Summary

- The Climate Prediction Center (CPC) is forecasting 50-60% chance of below normal rainfall for January through March.
- La Niña conditions are present and are likely (exceeding ~80%) through winter 2017-18, with a transition to ENSO-neutral most likely during the mid-to-late spring.
- Monitoring Atlantic Multidecadal Oscillation (AMO) index for switch to negative (cold) phase, this has the potential to contribute to drier-than-normal wet seasons.

U.S. Winter Outlook

Precipitation

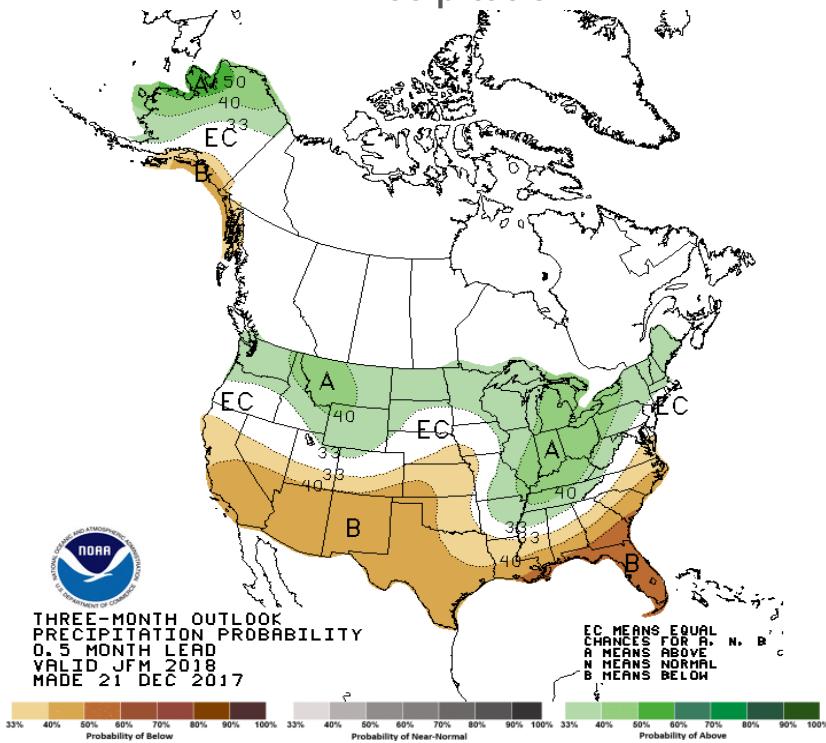

U. S. Seasonal Outlooks

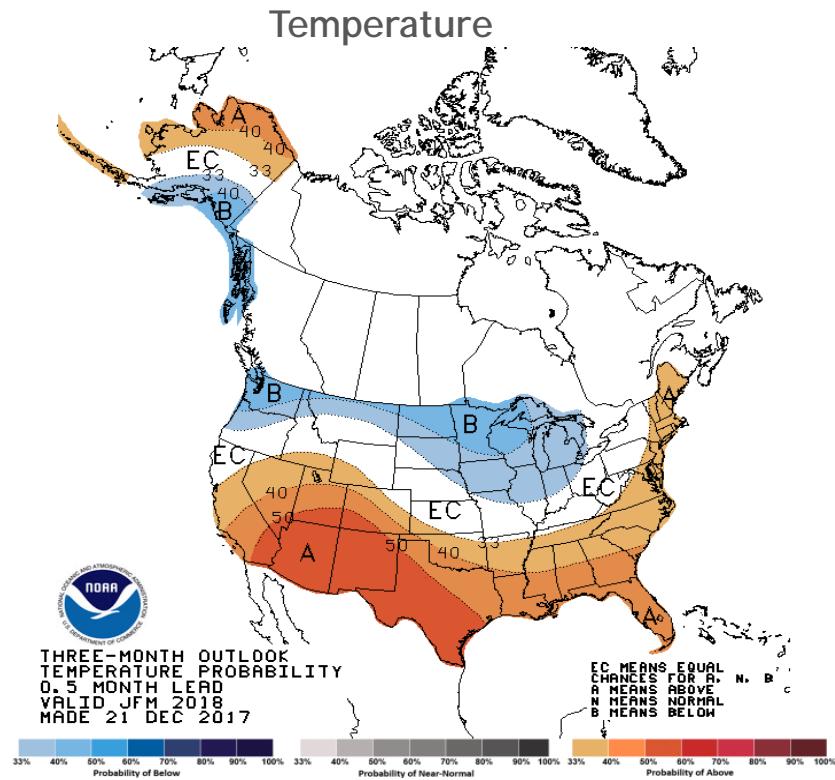

January - March 2018

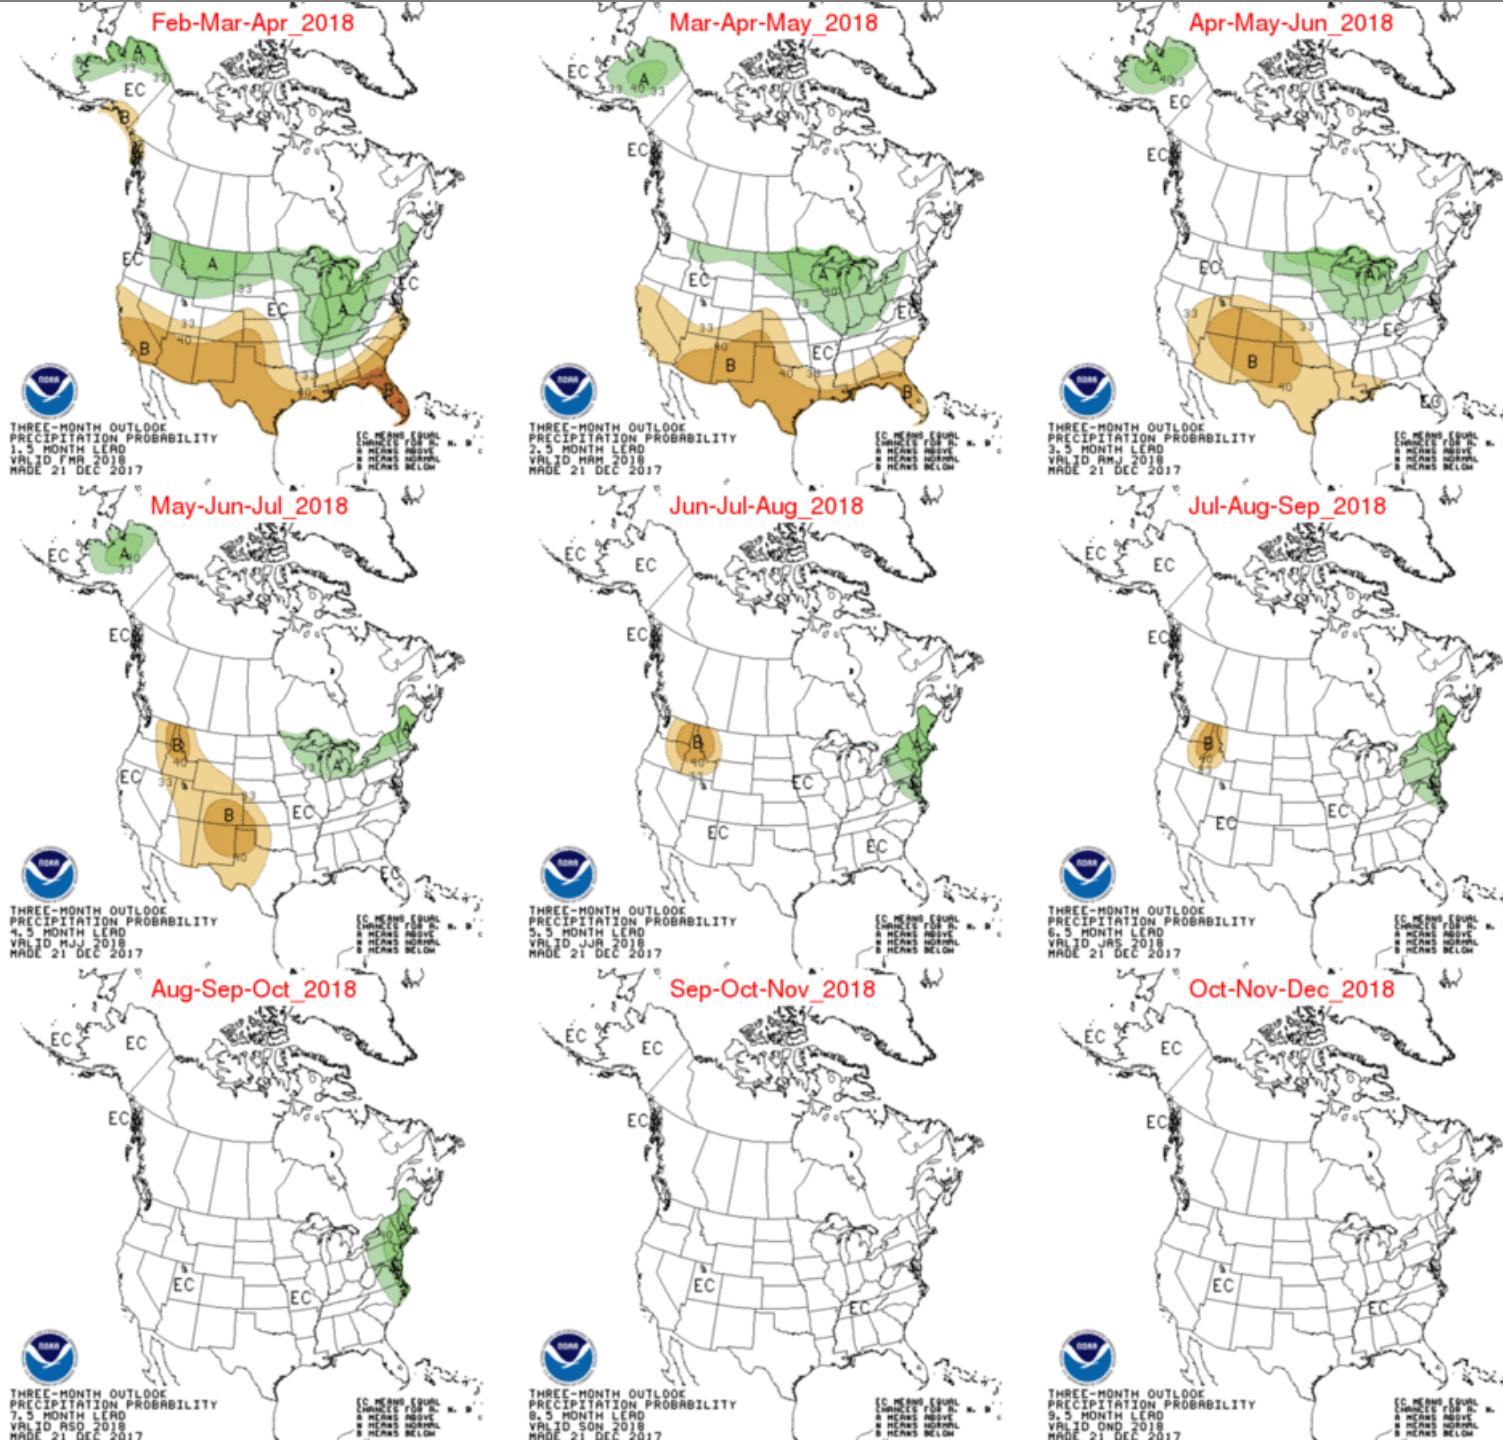

The seasonal outlooks combine the effects of long-term trends, soil moisture, and, when appropriate, ENSO.

Precipitation

Temperature

Teleconnections to South Florida

Climate anomalies being related to each other at large distances:

El Niño Southern Oscillation (ENSO)

South Florida dry season (November through May) rainfall is positively correlated with El Niño which has a frequency that ranges between 3 to 7 years while rainfall is negatively correlated with La Niña November through March with a potential increase in tropical rainfall during La Niña

Atlantic Multidecadal Oscillation (AMO)

Average annual inflow to Lake Okeechobee is nearly 50% greater during the warm phase compared to the cold phase of the AMO, easterly flow toward south Florida affected by phase

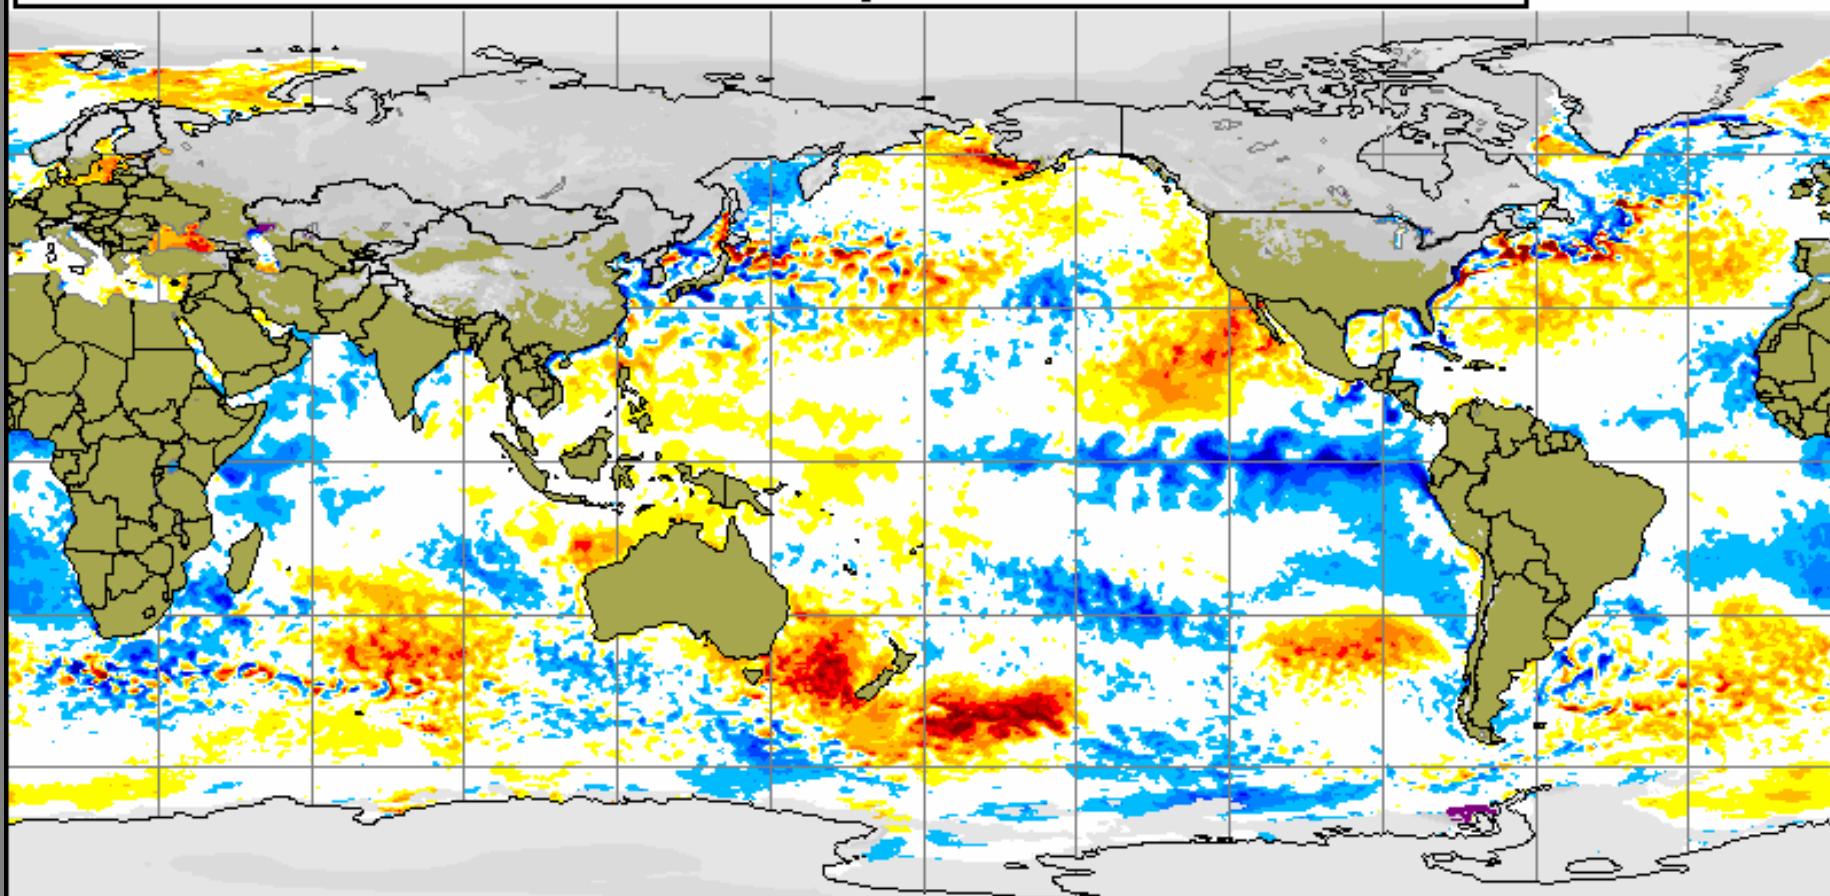

Pacific Decadal Oscillation (PDO)

Increases variations of south Florida dry season rainfall

Niño Region SST Departures ($^{\circ}$ C) Recent Evolution

The latest weekly SST
departures are:

Niño 4	-0.1 $^{\circ}$ C
Niño 3.4	-0.8 $^{\circ}$ C
Niño 3	-1.4 $^{\circ}$ C
Niño 1+2	-0.8 $^{\circ}$ C

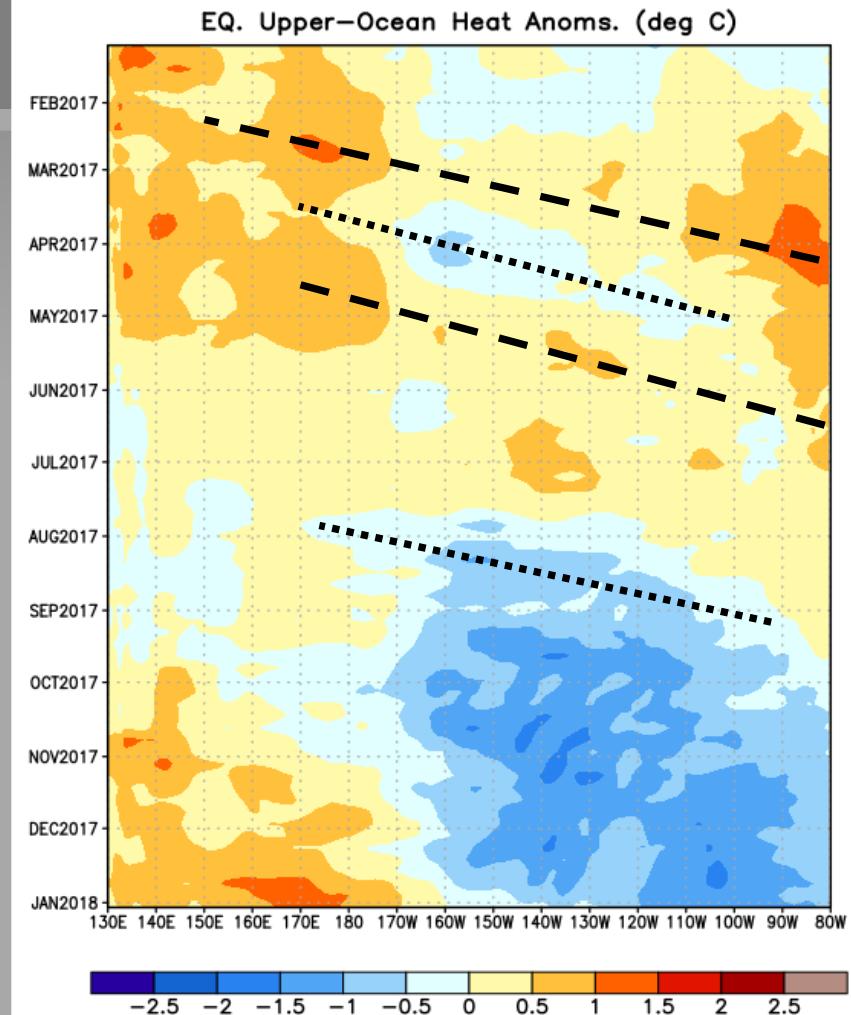

Weekly Heat Content Evolution in the Equatorial Pacific

From February 2017 through May 2017, positive subsurface temperature anomalies persisted in the western and eastern Pacific Ocean, with oceanic Kelvin waves resulting in temperature variability in the central Pacific.

During August 2017, an upwelling Kelvin wave resulted in below-average sub-surface temperatures across the east-central and eastern equatorial Pacific. Since September 2017, negative sub-surface anomalies have persisted in those regions.

Equatorial oceanic Kelvin waves have alternating warm and cold phases. The warm phase is indicated by dashed lines. Down-welling and warming occur in the leading portion of a Kelvin wave, and up-welling and cooling occur in the trailing portion.

IRI/CPC Pacific Niño

3.4 SST Model Outlook

The majority of models predict La Niña to persist into Northern Hemisphere spring 2018, with a return to ENSO-neutral thereafter.

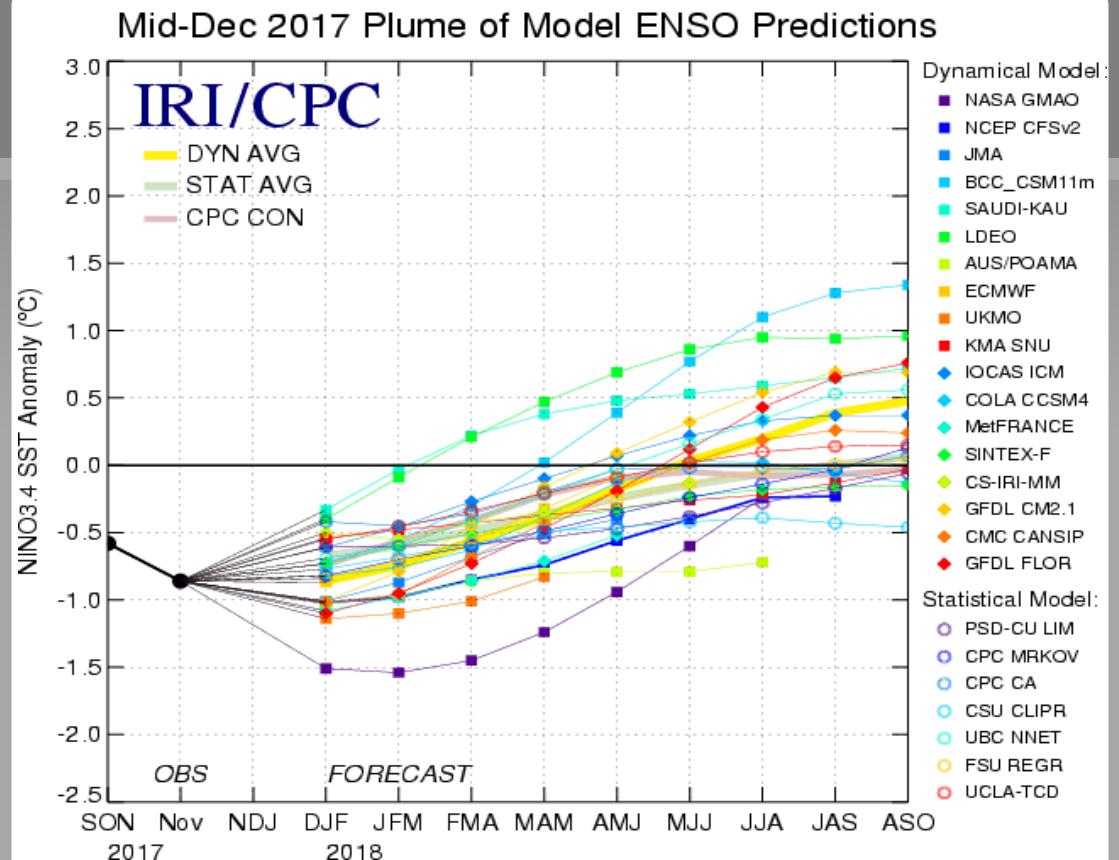

Figure provided by the International Research Institute (IRI) for Climate and Society (updated 18 December 2017).

Historical El Niño and La Niña Episodes Based on the ONI computed using ERSST.v5

Recent Pacific warm (red) and cold (blue) periods based on a threshold of +/- 0.5 °C for the Oceanic Niño Index (ONI) [3 month running mean of ERSST.v5 SST anomalies in the Nino 3.4 region (5N-5S, 120-170W)]. For historical purposes, periods of below and above normal SSTs are colored in blue and red when the threshold is met for a minimum of 5 consecutive over-lapping seasons.

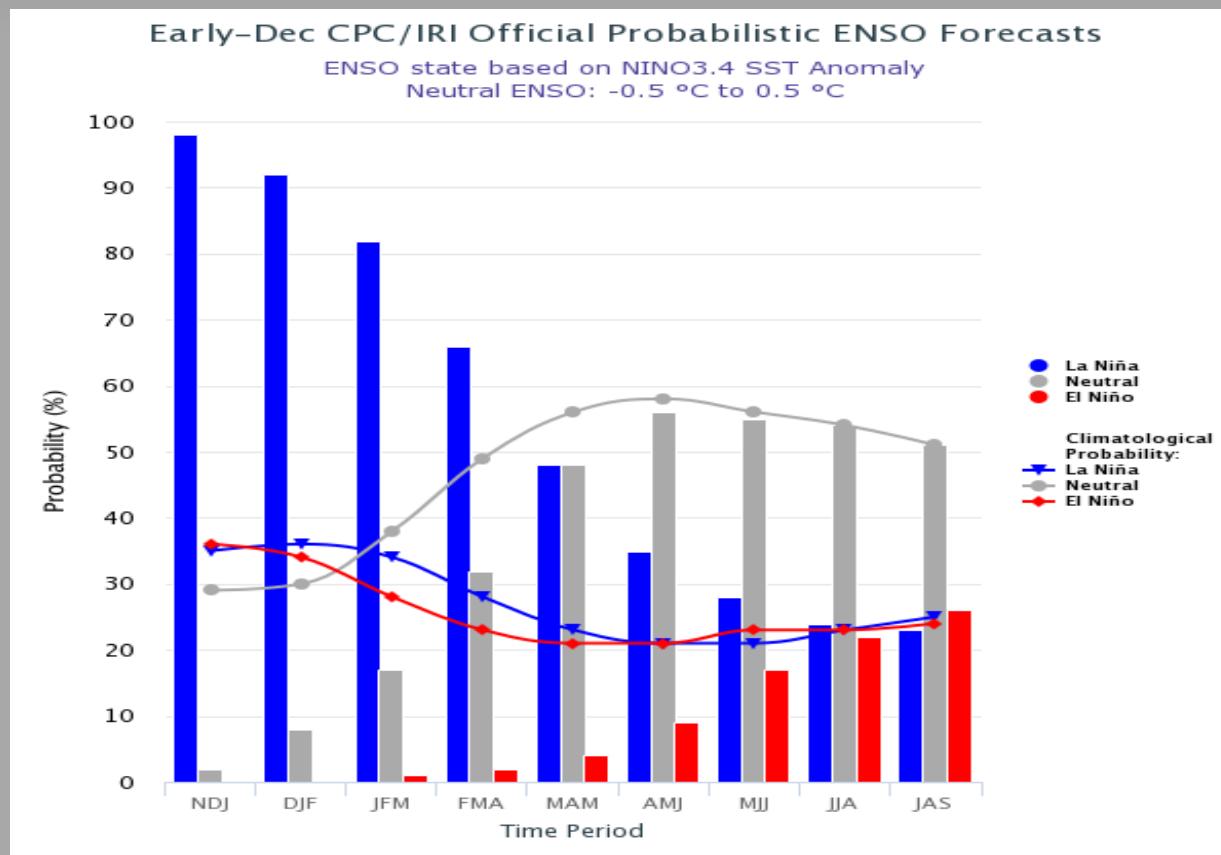

The ONI is one measure of the El Niño-Southern Oscillation, and other indices can confirm whether features consistent with a coupled ocean-atmosphere phenomenon accompanied these periods. The complete table going back to DJF 1950 can be found [here](#).
