Marsh (IR-3, Figure B.3-120) and Taylor Slough (IR-1, Figure B.3-121) were also slightly wetter. The North C-111 area was inundated for 407 weeks in L31FC compared with 340 weeks in ALT3 (NSM45P was inundated for 973 weeks).

- Overland flow across the western portion of Tamiami Trail into the ENP decreased slightly (by two percent, ***Table B.3-19***) while structural flow into the ENP increased by five percent (79 kac-ft, ***Table B.3-19***). Increased flow through the S-355 structures (+ 6 percent) was reflected in the relatively small increase (+ 3 percent) in overland flow through the eastern portion of Tamiami Trail. Increased flow at the S-332 structures was as a result of back pumping of the increased seepage. Surface water flows to Biscayne Bay remained unchanged.

- The mean annual water table elevation was higher to the west of the C-111 Canal and lower to the east of the C-111 Canal with L31FC (Figure B.3-123) than with ALT3 (Figure B.3-122).

- Canal stages in the L-31N Canal at S-174 were approximately 0.5 ft lower in L31FC than in ALT3 (Figure B.3-124) for 70 percent of the time.

- Peak stages were higher with L31FC to the west of the C-111 Canal (Figure B.3-125) and in the marsh areas to the east of the C-111 Canal than in ALT3 (Figure B.3-126). In the agricultural areas to the east of L-31N and C-111, peak stages were lower in L31FC than in ALT3.

- Flow down the L-31N Canal through S-331 was almost doubled (+56 kac-ft, ***Table B.3-19***) when the S-331 was no longer closed in the wet season in L31FC. Flows down C-111 through S176 were increased by 40 percent for the same reason. Much of this water apparently recharged the C-111 marsh areas on either side of the C-111 Canal, as there was only a small increase (+3 kac-ft, ***Table B.3-19***) in flow to the C-111 E spreader canal.

- The potential for reducing the risk of flooding to the east of the L-31N and C-111 Canal, with lower canal operational stages is shown in Figures. B.3-127 through B.3-131 that illustrate the stage exceedance frequency curves for selected model cells. Stages were lower at each cell in L31FC than in ALT3. At cell R10 C25 water table elevations were within 1 ft of the surface 2 percent of the time in L31FC compared to 15 percent of the time in ALT3 (Figure. B.3-127). In both cases the water table was within 2 ft of the surface approximately 50 percent of the time. At R13 C25 the water table was within 2 ft of the surface approximately 50 percent of the time in L31FC compared with 65 percent of the time in ALT3 (Figure B.3-128). At R15 C26 the water table was within 2 ft of the surface 15 percent of the time in L31FC compared with 23 percent of the time in ALT3 (Figure B.3-129). At R17 C27 high water table elevations were 2 to 4 ft below the surface with the water table in L31FC, up to 1 ft lower than ALT3 (Figure B.3-130). At R19 C27 differences between L31FC and ALT3 water table elevations were small, with L31FC up to 0.1 ft lower than ALT3 (Figure B.3-131).

B.3.5.11.4 Conclusions and Recommendations

Lower L-31N and C-111 Canal operational criteria have the potential to improve hydroperiods in Everglades National Park due to increased overland flow to the ENP. However, for the most part, increased flow is due to the return of increased seepage. The increase in seepage from the ENP to the LEC improves hydroperiods in the C-111 marsh areas. Lower canal stages decrease the flood potential to the agricultural areas to the east of the canals. It was recommended that lower operational criteria be used for the L-31N and C-111 Canals in ALT4 and subsequent Restudy alternatives.

Table B.3-18. Modifications to C-111 operational criteria. Stages in feet.

C-111 Operational Criteria				As modeled for the C&SF Restudy using SFWMMv3.4

B.3.5.12 Sea Level Rise Scenario

B.3.5.12.1 Overview

The University of Miami Rosenstiel School of Marine and Atmospheric Sciences geologist Harold Wanless (1989) has estimated that sea level rise along Florida's shoreline has accelerated to a rate of 8 to 16 inches per hundred years since 1932. This is more than six times the rate recorded by earlier tide-gauge record and that estimated from geological history for the past three thousand years. However, the recent accelerated rate of sea rise is not unprecedented. Global sea level rise has been occurring at varying rates since the end of the last major ice age fifteen thousand years ago. Average sea level rates as large as 3 to 6 feet per century have lasted for periods of thousands years at a time. It is generally accepted that sea level rise is associated with global warming through several processes including the melting of mountain glaciers and thermal expansion of the ocean waters. Past global warming was likely attributed to such factors as long-term increases in solar energy output and variations of the earth's orbit around the sun. Scientific evidence suggests that in the future anthropogenic activities may also contribute in a significant matter to global warming. Regardless of the cause for the warming, the effect of sea level rise poses a formidable challenge for water resources planning for the future.

The Environmental Protection Agency (EPA) is the lead federal agency for guiding coastal states on planning for sea level rise (Edgerton, 1991). This role is particularly difficult because of the scale and complexity of the interaction of processes on several different scales that are involved. However, the EPA has consulted with a large group of leading experts in the fields of climate variability, oceanography and glaciology to estimate the most probable sea level rise that will likely occur in the future (Titus and Naranyan, 1995). The scientists that contributed to the EPA estimates were generally experts from the National Academy of Sciences and the Intergovernmental Panel on Climate Change. The most probable global sea level rise for the year 2050 was estimated to be 0.5 feet higher than the 1995 level. This EPA estimate does not include the effects of local subsidence, erosion, compression and other tectonic instabilities that may occur at varying rates along the Florida coastlines. These additional factors may cause the relative rate of sea level rise at a particular location to be substantially different and most often at a larger rate than the global rate of sea level rise.

In this regional hydrologic analysis, only the effects of the global sea level rise are being considered. The lower east coast of Florida is generally a stable coastline. In an effort to estimate the effects of expected sea level rise on south Florida's regional water management objectives of the future, the SFWMM was modified to re-simulate the 2050 Base run with the sea level boundary condition adjusted to be 0.5 feet higher than the base condition. One of the major concerns associated with sea level rise is the potential for saltwater encroachment into the coastal freshwater aquifers. The SFWMM is not designed to address the full spectrum of issues that may arise related to the potential for salt water encroachment with a sea level rise scenario. However, by making some rudimentary assumptions an estimate of the potential impacts that sea level rise may have on regional water management issues such as the Everglades hydroperiod restoration and impacts to regional water supply can be realized. It was with this rationale that water levels maintained within key coastal canals during dry conditions were increased by 0.5 feet. This perfunctory increase in canal maintenance levels was considered the minimal adjustment that would be required to offset the saltwater encroachment that may otherwise occur. Notwithstanding, preliminary analysis with density-dependent groundwater models suggest that the canals may need to be maintained at even higher levels to adequately offset the projected 0.5 feet rise in sea level. It should also be recognized that significant infrastructure changes may also be required.

B.3.5.12.2 Evidence of Past Sea Level Fluctuation

Globally sea level rise has been observed during the last century to be at a rate between 0.3 to 0.8 feet per 100 years. Historical global tide gage records supporting this fact exist at the Permanent Service For Mean Sea Level[1].

It is an observed fact that sea level rise relative to most coastal regions in the world is occurring and causing major problems just at the time when rapid coastal development is taking place (Douglas, 1995, 1996).

The Intra-Americas Sea has experienced sea level rise at similar rates as the global average based on 62 tidal gages located in the region of the Caribbean Sea, Gulf of Mexico, Bahamas, and Bermuda (Maul, 1993)

Sea level rise relative to coastlines is often larger than the eustatic (global) sea level rise due to land subsidence and geological instabilities. Sea level rise observed at Key West from 1913 through 1987 was estimated to be about 0.07 feet per decade (Maul and Martin, 1993). This site is particularly noteworthy because it is geologically stable.

In summary, if the sea level along the southeast coast of Florida continues to rise at the same rate that has occurred in the past 100 years, then the projected sea level rise between 1995 and 2050 will be between 0.3 and 0.4 feet. This rate of sea level rise does not include the increase in the sea level rise rate that is expected to occur due to anthropogenic effects.

---

[1] http://www.nbi.ac.uk/psmsl/pmsl.infol.html). As of August 1997, this data base included over 43,000 station-years of record including annual means received from over 1,750 tidal gages around the world. This agency is served by an Advisory Group of leading experts around the world.

Table B.3-20 Relative Rate of Sea Level Rise along the Coastline of Florida (Maul and Martin, 1993)

Location	Rate (inches per century)
Key West	9.8
Miami Beach	9.4
Cedar Key	5.5
Fernandina Beach	8.7
Mayport	7.5
St. Petersburg	11.8
Pensacola	9.5

B.3.5.12.3 Projections of Sea Level Rise For The Future

In 1987 Congress directed the Environmental Protection Agency (EPA) to be the lead Federal Agency for dealing with the effects of global climate change (Edgerton, 1991). Recent research findings by the EPA reports on a probability-based projection for eustatic sea level change that can be adjusted to local tide-gauge trends to estimate the future sea level at particular locations. The projections are based on subjective probability distributions supplied by a cross section of climatologists, oceanographers, and glaciologists. The experts who assisted this effort were mostly authors of previous assessments by the National Academy of Sciences and the Intergovernmental Panel on Climate Change (IPCC).

A summary of the EPA's key findings is listed as follows (all increases in water levels are relative to those at the time the EPA report was published in 1995):

1. Global warming is most likely to raise the sea level 0.5 feet by the year 2050 and 1.1 feet by the year 2100. There is an estimated 10 percent chance that climate change will contribute 1.0 foot by the year 2050, 2.1 feet by 2100, and 3.5 feet by 2200. These estimates do not include sea level rise caused by factors other than greenhouse warming.

2. There is an estimated one percent chance that global warming will raise the sea level by 3.3 feet in the next 100 years and 13 feet in the next 200 years. Large rises in sea level given could occur either if Antarctic ocean temperatures warm by 5°C and Antarctic ice streams respond more rapidly than most glaciologists expect, or if Greenland temperatures warm by more than 10°C. Neither of these scenarios are likely.

3. Along most coasts, factors other than anthropogenic climate change will cause the sea to rise more than the rise resulting from climate change alone. These factors include compaction and subsidence of land, groundwater depletion, and

natural climate variations. If these factors do not change, global sea level is likely to rise 1.5 feet by the year 2100, with a 1 percent chance of a 3.7 feet rise.

B.3.5.12.4 SFWMM Simulation Assumptions

The specific coastal canal water levels maintained higher for the sea level rise scenario compared to the 2050 Base Run are illustrated in ***Table B.3-21***. In certain cases the initiation of flood control releases were also delayed to allow for a higher maintenance level when necessary. However, the water level at which maximum releases were made was not altered. Trigger levels for cutbacks were also raised by 0.5 feet, except for one interior trigger in Palm Beach County.

Table B.3-21 Special Operations for Coastal Canals for sea level rise (ft, NGVD)

B.3.5.12.5 Summary of SFWMM Simulation Results

- **Lower East Coast Service Areas water supply**

Lower East Coast Water Supply Cutbacks are simulated to increase significantly. This was especially true for LECSA1 and LECSA2, where the number

[2] When a range of water levels are listed, the modeling assumption is that the gate of the downstream structure will be gradually opened wider as the water level in the canal increases.

of months of cutbacks more than doubled. Phase two cutbacks occurred more often in LECSA2. The additional number of phase 1 and phase 2 cutbacks are due to the higher groundwater levels where water use cutbacks are triggered. Deliveries to LEC Service Area 2 and 3 increased significantly from the 2050 Base condition to the 2050 Base condition with sea level rise. Water supply deliveries for LECSA2 and LECSA3 also increased. This is due to the higher canal maintenance levels during dry periods in these two service areas.

- **Lower East Coast Flood Protection**

The peak stage difference map illustrates a significant increase in the number of years that peak stages were greater than 0.25 feet the base case along certain major canals in northern Miami-Dade and Broward counties. This indicates a potential increase in flood risk in these areas. Mean water levels were simulated to be higher throughout the same area.

- **Interior Hydrology**

The interior of south Florida does not appear to be significantly effected by a sea level rise of 0.5 feet.. The Lake Okeechobee, northern ENP, and WCAs performance measures illustrate this.

- **Coastal Ecosystems**

Certain coastal ecosystems (for example mangroves along coastal boundary in Miami-Dade County) may be impacted by the intrusion of high saline water. In the ENP for instance, if sea level rise occurs at a slow enough rate it is believed that the mangrove ecosystem would be able to migrate inward (Wanless, 1989). However, in the more developed areas of the LEC Service Areas the opportunity for migration may be limited. Estuaries throughout the District may need additional fresh water deliveries to balance increased high saline water entering these valuable habitats. This additional volume if required, is not known at this time. Therefore, it is not included in these sea level rise scenarios.

APPENDIX C
ENGINEERING CONSIDERATIONS AND COSTS

The purpose of this engineering appendix is to evaluate the major project features of each alternative presented in the Central and Southern Florida Project Comprehensive Review Study Feasibility Report (known as the "Restudy"). It is intended that this information will serve as the basis for preparation of future design memorandums and construction plans and specifications relative to the selected alternative.

C.1 SCOPE

The scope of this evaluation includes an investigation of hydrologic, hydraulic, geotechnical, and structural aspects of the major project features and associated components. This assessment considers their technical viability and associated costs related to engineering and construction principles and practices.

C.2 DESCRIPTION OF MAJOR PROJECT FEATURES

Each alternative presented in the main report consists of a combination of major project features and associated components described below. While the quantity, size, and location of each vary between different alternatives, their basic intended function remains the same.

C.2.1 Water Preservation Areas

Water preservation areas (WPA) are above ground storage reservoirs. They consist of relatively flat landmasses surrounded by impoundment levees to retain water and prevent un-regulated flows into and out of the area. They can serve a variety of purposes including potable water supply, environmental water supply, flood control, aquifer recharge, and recreation.

C.2.2 Aquifer Storage and Recovery

Aquifer storage and recovery (ASR) is a water management technology whereby underground aquifers are used as a reservoir to store excess water which later is withdrawn for use. In areas such as central and southern Florida where water availability is limited on a seasonal basis, excess water can be stored in the subsurface during wet periods and later withdrawn during dry periods to meet demands.

Current Environmental Protection Agency (EPA) standards require that pre-injection water quality meet primary drinking water standards. Unless an exemption to this requirement is allowed, the use of treatment facilities in conjunction with ASR for injecting collected stormwater will be needed.

C.2.3 In-Ground Reservoirs

In-ground reservoirs are essentially man-made lakes that store excess water for later use. They can serve a variety of purposes including potable water supply, environmental water supply, flood control, aquifer recharge, and recreation. Most areas in the central and southern Florida area have highly transmissive soils. Therefore, in order to store large volumes of water or drawdown the reservoir during dry periods, perimeter seepage barriers are needed.

C.2.4 Stormwater Treatment Areas

Stormwater treatment areas (STA) are synthetic wetlands. These areas rely on the concept of using plant material and microbes to naturally extract excess nutrients and pollutants from incoming water. The water is retained in the STA for a sufficient amount of time to achieve a desired chemical composition before discharging.

C.2.5 Advanced Wastewater Treatment Facilities

Advanced wastewater treatment facilities provide treatment of reclaimed water for direct release into natural areas. The superior treatment technology removes phosphorous, nitrogen, and other nutrients left by normal wastewater treatment processes to provide acceptable water quality.

C.2.6 Associated Components

With all the major features listed above there are associated components that enable them to perform their intended function. These components include:

- <u>conveyance canals</u> - for moving water to and from different locations
- <u>levees</u> - earth barriers to impound water
- <u>pump stations</u> - to regulate water flow from lower to higher elevations
- <u>gravity control structures</u> - spillways and culverts to regulate water flow
- <u>injection wells</u> - wells and pumps with treatment facilities to provide ASR
- <u>cutoff walls</u> - to prevent groundwater movement

C.3 ENGINEERING CONSIDERATIONS

C.3.1 HYDROLOGY

To support the development of alternatives for the Restudy, hydrologic modeling has been conducted using the South Florida Water Management Model (SFWMM). The SFWMM calculates the flow pattern of water across a region beginning with Lake Okeechobee and ending at Florida Bay. The eastern boundary is essentially the coastline while the western boundary ends in Big Cypress National Preserve.

The region is divided into a 2-mile by 2-mile grid pattern in order to determine average overland and groundwater flows and stages for each grid. Daily average depth and flow values are calculated for overland areas including existing Water Conservation Areas and flood control structures. Associated components of the major project features (levees, canals, ASR, structures, etc.) are also included. The predictions of stage and flow are considered adequate for developing estimates of new facilities needed; however, they are not consistent with investigations for detailed design work. It is anticipated that additional modeling will be required for future design efforts.

C.3.2 HYDRAULIC CRITERIA AND DESIGN

The hydraulic design for components in each alternative plan is based on accepted engineering practice and applicable provisions of US Army Corps of Engineers publications. Documents referenced include engineering regulations, circulars, manuals, and the Waterways Experiment Station report “Hydraulic Design Criteria,” relative to the design and construction of civil works projects. Engineering designs and analyses are formulated by utilizing sound engineering judgement, experience gained from past projects and studies, and criteria successfully used for the design of flood control works throughout peninsular Florida. Hydraulic design and analysis assumptions for this study are made to provide a systematic and simplified approach for designing each component. Allotted time and funding limitations restricted the ability to compile the level of information normally required for feasibility reports.

C.3.2.1. Conveyance Canals

Reservoirs and STAs were sited at locations determined by the planning group. Project canals were designed to link reservoirs and STAs with existing canals to minimize the need for lengthy new runs. Topography in most project areas has very small changes in elevation over large distances. Design water surface profiles for canals in south Florida have very small head losses over very large distances. Soils in the project area are subject to erosion when velocities exceed 2.5 ft/sec. Subsequently, slope and velocity are the controlling criteria for channel designs in south Florida. Canals for the project features outlined in this report are sized to carry the design discharge with an average velocity of approximately 1.0 ft/sec. This is based on previous experience with existing canals in the Restudy area. Short canal segments and approach canals to spillways or pump stations are designed to provide velocities of up to 2.0 ft/sec so that real estate requirements can be minimize.

Canal excavation quantities are primarily based on the assumption that the surrounding over-bank areas are completely flat. If topography at the exact site location is unknown, then elevations shown on United States Geological Service quadrant maps are used to determine design stages. It is assumed that excavated material will be used to construct adjacent levees. These assumptions may have to be revised when feature locations are accurately established and topographic surveys are available.

C.3.2.2. Levees

Levees are sized with a top width of 10 ft. Side slopes are assumed at 1 vertical : 3 horizontal. This is a typical average side slope used on many of the existing levees in the study area. The top elevation is set 3 ft above the design water surface elevation. This allows for wave run up, erosion, and a margin of safety from overtopping. Overtopping sections will be chosen at locations that cause the least amount of damage. In some cases the levee dimensions are set to match specific dimensions given in the alternative description. It is assumed that material for the levees can be excavated from adjacent canal construction.

Reservoir containment levees are aligned to conform to topographic features or according to real estate considerations. Levee volumes and depths of storage are determined based on the objective of the project element. If no restrictions are imposed by real estate or topography, the assumption is made that the reservoir or STA area is rectangular in shape with a length twice as long as its width. Levee lengths for designated areas are scaled from current maps. Reservoir depths for components varied from 4 to 10 feet.

C.3.2.3. Pump Stations

Design and operation of pump stations is based on the assumption that new structures will be operated in the same manner as existing pump stations constructed by the Jacksonville District. Main pumping station capacities are sized in one of three ways:

1. To fill water storage areas or reservoirs within a specified amount of time.
2. To match existing permitted flood control pump stations.
3. Based on a specific removal rate from a given drainage area.

4. To return seepage water from a reservoir or STA levee back to the reservoir or STA.

Pumps are designed for up to 10 feet of lift. Total pump capacities are computed by taking average seepage rates through levees and adding them to pump discharges required for flood control and other purposes.

Seepage through levees is based on very general seepage rates ranging from 2.5×10^{-10} to 2.9×10^{-10} cubic feet per second (cfs)/ft/ft for the restudy area. Actual rates could vary considerably depending on site conditions. Seepage pumps are sized to pump one-half of the estimated seepage. Reservoir stages would fluctuate such that the amount of seepage for a "full condition" would rarely need to be pumped. Loss of seepage during high stage times is deemed not to be a critical concern.

C.3.2.4. Gravity Control Structures

Spillways, culverts and other gravity control are assumed to be constructed and operated in the same manner as existing spillways and culverts built by the Jacksonville District. Structures are designed to provide a full range of releases required to meet flood control, environmental management, and water supply goals of the project. Spillways and gated culverts are sized to address one or all of the following criteria:

1. To pass peak discharges and prevent overtopping of project containment levees.
2. To provide discharge capacity required for emptying the component reservoir within a specified amount of time.
3. To provide greater control of water now lost to tide.

C.3.3 SOILS AND GEOLOGY

C.3.3.1. Surface Features

Generally, the topography of central and southern Florida is relatively flat. However, there is a narrow coastal ridge that rises to elevations of 50 feet NGVD, beginning just north of Jupiter Inlet and extending south all the way to Homestead. From this ridge, the ground slopes gently downward in the direction of the Everglades to the west.

The Everglades are "*a flat plane with negligible relief that slopes gently to the south-southwest, from an elevation of about 15 feet south of Lake Okeechobee, to sea level about 75 miles away*" (Randazzo and Jones, 1997). To the west of the Everglades are areas of slightly higher ground known as the Immokalee Rise and the Big Cypress Spur. Further to the west is the Southwestern Slope and then, finally, the Coastal Swamps along the Gulf of Mexico.

C.3.3.2. Aquifers

There are three principal aquifers in the region of the Restudy: the Biscayne Aquifer, the Undifferentiated Surficial Aquifer, and the Upper Floridan Aquifer. The Biscayne Aquifer is a surficial aquifer that extends from the lower quarter of Palm Beach County southward through Broward and Dade County. The Undifferentiated Surficial Aquifer is a shallow aquifer, like the Biscayne, and is present in most of Palm Beach County. The other principle aquifer in the region of this study is the Floridan Aquifer, which is much deeper than the other two aquifers.

C.3.3.2.1. Undifferentiated Surficial Aquifer

The Undifferentiated Surficial Aquifer is a non-artesian fresh-water aquifer that covers much of peninsular Florida. Over most of this area, this aquifer is made up of unconsolidated sand, shelly sand and shell. However, in Palm Beach County this aquifer has many areas that are made up of limestone beds that are similar to the make-up of the Biscayne Aquifer. This aquifer is up to 250 feet thick in parts of Palm Beach County. Transmissivity values as great as 50,000 feet squared per day have been reported in places where this aquifer is thick and permeable (Randazzo and Jones, 1997).

C.3.3.2.2. Biscayne Aquifer

The Biscayne Aquifer is a non-artesian, highly permeable fresh-water aquifer. It is made up mostly of limestone and sandy limestone, and yields large volumes of water. The Biscayne Aquifer is 100 to 400 feet thick in coastal Dade and Broward counties but thins to a few feet near the westward boundary of the counties (Hyde, 1965, R 1975). Transmissivity values greater than 1,000,000 square feet per day were calculated from aquifer tests in Brevard County (Fish, 1988). A thick, clayey confining layer, which in places is up to 1,000 feet thick, underlies the Biscayne Aquifer and separates it from the underlying Floridan Aquifer (Randazzo and Jones, 1997).

C.3.3.2.3. Floridan Aquifer

The Floridan Aquifer not only underlies the Undifferentiated Surficial Aquifer of Palm Beach County and the Biscayne Aquifer of Broward and Dade Counties, but also the entire state of Florida. In north Florida the Floridan Aquifer contains fresh water and is generally continuous from top to bottom. However, in south Florida the Floridan Aquifer contains brackish water, and is a system that is subdivided by a series of confining layers known as the Upper Floridan and the Lower Floridan Aquifers.

The thickness of the Floridan Aquifer and the depth to its upper boundary vary according to location. In West Palm Beach, Broward and Dade Counties, the Upper Floridan Aquifer has a thickness of roughly 100 to 300 feet, and a depth to the upper boundary that varies from about 600 to 1,000 feet beneath the ground surface (Miller, 1990). Also, according to that hydrogeologic cross section, in the regions to the immediate north and west of Lake Okeechobee the thickness of the Upper Floridan Aquifer is on the order of 500 feet, and the depth to its upper boundary is about 400 feet beneath the ground surface. The confining layer between the surficial aquifers and the Upper Floridan Aquifer consists of a layer clayey soils, which in places is up to 1,000 feet thick.

Estimated transmissivities of the Upper Floridan Aquifer vary between 10,000 and 50,000 sf/day in Palm Beach, Broward and Dade Counties, and between 100,000 and 250,000 sf/day in the regions just north and just east of Lake Okeechobee (Bush and Johnson, 1988). Bush and Johnson based these estimates on what they described as aquifer tests, geology, and simulation.

The Upper Floridan Aquifer is separated from the Lower Floridan Aquifer by a layer of relatively impermeable rock. This confining layer is roughly 300 to 500 feet thick in Palm Beach, Broward and Dade Counties, and 800 feet thick in the areas just north and east of Lake Okeechobee. The Lower Floridan Aquifer in Palm Beach, Broward and Dade Counties, and in the areas around Lake Okeechobee, begins at depths ranging from about 1,300 to 1,800 feet and ends at depths ranging about 3,500 to 4,000 feet (Miller, 1990). The Lower Floridan Aquifer is up to 3,000 feet thick and is comprised of a complex system of very permeable rock and a series of confining units. This system contains three permeable zones and two confining units. The confining units consist of low-permeability carbonate rock. The deepest permeable zone of the Lower Floridan Aquifer contains a formation known as the Boulder Zone from a depth of about 3,000 to 3,500 feet.

C.3.3.3. Subsurface Geologic Formations of Aquifer Systems

The aquifer systems in Florida are defined primarily on the basis of permeability and not on geologic formations. This is because, in any particular aquifer system, the top and base of that aquifer system does not correspond everywhere with the top and base of any single geologic formation.

C.3.3.3.1. Undifferentiated Surficial Aquifer

The Undifferentiated Surficial Aquifer system is present over much of Florida, but is a major source of ground water only in Martin, Palm Beach, Hendry, Lee, Collier, Indian River, St. Lucie, Glades, and Charlotte counties. In southern Florida, this aquifer system is made up of *"beds of shell and sand of the Anastasia Formation, beds of shell and limestone in the Tamiami formation, or limestones in the upper part of the Hawthorne Formation"* (Hyde, 1965, R 1975).

C.3.3.3.2. Biscayne Aquifer

According to Klein and Causaras, *"The Biscayne Aquifer's most productive water-yielding formations are the Fort Thompson Formation, the Miami Limestone, and, locally, the Anastasia Formation"* (Klein and Causaras, 1982). They also stated, *"the Biscayne is underlain by a thick sequence of low-permeability clay beds that are as much as 1,000 feet thick in places and separate the aquifer from the underlying Floridan aquifer system…"* .

C.3.3.3.3. Floridan Aquifer

Based on a chart by Miller (1986), Randazzo and Jones wrote, *"the most permeable and most productive part of the Upper Floridan aquifer consists mostly of the Suwanee and Ocala limestones and the upper part of the Avon Park Formation."* They also reported, *"the Lower Floridan aquifer consists mostly of the lower part of the Avon Park Formation, the Oldsmar Formation, and the upper part of the Cedar Keys Formation."*

C.3.4 GEOTECHNICAL

C.3.4.1. Above-Ground Impoundments

There are several above-ground impoundments included in the Restudy. The components for which the largest above-ground reservoirs are planned are North of Lake Okeechobee storage (component A), EAA storage (component G), Caloosahatchee storage (component D), and St. Lucie storage (component B). The maximum depth of impoundment ranges from 4 feet (components Q and R), to 12 feet (component VV).

The local geologic information indicates that the surficial soils throughout south Florida are not very deep and that they are underlain by very permeable shallow aquifers. Therefore, core borings and field permeability tests will have to be drilled in all of these areas to determine the thickness and permeabilities of the surficial soils. If it is determined that the surficial soils do not have low enough permeabilities to hold water in the impoundments, alternative approaches to modifying the bottom of the impoundment areas will be necessary. The least expensive of these alternatives would be to modify the in-situ materials. Other alternatives would be to bring in a material to line the impoundment areas. These materials could be a clay liner or a high density polyethylene (HDPE) liner rolled out over the bottom of the impoundment area.

As previously stated, creating a low-permeability liner by modifying the in-situ materials is the most economical alternative. If the in-situ materials are sandy, this could be accomplished by mixing a small percentage by weight of dry bentonite with the sand. When the bentonite-sand mixture becomes moist, it will create a low-permeability liner for the impoundment area. If the in-situ materials are limestone, the top two feet of limestone could be scraped or ripped by bulldozers, processed in-place by crushing and then compacted by steel-wheeled vibratory rollers to create a low-permeability liner. The processed and compacted in-place limestone may, itself, have an appropriate permeability range to provide for the retention of water while allowing some of the water to recharge the surficial aquifer from the impoundment. If necessary, admixtures such as bentonite or portland cement could be added to the limestone to lower the permeability of the processed and compacted limestone liner.

C.3.4.2. In-Ground Reservoirs

Three in-ground reservoirs are included in the Restudy. These are the C-51 and Southern L-8 Reservoir, located in central Palm Beach County, and the North Belt and Central Belt Impoundment Areas, which are located in the north-central Dade County.

C.3.4.2.1. C-51 and Southern L-8 Reservoir

This site is listed in the Restudy as component GGG. Presently, most of this site is farmland. There is a rock quarry located at the site's north end. The reservoir will be constructed over time as the byproduct of a rock mining operation that is currently in its early stages. Subsurface information is not presently available at this site, but field explorations are planned for the near future. It is currently assumed, based on published geologic data, that the subsurface conditions are similar to those at the Central Lake Belt area. If this is so, the installation of a seepage barrier around the perimeter of the site the installation of a seepage barrier around the perimeter of the site to a depth of about 100 feet beneath the ground surface will be required to prevent the drainage of water from the surrounding surficial aquifer during drawdown of the reservoir. The technology for the design and installation of this seepage barrier is discussed in the paragraph below about the North Lake Belt and Central Lake Belt Storage Areas.

C.3.4.2.2. North and Central Lake Belt Storage Areas

The two in-ground reservoirs planned for Dade County are listed in the Restudy as the North Lake Belt Storage Area (component XX), and the Central Lake Belt Storage Area (component S). Rock mining operations are presently being conducted in both of these areas and will continue for a number of years. However, once mining in these areas is complete, the resulting lakes will be utilized as in-ground reservoirs.

The highly permeable Biscayne Aquifer, from which the mined rock is taken, extends to depths of about 80 feet from the ground surface. This depth is based on the experience of the rock quarries local to this area. Although these quarries will not share proprietary information concerning the depth and quality of rock in their mines, some of their representatives have stated in the past that it is common for them to mine rock to depths of 80 feet and then encounter clayey strata. Based on this information, it was decided that a seepage barrier would need to be constructed so that drawdown of the lake will not result in the draining of the surrounding Biscayne aquifer. The three options considered to constuct a seepage barrier were as follows:

1. Soil-Slurry Backfilled Trench. This would be accomplished be excavating a trench through the depth of the Biscayne aquifer and backfilling around the perimeter of the in-ground reservoir with a soil-slurry mixture.

2. Soil-Slurry Backfilled Trench with HDPE Liner. In this option the seepage barrier would be similar to the soil-slurry backfilled trench. However, a HDPE liner would be installed as part of the seepage barrier.

3. Injection Grouting. In this option, a seepage barrier would be constructed be a drilling and injection grouting operation.

The HDPE liner was considered to be the best option from a constructability standpoint due to the highly porous nature of the Biscayne aquifer and the much greater difficulty of attaining a seepage barrier without leaks by the other methods. The extremely high porosity of the limestone in this formation would make the construction of a seepage barrier be the injection grouting method, without significant leakage, almost impossible to achieve. Achieving a reasonably impermeable seepage cutoff wall by the trench and soil-slurry backfill method would also be difficult due to the likelihood that some of the slurry will be lost in the cavernous limestone along the trench alignment and result in holes in the seepage barrier. Therefore, from a constructability standpoint the HDPE seepage barrier was considered the best option for obtaining an impermeable seepage barrier. Also, the cost of constructing the HDPE seepage barrier would likely be only marginally greater than that of the soil-slurry backfilled trench without the HDPE sheeting. This is because the only difference in the two construction procedures is the placement of the HDPE sheeting prior to the backfilling of the trench. The cost of adding the HDPE sheeting would be marginal compared to that of the total construction procedure.

The HDPE seepage barrier would be installed by the use of a trench excavation machine. This type of machine uses four large cutting wheels, with carbide bits, mounted at the tip of a large boom that is suspended in the excavation by a crane. The excavation is made in consecutive cuts of nine feet. The excavation is made as the cutting wheels of the boom grind the rock and as the boom moves downward under its own weight. The cuttings are removed from the excavation by circulating slurry, which is also used to hold the excavation open. When a nine-foot length of excavation is complete, the boom is removed and a nine-foot section of HDPE liner is placed into the excavation, which is subsequently backfilled with the ground rock that was excavated from the trench. The production rate achieved by a contractor at a job in south Florida was 300 sf/hr.

It is estimated that the HDPE liner would have to be keyed about 20 feet into the confining layer under the Biscayne Aquifer (100 to 120 feet beneath the ground surface) in order to prevent seepage under the liner. It is thought that the clay layer encountered by the local rock mines at depths of about 80 feet, is the confining layer under the Biscayne Aquifer. However, subsurface core boring data will need to be obtained to determine the depth to the confining layer around the rock mines.

When the rock quarry operation is completed some years from now, a levee will be constructed around the site to allow for the storage of water above the present ground level. The levee will most likely be constructed from crushed limerock, which is locally available. Since it is anticipated that seepage through the levee will be minimal, a liner will not be required in the levee above grade. The liner that will be installed beneath the original grade will not only function to prevent the draining of the Biscayne aquifer during draw-down of the reservoir, it will also, in conjunction with the levee, enable the reservoir's water level to be raised above the original ground surface without seepage loss into the Biscayne Aquifer.

C.3.4.3. Aquifer Storage and Recovery Wells

There are six components of the Restudy where ASR wells are proposed. The component in which the largest number is proposed is GG4 - Lake Okeechobee ASR. 200 hundred wells are proposed for this component, each of which will have a capacity of 5 million gallons per day (MGD) for a total site capacity of 1,000 MGD.

The other components for which ASR wells are proposed are the Caloosahatchee C-43 Basin (22-10 MGD wells), the WPA in Palm Beach County (25-5 MGD wells), the Lower East Coast Service Area 1 (34 well clusters where each cluster will consist of two 2.5 MGD withdrawal wells and one 5 MGD ASR well), the Hillsboro Canal Water Preserve Area in Palm Beach County (30-5 MGD wells), and the Agricultural Reserve Reservoir (15-5 MGD wells).

C.3.4.3.1. Description of an ASR Well

The purpose of an ASR well is to store excess freshwater that is available during the rainy season and would otherwise be released out to sea. The concept is to pump the excess water from a surface reservoir into the Upper Floridan Aquifer where it can later be recovered for use during the dry season or during a period of prolonged drought.

In south Florida, the Upper Floridan Aquifer contains brackish water that is not suitable for irrigation or for residential or commercial use. However, the Upper Floridan Aquifer is very permeable and can be utilized as an underground reservoir by pumping in freshwater, within the aquifer, which can be recovered for later use. Mixing of the waters pumped into the Upper Floridan Aquifer with those of the surficial aquifers is not a concern because the Upper Floridan Aquifer is located deep beneath the surficial aquifers, and is separated by a very thick confining layer.

It is estimated that the upper boundary of the Upper Floridan Aquifer is located between 600 to 1,000 feet beneath the ground surface, and that the aquifer is between 100 and 300 feet in thickness. Therefore, an ASR well would have to be drilled to depths of up to 1,300 feet, and perhaps deeper depending on local stratification. The width of an ASR well in the water bearing strata would be between 18 and 24 inches. Wells of such depth have to be drilled to a larger diameter (on the order of 42 inches) at the shallower depths in order to provide room for casing in the upper layers. However, as the casing is sleeved to greater depths the diameter will taper to the design diameter in the aquifer range. The experience of others in Florida has shown that, though casing is required at the higher elevations, a deep well can be left uncased in the aquifer strata because of the strength of the limestone. Well designs will be tested and verified during pilot testing programs.

C.3.4.3.2. Sub-Surface Exploration for an ASR Well – Pilot Wells

Depths of core borings drilled using techniques that are standard in geotechnical engineering are limited between 200 to 300 feet. Because it is anticipated that the ASR wells will be drilled to depths on the order of 1,300 feet, these standard drilling techniques will not be feasible for the purpose of performing a preliminary subsurface exploration for the wells. In fact, deep well-drilling techniques are required to construct borings of such great depth. Therefore, the subsurface will be explored by drilling full-scale pilot wells at the proposed ASR locations. The subsurface information obtained from drilling each pilot well will be used in the design of additional permanent wells that will be constructed at their respective locations.

C.3.4.3.3. Associated Buildings and Facilities

The Restudy will incorporate not only the main features described above, but also the levees, canals, and several buildings and facilities that will work in conjunction with the main features. The buildings and facilities will include pump houses, machine and instrument houses, water control structures, water treatment plants, etc. Geotechnical field explorations will be needed for each of these items in order to have the necessary data to design the required foundations.

C.3.5 ENVIRONMENTAL

C.3.5.1. Stormwater Treatment Areas (STAs)

The designs for the stormwater treatment areas in the alternative plans are based on the same concepts outlined for the Everglades Construction Project (ECP) by Burns and McDonnell (reference 9). The analytical relationship used to calculate effective areas needed to reduce phosphorus levels to the interim target of 50 parts per billion (ppb) was based upon research and observations in Water Conservation Area 2A and developed by Walker (reference 10). The only variation from the parameters used in the ECP calculations involve the period of record. Historical data was not always available from the 1979 to 1988 base period of the ECP; therefore, the data utilized was best available. This similarity to the ECP area computation was intentional to allow easy comparison with Everglades Construction Project even though empirical evidence from the Everglades Nutrient Removal project suggests the parameters may be overly conservative. The primary factors involved in the analytical relationship include surface flow hydraulics, water budgets, nutrient uptake and biological factors. The most significant factors in the computation of the required effective area of the STAs are the mean inflow concentration and volumes, the desired outflow concentration and the effective settling rate constant.

Specific fixed parameters used in the Restudy sizing are taken from the Burns and McDonnell calculations (reference 9) and repeated below:

- The effective settling rate constant is 10.2 meters/year.
- The average annual rainfall is 48.53 inches.
- The total atmospheric deposition of phosphorus is 5 ppb.
- The average annual evapotranspiration loss is 45.26 inches.
- The average discharge concentration of phosphorus is targeted at 50 ppb.

The transposition of fixed parameters from the conceptual design calculations for the ECP to other areas within the Central and South Florida Project is deemed acceptable for the conceptual design stage of the Restudy and readily allows comparison with the stormwater treatment areas of the Everglades Construction Project. Similar methods of wetland treatment area calculations available (Kadlec and Knight) should provide equivalent results.

C.3.5.2. Aquifer Storage and Recovery Water Treatment

The EPA imposes water quality requirements on discharges to groundwater. The strictest requirements are mandated for discharge to potable water aquifers. Lake Okeechobee is an agricultural watershed, so it is impacted by pasture and farming operations that produce run-off containing fecal coliform bacteria such as Eschericia coli (associated with avian and mammalian wastes). These total coliforms will likely be the main factor / parameter guiding treatment requirements in this and other areas sighted for ASR.

Coliform water quality data for Lake Okeechobee is unavailable; however, there is extensive total coliform data for the Everglades Nutrient Removal Project (STA-1 West) located in the vicinity. This area is supplied by discharge canals from Lake Okeechobee. The data shows coliform levels are on the order of 1200 organisms per 100 milliliters. Some level of minimal treatment will be required to reduce these coliforms down to 0 organisms per 100 milliliters.

The South Florida Water Management District (SFWMD) has proposed several approaches to treatment ranging from de minimus to ultra filtration via 20-100 micron disk filters. Future work will investigate the actual coliform numbers and determine if higher degrees of treatment are needed. If required, a least cost treatment method will be proposed.

Coliforms (like all living organisms) have a finite lifespan. They die off at a rate governed by temperature. The following equation provides a rate estimate for the 90% reduction of coliforms by natural processes:

$0.10 = e^{(-K_b\ t_{90})}$ where K_b = decay rate (1 to 5.5 for freshwater and 20 °C) and t_{90} = time in days

$t_{90} = 0.4 \text{ to } 2.3 \text{ days}$

One can see that a 30 day storage period will provide 14 orders of magnitude reduction, which essentially reduces coliform numbers to zero.

The discharge of stored water can also be designed to provide further treatment. By using subsurface toe drains, any residual coliforms will be removed. Removal via the toe drains mimics slow sand filtration where coliform removal is almost total. The media envelope around the toe drain can be selected to further maximize treatment. These toe drains will be supply points for surficial wells used for treatment of pre-injection ASR water.

The water will go through several further stages of coliform reduction via the well injection process and subsequent aquifer storage. The well screen and injection into the rock aquifer will reduce pathogens. The lag time between injection, storage, and retrieval is on the order of several months. Therefore, reduction will occur as the aquifer is an anoxic environment and the coliforms are facultative organisms requiring some oxygen. After this storage period, the system will undergo post aeration and disinfection to potable water standards.

Recent correspondence from the EPA indicates that a willingness to consider a flexible approach to constructing and permitting ASR wells proposed in the

Comprehensive Plan (U.S. Environmental Protection Agency. 1999). For these facilities, the EPA believes that the proposed “raw” water ASR components can be implemented consistent with the SDWA and EPA’s regulations if “risk-based” analyses of the projects demonstrate that the USDW will not be endangered in a way that could adversely affect the health of humans. This approach would depend on a number of factors: 1) that a more comprehensive evaluation of the quality of the proposed source waters confirms that total coliform bacteria is the only problematic parameter; 2) that a demonstration can be made that biological contaminants will experience “die-off” such that the presence of these contaminants in the USDW will not cause a violation of the MCL or pose an adverse health risk; 3) that both modeling and test monitoring confirm dieoff after injection of biological contaminants within a reasonable time-space continuum after injection into a saline/brackish aquifer; 4) that the use of ASR technology on the scale and with the number of well proposed, results in recovery of a reasonable amount of injected waters and of reasonable quality; 5) that there are documented environmental benefits to be derived by the storing of water in this manner; and 6) that use, and treatment if necessary, of the recovered water is consistent with its intended primary purpose, ie, for ecosystem restoration.

C.3.5.3. Advanced Wastewater Treatment

The historic Everglades marsh was a low-nutrient (phosphorous limited) ecosystem. The Florida Department of Environmental Regulation (FDEP) has determined that violations of the state water quality standard for nutrients has occurred in the Everglades. These violations have specifically occurred as high concentrations of total phosphorus discharged from the Everglades Agricultural Area (EAA) to the Water Conservation Areas (WCAs). The Everglades Forever Act (EFA) requires the DEP to establish, by rule, a numeric criterion for total water column phosphorus in the Everglades Protection Area. This area includes the Everglades National Park (ENP), where the statutory default phosphorus criterion is 10 parts per billion (ppb). The Settlement Agreement to the federal lawsuit concerning the Everglades establishes a long-term phosphorus concentration limit for Taylor Slough of 11 ppb.

C.3.5.3.1. Water Quality Requirements

The re-use of wastewater effluent will be governed by two major water quality parameters: total phosphorus and fecal coliforms. Re-use of wastewater is regulated by the FDEP, and they categorically require filtration prior to re-use. The area of re-use is proximate to the Everglades where background total phosphorus (TP) levels are below 10 ppb. Implementation will require, perhaps, even further treatment to remove pathogens and TP down to levels that the FDEP will permit for discharge to groundwater. Modeling is required to ascertain impacts to the shallow aquifer, as well as to determine the extent of further treatment and special requirements such as detention or secondary disinfection. The acceptance of any re-use plan will require negotiation and acceptance by the FDEP to be feasible.

Wastewater effluent typically has a TP 1000-7000 ppb, and is high in coliforms (>10,000 organism per milliliter). Advanced municipal wastewater treatment facilities are capable of producing effluent containing approximately 500 ppb TP. This is 10 times the limit for discharges from STA-1 East, and 50 times the limit for ENP. Of concern is that under certain conditions, the hydraulic gradient in the area would be from east to west (toward ENP). The limestone underlying this area is very porous, therefore the released wastewater can possibly migrate to the ENP. The FDEP will likely impose special treatment requirements such as secondary disinfection or detention. Additionally, the distance and routing from the re-use facilities is unknown. These issues will impact costs, but their effect cannot be accurately estimated at this level of investigation.

C.3.5.3.2. Treatment Methods

Filtration systems employ flow equalization, chemical addition rapid mixing, flocculation, and gravity filtration. The chemical addition allows the formation of chemical floc particles. These are passed through 3 feet of media comprising 3 layers: coarse activated carbon, anthracite coal, and fine sand. Filters will require a pumping station to deliver the water to permit down-flow filtration. They are designed for runs of 1-4 days (between backwashes) and flow rates of 1-6 gallons per minute (gpm). The facilities will require a backwashing system, solids treatment, and disposal.

This technology is used on a large scale in Wahnbach, Germany. This plant treats 113 MGD of stormwater with an influent TP ranging from 90-260 ppb, and produces an effluent TP of 10 ppb or less. Filtration is a common method of water treatment in the US, and is used successfully to treat Mississippi River water. It is used to remove large amounts of color and colloidal materials from Lake Washington Pond water in Melbourne, Florida. Wastewater effluent is typically higher in TP (1000-7000 ppb); however, supplemental chemical feed at the existing wastewater plants (and perhaps other process optimization) could be used to reduce effluent TP to 100-200 ppb, and minimize filtration operation and maintenance costs. Treated potable water grade effluent would be delivered to the seepage locations by a pump station and pipeline. Further analysis is needed to determine required seepage areas and ponds.

C.3.6 STRUCTURAL / MECHANICAL

Due to planning constraints, site information for the proposed structures was not available. The lack of specific locations, topography and subsurface conditions, coupled with the large volume of structures did not afford the development of drawings and stability analyses as is usually done during the feasibility phase. As a result, only conceptual designs were performed for a select number of structures. These designs are based on similar, previously built structures taking into account water surface elevations and flow rates determined during hydraulic modeling. Costs estimates for structures in each alternative are generated using the conceptual designs supplemented with construction cost data from the US Army Corps of Engineers and the South Florida Water Management District.

C.3.6.1. Pump Stations

Discharge capacity of the various pump stations in each alternative differs considerably. Some are small and for the purpose of controlling seepage through impoundment levees. Others are larger, for regulating the movement of water from storage and treatment areas through canals to places in need of municipal or environmental supply. Review of previously built structures in the central and southern Florida area has shown that pump station capacity is the most influential parameter in determining construction cost.

C.3.6.1.1. General

The layout and design of pump stations built by the US Army Corps of Engineers is governed by Engineering Manual (EM) 1110-2-3102, "General Principles of Pumping Station Layout and Design." In the manual, three distinct sizes of stations are inferred based on capacity. Small stations are considered less than 100 cfs, medium are between 100 cfs and 1060 cfs, and large are 1060 cfs or greater. EM 1110-2-3104, "Structural and Architectural Design of Pumping Stations," prescribes structural loadings and architectural details to be used.

Pump stations will incorporate a wet pit (sump) with vertical mixed-flow or axial-flow pumps. The two basic types of pump sump used in civil works stations are formed suction intake (FSI) and rectangular wet pit. FSI generally improves flow conditions and thus pump performance, but are more expensive to construct. Therefore, they will only be used in situations where pump performance is in question due to poor alignment of the intake canal or the ability of a large station to deliver its design capacity. The configuration used will conform to the requirements of EM 1110-2-3105, "Mechanical and Electrical Design of Pumping Stations."

C.3.6.1.2. Small Stations

Small stations typically will consist of a single pump enclosed in a small building. A hatch in the roof is required to remove equipment with a mobile crane for servicing unless the location of the structure is extremely remote. In this case an overhead crane must be constructed in the station. Trash racks will be provided except for stations of minor importance. The ability to dewater the pump sump for maintenance and inspection will also be incorporated. Since stations of this size will not be manned, additional facilities such as office space and bathrooms are not usually needed.

C.3.6.1.3. Medium and Large Stations

Because of the importance of medium and larger size stations, two or more smaller pumps are used to provide the station design capacity instead of one large pump. This is necessary to provide backup capability in the event of a malfunction or during maintenance operations. Regulations also require auxiliary appurtenances that increase the size of the structure footprint and elevation. Office space, maintenance work areas, overhead cranes, and sanitary facilities will all be provided. The US Army Corps of Engineers Hydroelectric Design Center (HDC) must engineer large stations. These stations also require a separate Feature Design Memorandum to be prepared for the pumping equipment before design is started on the station.

C.3.6.1.4. Construction Considerations

The type of structure being built coupled with high water table conditions in central and southern Florida necessitates the use of dewatering measures during construction. Depending on the size and location of the station, this can typically be accomplished by two methods. If real estate is available and soil conditions allow a sufficient area can be excavated and well points used to control groundwater. If real estate is limited and/or highly permeable soil is encountered, a more expensive steel sheetpile cofferdam is necessary.

Location of the structure is important for accessibility reasons. Remote sites may require the addition of access roads and utility lines. Additionally, the proximity of ready-mix concrete plants is an issue for stations requiring large pours. Unit costs for concrete may escalate due to delivery distance or the use of on-site batch plants.

C.3.6.2. Gravity Control Structures

The primary purpose of these outlet works is to permit controlled release of water from storage areas. Small flow requirements will be handled with culverts, whereas larger ones will require spillway structures. As with the pump stations, discharge capacity of the proposed gravity control structures differs considerably between alternatives and is very influential in determining construction costs.

C.3.6.2.1. Culverts

There are four types of materials used for culverts: concrete, steel, aluminum, and plastic. Each has a different service life depending on protective coatings used and the project environment encountered. During design, the selection of materials for culverts will be based engineering requirements and life cycle performance. Economic analyses will compare 50, 75, and 100-year project lives depending on the relative importance of each structure. The analyses will include initial construction costs and future costs for maintenance, repair, and replacement associated with the type of material used.

The design and construction of culverts is governed by EM 1110-2-2902, “Conduits, Culverts, and Pipes.” This manual generally follows The American Society for Testing and Materials (ASTM) and The American Association of State Highway and Transportation Officials (AASHTO) standard provisions for the different culvert material types. The culvert shape (circular, box, elliptical, arch), size, and flow control (gated or non-gated) will depend on hydraulic requirements and specific site conditions encountered. Culverts through existing embankments may be constructed by tunneling and jacking when conventional excavation and backfill methods are not be feasible.

C.3.6.2.2. Spillways

The purpose of spillways proposed for this project is to provide a means of controlling the flow of water from reservoirs. Non-gated spillways provide extremely reliable operation and are inexpensive to maintain; however, the relatively flat topography of central and southern Florida along with economical, environmental, and political considerations does not favor this type of structure. Spillways controlled by gates allow a lower maximum reservoir water surface and thus a lower top of levee than non-gated spillways. This reduction will almost always result in savings when available lands and the cost of levee construction are a factor.

To satisfy safety concerns, a gated spillway must include two or preferably three gates. The two types of gates predominantly used by the US Army Corps of Engineers are the tainter gate and the vertical lift gate. Tainter gates are advantageous when large operating heads exist. Their concentric radial geometry causes the resultant hydrostatic force to pass through the pivot point (trunnion), meaning no moment from this force has to be overcome by the gate hoist. For small head situations as has historically been the case in central and southern Florida, vertical lift gates are regularly used. With vertical lift gates the hydrostatic load is transferred to the concrete structure through slots formed into the sides of the piers. The gate moves within these slots on rollers. Mechanical hoist systems used to raise and lower the gates must overcome the friction in the rollers caused by the hydrostatic load.

The layout, structural analyses, stability analyses, reinforcement details, etc., for the design of spillways is governed by EM 1110-2-2400, “Structural Design of Spillways and Outlet Works." The dimensions, elevations and shapes of the approach channel, weir, energy control structure (e.g., stilling basin), and discharge channel must meet the hydraulic requirements of EM 1110-2-1603, "Hydraulic Design of Spillways."

C.3.6.3. Cutoff Walls

Cutoff walls are vertical subsurface barriers designed to reduce or contain ground-water flow and limit fluid loss into surrounding soils. Their effectiveness is highly dependent on soil conditions, especially the presence of a confining layer to "key" the base of the wall into. Without the confining layer at the base of the cutoff wall, groundwater seepage will be reduced but not eliminated.

C.3.6.3.1. Steel Sheetpile

Steel sheetpile walls have been used in civil engineering applications for years. The walls are constructed by driving individual sections of interlocking steel sheets into the ground with impact or vibratory hammers to form an impermeable barrier. The retaining sheetpile walls deflect from water and lateral earth pressure applied to them. The flexure tightens the interlocks making the connection more water-resistant. Sheetpiling has exceptional strength and life expectancy, but is generally an expensive alternative compared to other vertical containment measures. This is especially true for deep walls when stiff soils and rock are encountered which make driving sheetpile difficult.

C.3.6.3.2. Slurry Trench / Synthetic Membrane

These subsurface barriers consist of a vertically excavated trench that is filled with slurry. The slurry hydraulically shores the trench to prevent collapse allowing the membrane panels to be inserted to the desired depth using a steel frame. Synthetic membranes used for vertical cutoff walls are generally made from high-density polyethylene; however, other polymers have been used. Membrane sheets can be continuous, but usually finite length panels that interlock are preferred. The final depth of installation is a function of the trenching equipment capability. Most slurry trenches are constructed of a soil, bentonite, and water mixture, which along with the synthetic membrane provide a low permeability barrier. As with steel sheetpile, the required wall depth and encountered soil conditions significantly affect construction costs.

C.4 PROJECT COST ESTIMATES

The construction cost estimates for the Restudy are accomplished by a variety of means. The volume of estimates to be achieved in a short time frame and the lack of design information necessitated innovative approaches to deriving component cost. The components are similar in that they generally contain a limited variety of features. Namely the features are levees, canals, spillways, culverts, pump stations, aquifer storage and recovery systems, and cut-off walls. The design information was, as a rule, limited to the sizing of the features. For example the design of a canal might be specified as one mile long, bottom width 20 feet, depth 10 feet. The components consist of a combination of features with various individual size parameters. All component features were estimated utilizing MCACES (Micro Computer Aided Cost Engineering System). Spreadsheet models were developed to facilitate quantity calculation, equipment production rates, cost risk assessment, and narrative descriptions. Although all cost estimates for this study were accomplished in MCACES, for conciseness and readability the costs are presented in Attachment A in a spreadsheet format.

C.4.1 BASIS OF COST

C.4.1.1. Labor Rates

Labor rates were developed from several sources. The Davis Bacon General Decision #FL980032, February 1998 (including Dade, Broward, Collier, Lee, Martin, Palm Beach, and St. Lucie counties), was the primary data source. The other sources were the MCACES National Labor Rates Database, and "Open-Shop Wage Rates For Journeymen," published June 29, 1998, in ENR magazine. As is usual practice, rates for all anticipated labor designations were developed for the Review Study Labor Rates Database. Development included interpolation for crafts not expressly identified in the source data. The rates include basic rate, payroll tax and insurance, and fringe benefits. Basic rates were revised to allow for any inconsistencies and to update labor rates to the effective pricing date.

C.4.1.2. Equipment Rates

Equipment rates are from EP 1110-1-8 Volume 3, September 1997, "Construction Equipment Ownership and Operating Expense Schedule Region III" (Southeast Region).

C.4.1.3. Material Costs

Material costs were obtained from the MCACES Unit Price Book database dated January 1996, published cost data, and previous estimates for similar work.

C.4.1.4. Contractor Costs

Prime contractor costs were added to direct costs. The aggregate percentage used was 29.54 percent of direct costs. No subcontractor costs were included.

C.4.1.5. Planning, Engineering, and Design Costs

Planning, engineering, and design costs are included in the estimates. The cost was not estimated. The cost included in the estimates is calculated as a percentage of construction cost.

C.4.1.6. Supervision and Administration Costs

Supervision and Administration cost is included in the estimates. The cost was not estimated. The cost included in the estimates is calculated as a percentage of construction cost.

C.4.1.7. Out of Scope Cost

The cost for each component includes cost for out of scope items. This cost is not properly a contingency cost. The limited designs and estimating models omitted unknown but necessary appurtenant and supporting construction items. A cost for out of scope items was included at the project level in the MCACES estimates.

C.4.2 FEATURE COST BASIS

C.4.2.1. Earthwork

Spreadsheet models were developed and used to calculate various earthwork quantities and equipment production rates. The quantity models accommodated inputs for material swell, material compaction, unsuitable material, amount of rock, incidental construction necessary, and the design criteria. The spreadsheet production rate models were based on methods and data provided in “Caterpillar Performance Handbook,” editions 20 and 24. The earthwork estimates were produced by creating MCACES models and crews for specific tasks. Appropriate MCACES models and crews were imported into the estimate and then the model’s applicable parameters were retrieved from the spreadsheet models.

C.4.2.2. Structures

C.4.2.2.1. Pump Stations

Analysis of historic pump station costs compared with pumping capacity revealed that the costs are directly proportional to the pumping capacity. The method involved updating the historic costs to a particular pricing date before performing a linear regression analysis. The linear regression analysis provided the basis for the MCACES pumping station cost models. There are three models for pumping stations, and all three rely on the direct proportionality of cost to pumping capacity. The first model is for pumping plants with a capacity of 0 to 125 cfs. The model basis is a historic estimate for a seepage pump plant of small capacity. The model plant's design is typical of the design required for small pump plants in the study area. The second model is for pumping plants with a pumping capacity of 126 cfs to 1060 cfs. This model is based on S332D, a 550 cfs pumping plant for which there is a historic MCACES government estimate and bid results. The MCACES estimate for S332D was first proportioned to reflect the winning bid, and then updated to the effective pricing date of October 1998. The third model is for pumping plants with capacity over 1061 cfs. This model is based on recent feasibility cost estimates for S319 and S362. These pump stations have a design capacity of 3800 and 4200 cfs, respectively.

C.4.2.2.2. Spillways

The logic applied to pump station models was also applied to spillway structures. Gated spillways were modeled after S65 for which there were historic estimates. Manipulation of this model from application to application was necessary in order to match not only the flow capacity, but also the number of gates indicated by the design data.

C.4.2.2.3. Culverts

The MCACES corrugated metal culvert model was derived from several different historic estimates. Manipulation of this model from application to application was necessary in order to match the designed culvert diameter. An expressly produced MCACES model for concrete box culverts was used for that type culvert is specified.

C.4.2.2.4. Uncommon Structures

The cost estimates for ASRs, re-use facilities, and deep cut-off walls relied upon data provided by vendors, contractors, and outside agencies. SFWMD provided much of the data incorporated in the ASR cost estimates. Bower of America Corporation provided information related to the excavation and construction of deep cut off walls in rock.

C.4.3 COST RANGE ESTIMATES

C.4.3.1. Contingency Cost

The contingency cost for the construction cost estimates produced for this study is the difference between the point estimate and the "90% confidence level" estimate. The possibility that a particular feature may indeed not be built, or that its capacity or configuration may indeed be radically altered, is not within the scope of cost risk analysis. The range estimates are based on the scope of work presented in the limited design information. The design variances assumed for cost risk analysis are within a range that would not change the fundamental nature of the component feature.

C.4.3.2. Cost Risk

The cost risk associated with each feature was appraised separately. Because of the lack of design information and lack of specific geological information, the cost estimates are considered generic estimates which are not site specific. The unknowns themselves are sometimes unknown. This makes the creation of a range of costs more meaningful as a basis for decisions related to funding and execution of further studies on particular components or features.

The cost estimates were prepared using the data provided and a series of assumptions. The design data itself can not be taken as exact. From the standpoint of cost, it must be assumed that a design specific such as levee length is, in actuality, the most probable value of a range of values. The cost estimates rely on assumed values for criteria essential for the estimate, but for which there is no engineering data. An example is the swell factor for excavated material. For the point estimate, a single value is assumed. While for the range estimate, a variety of values may be assumed. A pessimistic cost estimate could be produced by incorporating the worst case of all input criteria necessary for the estimate. The likelihood of this happing is almost nonexistent. The more likely case is that the different criteria fall at various values within their likely range of values.

C.4.3.3. 90% Confidence Interval

The mechanism utilized to establish a cost range is “Crystal Ball.” It is a computer program Monte Carlo simulator produced by Decisioneering of Denver, Colorado. The high end of the range estimates presented are, as a rule, the 90% confidence level estimates.

C.5 OPERATION AND MAINTENANCE COST ESTIMATES

The estimated operation and maintenance (O&M) costs summarized for the Restudy are based upon work originally developed by Burns & McDonnell (reference 9) for the South Florida Water Management District. Labor rates, equipment costs, equipment replacement, equipment life, fuel consumption, and maintenance expenditures for functions such as mowing, spraying, exotics removal, control structures, pump stations, etc. were generally based upon the historical data of the South Florida Water Management District in operation of the Central and South Florida Project. Costs were updated from fiscal year 1993 to 1998 using current costs or an escalation factor of 3.5 per cent per year as applicable. The following text summarizes the basis for specific facility components:

- Pump Stations. Pump stations above 250 cfs are projected to use manually operated diesel pumps. Crew sizes are based upon District operating experience. Additional support crew members (machinists, mechanics, etc. are added for multiple pump stations on a basis of five members for every six stations. Smaller pump stations are projected to use electric pumps. Estimated costs for the latter stations are based upon remote operations; hence, involve a lump sum annual cost. A thirty-year life expectancy is projected for major components such as engines, pumps and generators.

- Primary Control Structures. Structures such as gated spillways, etc. require regular maintenance estimated at an annual cost per year. Mechanical and electrical components have a life expectancy of 20 years and major renovation is projected at that point.

- Levee Maintenance. District experience is the basis for the average annual estimated costs. Mowing of flat surfaces and sloped surfaces are estimated at established costs per acre. Exotics control and growth retardance estimates are also based upon an established per acre cost. Regular mowing and spraying is projected for top and side slopes of the levees.

- Wetlands and Reservoir Maintenance. Maintenance costs are based upon District experience on a per acre basis for activities such as spot spraying for exotics control, minor structure maintenance (gated culverts, etc.) and similar activities.

Note that operation costs to a great degree and maintenance costs to a lesser degree will be directly influenced by weather conditions; thus, subject to wide variation. Consequently, average costs are the norm. At best, the estimates provided an accurate basis for the comparison of alternatives during selection of the preferred alternative. At this stage of the Restudy, it is incorrect to believe that the O&M costs are any more accurate than the engineering assessments from which they are derived. The estimates are a reasonable assessment of operation and maintenance costs of the recommended components based upon an average weather year. More accurate estimates will be derived as the design of components proceeds to the detailed design stage based upon normal studies and analyses that precede development of plans and specifications for construction. At that point sizes, locations and performance characteristics of the recommended components will be available. Even then, however, the estimated cost accuracy is dependent upon the average weather year concept. As Mother Nature has yet to consistently provide us with average weather years, the estimates will remain simply that…estimates based upon historical data, that over a period of years, will reasonably project the total outlay of funds for the term of study.

ENVIRONMENTAL EVALUATION ANALYSES

D.1 INTRODUCTION AND SUMMARY

Formulation of the C&SF Restudy Plans included identifying and evaluating potential environmental responses and water supply impacts for the study area. The Restudy team was composed of many agency representatives and disciplines. This multi-agency-interdisciplinary team developed and documented performance measures/indicators, and other analytical tools including the River of Grass Evaluation Methodology (ROGEM), Across-Trophic-Level System Simulation (ATLSS), and water quality models, so the environmental and other (water supply) benefits and impacts of the plans could be considered during alternatives development. This multi-faceted approach resulted in a comprehensive plan with positive environmental benefits and protection of water supply for environmental and other (urban and agricultural) uses. This appendix includes a description of the performance measures used and the methodologies developed to evaluate the alternative plans. The plan formulation section of the main report- Section 7 - provides a more detailed account of the process followed during plan formulation. This appendix does not repeat the details of Section 7 of the main report; rather, it focuses on the environmental, water quality, and water supply evaluation and results of the analyses.

A preliminary list of benefits and impacts to be assessed during plan development and evaluation was identified in the early phases of the feasibility study. However, it was not immediately obvious how to integrate the different analyses while developing and evaluating plans. An iterative process of developing an alternative plan, evaluating it, and using the results to develop an improved alternative was identified. It was decided that two teams would be formed to carry out these iterative steps: an Alternative Evaluation Team (AET) and an Alternative Development Team (ADT). The AET was charged with evaluating and recommending modifications to alternatives. The ADT was charged with developing and modifying plans that would meet hydrologic targets identified by the AET.

This appendix includes the results of the analyses conducted by the AET and explains how the results were used to produce a Comprehensive Plan. It also explains how the study area with its numerous and often conflicting environmental, water quality, and water supply interests was investigated to include consideration of its unique resources and interests by utilizing appropriate AET subteams (see below) before being evaluated comprehensively by the AET collective. The results of the following evaluations and findings are presented: River of Grass Evaluation

Methodology, ATLSS, water supply measures and targets, and water quality models and methodologies.

D.2 AET ORGANIZATION AND PROCESS

In the fall of 1997 the C&SF Restudy team established the AET for the purpose of providing technical evaluations of alternative plans. The AET was requested to accomplish and document the following:

- approve appropriate ecological and water supply performance measures (specific parameters and targets, discussed in following sections, required to meet ecological and/or water supply objectives) for evaluating the alternative plans,
- evaluate each alternative plan based on how well that plan achieves the targets that are described in the approved performance measures,
- recommend improvements in each alternative plan, based on how well each plan performs relative to the targets identified in the performance measures, and
- identify, at the conclusion of the plan evaluation process, the plan or plans which best achieve the ecological and water supply targets identified by the performance measures.

The AET was a multi-agency team composed of 45-50 biological and physical resource specialists. The 13 federal, state and county agencies with regular representation on the AET are listed in Table D.7.1.1. When it became obvious to the AET that the group was composed of scientists, engineers, and planners with technical expertise in specific areas within the study area, and because the study area was so large the AET decided to divide up into subteams. Consequently, each subteam had the lead responsibility for a specific subregion or topic/issue. A list of the subteams and subteam chairs is provided in Table D.7.1.2.

Each AET subteam was responsible for:

- developing and recommending a set of measures to evaluate performance of the plans in each subregion or topic/issue,
- using the approved performance measures to evaluate how well each alternative plan achieved the targets established for that subregion or topic area,
- collecting and synthesizing all other technical and public comment on each alternative plan, applicable to that subregion or topic,
- reporting to the full AET on recommended performance measures and on the subteam's evaluation of each alternative plan, and
- recommending improvements to the ADT concerning the performance of future alternative plans.

D.3 EVALUATION STRATEGIES

During the initial cycles of the alternative plan evaluation process, the AET developed performance measures. Plans were evaluated using these measures with the expectation that it would be possible to design a plan that would meet all of the performance measure targets. The initial strategy in plan development was that available water in south Florida could be sufficiently increased, and that water could be re-distributed, such that all environmental, urban and agricultural demands could be met.

As the evaluation process proceeded through alternative plans 3-6, it became increasingly certain that, given the physical, operational, legal and societal constraints present in southern Florida, it would not be possible to fully achieve every performance measure target. The affect these constraints had during the evaluation of alternative plans was to create "conflict," where either the volume of water was insufficient, or management options for local or subregional water supplies were sufficiently limited, so that alternative plans could not meet all targets in all areas at all times. Lacking the ability to reach all targets, it became necessary for the AET to establish guidelines for selecting priorities from among conflicting performance measure targets.

The following guidelines were adopted by the AET, as assistance for deciding priorities and strategies for dealing with conflicts among ecological performance measure targets.

1. The hydrological patterns predicted by the Natural Systems Model (NSM), at regional, subregional and indicator region scales, are the patterns that are most likely to lead to the recovery of complete natural systems at the same scales, and generally should be considered to be priority targets for the natural wetlands of south Florida. Indicator regions were created as a means for reducing the degree of uncertainty or error among NSM-based targets, by addressing criticisms raised by a technical review of the NSM (USGS 1997). The USGS review suggests that the NSM is likely to be more accurate in its predictions of regional or subregional hydrological patterns than with predictions of local or point hydrological conditions. The assumption with the indicator regions is that the mathematical means of the hydrological values from a number of adjacent cells with similar topographical and community characteristics will more accurately represent the pre-drainage condition than will a measure from a single cell or point within a cluster of cells.

2. When not all NSM-like hydrological parameters can be recovered within one area, or when meeting these targets in one area reduces the ability of a plan to meet NSM targets in a different part of the natural system, the Conceptual Ecological Models provide additional guidelines for the priority hydrological targets within each landscape and subregion. Each Conceptual Ecological Model identifies critical

ecological pathways, which show the hydrological parameters that are most responsible for the major, adverse ecological changes, and which should be targeted for priority attention in any ecological restoration program. The initial versions of the Conceptual Models are presented in Attachment A of this appendix. These initial versions will under go further revision, as well as peer review. The process that will be followed to review and update the models is described in Section 10, Implementation Plan of the Main Report.

3. In general, no target should have priority, if in meeting the target in one region, long-term ecological damage (compared to current conditions) is caused in some other part of the natural system (i.e., restoration should not cause additional, long-term ecological damage). However, some members of the team, recognizing that substantial changes in community structure and natural system boundaries have occurred over the past 100 years, were willing to see additional local community shifts (short-term “damage”) occur if these would allow the realization of larger scale restoration targets. This view is consistent with the recognition by most Everglades ecologists that a successful Everglades restoration program will be one that recovers those ecological characteristics that defined the original system to a sufficient degree so that a “new” Everglades-type ecosystem is created (Davis & Ogden 1994). While the new Everglades can not possibly duplicate the old, it will be able, if recovery is successful, to sustain Everglades-like ecological patterns in a region which has been substantially reduced in overall spatial extent.

4. It is appropriate to set priorities for ecological targets based on non-NSM criteria, where there is a compelling technical basis for doing so. Refer to the following section titled Performance Measures for an explanation of four situations where it might be suitable to set non-NSM targets.

5. Non-NSM ecological targets may not have priority, if in meeting these targets in one region, it becomes substantially more difficult to reach ecological targets in other regions.

6. Fundamentally different strategies for achieving restoration objectives were previously characterized in the 1994 Restudy Reconnaissance Report as “cookie cutter” vs. “xerox reduction” approaches. The debate is should the goal be “point-for-point” matches with NSM patterns in the remaining portions of the natural system (cookie cutter), or should the goal be to recreate the original community and landscape proportions in an Everglades that is now one-half the original extent (Xerox reduction)? While this question promoted a useful conceptual debate, most recent answers have been, (a) we should do neither (e.g., non-NSM targets have a higher priority), or (b) we should do some combination of the two.

The AET, in setting targets and priorities, developed its own strategy. Subteams used indicator regions for the natural wetlands of south Florida as a basis for evaluating the performance of various alternatives. Indicator Regions were identified as groups of adjacent 2X2 cells within the SFWMM and NSM grids intended to show the hydrological behavior in small, logical subregions common both to the present and pre-drainage Everglades systems. Because indicator regions have ground elevations and community structure that is similar to much more extensive areas of the natural system, the hydrologic patterns predicted to occur in each indicator region were used to evaluate how well alternative plans achieved hydrological restoration targets at subregional and, when considered in aggregate, at regional scales.

Although the team attempted to approximate the NSM targets in the indicator regions (i.e., a cookie cutter approach), the team also recognized that the proportion of long-hydroperiod sloughs to short-hydroperiod prairies in the current Everglades is similar to the proportion between these two landscapes in the pre-drainage system (and therefore, a Xerox reduction strategy was also achieved). The analysis of the proportion of area in the different landscape features of south Florida, in the pre-drainage and current systems, was based on data presented in Davis et al. 1994. Davis et al. used the map in Davis 1943 to calculate "pre-drainage" proportions, and superimposed a modern map over the Davis 1943 map to calculate current proportions. Hydrological models were not used for this analysis. The point of the analysis was that the proportions of the short-hydroperiod and long-hydroperiod wetlands have not changed and that priorities do not need to be given to "correcting" them.

The AET also generally preferred to attempt to meet all hydrological targets for all of the remaining natural area, rather than setting a priority for:

- a discrete subset of the hydrological targets (exceptions here were the priority set for the recovery of NSM-like uninterrupted hydroperiods and for decompartmentalization of the system),
- certain portions of the remaining natural system over others.

The position of the team was that recovery of an Everglades-like system is more likely to occur through recovery of a strong balance of all of the hydrological features that characterized the pre-drainage system (e.g., spatial extent, duration of hydroperiods, sheet flow, flow volumes into estuaries, depth patterns, etc.) than by achieving an NSM target for a small subset of these features, even if the balanced approach falls short of meeting full NSM for any one target. Ultimately, each priority was judged by the question of how likely it is that the target will provide the greatest long-term benefits to the regional system.

D.4 PERFORMANCE MEASURES

Each performance measure was based on one or more ecological or water supply objectives, and described the hydrological parameters, data format and hydrological targets required to meet that objective. Collectively, the performance measures defined the overall, regional hydrological patterns that should result in meeting the ecological and water supply objectives of the project.

Most of the performance measures developed for the natural system were based on hydrologic patterns predicted by the NSM. The AET position was that the NSM is the best available predictor of broad-scaled, pre-drainage hydrologic patterns. The opinion of the AET was that the hydrologic patterns predicted by the NSM are generally consistent with what is known or hypothesized about the optimum hydrological patterns for a number of characteristic animals and communities in the Everglades basin (e.g., soils, plant community patterns, freshwater fishes, alligators, wading birds). The team agreed that it was appropriate to use the NSM as a basis for ecological performance measures so long as appropriate scales were used; that is, for broad patterns of water depth and distribution, and the duration of flooding, but not for cell by cell comparisons, depth targets at scales less than plus/minus 0.5 feet, or precise estimates of flow volumes. As mentioned in Section D.3 paragraph 2 above, the draft Conceptual Models (Attachment A) were relied on to provide guidelines for establishing hydrologic targets which differ from NSM.

The AET agreed that it was appropriate, or even desirable, to set other hydrological targets (i.e., rescaled NSM or non-NSM) where,

(1) the NSM is a relatively poor predictor of pre-drainage conditions such as along model boundaries and where local topographical features are poorly expressed by the models,

(2) biological information for a species or community suggests a hydrological pattern that is different from that predicted by the NSM once existed,

(3) the spatial extent, topography, and the shape and location of natural boundaries have been so altered that restructuring of the remaining natural system may be required in order to achieve ecological or biological balance and long-term restoration objectives, and/or

(4) special consideration is needed for species listed as endangered, threatened, or of special concern by federal or state law.

Initially, the AET approved a large number of performance measures and performance indicators for use in evaluating and interpreting the alternative plans. With increasing experience during the evaluation cycles, the AET subteams learned that a relatively small subset (<100) of the total number of approved performance measures was successful in measuring how well each plan achieved the project objectives. This subset of performance measures became the key set of measures used by the subteams to evaluate the final alternatives. These key performance measures are briefly summarized in Section D.5, AET Results and Documentation**.** The format for documenting the performance measures is presented in Table 3.

The technical documentation for the key performance measures was prepared by the appropriate subteam at the time each new performance measure was submitted to the full AET for approval. Each documentation report followed a standard format. An essential feature of the documentation was the description of the hydrological targets that were prerequisite for meeting the ecological or water supply objective addressed by that measure. The documentation described the desired format for post-processing these data, following the model runs, which allowed the subteams to most effectively evaluate and compare how well one or more plans achieved the essential hydrological targets. The documentation for the performance measures is presented in Attachment B to this appendix.

For most of the ecological performance measures which have NSM-based hydrological targets, the target parameters were established for indicator regions (see Fig. 1 for map of indicator region locations), rather than for single cells or point locations.

D.5 AET RESULTS AND DOCUMENTATION

D.5.1 Development and Evaluation of Plans Starting Point through 5, Identification of Plans A-D

Starting in September 1997, the Restudy team began developing alternative comprehensive plans. During this phase, two base conditions (1995 and 2050) and six alternatives (Starting Point and alternatives 1 - 5) were formulated and evaluated. The results of each of these evaluations were documented and posted on the Restudy webpage as AET reports. Plan 6 was formulated but was evaluated as Plan D for the reasons that follow.

The alternative development phase of the study was an iterative process that began with the Starting Point alternative. Beginning with the Starting Point each subsequent alternative plan was formulated based on the results of the evaluation of the previous alternative. The iterative nature of this phase allowed both the AET and the ADT to learn more about the particular components of the plans including how the components performed under a range of conditions. Further, use of the

Internet provided a medium by which to solicit considerable agency and public comment. The process also gave the teams additional information about the components in regard to engineering and technical feasibility. Therefore, as the teams progressed with formulation of the alternatives, knowledge gained resulted in a refinement (structural and operational) of components in later alternatives.

Repeated modifications to the components created inconsistencies between the alternatives. To ensure that all the alternatives hydrologic output was comparable, the structural and operational components of the alternatives were standardized (i.e. if component x is a component in more than one plan it is modeled the same for each plan). The base conditions were also revised. Because the base conditions and the earlier alternatives were revised, the results of Alternative 6 as well as earlier alternatives were labeled according to a different nomenclature: Revised Alternative 3 was named Plan A, Revised Alternative 4 became Plan B, Revised Alternative 5 became Plan C, and Alternative 6 became Plan D. The changes to the earlier alternatives improved performance and at the same time, equalized the uncertainties between the plans. The final evaluations are presented in an evaluation matrix that displays Alternatives A – D and the 2050 base condition, and Alternatives D, D13R, and the 2050 base condition as described in the following paragraphs.

D.5.2 Decompartmentalization Scenarios and Results

At a joint AET/ADT/Restudy Team meeting on December 15, 1997, various approaches for modeling decompartmentalization were discussed. Three scenarios were formulated as a result of that discussion that progressively removed more of the internal compartments between the WCAs, beginning at the bottom with the L-29 and moving progressively north and east. These scenarios were modeled as variations of Alternative 3. Results were posted on the web site on January 30, 1998, and evaluated at the AET meeting on February 9, 1998.

The AET evaluation showed that as decompartmentalization increased from south to north, flows to Shark River Slough increased. The removal of the L-29 also helped WCA-3A south (Indicator Region 14) where extreme high water conditions were greatly reduced.

Unfortunately, decompartmentalization also caused some unintended consequences. Drying conditions in Loxahatchee NWR (WCA-1), WCA-2A, and northeast Shark River Slough were exacerbated, increasing the dependence on the Lake for water supply. Extreme high water conditions in WCA-3B and eastern WCA-3A increased as decompartmentalization increased. The full decompartmentalization scenario resulted in the most extreme high water conditions in WCA-3B of any scenario.

Because one of the basic tenets of the AET was to “do no harm” to one part of the natural system in order to restore another, the team recommended taking a more moderate approach to decompartmentalization, understanding that if ways to mitigate the problems could be found, decompartmentalization of the upper part of the system could be reexamined at a later date. Therefore, for Alternative 4 and subsequent alternatives, the AET suggested the ADT retain the barriers in the northern part of the system. The barriers between Loxahatchee NWR and WCA-2A and between WCA-2A and WCA-3 were kept to prevent excessive drydowns in the refuge and in WCA-2A and to protect the Lake's littoral zone. The barrier between WCA-2A and WCA-2B was retained to prevent the excessive depths in WCA-2B seen in the more decompartmentalized scenarios. By artificially retaining water in the upper part of the system longer, the team avoided exacerbating the extreme high water conditions in WCA-3B.

D.5.3 Final Development and Evaluation of Alternatives A-D and D13R Process

D.5.3.1 Building the Matrices, River of Grass Evaluation Methodology

The AET reported its final set of evaluations of the revised base conditions and the final alternative plans, A through D, during a 21-22 May 1998 meeting. The AET subteams met to discuss their findings and to develop a way to show and compare the evaluation scores created for each plan. All teams used a final subset of key hydrologic performance measures to develop the numeric scores and related these scores to the habitat and restoration objectives. The procedures used by each of the subteams are discussed in detail in Section D.8. along with an interpretation of the outputs.

The natural systems subteams followed the River of Grass Evaluation Methodology (ROGEM) to develop environmental outputs for the natural areas during the final evaluation of Alternative Plans A-D. The River of Grass Methodology output was used to quantitatively describe the potential habitat quality created by the alternative plans, based on linkages between hydrologic characteristics and habitat restoration targets. The River of Grass Evaluation Methodology used during the Reconnaissance phase of this study used U. S. Fish and Wildlife Service’s Habitat Evaluation Procedure (HEP) to develop community models. HEP uses Suitability Indices in community models to indicate fish and wildlife responses to changes in habitat quality. For this feasibility phase of the study, the Lake Okeechobee, St. Lucie and Caloosahatchee Estuaries subteams followed the HEP procedure to develop Suitability Indices, equations, and numeric output for their subregions. The balance of the AET subteams normalized the performance measure output(s) and used best professional opinion to provide numeric outputs for their subregions.

Key performance measures, by subregion, critical to achieving the ecological objectives of the study were selected for the final evaluation of alternatives A-D and are presented in Section D.6. The River of Grass Evaluation Methodology, through mathematical equations and professional expertise, was used to describe relative habitat quality in the natural system (based on linkages between hydrological patterns and habitat restoration targets) that would result from the plans evaluated. The final performance measures were normalized through mathematical equations to generate numeric outputs (scores) ranging between 0.0 and 1.0 for each subregion and each performance measure. The outputs were treated as ordinal numbers ranging from 0.0, which indicates low habitat quality, to 1.0, which indicates that the plan evaluated fully meets the restoration objective and would provide optimum habitat quality.

Use of the River of Grass Evaluation Methodology equations allowed comparisons of scores among the different base conditions and alternative plans within each of the natural areas. For the water supply objectives a similar method of developing numeric outputs was followed. According to the methodology, the base or alternative plan with the highest numerical score is the best plan for that performance measure (or measures where several are combined in an equation). These results were reported in the matrices.

Although ATLSS and Listed Species (Threatened and Endangered Species) results were not presented during the May meeting (they had not been completed) it was agreed that they would be included when available. Preliminary Water Quality results were presented at the May meeting. It was agreed that the final Water Quality results would also be added to the appropriate matrices for presentation to the full Restudy team during the June meeting.

The numeric outputs (scores) resulting from the ecological and water supply evaluations were entered into a set of matrices. Supporting documentation by each subteam for developing their matrix is explained in each subteam's narrative report. The subteam reports are presented in Section D.8 of this appendix. Each subteam report provides technical documentation for the matrix. The documentation includes a list of the performance measure(s) used, the geographical area or indicator regions covered, and an explanation of the River of Grass Evaluation Methodology or water supply equation(s) used to develop the outputs.

The supporting documentation includes an interpretation of the meaning of the numerical scores relative to the long-term ecological or water supply objectives addressed by the performance measure(s) in that matrix. The documentation provides additional explanations about how the subteam interpreted the scores relative to the targets. The interpretations rely in part on the "best professional opinion" of the subteam members as a means for providing an interpretation of the scores in the matrices.

The numerical matrices were prepared by the AET subteams primarily for use by the full AET; however, it is important to know how the numbers in the matrices were calculated, as a basis for understanding how these numbers should be used and interpreted. For several reasons caution should be used in comparing scores among different matrices or among different rows within a matrix. The most appropriate comparisons among the scores are within a single row for a single subarea (for example, Shark River Slough) as a basis for comparing how well several different plans performed at moving towards or achieving the subareas' target(s). However, because different equations were used among the different matrices, direct comparisons of the scores in the different matrices would not be valid. Due to the documented levels of error in the hydrological models, one should not assume significance in relatively small differences in numerical scores in the matrices, since the numerical scores imply a greater degree of predictive power than is possible. Because ecological thresholds and relationships for the biological elements in the extensively altered natural system are poorly known, the narrative interpretations provided with each matrix should be consulted for an improved understanding of the ecological strengths of each plan.

For these reasons, the full AET made its final comparisons of the 2050 base condition and plans A-D by using three summary evaluation criteria:

- plan ranking
- plan grade
- plan color

These criteria which are further explained in the following section, were designed to convert the numerical scores in the subteam matrices into more qualitative descriptions of plan performance.

D.5.3.2 Summary of AET Results for Alternative Plans A – D

The results of each subteam evaluation for the 1995 and 2050 Bases and Alternative Plans A-D are presented in detail in later sections of this appendix. Refer to the Table of Contents for this Appendix if seeking particular subteam evaluations. The following paragraphs provide a summary of the subteam evaluations.

The AET used the different matrices as a basis for organizing the large numbers of scores for the two base cases and four alternative plans. The documentation and interpretation for these matrices are described in each of the individual subteam's reports, which follow this introduction. References that pertain to documentation of the matrices can be found in the reference section of the Feasibility Report. The matrices allowed comparisons among the two bases and four alternative plans, for purposes of ranking the different plans, and to evaluate how well each plan performed relative to, (1) the targets defined by the performance measures and (2) the performance of the 2050 Base (future without plan condition).

The evaluation criteria - plan ranking, plan grade, and plan color - used to compare the four alternative plans (A – D) and the 2050 Base were derived from the numerical output from the River of Grass Evaluation Methodology by all subteams except the Northern/Central Everglades team. The Northern/Central Everglades subteam ranked, graded, and assigned colors before they used ROGEM, and used these rankings, grades, and colors as inputs to ROGEM.

D.5.3.2.1 Plan Ranking

For each sub-region, the alternative plans and the Without Plan Condition were ranked from one through five. The best plan for each sub-region was awarded a one (1), the worst plan earned a score of five (5), and the intermediate plans received values from two (2) through four (4). Ties were dealt with by averaging. For example, if two plans were tied for first place, they each received a score of 1.5, the average of 1 and 2. If three plans tied for first place, they each received a score of 2, the average of 1, 2, and 3. This system ensured that 15 points for each sub-region were allocated across the alternatives, equalizing the contribution of each sub-region to the final sum of rankings. The results of this evaluation are included in ***Table 7-8***. The plan with the lowest cumulative score received the highest rank. For example, Plan D, the highest ranked plan, scored 45 points compared to the Without Plan condition which received 102 points.

D.5.3.2.2 Plan grades

Plan grades were created based on the numerical output (from the River of Grass Evaluation Methodology or water supply equation) for each subregion/topic. A letter grade (A,B,C,D,or F) was assigned based on these numeric scores. Letter grade A was best at meeting the performance measure targets and restoration or water supply objective; and letter grade F failed to meet the performance measures, similar to the letter grading system used in academia. More than one plan could receive a similar grade for a subregion/topic, if two or more of the plans performed similarly for the performance measures for the subregion/topic. For example, Loxahatchee National Wildlife Reservation earned a letter grade A for plans A-D since it fully met the Performance Measure target and the restoration objective. Table 5 lists all the plan grades for each subteam.

D.5.3.2.3 Plan colors

Plan colors (green, yellow, and red) were created by converting plan grades into a "best professional opinion" prediction by the members of each subteam on how likely each plan and base case would achieve the long-term ecological or water supply objectives which are identified for each performance measure. Each color provides a prediction of how likely a plan will achieve the recovery and long-term sustainability objectives defined by the performance measure(s), and a recommended priority for further improvement in the design and operation of the plan evaluated. Green indicates the current plan is likely to recover and sustain the ecological or water supply objective described by the performance measures, and that further plan improvement is unnecessary or a low priority. Yellow indicates achievement of the long-term objectives is uncertain, and that improvement in the plan is a moderate priority. Red indicates the recovery and long-term sustainability of the target objective are unlikely, and that the current plan requires improvement if these targets are to be met. Refer to Table 6.

D.5.3.2.4 Summary of Plans A-D Based on Rankings, Grades, and Colors

Results of the rankings, grades, and colors show that Alternative D is the best overall plan for meeting the performance measures. For these same criteria, Alternative C is the second best plan. Table 7 shows that for Listed Species, Alternative D ranks slightly higher than the other alternatives, with Alternative C ranking second. All tables show that for almost all performance measures, one or more plans provide substantial benefits (i.e., improvements) over the 2050 Base. The AET recommended Alternative D, with the proviso that steps be taken to correct specific weaknesses in the alternative.

Overall, Alternative D performed best for:

- Lake Okeechobee,
- Caloosahatchee Estuary,
- Lake Okeechobee Service Area,
- Lower East Coast,
- Loxahatchee NWR,
- Holey Land and Rotenberger WMAs,
- southern and southeastern Big Cypress basin,
- southern Everglades Rocky Glades.

Alternative D, as modeled, did not meet (reds in Table 6) performance targets in:

- portions of WCAs 2 and 3, and
- Shark Slough.

Alternative D moved towards meeting (yellows in Table 6) targets for:

- St. Lucie Estuary, and
- Florida Bay.

The AET recommended that ad hoc teams of ecologists, hydrologists and modelers be created to determine both the immediate and long-term strategy for improving the performance of Alternative D in the red and yellow scored areas.

The AET also highlighted three specific strengths of Alternative B, which, if incorporated into Alternative D, would bring the different ecological strengths of these two plans together in a single final plan. These plan B strengths were:

- higher volumes of flow into the Florida Bay estuary compared to other plans,
- greater success at reestablishing system connectivity, and
- improved levels of sheet flow, compared to other plans.

These three features were a consequence of the greater extent of system-wide decompartmentalization, which characterized Alternative B. The AET recommended that an ad hoc team explore the feasibility of merging these features of B into D.

D.5.4 Selection and Refinement of Initial Draft Plan (D13R)

At the Restudy meeting the week of June 2, 1998, Alternative D was selected as the initial draft plan. The full team supported the AET recommendation that Alternative D needed refinement to improve its performance in five key areas: WCA-2, WCA-3, Shark River Slough, Florida Bay, and the St. Lucie Estuary.

During the period from June 5-15, 1998 a team of engineers and ecologists conducted an intense iterative process to attempt to improve the hydrologic performance of Alternative D in the WCAs and Everglades National Park. During this week and a half, many refinements to operations and structures were made to Alternative D. Initially, the refinements consisted of only operational changes (iterations D1-D7) that proved inadequate to meet the desired performance. It was evident that structural changes to the Plan were necessary: Plans D8-D13R were developed and modeled. The final model iteration, D13R, accomplished refinements to the initial draft plan that improve its performance in the remaining Everglades, to provide for a sustainable Everglades ecosystem and move towards restoration.

The fifth area where improvement was desired was the St. Lucie Estuary. During the same time that the Everglades team was working on Plans D1-D13, the Indian River Lagoon Feasibility Study modelers were working to improve the St. Lucie Estuary performance. Improvements made include increasing storage in the C-23, C-24, North Fork and South Fork basins as well as making refinements to the estuary triggers.

Modifications made to the initial draft plan achieved improved performance in the WCAs and Everglades National Park without compromising Lake

Okeechobee water levels or water supply to LOSA and LECSA. The modifications improved adverse high and low water conditions in the WCAs. Flow volumes to Shark River Slough were increased while seasonal distribution of flows as indicated by NSM was maintained. The number of drydowns in Shark River Slough was reduced to three events over the period of record compared to two events under NSM. Salinity in Florida Bay coastal basins as indicated by P33 stages was also improved. These improvements were achieved through partial decompartmentalization of WCA-3 and the Park, which makes Alternative D13R more like Alternative B as desired by the AET and the Restudy Team. Performance in the St. Lucie Estuary came closer to meeting targets.

Table 5 is a summary table of letter grades for the 2050 Base Case, and Initial Draft Plans D – D13R. Table 6 shows the same for color ranking.

D.5.5 Scenarios D13R1-4

During the period November 1998 through January 1999 hydrologic modelers, engineers, and ecologists developed and evaluated a series of scenarios (referred to by some as the “new water” scenarios). The objective of these scenarios was to capture additional volumes of fresh water, primarily to improve the performance of Alternative D13R in the southern Everglades and Biscayne Bay, and to redistribute water in the Water Conservation Areas. The summary of Scenario D13R4 results are presented in Section D.9 of this Appendix. The more detailed report is in Attachment E. to this Appendix. The earlier Scenarios D13R1-3 were not fully documented because the process of developing and documenting them was quick and iterative with improvements being made immediately to develop a new scenario after AET teams completed their analyses. Time was not spent on documenting the results of scenarios D13R1-3 but rather on improving their performance as a new scenario. Scenario D13R4 was documented when time ran out for developing additional scenarios but it had been clearly demonstrated that improvements to D13R could be achieved.

The Alternatives Evaluation Team recognized that much new information regarding the potential performance of D13R was gained through the modeling of the four scenarios. The hydrologic responses during the modeling convincingly demonstrated the operational flexibility and robustness of D13R, and offers encouraging documentation that additional improvements to the natural system can be achieved during the detailed planning phases of the restoration program.

D.6 OVERVIEW OF FINAL PERFORMANCE MEASURES (PMS) USED BY AET SUBTEAMS

This section provides a brief summary of the final subset of performance measures that were used to evaluate Plans A-D and the problem to be improved or corrected by the alternative plans. While the subteam reports presented in Section D.8 include a far more detailed discussion of the Performance Measures, the subregion/topic problem(s) and evaluation results of Plans A-D, the following list and brief discussion of the final Performance Measures was developed to provide a quick and concise guide to what the Alternatives Evaluation Team believed were the most important and desirable hydrologic conditions to be obtained within each of the subregions. Likewise, this section does not discuss the results of the alternative plans because the results are summarized in the tables in Section D.7. Tables showing Plan Rankings, Letter Grades, and Colors, along with a detailed discussion can be found in Section D.8. The final Performance Measures, by subregion/topic are discussed in the following sections.

D.6.1 The Total System Matrix: Continuity, Sheetflow, and Fragmentation

The total system matrix was evaluated according to three attributes: continuity, sheetflow, and fragmentation.

D.6.1.1 Continuity (expressed as Water Surface Elevation Differences Across Barriers)

Water surface elevations on either side of the C&SF Project structures (canals and levees) tend to be very different (i.e. pooling upstream and too dry downstream) from what they were originally. These conditions adversely effect aquatic organisms and their prey. Different species of wading birds, for example, rely on various depths of shallow marsh to capture prey. Abrupt changes in depth, from too deep and to too shallow, limit feeding opportunities in these modified areas.

Final performance measures (PMs) used were based on a count of the number of weeks where the difference in water surface elevations across eight barriers within the remaining Everglades exceed the difference predicted by NSM 4.5F. The eight barriers were L-39 (between Loxahatchee NWR and WCA-2), L-38 (Between WCA-2 and 3), Miami Canal South, Miami Canal North, L-67, Tamiami Trail West of L-67, Tamiami Trail East of L-67, and L-28.

D.6.1.2 Sheetflow (expressed as Overland Flow Volume Transects)

Today's Everglades have been highly modified from a vast expanse of sheetflow to a compartmentalized system. The C&SF Project caused pooling on the upstream side and excess drying on the downstream side of hydrologic barriers. Ponded systems favor some species while flowing systems favor others. Differences resulting from these two systems include: food types and sources, migration of macroinvertebrates, dispersion of nutrients, aeration and diffusion of gases in water, particulate suspension, and thermal stratification. Sheetflow also helps shape tree islands, supports microhabitats on the upstream and downstream sides, enhances the uptake of nutrients from the water column and creates an environment that precipitates phosphorus, along with calcium carbonate, into the substrate.

Final PMs used were flow volumes (wet season and dry season average overland flows) across 26 transects grouped into categories representing their general area: Big Cypress, Central Everglades, Central Everglades, Southern Everglades, Tamiami Trail, and L-67.

D.6.1.3 Fragmentation (expressed as miles of canals and levees)

Levees block the flow of water and thereby restrict the movement of aquatic and semi-aquatic life forms. Land-based predators use levees to invade the marsh interior and prey upon animals that try to cross these terrestrial habitats. Levees also act as conduits by supporting invasion of terrestrial plants into natural areas. Canals act as corridors for non-native animals and plants that extend their ranges from points of introduction and move into wetlands where they alter habitats and affect food webs. Artificial, deep-water habitats provide thermal and spatial refuge to large numbers of both non-native and native aquatic predators in the dry season, enhancing their survival and ultimate population sizes. During the dry season, these predators feed heavily on small marsh fishes and invertebrates that move into the canals from adjacent wetlands.

Final PMs used were the number of miles of canals and levees in the South Florida Water Management Model bordering or bisecting natural areas.

D.6.2 Lake Okeechobee

Lake Okeechobee is a valuable regional as well as local natural resource. Fluctuation and timing of lake stages affect the distribution of native and exotic plant communities, and overall habitat quality (cover, nesting sites, foraging habitat) for fish, birds, and other wildlife. Extreme low lake levels can result in loss of the littoral zone as habitat for aquatic biota and promote expansion of exotic plants into pristine native-plant dominated regions of the lake. Prolonged moderate low lake levels also reduce areas of the littoral zone available for wildlife habitat and promote exotic plant expansion. Extreme high lake levels can result in wind and wave damage to shoreline plant communities, and transport phosphorus-laden pelagic water into pristine inner regions of the littoral zone. Prolonged moderate high lake levels limit light penetration to the lake bottom (which results in loss of benthic plants and algae that stabilize sediments and provide habitat), and promote greater circulation of phosphorus-rich waters from the mid-lake to less eutrophic near-littoral regions, where phosphorus inputs stimulate algal blooms.

While extreme or prolonged high and low lake levels are damaging to the ecosystem, some variation within an intermediate range has great benefits. In particular, a spring recession of lake levels from near 15 feet to 12 feet NGVD has been shown to favor nesting birds and other wildlife in the marsh, allow for re-invigoration of willow stands, and permit fires to burn away cattail thatch. Yearly recessions to 12 feet also facilitate the growth of submerged plant communities, which serve as habitat for commercially and recreationally important fish. The goal is to have a substantial number of these events.

Final performance measures used were:

1. Frequency and duration of extreme low lake stages (number of events <11 ft),

2. Prolonged moderate low lake stages (number of prolonged [>12 months] events <12 ft),

3. Number of extreme high lake stages (>17 ft),

4. Prolonged moderate high lake stages (number of prolonged [>12 month] events >15 ft), and

5. Spring recession patterns based on number of years January through March lake stages decline from near 15 ft to 12 ft. without reversals >0.5 ft.

D.6.3 Lake Okeechobee Service Area (LOSA)

Water supply effects the frequency, duration, and severity of water supply cutback events in the Lake Okeechobee Service Area (LOSA). The service area includes the Everglades Agricultural Area, the Caloosahatchee, St. Lucie, S-4, and L-8 Basins, and the Seminole Indian (Brighton and Big Cypress) Reservations.

Performance measures were developed to evaluate the frequency, duration and severity of water supply cutback events in the Lake Okeechobee Service Area. Water restriction events vary as to how often they occur (frequency), how long an event lasts (duration), and how much of the water that would normally be demanded is not delivered (severity). Scores were developed for each of these characteristics.

The number of years with water restrictions from the "Frequency of Water Restrictions" graphic was used to identify water shortages. The established performance target is that there be no more than three years during which cutbacks occur over the 30-year period of performance available from each simulation.

The "LOSA Supply Side Management Report" was used to develop a combined duration/severity score, for relative comparisons of alternatives only.

D.6.4 Lower East Coast (LEC)

During the dry season structural releases are periodically made from the Water Conservation Areas (WCAs) and Lake Okeechobee to maintain ground water levels and to minimize the possibility of saltwater intrusion along the Lower East Coast. This water is required to recharge secondary canal networks, wellfields and other recharge areas, and lakes. When water stored in the WCAs and Lake Okeechobee is scarce, the urban water supply demands are restricted (cut back) in order to conserve the remaining supplies in the regional system.

Several final PMs were used:

1. The ability to meet the 1-in-10 year water supply planning goal: The planning goal is to find a balance between ability of the regional system to supplement recharge of the aquifer and meet the public water supply planning goal of a 1-in-10 year level of service in the lower east coast of Florida. The planning goal is in terms of the frequency of cutback events and is defined as no more than three cutback events, no more than seven months in duration over the period of record.

2. Percentage of months not in a water supply cutback: The duration of water supply cutbacks was used as an indicator of the reliability of water supplies.

3. Stage duration curves in south Miami-Dade canals: **s**altwater intrusion criteria do not exist for the major canals in southern Miami-Dade County. However, water levels in these canals were evaluated because encroachment of the salt front into the Biscayne aquifer has occurred previously in this area. Also, major public water supply wellfields are located in southern Miami-Dade County. This area was evaluated by using the stage duration curves for the following structures: C-100A @ S-123, C-1 @ S-21, C-102 @ S-21A, and C-103 @ S-20F.

D.6.4.1 Performance Measure Used in the Agricultural Area along the L-31N

Six cells in the western areas of southern Miami-Dade County were evaluated. End of the month stage duration curves for 1983-1993 were used to compare an 11-year target stage duration curve to the 31-year stage duration curves for the bases and alternatives.

D.6.5 Northern/Central Everglades

Modifications to hydropatterns have resulted in adverse impacts on the flora and fauna inhabiting portions of the Everglades that now exist as Water Conservation and other managed areas. The Performance Measures identified for use in the Restudy were developed to evaluate a plan's potential for:

- protection and accretion of peat soils (indicated by a low predicted occurrence of extreme low water [depths more than 1.0 ft below ground surface]);
- persistence of tree island communities (indicated by a low predicted frequency of extreme high water); and
- an inundation pattern suitable for an Everglades sawgrass or ridge-and-slough marsh (indicated by a number and mean duration of inundation events that either closely matched the target for that indicator region, or that fell within the range of patterns predicted by the NSM for that landscape type).

The final set of Performance Measures used was:

(1) Inundation pattern (number and mean duration of inundation periods);

(2) Extreme high water (number and mean duration of high water events); and

(3) Extreme low events (number and mean duration of low water events).

Target variable values for the performance measures were those predicted by NSM 4.5, Final, with four exceptions:

(1) Indicator Region 17, performance was evaluated by comparing values to the average of NSM values for Indicator Regions 14 and 18; this was because the NSM depths in this indicator region had been identified during evaluation of alternatives 1-3 as being lower than desirable for this relatively pristine marsh area;

(2) LNWR, the targets were 1995 Base values, in keeping with the refuge's current regulation schedule;

(3) High water extremes, the performance target was that the number and duration of events be less than or equal to NSM values; and

(4) Low water extremes, the performance target was for frequencies and duration of events to be minimized.

The final evaluation classified the indicator regions into ten subregions that correspond to areas with distinct hydrologic performance. These are:

(1) Loxahatchee NWR (Indicator Regions 26 & 27);

(2) Holey Land & Rotenberger WMAs (Indicator Regions 28 & 29);

(3) WCA-2A (Indicator Regions 24 & 25);

(4) WCA-2B (Indicator Region 23);

(5) NW WCA-3A (N of Alligator Alley & W of Miami Canal; Indicator Regions 20 & 22);

(6) Northeastern WCA-3A (N of Alligator Alley & E of Miami Canal; Indicator Region 21);

(7) Eastern WCA-3A (S of Alligator Alley, E of Miami Canal; Indicator Region 19);

(8) Central & Southern WCA-3A (S of A. Alley, W of Miami Canal; Indicator Regions 14, 17 & 18);

(9) WCA-3B (Indicator Regions 15 & 16); and

(10) Pennsuco Wetlands (Indicator Regions 52 & 53).

D.6.6 Southern Everglades

Southern Everglades were was evaluated according to two regions: Shark River Slough and Rockland Marl Marsh.

D.6.6.1 Shark River Slough

Ecological values and indicators of restoration success in Shark River Slough that are linked to the hydrologic performance measures in the conceptual model include:

- increased nesting success and abundance of American alligators and a corresponding increase in the number of occupied alligator holes to serve as drought refugia and to increase habitat heterogeneity,
- increased population density of aquatic fauna,
- increased abundance of wading birds and wood storks,
- re-establishment of coastal nesting colonies of wading birds and wood storks,
- earlier timing of colony formation by wading birds and wood storks,
- resumption of the return frequency of wading bird and white ibis super colonies,
- enhanced production and community composition of periphyton,
- accelerated accretion of peat soils, and
- persistence and resilience of macrophyte and tree island plant communities including the cessation of sawgrass expansion into wet prairies and sloughs.

Priority performance measures for the ecological restoration of Shark River Slough are identified in the Everglades Sloughs Conceptual Model. Those measures, in order of priority, are:

(1) duration of uninterrupted flooding,

(2) drought severity as measured by the duration of dry conditions,

(3) water depth during periods of flooding,

(4) total annual flow volume, and

(5) seasonal distribution of flow in mid Shark River Slough.

NSM4.5 Final (NSM4.5F) characterized Shark River Slough as a predominantly aquatic system that was continually flooded and flowing during wet and dry seasons and during wet years and all but the most extreme dry years. NSM4.5F indicated that Shark River Slough would have dried only two, three and six times during the 31-year period of record in the NE, Mid and SW indicator regions, yielding uninterrupted periods of inundation that averaged 535, 401 and 226 weeks. Water depths averaged 1.8, 1.6 and 1.2 feet during periods of flooding in the three respective indicator regions. Dry conditions lasted for an average of four, three and six weeks respectively.

D.6.6.2 Rockland Marl Marsh

Ecological values and indicators of restoration success in the Rockland Marl Marsh that are linked to the hydrologic performance measures in the Conceptual Model include:

- re-colonization and population resurgence by American alligators and a subsequent increase in the number of occupied alligator holes to serve as dry season refugia for aquatic fauna and to increase habitat heterogeneity,
- increased population density of aquatic fauna,
- increased seasonal abundance and foraging activity of wading birds and wood storks,
- enhanced production and community composition of periphyton,
- accelerated accretion of marl substrate,
- increased nesting success and population size of Cape Sable seaside sparrows, and,
- persistence and resilience of highly diverse macrophyte and tree island plant communities.

Priority hydrologic performance measures for the ecological restoration of the Rockland Marl Marsh are identified in the Marl Prairie/Rocky Glades Conceptual Model. Those measures, in order of priority, are:

(1) duration of uninterrupted flooding,

(2) drought severity as measured by the duration of dry conditions, and

(3) number of wet season water level reversals when the depth drops to less than 0.2 feet during a period of flooding.

NSM4.5F characterized the Rockland Marl Marsh as a seasonally flooded system where water levels typically dropped below the ground surface during most years, except during prolonged high rainfall periods when the marsh remained flooded for multiple years. NSM4.5F indicated that uninterrupted periods of inundation averaged 44 weeks. Only two wet season water level reversals occurred during 31 years. Dry conditions lasted for an average of 26 weeks.

D.6.7 Florida Bay

Ecological values and indicators of restoration success in the Florida Bay mangrove estuary and coastal basins that are linked to the hydrology/salinity performance measures in the conceptual model include:

- increased production of low-salinity mangrove fish and invertebrates,
- re-establishment of coastal nesting colonies of wading birds and wood storks and eastern Florida Bay colonies of roseate spoonbill,
- earlier timing of coastal colony formation by wading birds and wood storks,
- resumption of the return frequency of wading bird and white ibis super colonies,
- increased growth and survival of juvenile American crocodiles,
- increased cover of low-to-moderate salinity aquatic macrophyte communities in coastal lakes and basins,
- return of seasonal waterfowl aggregations to coastal lakes and basins,
- enhanced nursery ground value for sport fishes and pink shrimp in coastal basins, and
- persistence and resilience of the mangrove, salt marsh and tidal creek vegetation mosaic.

Priority performance measures for the ecological restoration of the Florida Bay coastal basins are identified in the Florida Bay Mangrove Estuarine Transition Conceptual Model. All performance measures are based on relationships between mean monthly salinity in five coastal basins, from Joe Bay to North River Mouth, to water stage at the P33 gage in mid Shark River Slough. The final PMs used are:

(1) number of months during the period of record when stages equal or exceed 6.3 feet msl at P33,

(2) number of months during the period of record when stages equal or exceed 7.3 feet msl at the P33 gage,

(3) cumulative salinity difference (ppt) from the undesirable high salinity levels that were identified for each basin, and

(4) cumulative salinity difference (ppt) from desirable low salinity levels that were identified for each basin during the wet/dry season months of August-October.

D.6.8 Model Lands / C-111

The Model Lands Alternatives Evaluation Matrix consists of the following performance indices, which are applied to each of the four indicator regions in the Model Lands area: 4, 5, 6, and 47:

(1) High water index: The proportion of time that water levels are below the high water threshold which has been specified for the indicator region. The target is 1.00, however proportions down to 0.90 are acceptable to allow for interannual variation. This index quantifies the period of time that water levels are so high that they may stress the vegetation communities naturally characteristic of these areas.

(2) Low water index: The proportion of time that water levels are above the specified low water threshold. The target is 1.00. This criterion seeks to minimize the period of time that water levels are below a specified low water level.

(3) Extreme low water index: The proportion of time that water levels less than 1 ft below the specified low water threshold. Target is 1.00. Values near 1 indicate that dry season levels are above the extreme low water level almost all of the time. Values closer to 0 indicate that dry season water levels typically fall at least another foot below the specified low water level.

(4) Relative dry period slope index: Relative measure of the steepness of the slope of the stage duration curve during dry periods. The index can vary from almost 0 (very steep slope; water levels drop dramatically during dry periods) to approximately 1.0 (slope shallow; water levels relatively stable throughout the dry season). Values closer to one are preferred.

(5) Wet season inundation pattern index: Proportional measure of how many times during the 31-yr simulation that water levels drop below surface elevation during the July-October portion of the wet season. The best alternative received a score of 1.0 and the worst received a score of 0.0. This criterion gives a relative ranking for how many times the aquatic habitat is disrupted by dry-downs during the core months of the wet season. The months June and November were omitted from the analysis to allow for variation early and late in the season.

(6) Late wet season inundation index: Proportional measure of how many times during the 31-yr simulation that autumn periods of inundation ended during the months of November and December. This index was applied only to Indicator Region 5 (Model Lands South), which includes habitat critical for Roseate Spoonbill feeding. A good year for wading bird feeding would be characterized by standing water in this indicator region well into January. Premature drydowns in the early dry season in this region may severely reduce available food to support Roseate Spoonbill nesting. The best alternative received a score of 1.0 and the worst received a score of 0.0.

D.6.9 Big Cypress

The Big Cypress area was evaluated as three areas, North Big Cypress, South Big Cypress, and Southeast Big Cypress. The following is a summary description of the PMs and problems by subarea:

D.6.9.1 North Big Cypress National Preserve.

Impacts in north Big Cypress are due primarily to agricultural development and its associated canals upstream (north) of this area. However, the results were suspect because there are model boundary problems with hydrologic model output in this area since the area to the north is included in the Natural System Model, but not the South Florida Water Management Model. PMs used were:

(1) Percent of North Big Cypress National Preserve that matches NSM (mean NSM hydroperiod matches)/100. This PM provides a spatial measure of one of the more impacted portions of the Big Cypress that lies along its northern border.

(2) Reduction in percent of time inundated from NSM condition based on indicator regions 42-43. This PM provides a measure of deviation from NSM hydroperiod for these indicator regions.

(3) Maximum deviation from NSM stage duration curve using indicator regions 42-43. This PM used normalized weekly stage duration curves to provide a measure of how much water levels have been altered from NSM conditions as a function of the NSM range of fluctuation for these indicator regions.

(4) Average flood duration for indicator regions 42-43. This PM provides a measure of deviation from NSM for average duration of individual flooding events for indicator regions 42-43.

D.6.9.2 South Big Cypress National Preserve.

Final PMs used for the southern portion of the Preserve:

(1) Percent of South Big Cypress National Preserve that matches NSM (mean NSM hydroperiod matches)/100. This PM provides a spatial measure of the relatively unimpacted portion of the Big Cypress.

(2) Reduction in percent of time inundated from NSM condition based on indicator regions 31, and 36-40. This performance measure provides a measure of deviation from NSM hydroperiod for an indicator region.

(3) Maximum Deviation from NSM stage duration curve based on indicator regions 31, 36-40. Normalized weekly stage duration Curves were used to measure how much water levels have been altered from NSM conditions as a function of the NSM range of fluctuation for the indicator regions.

(4) Average flood duration for indicator regions 31, 36-40. This PM provides a measure of deviation from NSM for average duration of individual flooding events for indicator regions 31, 36-40.

(5) Percent change in flow from NSM condition/100. Total flows during the wet and dry season for a flow cross section ("Eastern Big Cypress") were used to express hydrologic conditions and how they changed in response to proposed alternatives.

D.6.9.3 Southeast Big Cypress.

Final PMs used for the southeast Big Cypress were:

(1) Reduction in percent of time inundated from NSM condition. This PM provides a measure of deviation from NSM hydroperiod for indicator region 13.

(2) Maximum deviation from NSM stage duration curve. This PM used normalized weekly stage duration curves to provide a measure of how much water levels have been altered from NSM conditions as a function of the NSM range of fluctuation for indicator region 13.

(3) Average flood duration for indicator region 13. This PM provides a measure of deviation from NSM for average duration of individual flooding events for indicator region 13.

(4) Percent change in flow from NSM condition/100. Total flows during the wet and dry season for a flow cross section ("Lostman's Slough") were used to express hydrologic conditions and how they changed in response to proposed alternatives.

D.6.10 Caloosahatchee Estuary

Caloosahatchee Estuary has been adversely impacted by extreme water delivery events from Lake Okeechobee and local drainage basins. These events cause extreme ranges in salinity as well as severe physical alterations within the estuary. The following are the final performance measures used:

1. Minimum mean monthly flows less than 300 cfs. This PM is based on the number of times the minimum mean monthly flows from the lake and watershed fall below 300 cfs at S-79. Insufficient fresh water discharges had direct effects on estuarine seagrasses, fish and invertebrates, including critical indicator species (eg. Vallisneria) by enabling the estuary to become too saline.

2. Mean monthly freshwater discharges exceeding 2,800 cfs. This PM is based on the number of times mean monthly flow exceeds 2,800 cfs as measured at S-79. High volume discharges to the estuary contribute to poor estuarine water quality conditions including increased turbidity, color and violation of favorable salinity envelopes. These conditions have direct effects on estuarine seagrasses by reducing light penetration necessary for photosynthesis, destroying fish and invertebrate habitat, and contributing to unfavorable salinities for aquatic vegetation, fish and invertebrates, including critical indicator species (e.g., the American oyster, turtle grass, and Vallisneria).

3. Fresh water discharges exceeding 4,500 cfs. This performance measure is based on the number of times mean monthly flows exceed 4,500 cfs at S-79. Mean monthly flows above 4,500 cfs results in freshwater conditions throughout the entire estuary causing impacts to estuarine biota. This volume of flow also begins to reduce water quality and adversely impact biota in San Carlos Bay.

4. Zone A discharges from Lake Okeechobee. This PM is based on the number of days of Zone A discharges from the lake, measured as 7,800 cfs per day at S-79. Zone A discharges have rapid and serious effects on estuarine seagrasses in the Caloosahatchee River Estuary and San Carlos Bay by reducing light penetration necessary for photosynthesis destroying fish and invertebrate habitat, and contributing to unfavorable salinities for estuarine biota.

D.6.11St. Lucie Estuary

The St. Lucie Estuary receives freshwater inputs both through interbasin transfer from Lake Okeechobee and from local watershed contributions. The maintenance of flows to the estuary to achieve the appropriate salinity regime therefore must manage both watershed runoff and regulatory flows from Lake Okeechobee. Final PMs used were:

1. Minimum flows (mean monthly flows <350 cfs). This PM is based on the number of months the mean monthly flows fall below 350 cfs. The target is to have no more than 50 months with mean monthly flow less than 350 cfs. Insufficient freshwater discharges during the dry season contribute to reduced estuarine productivity. Minimum levels of inflow and nutrients usually occur at the end of the dry season (April and May). It is during these months that numerous species of juvenile fish depend on an abundant food supply of phytoplankton and zooplankton which requires a minimum level of fresh water and nutrients.

2. Moderately high flows (mean monthly flows >1,600cfs). This PM is based on the number of months with mean monthly flows > 1,600 cfs. The acceptable violations (target) allowing for natural variation is nine. As flows exceed this limit, salinity is reduced below desirable levels for some estuarine resources. High volume discharges to the estuary contribute to poor estuarine water quality including increased turbidity, and violation of the favorable salinity envelope. These events have direct effects on submerged aquatic (SAV) by reducing light penetration necessary for photosynthesis, degrading fish and invertebrate habitat, and contributing to unfavorable salinity concentrations for aquatic vegetation, fish and invertebrates, including the indicator species (American oyster and SAV).

3. High flows (mean monthly flows>2,500 cfs). This PM measures the number of times mean monthly flows from the lake and watershed exceeds 2,500 cfs. The target is no more than three months with mean monthly flows > 2,500 cfs. Mean monthly flows above 2,500 cfs result in freshwater conditions throughout the entire estuary causing severe impacts to estuarine biota. This volume of flow begins to impact the Indian River Lagoon to the north and south of the St. Lucie Inlet.

4. Zone A discharges. This PM is based on the number of days of Zone A discharges from Lake Okeechobee (7,200 cfs per day at S-80). The target is zero (0) violations. Zone A discharges transport large amounts of sediment and results in freshwater conditions within the entire estuary. These events can have rapid and serious effects on estuarine SAV by reducing light penetration necessary for photosynthesis, destroying fish and invertebrate habitat and contribute to unfavorable salinity concentrations for most aquatic life. Zone A discharges cause adverse effects on large areas of the Indian River Lagoon surrounding the St. Lucie Inlet and possibly influence nearshore ocean habitats adjacent to the Inlet.

D.6.12Lake Worth

Lake Worth has been adversely impacted by altered salinity. The performance measure used in this analysis for the Lake Worth Lagoon was “Wet/Dry season average flows discharged to Lake Worth Lagoon through S-40, S-41, and S-155 for the 31 year simulation.” The restoration target is to create estuarine conditions, to the extent possible, in the Lake Worth Lagoon. An estuarine salinity envelope of 23 ppt to 35 ppt has been chosen as the target salinity range. This is a viable salinity range for a number of organisms, many which are commercially and recreationally important. To attain this salinity a maximum flow needed to be developed. Previous hydrodynamic modeling indicated that 500 cfs creates a steady state salinity of 23 ppt. For the low flow part of the salinity envelope, 0 cfs is the target. Enough ground water occurs that should still allow estuarine conditions. Based on past modeling, this flow range of 0-500 cfs should create the salinity range of 23 ppt - 35 ppt.

Performance Measure: Wet/Dry Season Average Flows Discharged to Lake Worth through S-40, S-41 & S-155 for the 31-year simulation.

D.6.13 Biscayne Bay

Operation of coastal water control structures results in rapid changes in salinity gradients within Biscayne Bay that may occur on a daily basis and over several months, particularly during the rainy season. During the dry season, hypersalinity has been observed as a result of evaporation, retention of canal flow, and bay circulation. The presence and operation of the canals and construction of permanent oceanic inlets has resulted in a loss of estuarine function and shifted Biscayne Bay to more of a lagoon, adversely impacted from freshwater pulses and highly variable salinities. These conditions have been at least partly responsible for the loss of historically abundant estuarine species, such as red drum, black drum, and eastern oyster, the loss of juvenile fish habitat, and the significant increase in stress-tolerant fish species such as the gulf toadfish.

Performance measures were developed based on the potential effect of water management alternatives on surface water reaching Biscayne Bay. Canal discharges from gauged structures on canals that discharge into the bay were used. Based on SFWMM hydrologic model output, the bay was divided into five regions from north to south, based on the mean monthly discharge from water control structures in these regions. The regions were:

- Snake Creek (S29),
- North Bay (G58, S28, S27),
- Miami River (S25, S25B, S26),
- Central Bay (G97, S22, S123), and
- South Bay (S21, S21A, S20F, S20G).

Model output for each alternative provides results as the sum of discharge from the structures in each region in terms of a mean annual wet season and dry season volume. To judge the performance of a water management alternative in meeting restoration targets, model results were compared to surface water budget targets that were considered appropriate to achieving restoration of the Biscayne

Bay ecosystem. These targets consist primarily of the existing average annual inflow to Biscayne Bay as defined by the 1995 Base hydrologic period, with a 2% increase in total inflow budget to be applied in the dry season to the Central and South Bay regions. A separate target for Snake Creek (S29) was also developed based on canal discharge that would maintain salinity suitable for oyster survival.

D.6.14 Keystone/Endangered Species/ATLSS

Evaluation of Restudy Alternatives' performance with regard to threatened, endangered and keystone species was accomplished through a combination of several methods. ATLSS modeling results provided information on expected biological responses of several species and species groups. The nature and extent of information available through ATLSS results varied among species and species groups depending on the progress of each model's development. For example, highly sophisticated results were available for the Cape Sable seaside sparrow's western population and for fish abundance because development of these models was nearly complete at the time of evaluations. Less sophisticated foraging or breeding conditions indices were available for the snail kite, wading birds, and others because these models were in an earlier stage of development. ATLSS results for each Alternative were compared with results for other Alternatives as available, 2050 Base conditions, and in most cases, with 1995 Base conditions. When results indicated that the Alternative would improve species' biological response as compared to other scenarios, the subteam concluded that there was evidence to suggest that the Alternative was beneficial for those species as compared to the other scenarios.

Additional sources of evidence were considered as they were available. These included:

(1) Crocodile Habitat Suitability and Wood Stork Nesting Patterns performance measures;

(2) information on known hydrological responses of species gleaned from Volume I of the Multi-species Recovery Plan for the Threatened and Endangered Species of South Florida, Technical/Agency Draft; and

(3) discussions with research biologists widely recognized as experts on particular species.

These sources of information were considered along with ATLSS modeling results to form a "weight of the evidence" or "consensus" conclusion by the subteam members and species experts. Results of the analyses are presented in Table 7.

D.6.15 Water Quality

The Water Quality Team utilized two water quality models in their analyses: the Lake Okeechobee Water Quality Model, which simulates lake eutrophication processes and the Everglades Water Quality Model, which simulates phosphorus transport in the Everglades Protection Area. In addition, an evaluation of the effect of Restudy alternative plans on hydraulic and phosphorus loads into and predicted performance of the Everglades Construction Project was performed by William W. Walker, Jr. (Walker, 1998) using hydrologic outputs of the South Florida Water Management Model. The Water Quality Team also utilized hydrologic outputs from the South Florida Water Management Model to evaluate the extent of hydrologic change and corresponding water quality impacts or benefits resulting from the implementation of the alternative plans in other subregions of the study area.

The Water Quality Team's evaluation was conducted on a sub-regional basis by dividing the study area up into subregions. The team did not empirically evaluate the effect of Restudy alternatives on water quality conditions in the Big Cypress basin or the Holey Land and Rotenberger Wildlife Management Areas. For those areas, a qualitative assessment was made based upon the proposed operation of the components contained in the alternatives. Results of the water quality team are presented in Table 8.

The Water Quality Team considered in detail existing federal, state, and Tribal water quality regulatory programs in the study area. For each alternative plan, the plan's components were examined to identify potential water quality impacts or benefits resulting from the operation of that component and the regulatory or ecosystem management programs affecting the future implementation of the component. Specific issues which were considered by the Water Quality Team during evaluations of alternative plans include numeric and narrative water quality criteria, designated uses of source and receiving water bodies, special classifications (e.g., Outstanding Florida Waters), and existing and projected pollution loads.

D.7 AET SUMMARY TABLES.

D.7.1 Tables: List of Participating Agencies, AET Subteams, Format for Documentation of Performance Measures, Plan Ranking, Letter Grades, Colors, ATLSS & Listed Species

The following tables provide important background information concerning the AET participants, supporting documentation for the PMs, and the results for Plans A-D13R.

Table D.7.1.1: List of Agencies with Regular Representation on the AET

Federal	U.S. Army Corps of Engineers
	National Park Service
	Fish and Wildlife Service
	U.S. Geological Survey
	Environmental Protection Agency
	National Oceanographic and Atmospheric Agency
State	South Florida Water Management District
	Florida Game and Fresh Water Fish Commission
	Department of Environmental Protection
	Department of Agriculture and Consumer Services
County	Palm Beach County
	Broward County
	Miami-Dade County

Table D.7.1.2: AET Subteams and Subteam Chairs

Subteam	Chair(s)-Agency
Lake Okeechobee	Karl Havens - SFWMD
Caloosahatchee, St. Lucie & Lake Worth Estuaries	Steve Traxler - USACE
Lake Okeechobee Service Area	Carl Woehlcke - SFWMD
Lower East Coast Service Area	Brenda Mills - SFWMD*
Northern/Central Everglades	Lorraine Heisler - FGFWFC Winifred Park, SFWMD
Southern Everglades/Florida Bay	Sue Perry - NPS Robert Doren - NPS Steve Davis - SFWMD
Big Cypress	Mike Duever - SFWMD
Biscayne Bay	Gwen Burzycki - Miami-Dade County Tom Smith - USGS
Model Lands/C-111 Basin	Joan Browder - NOAA
Endangered & Indicator Species	Heather McSharry - FWS
Total Systems	Cheryl Buckingham - FWS
Water Quality	Eric Hughes - EPA Eric Bush - FDEP

* Initially representing Broward County.

Table D.7.1.3: Format for Documentation of Performance Measures.

Footnotes
1) Ranking of alternatives for Lake Okeechobee is based on evaluation of selected performance indicators. Comparing alternatives, differences greater than one percent in relative performance calculated by the model were assigned different ranks. Although the differences between simulated conditions for the alternatives are within the uncertainty of the model, the Water Quality Team felt it was important to rank the plans for Lake Okeechobee from a water quality perspective.
2) Water Conservation Areas 2 & 3 rankings were weighted to account for relative size (acreage).
3) Ranking of the alternatives based on an evaluation of potential water quality impacts/benefits in the LEC is primarily based upon salinity targets in Lake Worth and Biscayne Bay. The presumed water quality benefits resulting from an evaluation of the hydraulic performance of selected reservoirs were also evaluated. For those performance indicators, a score of zero was assigned to alternatives for which no hydraulic performance for the reservoirs was observed.

D.8 SUBTEAM REPORTS ON ALTERNATIVES A – D13R

D.8.1 Total System Subteam Decompartmentalization Matrix

D.8.1.1 Continuity: Water Surface Elevations Across Barriers

One of the problems resulting from using canals and levees to improve water management for water supply and flood control is that water surface elevations on either side of the barriers tend to be very different, i.e. pooling upstream and too dry downstream. The physical disconnection of the two wet areas is not addressed by this index but is addressed in the sheetflow index. The direct effects of pooling and drying on wildlife are addressed in the various measures of hydroperiod and ponding depths within each subregion group. This index addresses the discontinuity in water surface elevations and the effects of unexpected conditions on aquatic organisms and the species that rely on them. Different species of wading birds, for example, rely on various depths of shallow marsh to allow them to capture prey. Abrupt changes in depth, one too deep and one too shallow, limit their feeding area. This index is limited because, by using water level differences >0.5 feet as the top category, differences far greater than that maximum receive the same score.

Performance Measures:

Count of Water Level Differences Relative to NSM Water Level Differences for eight different man-made barriers within the remaining Everglades.

Strategy for Developing Indices:

The Count of Water Level Differences illustrates the number of weeks where the difference in water surface elevations across the barriers exceed the difference predicted by NSM 4.5F by 1) <0.25 feet, 2) <0.5 feet and 3) > 0.5 feet. Using those data, the following formulas were used.

To get an index score that rated highly a large number of weeks where differences in elevations were similar to NSM, this formula was used:

exp(-(x-1612)^2/2*w2)), where w = 900 and x = number of weeks where water surface elevation differences differed from NSM < 0.25 feet.

To get an index score that rated highly a low number of weeks where differences were more than 0.5 feet greater than NSM, the inverse of the formula was used:

1 – [exp(-(x-1612)^2/2*w2))], where w = 900 and x = number of weeks were water surface elevation differences differed from NSM > 0.5 feet.

Using these formulas, the highest scores were received by plans with the highest number of weeks that differed little from NSM *and* the lowest number of weeks differing greatly from NSM. This was done to avoid excluding the intermediate category containing the number of weeks where water level differences were >0.25 feet and <0.5 feet. The two scores were combined by averaging the two values; no weighting was involved. Weighting could have been added to the equation by using a different value for “w” depending on how far above 0.5 feet the difference was. In some cases, it was up to four feet greater than NSM.

Results

Flows through the northern part of the system across L-39 (between Loxahatchee NWR and WCA-2A) and L-38 (between WCA-2A and WCA-3A) remained unchanged between alternatives because the AET chose not to include them in any of the decompartmentalization scenarios. For that reason, their scores remained at zero throughout the analysis. Miami Canal North (MCN) improved slightly in alternatives B, C, and D. Miami Canal South (MCS) remained the same throughout and received a consistent score of 1.0. L-67 scored the best in Alternative B, the alternative in which it was completely removed. Alternatives C and D used other methods, including weirs, to operate flows across the L-67 barrier but were unsuccessful at reaching NSM-like water surface elevations on both sides of the barrier. These results must be tempered with the knowledge that the weirs may still operate successfully once their configuration and operation have been optimized. At the time, there had not been much chance to do so. Tamiami Trail west of L-67 (TTW) received its best score under Alternative B where it was completely removed. Alternatives C and D had fairly good scores with improved operations of the reinstalled structures. Tamiami Trail east (TTE) was removed in alternatives B, C and D and received a 1.0 for those three. L-28 received its best scores in alternatives B and C, although Alternative A and the 2050 Base received a 0.9.

In the table below, AVE1 is the average of the scores for the barriers excluding L-39 and L-38. This was an attempt to see the effect of these two very low scores on the final scores. AVE2 is an average of all eight scores. The AET decided to use AVE1 on which to base its color and grade and ranking scores in order to receive the benefits of the decompartmentalization that did occur. However, it should be noted AVE2 illustrates the overall system-wide benefit to the system, which only improves with alternatives B and D13R.

In Alternative D13R, the differences between water surface elevations on either sides of barriers inside of the remaining natural areas were more like NSM than the 2050 Base. As in Alternative B, the upstream pooling effects disappeared when barriers like Miami Canal, Tamiami Trail and L-28 are removed, but, unlike

Alternative B, water flows more evenly throughout the system than it did in the 2050 Base. The removal of the southern portion of L-67 improved the continuity score slightly.

D.8.1.2 Sheetflow: Flow Volume Transects

Justification

The natural system hydrology model (Fennema et al., Chapter 10) indicates that water management produced a significant change in the overland flow patterns in the Everglades. The Everglades was generally more of a flowing system with greater spatial extent and longer periods of inundation than exist today. Regional sheetflow patterns have been significantly disrupted and overland flow volumes reduced by the impoundment of Lake Okeechobee, construction of WCA levees and irrigation / drainage canals in the EAA, and the loss of dry season lag flows from the dense sawgrass plain that formerly covered the present EAA. Flow patterns out of Lake Okeechobee have shifted from primarily wet season flows in response to rainfall to dry season flows in response to urban and agricultural water supply demands.

Impoundment of water in the WCAs and diversion of surface water flows to the east, combined with ground water and levee seepage loses eastward in the modified system, have significantly contributed to reduced flows and the resultant loss of persistent hydroperiods in southern Everglades (Davis and Ogden 1994).

Instead of a vast expanse of sheetflow, the Everglades has become a series of pools, with pooling on the upstream and excess drying on the downstream side of barriers. “Ponded systems favor certain species and flowing systems favor others. There are many physicochemical differences in the two systems: food types and sources, migration of macroinvertebrates, dispersion of nutrients, aeration and diffusion of gases in water, particulate suspension, and thermal stratification are some examples. Ponding in the WCAs amounts to regulation for certain species—the zoo approach, which is not an ecosystem approach. From a water conservation perspective, ponding may be wise; and in a water-limited system, ponded water for fish is a real improvement over no water for fish. It would be possible to match regulated hydroperiods month to month with natural hydroperiods and still have a completely different ecosystem due to the difference in water movement. This is another reason why a hydroperiod analysis is singularly insufficient to create the intended biological conditions." (US Army Corps of Engineers, 1994).

Sheetflow also shapes tree islands, supports microhabitats on the upstream and downstream sides, enhances the uptake of nutrients from the water column and creates an environment that precipitated phosphorus, along with calcium carbonate, into the substrate.

Performance Measure: Flow volume across transects

Strategy for Developing Indices:

The 26 transects were grouped into five categories representing their general area: Big Cypress Group (T24, T25, T26), Central Everglades (WCA-3A) Group (T7, T8, T12), Southern Everglades Group (T21, T23A, B, &C), Tamiami Trail Group (T17, T18) and the L-67 Group (T13, T14). For each group, an index was calculated for each transect based on the wet season and the dry season average annual overland flows. For each base condition and alternative, the flow value was divided by the NSM value to obtain wet season and dry season proportions, which were then scaled. Scaling, using the normalized curve formulas described below, was used to obtain values between 0.0 and 1.0. In cases where the proportion of wet season flows exceeded NSM, they received a value of 1.0. For dry season flows, excess flows were treated the same as insufficient flows. For example, for the Cypress Group:

IF (wet season flows >= NSM volumes, then Index = 1.0, else EXP(-((wet season flow – NSM)/NSM)^2/(2w^2))), where w = 0.5 gave the most reasonable values.

IF (dry season flows = NSM volumes, then Index = 1.0, else EXP(-((dry season flow – NSM)/NSM)^2/(2w^2))), where w = 0.5 gave the most reasonable values.

Then, the wet season and dry season indices were averaged with the dry season weighted twice as heavily:

Index(T7) = CIV(wet) 8 2(CIV(dry))

The overall Central Everglades Score, therefore, was:

Score = (Index(T7) * Index(T8) * Index(T9) /3

Results: Improvements were seen over the 2050 Base in the Big Cypress Group (CYP) in all alternatives. Improvements in C and D over Alternative B echo the results seen by the Cypress subteam. The Central Everglades (CEver) transect groups were best served by the 1995 Base, but all alternatives were better than the 2050 Base. The Southern Everglades (SEver) transect groups received the highest score in Alternative A, but alternatives B, C and D were also very good with scores of 0.9. The Tamiami Trail Group (TT), comprising both east and west portions, also faired best with Alternative A, with good scores in alternatives B, C, and D. L-67 varied from a score of 0.0 in the 2050 Base to a moderate top score of 0.6 in Alternative B. Overall, all the alternatives scored higher than the 2050 Base and, when averaged, over the 1995 Base. Alternative A, which contained no decompartmentalization effort, received some of the highest scores, in the Southern Everglades and Tamiami Trail. The Big Cypress score was improved slightly with the reinstallation of L-28.

In D13R, where L-28 was removed again, the effects on flow volumes in Big Cypress were small and consisted of lower volumes in T25 (Eastern Big Cypress) and higher volumes in T26 (Lostman’s Slough). Flow volumes across transects looked better in D13R than the 2050 Base. Flows across Tamiami Trail not only increased 92% over 2050 Base but the proportion flowing east of the L-67 vs. west of L-67 improved from only 11% in 2050 Base to 55% in D13R. NSM’s east/west proportion was 62%. Flows through southern WCA-3A increased from only 62% of NSM volumes in the 2050 Base to 110% of NSM in D13R without causing excessive high water events. Flows in western WCA-3A were spread more evenly into the dry season in D13R, preventing the premature dry season drydowns seen in the 2050 Base.

D.8.1.3 Fragmentation: Miles of Canals and Levees

Justification

In its effort to control floodwaters and provide water supply, the C&SF Project created miles of canals, levees, and water control structures with associated deep pools. Canals and levees usually coexist; construction of a canal usually means a spoil levee exists alongside it just as a levee requires a borrow canal. Roadway construction usually involves combinations of levees and canals, sometimes with culverts to allow water to flow underneath. Water control structures are usually even more complex, involving combinations of levees, canals and deep pools. In some places, multiple canals, levees and water control structures form intricate patterns - and formidable barriers to wildlife.

When levees block the flow of water, they also restrict the movement of aquatic and semi-aquatic life forms in the water. Land-based predators use the levees to invade the marsh interior, preying upon animals that try to cross the intrusive fingers of terrestrial habitat. Levees also act as conduits, allowing terrestrial plants to invade. Canals act as corridors particularly for non-native animals and plants that can extend their ranges rapidly from points of introduction and can move into wetlands where they can alter habitats and affect food webs (Loftus and Kushlan 1987; Loftus 1986). Artificial, deep-water habitats provide thermal and spatial refuge to large numbers of both non-native and native aquatic predators in the dry season, enhancing their survival and ultimate population sizes. During the dry season, these predators prey heavily on small marsh fishes and invertebrates moving in from the adjacent wetlands (Howard et al. 1995).

Performance Measure Fragmentation Miles of Canals and Levees

Strategy for Developing Index

The Alternatives Evaluation Team chose to focus its attention on reducing the number of canals and levees in the natural areas, believing that these artificial structures affect natural resources more so than those found within urban or agricultural areas. Therefore, the Total System Performance Measure for Fragmentation: Miles of Canals and Levees uses only the number of miles of canals and levees within the Everglades Protection Area, Big Cypress National Preserve, Holey Land, and Rotenberger Wildlife Management Areas. The list of which structures were included can be found on the web site under “View Maps and Tables”, “Individual Maps and Tables” and the last category “Model Inputs.”

The lengths used in the Fragmentation performance measure are as they are modeled by the SFWMM. Model miles are useful for comparative purposes, which was the point of the evaluation, but model miles are unlikely to exactly match the number of miles actually implemented.

The AET discussed including only the "primary barriers to sheet flow" within the natural area in the performance measure, but agreed that the problems with canals and levees go far beyond their direct affect on sheet flow. They also convey exotic species, for example, and canals appear to serve as sinks and refuges for large fish and possibly other predators. Their effect appears to extend into the adjacent marsh. In the interest of including the impacts of all the canals and levees in the natural area, we did not limit ourselves to just those that pass through the center of the system but included perimeter canals around the marshes as well.

Due to the amount of time available, the Alternatives Evaluation Team chose not to continue to track the number of structures because there were cases where single, large structures were replaced with several smaller, passive structures. Alternatives would receive lower scores for having structures that the Alternatives Evaluation Team believed were better - simply because there were more of them.

Using the numbers of miles canals and levees posted for the 1995 Base and the 2050 Base, the larger was considered to be the worst case scenario, the 100% build-out value. For each alternative and base condition, the number of miles of canals and levees were each divided by the maximum value and scaled using the following formula. For example, the index for canals for Alternative A was calculated as follows:

Canals(A) = exp ((x-x*)/x*)^2(2w^2)-1), where w = -2.773, x = # of miles or levees for Alternative A, x* = the worst cast value.

Then, for each alternative and base condition, the canal and levee index scores were combined, canals receiving aweighting of two:

Fragmentation Score = $(Canals_{alt} * Canals_{alt} * Levees_{alt})/3$

The number of structures was available but the AET decided not to use these data in this analysis. The analysis would have been confusing because the weirs added to alternatives C and D were treated as additional structures, nullifying the beneficial effects of the weirs.

Results: Within the "natural" area, the 1995 Base condition had 330 miles of canals and 400 miles of levees. The 2050 Base condition had 311 miles of canals and 400 miles of levees. Alternative A provided no benefits over the 2050 Base because it did not remove any canals or levees. Alternatives B, C, and D reduced the numbers of canals and levees substantially. Alternative B performed the best with 184 miles of canals and 318 miles of levees, 19 and 26 miles respectively fewer than Alternative D. Still, Alternative D had 127 fewer miles of canals and 56 fewer miles of levees than the 2050 Base.

In Alternative D13R, the number of miles of canals and levees fragmenting the remaining natural system was reduced even further to Alternative B amounts. Alternative D13 and the D13R scenario have 184 miles of canals and 318 miles of levees. There were 146 fewer miles of canals and 82 fewer miles of levees in D13R. Thus, the number of miles of canals and levees removed in Alternative D13R (and D13R4) within the natural areas is: 146 + 82 = 228. Miles of canals were reduced by 40% while levees were reduced by 20% over the 2050 Base.

D.8.1.4 Discontinued Performance Measures

The other AET subteams used conceptual models to develop their performance measures. Although a conceptual model for the total system has yet to be developed, Davis and Ogden have described the defining characteristics of the total system as (1) large spatial extent, (2) habitat heterogeneity, and (3) dynamic storage and sheet flow (Davis and Ogden, 1994). Early performance indicators and measures were based on hydrologic model outputs that the Total Systems team believed could represent some aspects of these defining characteristics. These early measures were used in the evaluations of the Starting Point and Alternatives 1-4, but then discarded. The AET preferred to use the Continuity, Fragmentation and Sheetflow performance measures and therefore used them for the remaining analyses.

The problem with the early performance indicators and measures was that they depended heavily on matching NSM targets. As the iterative process of formulating Alternatives 1-4 proceeded, the number of cells where NSM was no longer the target increased, eventually including Loxahatchee NWR (WCA 1), Rotenberger, Holeyland, central WCA 3A, southern WCA 3B, the western sparrow indicator region, and finally the entire western sparrow range. As a result, these performance indicators and measures no longer represented as much of the system and became, in fact, misleading.

During detailed design, the total system performance measures will be refined and/or new ones designed based on a conceptual model developed by a subteam of the RECOVER team. The total system conceptual model will expand on the defining characteristics of the south Florida ecosystem described above, identify critical pathways, and identify the parameters on which to base the performance measures. At that time, if appropriate targets can be established, some of these early ideas may be resurrected. Until then, they should be viewed only as early attempts to gain an ecosystem-wide perspective of the way some of the alternatives affected the system.

Hydroperiod Distribution. For each plan the Total Systems team compared the number of acres in each of the eight hydroperiod classes (0-30, 30-60, 60-90, etc.) to NSM. The result was a proportion. This measure was discarded when the number of acres where NSM was no longer the target grew so large that it was no longer meaningful.

Hydroperiod Matches. This measure was the percent of acres matching NSM for the Remaining Everglades. It was discarded when the number of acres where NSM was no longer the target grew so large that this measure was no longer meaningful.

Ponding Depths. This measure was the percent of acres matching NSM for the Remaining Everglades. This measure was discarded when the number of acres where NSM was no longer the target grew so large that it was no longer meaningful

Hydroperiod Improvement. This measure consisted of the proportion of total acres where hydroperiods were improved, compared to optimal NSM hydroperiods. This measure was discarded when the number of acres where NSM was no longer the target grew so large that it was no longer meaningful.

Dry year drydown Pattern. A performance indicator using a typical dry year (1989) hydroperiod distribution map. The measure consisted of a best professional judgement of poor, average, good, very good as determined by the Central Everglades Subregion Team comparing it to the NSM. This never became a performance measure for lack of quantifiable targets.

Pond Count. A score based on the number of drydown events and their duration for the Ridge and Slough area only. Because this measure represented a relatively small part of the system, it had limited use during plan formulation. However, it could be expanded into other areas during the detailed design phase.

D.8.2 Lake Okeechobee

Lake Okeechobee Priority Hydrologic Performance Measures

Five priority performance measures are calculated, weighted and summed using the River of Grass Evaluation Model (ROGEM) for Lake Okeechobee. The Lake Okeechobee ROGEM is comprised of metrics (Suitability Index Variables, or SIVs) that concern the fluctuation and timing of lake stages. These variables exert major controls over ecosystem structure and function. Fluctuation and timing of lake stages affect the distribution of native and exotic plant communities, and in turn the habitat quality (cover, nesting sites, foraging habitat) for fish, birds, and other wildlife (Aumen 1995). The ROGEM assumes that restoration of a more natural (within the constraints of the dike system) hydroperiod would result in positive biotic responses of the lake community.

Each SIV ranges from 0 (worst score) to 1.0 (best score). Relationships between hydrologic attributes and SIVs in this model are not linear, but reflect expert opinion that the degree of ecosystem stress is exacerbated by an increasing occurrence of undesirable events. This gives rise to a curvilinear relationship between hydrologic attributes and their SIVs. At a certain point (considered here to be four events or more per decade), the degree of stress is so severe that the ecosystem cannot recover its ecological and societal values.

An <u>extreme low lake stage</u> (<11 ft) performance measure (SIV_{MINX}) indicates the frequency of events that result in a loss of over 95% of the littoral zone as habitat for aquatic biota, and promote expansion of exotic plants into pristine native-plant dominated regions of the lake. The goal is to have a minimal number of these events. The performance measure score is calculated as follows:

- Lake stage never falls below 11 ft = 1.0
- Lake stage falls below 11 ft on 1 occasion per 10 yrs = 0.9
- Lake stage falls below 11 ft on 2 occasions per 10 yrs = 0.7
- Lake stage falls below 11 ft on 3 occasions per 10 yrs = 0.4
- Lake stage falls below 11 ft on 4 or more occasions per 10 yrs = 0

A <u>moderate low lake stage</u> (<12 ft) performance measure (SIV_{MINM}) indicates the frequency of prolonged (>12 continuous month) events that substantially reduce the littoral area available as wildlife habitat, and promote exotic plant expansion. The goal is to have a minimal number of these events. The performance measure score is calculated as follows:

- Lake stage never falls below the 12 ft / 12 month criterion = 1.0
- Lake stage falls below the 12 ft / 12 month criterion on 1 occasion per 10 yrs = 0.9
- Lake stage falls below the 12 ft / 12 month criterion on 2 occasions per 10 yrs = 0.7
- Lake stage falls below the 12 ft / 12 month criterion on 3 occasions per 10 yrs = 0.4
- Lake stage falls below the 12 ft / 12 month criterion on 4 or more occasions per 10 yrs = 0

An <u>extreme high lake stage</u> (>17 ft) performance measure (SIV_{MAXX}) indicates the frequency of events that may cause wind and wave damage to the shoreline plant communities, and transport phosphorus-laden pelagic water into pristine interior regions of the littoral zone. The goal is to have a minimal number of these events. The performance measure score is calculated as follows:

- Lake stage never exceeds 17 ft = 1.0
- Lake stage exceeds 17 ft on 1 occasion per 10 yrs = 0.9
- Lake stage exceeds 17 ft on 2 occasions per 10 yrs = 0.7
- Lake stage exceeds 17 ft on 3 occasions per 10 yrs = 0.4
- Lake stage exceeds 17 ft on 4 occasions per 10 yrs = 0

A moderate high lake stage (>15 ft) performance measure (SIV_{MAXM}) indicates the frequency of prolonged (>12 continuous months) events that may: limit light penetration to the lake bottom, resulting in a loss of the benthic plants and algae that stabilize sediments and provide habitat for invertebrates and fish; and promote greater circulation of phosphorus-rich turbid waters from mid-lake to less eutrophic near-littoral regions, where phosphorus inputs stimulate algal blooms. The goal is to have a minimal number of these events. The performance measure score is calculated as follows:

- Lake stage never exceeds the 15 ft / 12 month criterion = 1.0
- Lake stage exceeds the 15 ft / 12 month criterion on 1 occasion per 10 yrs = 0.9
- Lake stage exceeds the 15 ft / 12 month criterion on 2 occasions per 10 yrs= 0.7
- Lake stage exceeds the 15 ft / 12 month criterion on 3 occasions per 10 yrs = 0.4
- Lake stage exceeds the 15 ft / 12 month criterion on 4 occasions per 10 yrs = 0

A spring recession performance measure (SIV_{VAR}) indicates the number of years during which January to May lake levels decline from near 15 ft to 12 ft, without any reversals greater than 0.5 ft. These conditions appear to be favorable to nesting birds and other wildlife in the marsh. They also may allow for re-invigoration of willow stands, and permit fires to burn away cattail thatch. The goal is to have a substantial number of events. The performance measure score is calculated as follows:

- Stage recession between January and March from ~15 ft to ~12 ft NGVD, with no reversal greater than 0.5 ft NGVD, occurring every yr = 1.0
- Stage recession occurring, on average, every other yrs = 0.9
- Stage recession occurring, on average, once every three yrs = 0.7
- Stage recession occurring, on average, once every four yrs = 0.4
- Stage recession occurring less frequently than the above = 0

SIV Priority Weights

The five SIVs address important aspects of how water level and its seasonal variation affects the intrinsic ecological (e.g. habitat for wading birds and federally endangered species) and societal (e.g. recreational fisheries) values of Lake Okeechobee. However, the five SIVs are not considered of equal importance in regard to indicating an absolute level of stress (or benefit). A weighting scheme was developed based on best professional judgement to reflect the relative importance of each SIV as an index of lake ecosystem health. For simplicity, a weighting scale of 1 to 5 (1 being least important, and 5 being most important) is used.

The SIVs associated with the >17 ft and >15 ft / 12 month criteria are given priority weights of 5. Extreme or prolonged high water levels have been documented to affect numerous ecosystem attributes, including: littoral plant and periphyton communities; benthic plants and periphyton; fisheries habitat; and water quality (including turbidity, phosphorus, and algal blooms). These effects are well documented by scientific research (Sheng and Lee 1991, Havens 1997, Steinman et al. 1997).

The SIVs associated with the <11 ft and <12 ft / 12 month criteria are given priority weights of 4. Extreme or prolonged low lake stages also may cause harm to the ecosystem, but the impacts are less documented, and are not considered as serious on a lake-wide basis. That is, the effects primarily are restricted to the littoral zone proper, and negative impacts (e.g., loss of fisheries habitat) may in part be compensated for by enhanced growth of submerged plants in the southern near-shore pelagic region.

The SIV for spring lake level recession describes a seasonally-variable hydro-pattern that is considered by experts to benefit a variety of littoral zone values, including wading birds and certain native plant communities (Smith et al. 1995). It is the only SIV that relates to seasonal variation in lake levels, and that variation is considered by experts (Havens and Rosen 1997) to be critical for a healthy ecosystem. However, there is a high degree of uncertainty in scoring the spring recession attribute. For example, do recession events that occur slightly earlier or later than the designated optimal (January-May) period have equal or lesser benefit to the community? Do recession events that occur over higher or lower ranges of water depth than the designated optimum (15 to 12 ft) have equal or lesser benefit to the community? There are no clear answers to these questions, and therefore, until further research results are available, the SIV associated with this attribute is given a weighting of 3.

Integrated Scoring

A Community Suitability Index (CSI) integrates the scores of five hydrologic SIVs and their respective weighting factors, and has an overall range of 0 to 1.0. The weighted CSI model is:

$$CSI = (4*SIV_{MINX} + 4*SIV_{MINM} + 5*SIV_{MAXX} + 5*SIV_{MAXM} + 3*SIV_{VAR}) / 21$$

From the standpoint of Lake Okeechobee ecological values, Alternative D13R performs in an identical manner to Alternative D, and is considered beneficial to the lake ecosystem.

Evaluation of Alternatives A-D and the revised 1995 and 2050 base conditions using the Lake Okeechobee priority hydrologic performance measures, and the ROGEM equations.

D.8.3 Lake Okeechobee Service Area

The Lake Okeechobee Service Area includes the Everglades Agricultural Area, the Caloosahatchee Basin, the St. Lucie Basin, the S-4 Basin, the L-8 Basin and the Seminole Indian (Brighton and Big Cypress) Reservations.

Performance Measures and Indicators Used.

Performance Measures:

Two performance measure reports are used to evaluate the frequency, duration and severity of water supply cutback events in the Lake Okeechobee Service Area. These are the detailed “LOSA Supply Side Management Report” and the “Frequency of Water Restrictions” graphic. Water restriction events vary as to how often they occur (frequency), how long an event lasts (duration), and how much of the water that would normally be demanded is not delivered (severity) and scores are developed for each of these characteristics.

Scoring Procedures

The number of years with water restrictions from the “Frequency of Water Restrictions” graphic is the piece of information used to develop a score regarding the frequency of water shortages. The established performance target is that there be no more than 3 years during which cutbacks occur over the 30-year period of performance available from each simulation. This implies that all demands will be met in at least 27 years. The relevant period is 30 years because a crop/water service year from October to September is used in counting shortage events, instead of a calendar year. For example, in the 2050 base (revised) there are 14 years when all demands are met and 16 years with restrictions. In each case the score is developed as:

Score = (Number of Years When All Demands Are Met)/(Target years for All Demands Being Met) = (30 – Years With Restrictions)/27 with the limitation that the score is counted as “1” if the calculated score is greater than one.

The detailed “LOSA Supply Side Management Report” was used to develop a combined duration/severity score, for relative comparisons of alternatives only. The duration/severity scores apply only to months that are considered to have significant supply side management cutback volumes. For purposes of calculating the scores, months with less than 18,000 acre feet of supply side management cutback volumes are not considered significant and so are not included in the severity/duration scoring calculations. The duration portion of this score is the sum of the number of months with supply side management cutback volumes greater than 18,000 acre feet for each alternative. The severity portion considers the supply side management cutback volume in the worst month of each shortage event. The severity score given for each annual event is developed using the following table:

The Largest Monthly Supply Side Management Cutback Volume (cut) of Each Event	Severity Score
18,000 ac. ft. <=cut < 50,000 ac. ft.	1
50,000 ac. ft. <=cut < 100,000 ac. ft.	2
100,000 ac. ft. <=cut < 150,000 ac. ft.	3
cut >= 150,000 ac. ft.	4

The total duration/severity score is the sum of the two scores. As an example, the duration/severity score for the revised 2050 Base is developed below.

2050 Base Revised

Water Years With SSM Cutbacks	Highest Monthly Cutback	Severity Score	Duration Score (No. of Months with Supply Side Management Cutbacks > 18,000 ac.ft.)	Combined Duration Severity Score
1968	130,570	3	3	6
1971	62,060	2	3	5
1972	73,380	2	2	4
1973	132,150	3	6	9
1974	154,730	4	6	10
1975	30,610	1	1	2
1976	135,190	3	5	8
1977	99,110	2	6	8
1978	52,360	2	1	3
1981	184,910	4	5	9
1982	104,460	3	9	12
1986	122,620	3	2	5
1989	143,530	3	7	10
1990	103,560	3	8	11
1991	70,060	2	5	7
			Total	109

Because it was desired to put the duration/severity scores on a 0 – 1 scale and because there was no target or allowable number of points, it was decided to make the scale relative to the poorest performing alternative. In this case it is the 2050 Base (revised). Thus the scores for all alternatives and base cases have been developed as:

Scaled duration/severity score = 1 – (Combined Duration Severity Score for the alternative÷Combined Duration Severity Score for the Worst Alternative) = 1 – (Combined Duration Severity Score for the Alternative÷109).

Aggregating Scores

The final step in scoring the alternatives and bases in terms of water supply performance in the Lake Okeechobee Service Area is to aggregate the frequency and the duration/severity scores. This is accomplished by taking a weighted average of the two scores. In this case each of the scores was assigned an equal weight of 0.5, so the result is the simple average of the two scores.

Summary and Interpretation of Water Supply Scoring Results

This summarizes and interprets the scoring results achieved by applying the methodology set forth above. The results of the scoring are presented below in Table LOSA-1. Attachment LOSA-1 presents the calculations of the frequency scores and Attachment LOSA-2 presents the duration/severity scoring calculations contained in Table LOSA-1.

It is the opinion of the LOSA team that the resulting scores provide only an ordinal ranking of the alternatives. Differences or relative difference among the scores should not be interpreted as indicating a proportionate quantitative difference in performance. For this reason a ranking of the alternatives is provided in the rightmost column. A rank for the 2050 Base is provided because it could be selected as a “no action alternative”. No rank is provided for the 1995 Base because it can not be selected as an alternative. It is interesting to note that the rank order of each of the components is the same. This implies that the rank orders of the combined scores will be the same no matter how the components are weighted.

Table LOSA-1 – LOSA Water Supply Scoring Results

Base or Alternative	Frequency Score	Duration/ Severity Score	Combined Score	Rank
2050 Base (revised) (no action alternative)	0.519	0.000	0.259	5
1995 Base (revised)	0.704	0.431	0.567	NA
Alternative A	0.852	0.789	0.820	3
Alternative B	0.778	0.661	0.719	4
Alternative C	0.889	0.789	0.839	2
Alternative D	0.926	0.853	0.890	1

While the scoring procedure provides a ranking of the alternatives, information from the performance measures and performance indicators can be utilized to provide a qualitative interpretation of the performance of the alternatives relative to the goals and relative to each other. The principal goal utilized by the LOSA subteam was that the alternatives should be able to meet all demands in a 1-in-10 year drought. It was also agreed that the best available indicator that this was being done would be if the number of years with water shortage restrictions were not more than three in the 31-year simulation period. In developing the count of years with water restrictions, certain events with very minor restrictions were not counted. None of the alternatives reach this goal (three or less events) but several come close. Alternative D has five events, Alternative C has six events and Alternative A has seven events. By comparison Alternative B has nine events and the 2050 Base 15 events.

Inspection of the events in alternatives A, C and D indicates that some of the events do not involve very many months with supply side management cutbacks and some of the months have relatively small volumes of cutbacks. As part of the effort to produce a duration/severity score, a slightly more restrictive definition of the amount of supply side management cutbacks that were required before it was significant enough to be counted was used. Under this criterion, months with monthly supply side management cutbacks of less than 18,000 acre feet are not counted and the numbers of water years with restrictions become three for Alternative D and five for Alternative C and Alternative A. By contrast Alternative B remains at nine events and the 2050 Base remains at 15 events under the revised criterion.

The strong performance of alternatives A, C and D is further evidenced when the duration (total months of supply side management with restrictions greater than 18,000 acre feet) of the water restriction periods is considered. For Alternative D, LOSA is under restrictions only nine months in the 31-year simulation period. For Alternatives A and C the restrictions are 13 months. By contrast, for Alternative B the restrictions are 21 months and for the 2050 Base they are 69 months.

In summary, alternatives A, C and D are considered to come close to meeting the water supply level of service goal and are judged to have good performance, with Alternative D being clearly the best performer. Alternative B has significantly poorer performance than alternatives A, C and D. The performance of the 2050 Base, the no action alternative, is unacceptable.

Results of Alternative D13R

Modifications to Alternative D that resulted in the revised Alternative – D13R had no significant effect on the good performance of Alternative D with respect to Lake Okeechobee Service Area water supply. This is shown in Table LOSA-2 below. With only five years with shortages, the frequency score is the same. The duration/severity score for D13R is slightly better because there is one less month of category 1 supply side management cutbacks (see Attachment LOSA-2).

Table LOSA-2 – LOSA Water Supply Scoring Results Comparison of Alternative D and Alternative D13R

Base or Alternative	Frequency Score	Duration/ Severity Score	Combined Score
Alternative D	0.926	0.853	0.890
Alternative D13R	0.926	0.862	0.894

Calculation of Frequency Scores

Alternative	Number of Water Years with Restrictions	Frequency Score = (30 – Years with Restrictions)/27
2050 Base (Revised)	16	0.519
1995 Base (Revised)	11	0.704
Alternative A	7	0.852
Alternative B	9	0.778
Alternative C	6	0.889
Alternative D	5	0.926

Calculation of Duration/Severity Scores

Note that the scaled duration/severity score is calculated using the following formula: Scaled duration/severity score = 1 – (Combined Duration Severity Score for the Alternative÷Combined Duration Severity Score for the Worst Alternative) = 1 – (Combined Duration Severity Score for the Alternative÷109).

2050 Base (Revised)

Water Years With SSM Cutbacks	Highest Monthly Cutback	Severity Score	Duration Score (No. of Months with Supply Side Management Cutbacks > 18,000 ac.ft.)	Combined Duration/ Severity Score = Severity Score + Duration Score

D.8.4 Lower East Coast Service Area

Procedure and Scores of Alternatives and Base Conditions

Location

The Lower East Coast Service Area (LECSA) is divided into four service areas: North Palm Beach, and Service Areas 1, 2, and 3. The North Palm Beach Service Area extends from northern to central Palm Beach County, encompassing approximately one-third of the county and includes one primary canal, the C-17. Service Area 1 covers the remainder of Palm Beach County and a small portion of Broward County to just below the Hillsboro Canal. There are four primary canals that traverse the service area: C-51, C-16, C-12, and the Hillsboro Canal. Service Area 2 includes most of Broward County and a portion of Miami-Dade County. It extends south from the Hillsboro Basin to just south of the C-9, which lies in Miami-Dade County. Four primary coastal canals extend through Service Area 2: C-14, C-13, North New River, and C-9. Service Area 3 includes the remainder of Miami-Dade County from the C-9 Basin south to near the tip of the peninsula. There are three primary coastal canals in Service Area 3: C-4, C-6 and C-2. Although the county boundaries extend west to the center of the state, the service areas only include those portions of the counties east of the protective levees.

Background: Water Supply

The performance measures used for the Lower East Coast to evaluate Restudy alternatives for water supply relate to the frequency and duration of water supply cutback events and the ability to maintain primary coastal canals. Water supply cutbacks are mandatory reductions imposed by the District on the LECSA utilities and general population to conserve existing water supplies when a shortage is imminent. Water supply cutback events usually occur during the dry season, when replenishment of stored water is limited.

During the dry season structural releases are periodically made from the Water Conservation Areas (WCAs) and Lake Okeechobee to maintain ground water levels and to minimize the possibility of saltwater intrusion along the coast. The Lower East Coast uses this water from the regional system to recharge secondary canal networks, wellfields and other recharge areas, and lakes. These ancillary systems are maintained by the local utilities to continue meeting public water supply demands. During the wet season and under normal conditions, rainfall and seepage account for the vast majority of recharge to the LECSA surface and ground water system that supplies this area. During extended dry periods, Lake Okeechobee and the WCAs are important sources of surface water supply for large regions of South Florida. WCAs 1, 2A and 3A are the primary sources of supplemental surface water supply for the Lower East Coast Service Areas 1, 2, and

3, respectively. When water stored in the WCAs and Lake Okeechobee is scarce, for instance during a drought, the urban water supply demands are restricted (cut back) in order to conserve the remaining supplies in the regional system. Although the service areas are able to continue to meet some demands through local sources, all service areas are dependent on the WCAs and Lake Okeechobee to supplement surface water supply and support urban public water supply demands. This is true for all of the service areas except Northern Palm Beach Service Area, which relies on local supplies.

The availability of recharge water to the LECSA via surface or ground water through either seepage or structural flows from the regional system can be evaluated based on the surface water storage in Lake Okeechobee. The storage volume within the lake gives a more quantitative indicator that a water shortage condition may be approaching. The water supply cutbacks in the LECSA are based partly on the available surface water storage in Lake Okeechobee. However, the primary triggering mechanism for implementing the LECSA cutbacks is related to ground water levels within the LECSA.

Low ground water levels near the coast increase the vulnerability of the Biscayne aquifer to saltwater intrusion. Continuing to meet urban water demands may exacerbate ground water levels and therefore cutbacks are necessary when there is a threat to the resource. Low storage levels in the Lake Okeechobee at the beginning of the dry season are indicative of a prolonged storage problem that dictates when the cutbacks can be removed while low ground water levels indicate immediate problems within the LECSA. Either of these triggers, Lake Okeechobee or local ground water levels, can initiate a water supply cutback and are reflected in the ability to meet the 1-in-10 level of service water supply goal. Although regional water supplies or local ground water levels may rebound during the dry season, cutbacks are continued through the end of the dry season, May, to ensure protection of the Biscayne aquifer.

The availability of water from the regional system to recharge the LECSA via structural discharges can be evaluated based on the ability to maintain the primary coastal canals above their saltwater intrusion criteria. This third performance measure, maintaining the surface water levels and continuing their recharge functions, is critical to protecting the Biscayne aquifer from saltwater intrusion. However, it should be noted that saltwater intrusion could still occur even if the primary canals are maintained. Some areas along the salt front cannot be adequately recharged from the regional system to offset local demands on ground and surface waters or to abate saltwater intrusion. Local conditions and demands can contribute to the movement of the salt front as well by lowering ground water levels.

The primary coastal canal performance measure is indicative of the ability to meet the proposed criteria for minimum flows and levels for the Biscayne aquifer. Chapter 373, F.S. directs all of the water management districts to establish minimum flows and levels for surface waters and aquifers within their jurisdiction. The District will be proceeding with rule development for the minimum level criteria for the Biscayne aquifer in the near future. The minimum level criteria for the Biscayne aquifer was utilized in the SFWMM model to reflect future demands from the regional system.

The performance measures described herein rely upon a linear relationship between performance and the scores developed for comparative purposes. Only the 1-in-10 level of service performance measure was normalized. No weighting was applied to the performance measures since all were considered equally important to continue the functions of the Biscayne aquifer and other resources in the Lower East Coast.

Performance Measures and Indicators

Two performance measures and one performance indicator are analyzed for each service area. In Service Area 3, an additional performance indicator, Ability to maintain South Miami-Dade Canals, was analyzed. These performance measures were selected due to their ability to measure how the alternative performs in protecting the Biscayne aquifer and providing recharge to the aquifer for public water supply. These measures are indicative of how well the conceptual designs may perform together on a regional scale. Additional feasibility studies and detailed designs will need to be pursued prior to implementation of any of the components included in the Comprehensive Plan.

1) Ability to meet the 1-in-10 water supply planning goal: The frequency of water supply cutbacks is indicative of the reliability of regional and local water supplies through various weather and resource conditions. Water supplies in Lake Okeechobee supplement deliveries to the LECSA to maintain ground water levels to prevent saltwater intrusion near the coast. Public water supplies are reduced or cutback at the well field in response to low surface water levels in Lake Okeechobee or ground water levels near the coast. The planning goal is to find a balance between ability of the regional system to supplement recharge of the aquifer and meet the public water supply planning goal of a 1-in-10 year level of service in the lower east coast of Florida. The planning goal is in terms of the frequency of cutback events and is defined as no more than three cutback events, no more than seven months in duration over the period of record. A cutback event can begin in the fall and continue through the spring, therefore the maximum number of cutback events in the period of record is thirty. The score represents the number of cutback events during the period of record minus the three allowed events compared to the maximum number of years the 1-in-10 year level of service planning goal can be

met. Alternatives that equaled or exceeded the goal, i.e. had three or less cutback events, scored 100% (no extra credit was given for exceeding the planning goal).

Score =[1 - ((# of cutback events   3 years)/27 years)]100 = % of years goal met

2) Percentage of months not in a water supply cutback: The duration of water supply cutbacks is another characteristic of a drought event and is used as an indicator of the reliability of water supplies. The number of months of water supply cutbacks incurred in a service area capture the lengths of time urban demands are not met. The increased or decreased length of the cutback events is captured by counting the total number of months when the service area is in a water supply cutback, regardless of the severity of the cutback, as a percentage of the total number of months in the period of record. This percentage of time would be subtracted from one to reflect the improvement, increasing amount of time not in a water supply cutback, attributable to the alternative.

Score =[1-((# of months service area in cutback)/372 months)]100 = % of time in a cutback

3) Ability to maintain saltwater intrusion criteria: Maintaining the primary coastal canals above the saltwater intrusion criteria is critical to protecting the Biscayne aquifer from saltwater intrusion and is part of the proposed criteria for minimum flows and levels. Each Service Area includes several primary coastal canals that have saltwater intrusion criteria developed for them. In the SFWMM, the stage of the coastal canal is compared to the criteria on a daily basis. If the canal is unable to be maintained for a week, the event is counted towards the time the saltwater intrusion criteria was not met. All canals were weighted equally except in Service Area 3, where the C-6 and C-2 were weighted more than the C-4 due to their ability to provide wellfield recharge. The performance measure is reported as the percentage of time the canal stage is below the saltwater intrusion criterion, which is subtracted from one to report the percentage of time the canal is above the saltwater intrusion criterion.

Score = [1- % of time not able to maintain canals]100 = % of time able to maintain canals

4) Maintaining water levels in south Miami-Dade canals: At this time, saltwater intrusion criteria do not exist for the major canals in southern Miami-Dade County. However, it is important to evaluate water levels in these canals because encroachment of the salt front into the Biscayne aquifer has occurred previously in this area. Plus, major public water supply wellfields are located in southern Miami-Dade County. This area was evaluated by using the stage duration curves for the following structures: C-100A @ S-123, C-1 @ S-21, C-102 @ S-21A, and C-103 @ S-20F. The stage duration curves were used to evaluate the alternatives in

two ways: 1) the distance by which an alternative's water level fails to reach two feet NGVD at the 90th percentile of the stage duration curve; and 2) the percentile at which an alternative's stage duration curve meets the 50th percentile of the 1995 Base stage duration curve.

In the first scenario, two feet NGVD was used for comparison in keeping with the Ghyben-Herzberg relationship which estimates that one foot of fresh water head is required to protect 40 feet of aquifer. The aquifer along the coast in southern Miami-Dade is approximately 80 feet that would require two feet of fresh water head. The 90th percentile of the stage duration curve was used since that percentile reflects lower stages of the dry season when the risk of saltwater intrusion is increased. The score is calculated from the distance of the base conditions and alternatives to the two feet NGVD on the stage duration curve. Alternatives that equaled or exceeded the target scored 100% (no extra credit was given for exceeding the target).

Score = [(2 - Distance/2)] x 100 = % of meeting 2 foot target

The second scenario used the 50th percentile of the 1995 Base to evaluate performance since it represents approximately the midpoint between the wet and dry seasons and can be viewed as "average conditions" for the 1995 Base. The score reflects the percentile at which a base condition or alternative meets or exceeds the water level at the 50th percentile of the 1995 Base. Saltwater encroachment has occurred in the period of record and, therefore, exceeding the 50th percentile is considered an improvement but may not prevent further encroachment.

The base conditions and alternative scores were determined by averaging the scores for the two scenarios.

Flood Protection

Flood protection is one of the authorized purposes of the Restudy and will be evaluated and addressed during the detailed design phase of the study. Due to the grid size and type of model used during the Restudy alternative evaluation process, the performance measures available for the Lower East Coast Service Area are of limited value for direct evaluation of an alternative's affect upon flood protection. However, one performance indicator is applicable for the southern Miami-Dade County agricultural areas in Service Area 3, stage duration curves, and is used in this evaluation.

Urban Areas East of the Protective Levee in the Lower East Coast

Flood protection should be improved or at least not degraded by the selected plan. In many instances, the alternatives have reduced or eliminated adverse impacts to flood control associated with the components selected in the urban areas of the Lower East Coast. The alternatives provide additional water storage capacity through water preserve areas, reservoirs and aquifer storage and recovery, reducing the maximum stages in the canals during large rainfall events.

The risk of flooding may be decreased with the additional storage components; however, it is difficult to discern the improvements at this point in the alternative evaluation. The model used to evaluate the effects of the components on regional hydrology is not conducive for evaluating storm and flood events. The model uses a daily time step; storm and flood events occur within hours. One-performance indicator gauges the change in peak stages compared to the 1995 Base on a regional basis. The primary drawback of this performance indicator is that it does not distinguish between ground and surface water levels.

After the final plan is selected, this performance indicator will be used to identify areas of potential decreased flood protection coupled with site specific information regarding flood prone areas. Information regarding existing flood prone areas will be gathered from District and USACE staff familiar with the Lower East Coast supplemented with interviews with local government officials and other who have technical input. These areas will be mapped using the SFWMM grid cell boundaries and will be identified by the appropriate basin. These identified areas will undergo further evaluation in subsequent feasibility reports to determine what actions are necessary. In addition, portions of the study area outside of the boundaries of the SFWMM grid will need to be evaluated for flooding impacts through a separate process as well.

D.8.4.1 Agricultural Area along the L-31N

Performance Measure Used

One performance measure graphic was developed for use in six cells in the western areas of southern Miami-Dade County (Lower East Coast Service Area 3) to compare the relative performances of the different alternatives. It is labeled “end of the month stage duration curve 1983-1993”, and compares an 11-year target stage duration curve to the 31-year stage duration curves representing the performances of the bases and alternatives. The relative comparison of an 11-year curve to a 31-year curve appeared to be appropriate for use at the higher stages, but did not compare as well at the mid to lower stages.

Scoring Procedures

Because the comparisons between the curves are most appropriate at the higher stages, it was decided to use the point where the stage duration curves intersect with the “10 % time equaled or exceeded” line on the graphs. For each of the six indicator cells, the difference between where an alternative or base curve intersects the 10 % line and where the target curve intersects the 10 % line is measured (in tenths of a foot).

Only the increases in stages relative to the target are included in the matrix. In the first matrix, if an alternative falls below the target (performance is better that the target), a score of 0 is given. The values for all of the cells are summed and normalized so the final scores ranges between 0 and 1.

A second scoring methodology that gives credit for flood protection above the target was used for comparison. In order to normalize the alternatives' scores, five (5) was added to each sum so the final numbers were all positive. The resulting values are shown as an "alternative score".

Interpretation of Results

Using the first scoring methodology, all of the alternatives performed equally. There is no measurable difference between the stage duration curves at the 10% line. The operational changes that were implemented in the C-111 basin in all alternatives are thought to be the reason for this result. The 1995 Base produces the best performance, and the 2050 Base the worst, indicating that some of the components associated with the Experimental Water Deliveries Program have the potential to impact the level of flood protection in this area of Miami-Dade County.

In looking at the second scoring methodology where credit is given for an increase in flood protection in some of the northern cells, alternatives B and C perform the best, followed (in order) by alternative A, D, 1995 Base, and the 2050 Base. Since exceedence of the target line is a "bonus", and since it only occurred in some of the cells, it's not recommended to base selection of a preferred alternative on these results. They are presented only for informational purposes.

Alternative D13R performed equally to alternative D. There were no changes in operations in this area, so the performance did not change.

Other Issues

Isolated wetlands and other natural areas east of the protective levee: Performance measures for isolated wetlands and natural areas east of the protective levee, although important pieces of the remnant Everglades, are not included in this performance matrix. Due to the scale of the SFWMM relative to isolated wetlands, the impact of components cannot be accurately depicted. The scale of the model prevents evaluating features that are smaller than the four square mile grid, with the exception of canals and control structures. In addition, the differences between the alternatives and their components' potential impacts to wetlands may be imperceptible. The influence of the components located primarily west of the levee on ground and surface water levels in areas that have been severed from the regional system by the protective levee is limited. Some of these natural areas are dependent on discharges from primary canals that may be affected by projects located upstream. In these cases, the potential effect of the alternatives can be evaluated to identify problems. Two control structures that supply water to the Pond Apple Slough and North Fork of the New River in Service Area 2, C-11 at S-13 and C-13 at S-38, experience fluctuations in discharge across the alternatives. During the detailed design phase or perhaps as part of an Other Project Element, the potential impact to these areas should be taken into consideration and minimized, and if possible, their discharges increased to meet their demands.

Interpretation of Scores for LECSAs

Summary**:** Based on the above interpretation of the performance measures, Alternatives C and D perform equally well and substantially improve water supplies compared to the 2050 Base for the Lower East Coast Service Area. Alternatives C and D are the preferred alternatives. Alternatives A and B also improve upon the 2050 Base, but do not perform as well as Alternatives C and D.

North Palm Beach Service Area: The North Palm Beach Service Area scores very well, almost reaching the established goals in all alternatives. The average score for the alternatives exceeds 96%, with Alternative D reaching 99%. The performance of the primary canals reaches their goals in all of the alternatives. The 1-in-10 level of service planning goal scores are very high in all alternatives, above 95%. The duration of cutbacks scores are very high as well and are just shy of reaching their goal. Compared to the 2050 Base, any of the proposed plans relying on alternative sources would provide additional water supplies to meet projected water demands, reduce the frequency and duration of water supply cutbacks and help abate saltwater intrusion in the North Palm Beach Service Area.

Service Area 1: Service Area 1 performs very well almost reaching the established goals in all alternatives. The average score for the alternatives exceeds 96%, with Alternative D reaching 99%. The performance of the primary canals reaches their goals in all of the alternatives. The 1-in-10 level of service planning goal scores very high in all alternatives, above 95%. The duration of cutbacks scores are very high as well and are just shy of reaching their goal. Compared to the 2050 Base, any of the proposed plans relying on alternative sources would provide additional water supplies to meet projected water demands, reduce the frequency and duration of water supply cutbacks and help abate saltwater intrusion in Service Area 1.

Service Area 2: Service Area 2 performs well in all of the alternatives, with C and D performing better than A and B. The average score for the alternatives exceeds 88%, with Alternative D reaching as high as 95%. This compares very favorably to the 2050 Base, which scores only 54% for Service Area 2. Alternatives C and D perform almost equally as well as each other as Alternative A performs similar to B. The ability to maintain primary coastal canals performed well in all of the alternatives; it is just shy of reaching its goal for the four alternatives. The 1-in-10 level of service planning goal score for all of the alternatives is significantly higher than the 2050 Base, which has cutbacks almost every year, scoring a dismal 4%. Alternatives C and D perform better than alternatives A and B on reducing the frequency of cutbacks. Although Alternative C scores slightly lower than D, the actual difference is nine more months of cutbacks over the period of record in Alternative C. This is reflected in the duration performance measure. The duration of cutbacks scores improve significantly when compared to the 2050 Base. Compared to the 2050 Base, any of the proposed plans would provide additional water supplies to meet projected water demands, reduce the frequency and duration of water supply cutbacks and help abate saltwater intrusion in Service Area 2. However, alternatives C and D perform better than either A or B and are preferable.

Service Area 3: In Service Area 3, the overall performance improves in all alternatives compared to the 2050 Base, with C and D performing better than A and B. Alternatives C and D perform almost equally as well as each other, as Alternative A performs similar to B. The average score for all of the alternatives exceeds 79%, with Alternative D reaching as high as 92%. This compares favorably to the 2050 Base, which scores only 70% for Service Area 3. All of the alternatives performed well in maintaining the primary coastal canals. The other canals in southern Miami-Dade County do not perform well in Alternatives A or B, showing little to no improvement compared to the 2050 Base. Alternatives C and D do score significantly better for maintaining these canals, but fail to perform well enough to reach their target. All of the alternatives' performance improves significantly over the 2050 Base in meeting the 1-in-10 level of service planning goal, with Alternative D performing the best. The duration of cutbacks scores very high for all alternatives, with Alternative D performing the best. The difference in duration between alternatives C and D is only five additional months of cutbacks over the 31-year period of record. Except for maintaining water levels in southern Miami-Dade canals, the performance of all of the alternatives as evaluated in the matrix exceeds the performance of the 2050 Base. However, alternatives C and D perform better than either A or B and are preferable.

Comparison of Alternative D with Alternative D13R

Alternative D13R performs essentially the same as Alternative D. The two alternatives are indistinguishable in their ability to meet public water demands, minimize the duration of cutbacks, and maintain saltwater intrusion stages in the primary coastal canals. It meets most of the performance measures for the Lower

East Coast Service Area, greatly improving the ability to meet public water supply demands and prevent saltwater intrusion over the 2050 Base.

Considerations

The LEC subteam only considered the scores and their indication of an alternative's ability to meet performance measures when selecting a preferred plan. While the scores may reflect alternatives C and D perform better than alternatives A and B, many of the water supply components chosen for all the alternatives will require greater analysis to assure that they can be implemented. Because of the high-risk based nature of some of the key water supply features (ASR, seepage control, low-phosphorus reuse), plan selection is possible as general guidance only. However, selection of a plan may require selection of components from several of the alternatives, determination of the feasibility of the technologies included, and evaluation of the cost effectiveness of the components. The Implementation Plan should describe and address many of the specific concerns of the LEC subteam.

Subregion: Lower East Coast Service Area*

D.8.5 Northern / Central Everglades

Evaluation Methodology

Performance Measures Used in Final Evaluations

Model results for each alternative were evaluated at the level of individual Indicator Regions. Scores were then aggregated into spatially and hydrologically-distinct groups. Initially, evaluations were based on five performance measures, with each measure comprising one or two component variables. The performance measures and variables were:

1. Inundation pattern (variables: number and mean duration of inundation periods);
2. Extreme high water (variables: number and mean duration of high water events);
3. Extreme low events (variables: number and mean duration of low water events);
4. Interannual depth variation (variables: October and May between-year standard deviations); and
5. Average seasonal amplitude (variable: October mean depth minus May mean depth).

Performance measures 1-4 were approved by the AET early in the alternatives development process and had been used in prior evaluations of Alternatives 1-5. Performance measure 5 was added as a means to evaluate seasonal depth variation. After inspection of initial scores, however, use of measures 4 and 5 was discontinued, as it was found that performance for these measures was acceptable and varied little among the alternatives.

Target variable values for the performance measures were those predicted by NSM 4.5, Final, with four exceptions: (1) in Indicator Region 17, performance was evaluated by comparing values to the average of NSM values for Indicator Regions 14 and 18; this was because the NSM depths in this indicator region had been identified during evaluation of alternatives 1-3 as being lower than desirable for this relatively pristine marsh area; (2) in LNWR, the targets were 1995 Base values, in keeping with the refuge's current regulation schedule; (3) for high water extremes, the performance target was that the number and duration of events be less than or equal to NSM values; and (4) for low water extremes, the performance target was for frequencies and duration of events to be minimized.

During the first round of evaluations, the results for individual indicator regions were aggregated into three sub-areas: (1) Central Ridge and Slough (WCAs 2A, 2B, 3B, and most of 3A); (2) Sawgrass Plains (Holey Land, and Rotenberger WMAs plus NE WCA-3A); and (3) Loxahatchee NWR. However, because hydrologic performance of the alternatives did not fall clearly into these landscape-defined categories, the final evaluation classified the indicator regions into ten subregions that correspond with distinct hydrologic performance. These are:

1. Loxahatchee NWR (Indicator Regions 26 & 27)
2. Holey Land & Rotenberger WMAs (Indicator Regions 28 & 29)
3. WCA-2A (Indicator Regions 24 & 25)
4. WCA-2B (Indicator Region 23)
5. NW WCA-3A (N of Alligator Alley & W of Miami Canal; Indicator Regions 20 & 22)
6. Northeastern WCA-3A (N of Alligator Alley & E of Miami Canal; Indicator Region 21)
7. Eastern WCA-3A (S of Alligator Alley, E of Miami Canal; Indicator Region 19)
8. Central & Southern WCA-3A (S of A. Alley, W of Miami Canal; Indicator Regions 14, 17 & 18)
9. WCA-3B (Indicator Regions 15 & 16)
10. Pennsuco Wetlands (Indicator Regions 52 & 53)+

Index Calculation Method

Index values were developed for each performance measure and indicator region in order to simplify comparison of the alternatives. The method for calculating these indices is described below. It is important to note that the indices are valid only for making relative comparisons among different models for a single performance measure averaged over at most a few similar indicator regions. In addition, the scale of the index values for each performance measure does not map directly to any ecological interpretation of restoration potential for the alternative; it is color and letter grade scores that are used for that purpose. Indices and ranks function strictly as a means of ordering the alternatives and base cases relative to each other on the basis of their ability to achieve planning targets.

Inundation Pattern

For inundation pattern, subscores for the two variables, number and mean duration of inundation events, were calculated using the formula:

$$\text{score} = \exp[-2.773(\text{Target value-Alternative value/Target value})^2] .$$

This describes a smooth curve that assigns a maximum score of 1.0 only when the value for the alternative exactly equals the target value, and assigns a score of 0.5 when the alternative's value is 50% larger or smaller than the target value. Values that deviate from the target by less than 50% are assigned scores greater than 0.5 that increase to 1.0 as the alternative's value approaches the target. Values that deviate from the target by more than 50% are assigned scores less than 0.5 that approach zero as the distance from the target value increases.

The summary index for inundation pattern was calculated as the arithmetic average of the two subscores.

High Water Extremes

For high water extremes, subscores were calculated for number of high water events and mean duration of events. If the alternative's value for the variable was less than or equal to the NSM-defined target, then a score of 1.0 was assigned. If the alternative value exceeded the target, then the score was calculated using the formulae:

score for # events = exp[- (Alternative #events -Target #events) ^{2}/8)]; and

score for duration of events = exp[- (Alternative duration-Target duration) ^{2}/18)].

These formulae assign a score of 0.61 when the alternative value exceeds the target value by two events or by three weeks, respectively. Scores fall off toward zero as number and/or duration of events increases. The summary index for high water extremes was then calculated as the simple average of the two subscores.

Low Water Extremes

For low water extremes, scores were calculated for the two variables, number of low water events and mean duration of events, according to the formula:

score = exp[- (Alternative value) ^{2}/2(NSM value)^2)].

This assigns a score of 1.0 when the alternative's value equals zero, and a score of 0.61 when the alternative's value equals the NSM value. Scores between 0.61 and 1.0 identify performance that is "better" than NSM at reducing the number and/or duration of low water events, while scores of less than 0.61 approach zero as the number and/or duration of low water events gets large. As above, the summary index was calculated as the simple average of the two subscores.

Seasonal and Interannual Variability

Scores were assigned to seasonal amplitude, October standard deviation, and May standard deviation, using the same formula as that for inundation pattern. The summary index was then calculated as a weighted average:

Index = (0.5)(seasonal amplitude score) + (0.25)(Oct. st.dev. score+May st. dev. score).

As noted above, use of this index was discontinued after initial inspection of results, because alternatives generally performed well and did not differ appreciably. The few exceptions to this are described in the narrative evaluation below.

Combined Indices

Indices were aggregated in two ways: across performance measures within individual indicator regions; and across indicator regions within subregions. The individual indices and averages are listed in Tables Northern and Central Everglades – 1, 2 and 3 below.

(1) Spatial averages. For each performance measure, an average index value was obtained for each subregion, weighting each indicator region by the approximate spatial area of the landscape that it represented (defined by counting model grid cells in that region of the SFWMM). The weights assigned are listed in Table Northern and Central Everglades – 4 below.

(2) Overall performance average. For each indicator region, the three indices for inundation pattern, high water extremes, and low water extremes were averaged to obtain a summary score. This was a weighted average, with the index for inundation pattern given half the weight assigned to each of the other indices. This weighting was chosen in order to reduce the influence of the differences in inundation pattern indices on the overall average, on the rationale that an exact matching of NSM inundation values within an indicator region was not likely to be significantly better at promoting long-term sustainability of the marsh than was a pattern that was broadly consistent with NSM within that landscape region, but not necessarily a good match for the specific indicator region being scored.

ROGEM Analysis for the Northern/Central Everglades

The color and grading exercises (discussed below) offered an opportunity to interpret the index values in terms of their ecological significance and ROGEM scores were developed consistent with these evaluations. The Northern/Central Everglades Region Subteam ranked, graded, and assigned colors before they developed ROGEM values. The letter grades were converted into ROGEM values by assigning "1.0" to the grade of "A", "0.8" to "B", "0.6" to "C", "0.4" to "D" and "0.1" to "F".

Index scores were used for ranking plans to see how far alternatives varied from the targets and from each other. Unlike the color and letter grade scores, they were not useful in determining how successful any plan would be in meeting ecological goals. One additional drydown event over 31 years, for example, may not significantly differ from the target in terms of ecological health, however a 4-week increase in the mean average duration of high water events could indicate a highly significant ecologically deviation.

Ranking of Alternatives

The indices were used as a basis for ranking Alternatives A-D relative to each other and the 2050 Base. For each performance measure and indicator region, indices were rounded to the nearest 0.1 and then ranked from 1 to 5, with ties given the mean of the tied ranks. These ranks were then averaged across indicator regions using the spatial weights described above, and were also averaged, without weighting, across the three performance measures. This analysis acted as a check for the results obtained with the index values, by creating an ordering of alternatives that was less subject to possible shifts in rank that can occur when non-linear functions are averaged. Ranks for Alternatives A-D and 2050 Base are presented in Table Northern and Central Everglades – 5.

Color and Letter Grade Assignment

The indices and ranks described above allowed alternatives to be compared to the base cases and to each other. However, because the numeric scale is largely arbitrary from a biological perspective, an ecological interpretation of the alternative cannot be deduced from the index scores. A separate evaluation method was done for this purpose. Each performance measure for each indicator region was evaluated using best professional judgment of subteam members as to the ecological consequences of the predicted performance. Values were compared not only to target values and to the 2050 Base, but also to the 1995 Base and to output for other indicator regions where helpful. The subteam then assigned each indicator region a "color" score of Green, Yellow, or Red for each performance measure, and used these to choose a summary color for the indicator region. The criteria for color assignment were as follows.

GREEN. Green was assigned if the model performance was thought to predict conditions expected to promote a sustainable Everglades marsh community. The primary indicators for this were:
(1) protection and accretion of peat soils indicated by a low predicted occurrence of extreme low water (depths more than 1.0 ft below ground surface);
(2) persistence of tree island communities indicated by a low predicted frequency of extreme high water; and
(3) an inundation pattern suitable for an Everglades sawgrass or ridge-and-slough marsh, as indicated by a number and mean duration of inundation events that either closely matched the target for that indicator region, or that fell within the range of patterns predicted by the NSM for that landscape type.

YELLOW. Yellow was assigned if the ecological consequences of the performance were considered uncertain. This uncertainty generally fell into one of two classes: (1) performance deficits that appeared to be "fixable" as part of detailed design or during optimization of operational rules; and (2) uncertainty that could only be resolved via biological monitoring and adaptive management during implementation, because the key issues concerned uncertain biological results of the predicted hydrologic changes. In either case, yellow identified areas where special caution appears to be necessary in implementing any project changes.

RED. Red was assigned if the performance appeared unlikely to support a sustainable Everglades marsh. The primary criteria for this classification were:

(1) high predicted frequencies of extreme dry-outs that seemed certain promote continued peat loss,
(2) high predicted frequencies of extreme high water that would be expected to eliminate tree-island vegetation communities and adversely affect animals that depend on them, and/or
(3) inundation or depth patterns that fell well outside the range of conditions predicted by the NSM for that landscape type.

GRADES. Letter grades were assigned according to the following criteria:
Green areas: "A" or "B," depending on level of confidence in the restoration potential of the alternative;
Mixed Yellow/Green areas: grade of "B";
Yellow areas: "C" or "D," depending on degree and severity of uncertainty;
Mixed Yellow/Red areas: "D"; and
Red areas: "F."

Evaluation/Interpretation of Alternatives A-D

The following text describes, for each subregion, the specific performance evaluation and interpretation that led to the subteam assignments of colors and letter grades, and includes an interpretation of the overall performance of Alternatives A-D.

Loxahatchee NWR (Indicator Regions 26 and 27)

Loxahatchee NWR performs well in all four alternatives, matching targets defined by the 1995 Base. The number and mean duration of inundation events for alternatives B-D are nearly identical to 1995 Base values, with a 99% overall hydroperiod in southern LNWR and a 95% hydroperiod in northern LNWR. This is an improvement over the drier conditions predicted for the 2050 Base (94% hydroperiod in south, 90% hydroperiod in north). Alternative A is slightly drier than the 1995 Base, especially in the north, where there are 20 inundation events averaging 76 weeks in duration, as opposed to 13 events averaging 199 weeks in 1995 Base.

The occurrence of extreme low water is reduced in all four alternatives compared to the 2050 Base, with only one short-duration event in northern LNWR, as compared to the 2050 Base, which has five events averaging five weeks duration in the north, and two events averaging four weeks in the south. All four alternatives are close to the 1995 Base target of no more than one four week-long event in the north and zero events in the south.

All four alternatives also meet performance targets for extreme high water. High water events do not occur in the north, and, although common in the southern part of the refuge, high water events are fewer and of shorter duration than in the 1995 Base. Overall, southern LNWR experiences depths greater than 2.5 ft for 24-25% of the simulation period, as compared to 20% of time in the 2050 Base and 30% in the 1995 Base. There is some uncertainty about the effect of high water on tree islands in southern LNWR; however, the alternatives conform overall to current hydrologic management objectives for the refuge.

Holey Land and Rotenberger WMAs (Indicator Regions 28 and 29)

Both Holey Land and Rotenberger WMAs perform nearly identically in all four alternatives. The regulation schedule assumed for Rotenberger WMA appears to eliminate high water extremes effectively while maintaining suitable NSM-like inundation patterns. In Holey Land, depths greater than 1.5 ft occur 6-8% of time, but depths greater than 1.75 ft occur only 1-2% of time. In both WMAs, the frequencies and durations of extreme low water are less than those predicted by NSM; however, drought conditions still occupy 3-4% of the simulation period. Although there is uncertainty about the minimum conditions needed to protect peat soils, so long as the alternative provides dry season deliveries via the STAs, it should be possible to adjust operational details so as to avoid further soil loss in these areas.

It should noted that in Holey Land WMA, differences in performance relative to the 1995 and 2050 bases do not provide a realistic comparison with the alternatives, because the bases assumed a 0-2' regulation schedule that is not currently in use, nor is it likely to be implemented in the future. Hence, the subteam evaluation in this area was restricted to comparisons with target values.

WCA-2A (Indicator Regions 24 and 25)

In general, alternatives A-D exhibit problematic performance in WCA-2A, with uncertain results for southern WCA-2A (Indicator Region 24) and poor performance in northern WCA-2A (Indicator Region 25).

In southern WCA-2A, inundation patterns were very similar to NSM in all four alternatives, with alternatives B, C, and D performing slightly better than Alternative A. However, in northern WCA-2A, inundation periods were of much longer duration, with less frequent dry-outs, than NSM target values. Here Alternative A performed somewhat better than alternatives B, C, and D, which had only nine inundation events averaging 173 weeks duration, in contrast with the NSM target of 30 inundation events averaging 46 weeks duration. Hence, where NSM predicts that northern WCA-2A would have dried out approximately every year during pre-drainage times, alternatives B-D predict dry-outs to occur less than once every three years, on average, while Alternative A predicts the marsh to dry out in roughly two years out of five. Northern WCA-2A was also one of the only regions in the WCA system that performed poorly for seasonal variability; all four alternatives had annual amplitudes in depth between wet and dry seasons that were smaller than those predicted by the NSM, and the annual mean maximum depth occurred early in the wet season rather than later as predicted by NSM (see performance indicator "Temporal Variation in Mean Weekly Stage for Northern WCA-2A").

Although southern WCA-2A met NSM target values for inundation pattern, it experienced more extreme high water than either base, as well as more extreme low water than might be desired for protection of peat soils. Although extreme high water occurred only 1% of time in alternatives A-D, total high water was greater in all four alternatives than in either base (15-25 weeks as compared to ten weeks in the 2050 Base and three weeks in the 1995 Base). Extreme low water was somewhat reduced relative to both the 1995 and 2050 bases; however, the alternatives still predicted seven - eight extreme dry-downs lasting on average seven weeks duration. Although similar to NSM predictions for extreme low water, and slightly better than the 1995 Base, the subteam was still concerned that this frequency of extreme dry-outs might not be low enough to protect peat soils.

Overall, because northern WCA-2A had a very non-NSM-like hydropattern, and because high and low depth extremes in southern WCA-2A create uncertainty about future marsh conditions in this area, the subteam assigned a score of "yellow" in the south and "red" in the north for all four alternatives. However, it was also felt that performance, especially in the north, could be improved by changes in operational rules during future modeling efforts.

WCA-2B (Indicator Region 23)

WCA-2B was one of two regions in the northern and central Everglades that remained far from targeted performance for all four alternatives. Although the number and duration of inundation events was a good match for NSM targets in alternatives A-D, extremes of high water, low water, or both led to poor performance in all cases.

Alternative A had the weakest performance. Although it showed substantial reduction in extreme low water compared to both bases and the other three alternatives, this improvement was offset by a dramatic 59% of time in which depths exceeded more than 2.5 ft, a performance that was worse than even the 2050 Base, which had high water 56% of the time.

In contrast, alternatives B-D succeeded in reducing extreme high water and providing improvement over both bases. Nonetheless, depths greater than 2.5 ft still occurred 10-11% of time in these alternatives, which is far from the NSM value of 1%. Furthermore, the frequency of extreme low water remained at 5% of time, which is still much higher than the NSM prediction of 1%.

These performance problems are consistent with the observation that WCA-2B is also the area that shows the largest deviation from NSM-like patterns of seasonal and interannual variability, with interannual standard deviations that are one-to-two times the magnitude of those seen in NSM. The reason for this is that WCA-2B experiences very high water during wet periods followed by long periods that are unnaturally dry. This is most pronounced in Alternative A. Overall, the subteam concluded that although alternatives B, C, and D show significant improvement relative to both the 1995 and 2050 bases, the frequent occurrence and long duration of extreme high and low water make it unlikely that this area would be able to function sustainably as either a shorter- or longer-hydroperiod Everglades wetland.

Northwestern WCA-3A (Indicator Regions 20 and 22)

NW WCA-3A was rated “green” for all four alternatives A-D because all four models predict substantially reduced occurrence of extreme low water relative to both 1995 and 2050 bases, while other performance measures are close to target values. In the northwest corner of WCA-3A (Indicator Region 22) dry-downs in excess of 1.0 ft below ground occurred on five - eight occasions for an average of three-five weeks duration (1-2% of total time). Slightly to the south, in Indicator Region 20, extreme dry-outs occurred somewhat more frequently, with nine low water events averaging five – six weeks duration (3-4% of total time). Alternative C performed slightly better than alternatives A, B, or D in both indicator regions. All four alternatives performed better than the 2050 Base and much better than the 1995 Base, which had as much as 11% extreme low water in Indicator Region 22. There remains some concern that the area represented by Indicator Region 20 may still be likely to experience more extreme low water than will be sufficient to protect peat soils. However, it may not be possible to further reduce low water events beyond performance levels comparable to alternatives C and D without causing trade-offs, such as increased risk of cattail proliferation in ponded areas.

Along with the reduction in extreme low water, all four alternatives performed as well or better than both bases at matching NSM inundation patterns. In addition, Indicator Region 20 had lower frequencies of extreme high water relative to both bases, with the best performance occurring in alternatives A and B.

Northeastern WCA-3A (Indicator Region 21)

Alternative A performed best in this region, followed by Alternative B, although performance deficits occurred in all four alternatives. In general, this area has a problem with a tendency toward both too much high and low water.

For inundation pattern, alternatives B, C, and D all did well at matching NSM target values. Alternative A, however, was similar to the 2050 Base, with fewer, longer periods of inundation than NSM. Overall, Alternative D came closest to matching the target values for inundation.

For low water extremes, however, alternatives B, C and D all performed worse than the 2050 Base, with 17 events averaging seven weeks in Alternative B, 14 events averaging six weeks in Alternative C, and 15 events averaging five weeks in Alternative D. Although these values are similar to or less than those predicted by NSM for low water in this area, and all were substantial improvements over the 1995 Base, the subteam felt that the frequency (about one-in-two years) and duration (more than one month, on average) was larger than desired for protection of peat soils. Only Alternative A showed an improvement in low water extremes relative to the 2050 Base, and even it predicts nine low water events averaging six weeks in length.

Alternative A was also the only alternative that showed improvement over the 2050 Base with respect to extreme high water. Alternatives B, C, and D all exhibited an increase in the frequency of depths greater than 2.0 ft, with alternatives C and D showing the least favorable performance. This creates concern about the effect of extreme high water on wading bird rookery vegetation in this region.

Eastern WCA-3A (Indicator Region 19)

None of the alternatives performed well in this area. The region, east of the Miami Canal and South of Alligator Alley, is deeply ponded in both 1995 and 2050 bases and remains so in all four alternatives. Weekly mean depths greatly exceeded NSM targets, with alternatives C and D being the deepest, having depths that exceeded NSM by about 1-1.5 ft year round (see performance indicator, "Temporal Variation in Mean Weekly Stage for East WCA-3A"). Seasonal depth patterns in alternatives A and B are similar to the 2050 and 1995 bases but also exceed NSM depths by 1.0 ft or more through most of the year. As a consequence, only the performance measure for low water extremes shows good performance, in all except Alternative B.

High water extremes are most notable in this area. Alternatives C and D have depths greater than 2.5 ft 27% of the time. Alternative B, with 11% extreme high water, is similar in performance to the 2050 Base. Only Alternative A, with a high water frequency of 9%, predicts improvement over the 2050 Base. Although all the alternatives show substantial improvement over the 53% of extreme high water predicted by the 1995 Base, none of them approaches the NSM target of 0% of time with depths greater than 2.5 ft.
